Picture-In-Picture (PIP) controller

SAB9077H

FEATURES

Display

- 50/60 Hz PIP modes possible
- Twin PIP in interlaced mode at 8-bit resolution
- Sub-title mode features built in
- Large display fine positioning area, both channels independent
- Only 2 Mbit needed as external VDRAM (2 × 1 Mbit or 1 × 2 Mbit)
- Four 8-bit Analog-to-Digital Converters (ADCs; > 7-bit performance) with clamp circuit
- Most PIP modes handle interlaced pictures without joint line error
- Two PLLs which generate the line-locked clocks for the acquisition channels
- Display PLL to generate line-locked clock for the display
- Three 8-bit Digital-to-Analog Converters (DACs)
- 4 : 1 : 1 data format
- Data reduction factors 1 to 1, 1 to 2, 1 to 3 and 1 to 4, horizontal and vertical independent.

I²C-bus programmable

- Single and double PIP modes can be set
- Full field still mode available
- Several aspect ratios can be handled
- Reduction factors can be set freely
- Selection of vertical filtering type
- Freeze of live pictures
- Fine tuned display position, H (8-bit), V (8-bit), both channels independent
- Fine tuned acquisition area, H (4-bit), V (8-bit), both channels independent
- Eight main borders, sub-borders and background colours available
- Border and background brightness adjustable, 30%, 50%, 70% and 100% IRE
- Several type of decoder input signals can be set.

GENERAL DESCRIPTION

The SAB9077H is a picture-in-picture controller for multi-standard TV-sets. The circuit contains ADCs, reduction circuitry, memory control, display control and DACs.

It inserts one or two live video signals with original or reduced sizes into a live video signal. All video signals are expected to be analog base band signals. The conversion into the digital environment and back to the analog environment is done on chip. Internal clocks are generated by two acquisition PLLs and a display PLL.

The two PIP channels and a large external memory offer a wide range of PIP modes. The emphasis is put on single PIP, double PIP, split-screen mode and many multi-PIP modes.

Picture-In-Picture (PIP) controller

Picture-In-Picture (PIP) controller

SAB9077H

FUNCTIONAL DESCRIPTION**Pixel rate**

The internal chrominance format used is 4 : 1 : 1. It is expected that the bandwidth of the input signals is limited to 4.5 MHz for the Y input and 1.125 MHz for the U/V inputs.

The Y input is sampled with a $1728 \times H_{\text{sync}}$ (≈ 27.0 MHz) clock and is filtered and down sampled to the internal $864 \times H_{\text{sync}}$ (≈ 13.5 MHz) pixel rate.

The U and V inputs are multiplexed and sampled with a $432 \times H_{\text{sync}}$ clock and down sampled to the internal $216 \times H_{\text{sync}}$ (≈ 3.375 MHz) pixel rate.

Acquisition area

Synchronization is done via the acquisition H_{sync} and V_{sync} pins. With the acquisition fine positioning added to a system constant the starting point of the acquisition can be controlled.

The acquisition area is 672 pixels/line and 228 lines/field for NTSC and 276 lines/field for PAL. Both main and sub-channel are equivalent in handling the data.

Display mode

The internal display pixel rate is $864 \times DPH_{\text{sync}}$ which is 13.5 MHz. This pixel rate is upsampled by interpolation to $1728 \times DPH_{\text{sync}}$ before the DAC stage.

Display area

The display background is an area of 696 pixels for both PAL and NTSC, 238 lines for NTSC and 286 lines for PAL. This can be put on/off by the BGON bit independent of the PIPON bits. This area can be moved by the display background fine positioning (BGHFP and BGVFP). Its colour is determined by the BGCOL and BGBRT bits.

Within this area PIPs are defined dependent on the PIP mode. The PIP sizes are determined by the display reduction factors as is shown in Table 2. Whether a PAL or NTSC fixed number is used depends on the DPAL bit.

The display fine positioning determines the location of the PIPs with respect to the background. sub and main-channel both have their independent PIP size and location control, which is shown in Fig.3.

Table 2 PIP sizes

| REDUCTION | H/1 | H/2 | H/3 | H/4 | V/1 | V/2 | V/3 | V/4 |
|------------|-----|-----|-----|-----|-----|-----|-----|-----|
| Pixels | 672 | 336 | 224 | 168 | – | – | – | – |
| NTSC-lines | – | – | – | – | 228 | 114 | 76 | 57 |
| PAL-lines | – | – | – | – | 276 | 138 | 92 | 69 |

Picture-In-Picture (PIP) controller

SAB9077H

Fig.3 Display fine positioning.

PIP modes

The two independent acquisition channels can also be controlled independently on the display side. A wide variety of modes is possible but a subset of 7 modes is fixed and can be set easily by the I²C-bus. An overview of the preconditioned modes is given in Table 3. For all PIP modes the main and sub-display fine positioning must be set to obtain a display configuration.

DATA TRANSFER

The internal data path has an 8-bit resolution and 4 : 1 : 1 data format. The communication to the external VDRAM takes place at $864 \times H_{sync}$ (both display and acquisition).

Approximately 800 8-bit words can be fetched from the external VDRAM in one display line which is not enough to display one complete display line with true 8-bit resolution.

Two methods of reducing data are available. One is simply skipping the 8-bit to 6-bit (SKIP6, I²C-bus bit) and the other is a small form of data reduction to come from 8-bit to 6-bit (SMART6, I²C-bus bit). If both bits are set to logic 0 the device is in true 8-bit resolution mode. For the twin PIP mode the main channel is not placed in the VDRAM but in an internal buffer, 8 bit resolution is then possible for both PIPs.

PIP COMBINATIONS

Figures 4, 5 and 6 provide an overview of possible combinations as they can be shown on the screen. An example of fine positioning is given in the right four columns of Table 3.

More PIP modes can be obtained by varying the horizontal and vertical reduction factors to meet correct aspect ratios when using 16 : 9 screens.

In manual mode more PIP modes become available. Table 6 with associating text describes how to setup a PIP mode.

SAB9077H

I²C-bus description

The I²C-bus provides bidirectional 2-line communication between different ICs. The SDA line is the serial data line and SCL serves as serial clock line. Both lines must be connected to a positive supply via a pull-up resistor when connected to the output stages of a device. Data transfer may be initiated only when the bus is not busy.

The SAB9077H has the I²C-bus addresses 2C and 2E, switchable by the pin A0. Valid subaddresses are 00H to 18H (Table 4) and 20H to 32H (Table 6).

I²C-bus control is in accordance with the I²C-bus protocol.

First a START sequence must be put on the I²C-bus, then the I²C-bus address of the circuit must be send, followed by a subaddress. After this sequence the data of the subaddresses must be sent. An auto-increment function gives the option to send data of the incremented subaddresses until a STOP sequence is send.

Table 4 gives an overview of the I²C-bus addresses.

Table 4 Overview of I²C-bus addresses

Note

1. The data bits which are not used should be set to zero.

Picture-In-Picture (PIP) controller

SAB9077H

SA 00H PIP REGISTER

MPIPON and SPIPON bits switch respectively the main and sub PIPs of the SAB9077H on or off. The MFREEZE and SFREEZE bits make the current live pictures for the Main and Sub frozen. The writing to the VDRAM is stopped.

The MCOPIE bit copies the Main data direct to the output. This mode should only be set when MREDV is 1/1. Table 2 gives more information when to set this bit. The PIPMODE bits set the PIP mode in accordance with Table 3.

SA 01H DISPLAY REGISTER

M1FLD and S1FLD⁽¹⁾ bits control the use of the reserved second field in the VDRAM. If this bit is set to logic 0 then address spaces are reserved for both fields in the VDRAM. This avoids joint line errors. Whether these address spaces are used is dependent on the interlacing of the input signals and the NONINT bits. If a 1FLD bit is set to logic 1 then only 1 address space is used in the VDRAM for both fields. In some PIP modes the use of a second field is not possible since there is not enough space in the VDRAM, in these modes the 1FLD bit must be set to logic 1. The DNONINT bit controls the interlace mode of the display part. If set to logic 1 then data is only read from one field in the VDRAM. If set to logic 0 then both fields (if available) are used for display.

MNONINT and SNONINT bits control the interlace mode of the acquisition blocks. If set to logic 1 then data is only written to one field in the VDRAM (two fields remain allocated). If set to logic 0 then both fields (if available) are used for acquisition.

The NIPCOFF bit determines whether a grey bar is inserted in case a NTSC PIP is displayed in a PIP with PAL PIP size. The missing lines are equally divided between the top part and the bottom part of the PIP window and made 30% grey. If this bit is set to logic 0 the grey bar is displayed, if this bit is set to logic 1 the grey bar is omitted and the PIP data is shifted up.

SA 02H DISPLAY REGISTER

The DFILT bit controls an interpolating filter that changes the internal 864 pixels data rate to the output data rate of 2×864 pixels. If DFILT is set to logic 1 then the filter is on.

The FILLOFF bit controls filling of PIPs when the PIP mode is switched. If FILLOFF is set to logic 0 then all PIPs are filled with a 30% gray until their channel has been updated.

If FILLOFF is set to logic 1 then the VDRAM content is always visible. This is useful when a new, 'similar' to the previous one, PIP mode is set. The previous data can then be displayed.

The SMART6 and SKIP6 bits control the data transfer mode to the external VDRAM. For modes which display a complete line (672 pixels) a form of data reduction has to be carried out.

Two transfer modes are available. One is simply skipping the 8-bit data path to 6-bit (SKIP6). The other is carry out an intelligent data reduction which keeps an 8-bit resolution (SMART6).

The YTH bits control the video output. If the current Y-value is less than $YTH \times 16$ then the fast blank is switched off, the original live background will be visible. This feature can be used to pick up sub-titles and display them as On-Screen Display (OSD) anywhere on the screen.

SA 03H DISPLAY BACKGROUND FINE POSITIONING REGISTER

The BGHFP bits control the horizontal display positioning of the background. The resolution is 16 steps of 4 pixels. The BGVFP bits control the vertical display positioning of the background. The resolution is 16 steps of 2 lines/field. The background fine positioning moves the complete display. It is a general offset of all the PIP pictures and background, It is only meant to adjust once the centring of all PIP modes (see Fig.3).

SA 04H AND SA 05H DISPLAY SUB-CHANNEL FINE POSITIONING REGISTERS

These registers control the horizontal and vertical fine positioning of the display sub-channel with respect to the display background. This is the actual fine positioning (see Fig.3). The horizontal resolution is 256 steps of 4 pixels and the vertical resolution is 256 steps of 1 line/field.

SA 06H AND SA 07H DISPLAY MAIN-CHANNEL FINE POSITIONING REGISTERS

These registers control the horizontal and vertical fine positioning of the display main-channel with respect to the display background. This is the actual fine positioning (see Fig.3). The horizontal resolution is 256 steps of 4 pixels and the vertical resolution is 256 steps of 1 line/field.

(1) If the 1 FLD bits are set to logic 1 the NONINT bits of the corresponding channel must also be set to logic 1.

Picture-In-Picture (PIP) controller

SAB9077H

SA 08H DISPLAY REDUCTION FACTORS REGISTER

This register sets the display reduction factors, independent of the acquisition reduction factors. It sets the PIP size to a certain default value in such a way that the border drawn around the PIP is just fitting.

SA 09H ACQUISITION REDUCTION FACTORS REGISTER

This register sets the acquisition reduction factors, independent of the display reduction factors. If the HRED is 1 to 1 then the VRED must also be 1 : 1.

Restrictions are:

- The DREDH and AREDH must be the same
- The DREDV is equal or smaller than the AREDV (e.g DREDV is 1 to 2 and AREDV is 1 : 1).

SA 0AH AND SA 0CH ACQUISITION FINE POSITIONING REGISTERS

These registers determine the start of the acquisition area. Horizontal fine positioning can be adjusted with 16 steps of 2 pixels, vertical fine positioning can be adjusted with 256 steps of 1 line/field.

SA 0DH AND SA 0EH SELECTION REGISTERS

The MLSEL and SLSEL bits control which PIP is live. Both main channel and sub-channel can have one live PIP. Counting is done from upper-left to lower-right.

The MBSEL and SBSEL bits control which PIP border has a different colour. Both main and sub-channel can have a different PIP channel border selection. Counting is done from upper-left to lower-right.

SA 0FH BORDER SIZE REGISTER

This register controls the border size. The minimum horizontal border is 2 pixels. The minimum vertical border is 1 line. The vertical border size is multiplied by the FH mode number before it is displayed on the screen.

SA 10H AND SA 11H BORDER COLOUR AND BORDER SELECT COLOUR OF SUB-CHANNEL REGISTERS (see Table 5)

If SBON is set to logic 1 then the border of the sub-channel is visible. The SBBRT and SBCOL bits control the brightness and colour of the sub-channel border colour.

If SBSON is set to logic 1 then one sub-PIP border can have a different colour. This border is selected by the SBSEL bits.

The SBSBRT and SBSCOL bits control the brightness and colour of the sub-border selection colour.

SA 12H AND SA 13H BORDER COLOUR AND BORDER SELECTION COLOUR OF MAIN CHANNEL REGISTERS (see Table 5)

If MBON is set to logic 1 then the border of the main channel is visible.

The MBBRT and MBCOL bits control the brightness and colour of the main-channel border colour. If MBSON is set to logic 1 then one main PIP border can have a different colour. This PIP is selected by the MBSEL bits, the function can be switched on if MBSON is set to logic 1.

The MBSBRT and MBSCOL bits control the brightness and colour of the main-border selection colour.

SA 14H BACKGROUND CONTROL REGISTER (see Table 5)

If BGON is set to logic 1 then the background is visible.

The BGBRT and BGCOL bits control the brightness and colour of the background colour.

Picture-In-Picture (PIP) controller

SAB9077H

Table 5 Colour types and brightness levels

| COLOUR TYPE | | BRIGHTNESS LEVEL | | | |
|-------------|-------|------------------|-----|-----|------|
| COLOUR | VALUE | 4H | 5H | 6H | 7H |
| Black | 0H | 0% | 10% | 30% | 50% |
| Blue | 1H | 30% | 50% | 70% | 100% |
| Red | 2H | 30% | 50% | 70% | 100% |
| Magenta | 3H | 30% | 50% | 70% | 100% |
| Green | 4H | 30% | 50% | 70% | 100% |
| Cyan | 5H | 30% | 50% | 70% | 100% |
| Yellow | 6H | 30% | 50% | 70% | 100% |
| White | 7H | 60% | 70% | 80% | 100% |

Table 5 indicates how I²C-bus register settings control the colour and brightness. All colour registers are similar, they contain one on/off bit, two brightness bits and three colour type bits. To determine which colour is visible in the event two or more colours being displayed on the same position, the next priority scheme is followed:

1. Sub-select colour (SBS)
2. Sub-border colour (SB)
3. Main-select colour (MBS)
4. Main-border colour (MB)
5. Background colour (BG).

SA 15H AND SA 16H DECODER REGISTERS

The MVFILT and SVFILT bits can set the type of vertical filtering. The MUVPOL and SUVPOL bits invert the UV polarity of the incoming signals. The MVSPOL and SVSPOL bits determine the active edge of the V_{sync} (see Fig.7). The MHSYNC and SHSYNC bits determine the timing of the H_{sync} pulse (burstkey or H_{sync} timing). The MFPOL and SFPOL bits can invert the field identification (ID) of the incoming fields (see Fig.7).

SA 17H DISPLAY SETTINGS REGISTER

The FBDEL bits can adjust the fast blank delay in 8 steps of 1/2 a clock cycle (-8 to +7). 0H is mid-scale. The DUVPOL bit inverts the UV polarity of the border colours.

The DVSPOL bit determines the active edge of the V_{sync} (see Fig.7). The DHSYNC bit determines the timing of the H_{sync} pulse (burstkey or H_{sync}). The DFPOL bit can invert the field ID of the incoming fields (see Fig.7).

SA 18H PEDESTAL SETTINGS REGISTER

The PEDESTU and PEDESTV bits give the U and V DAC outputs an offset of -8 to +7 LSB when the FBL is switched off. This can be used to adjust the White point of the system.

Picture-In-Picture (PIP) controller

Additional I²C-bus register and PIP modes become available in sub addresses 20H to 32H.

An overview of these I²C-bus registers is given in Table 6.

The meaning and relation of the I²C-bus registers is shown in Fig.8. The background has a fixed size and can be fine positioned with BGHFP and BGVFP bits. The shown PIPs are only for one channel (main or sub), the other channel has the same control and can be displayed at the same time. The SDHFP and MDHFP bits determine the most left shown pixel for this channel in 256 steps of 4 pixels.

The SDVFP and MDVFP bits determine the most upper shown pixel for this channel in 256 steps of 1 line.

The SHPIC and MHPIC bits determine the horizontal picture size in 256 steps of 4 pixels, the minimum value is 4 pixels. The SVPIC and MVPIC bits determine the vertical picture size in 256 steps of 1 line, the minimum value is 1 line. The PIP mode is built-up of a maximum of four horizontal rows. The minimum is one row, more rows can be displayed by setting the vertical repetition rate number

VRPN bits.

The distance between the rows can be set by the SVDIS and MVDIS bits. Every row is built-up of a maximum of four PIPs. The minimum is one PIP, additional PIPs can be added with the HRPN values. The SHRPO and MHRPO bits determine the offset distance between the starting points of the first PIP. The distances between the starting points of the PIPs on a row are determined by the SHDIS and MHDIS bits.

SA 20H CONTROL REGISTER

The PRI0 bit sets the priority between main and sub channel. If PRI0 is set to logic 0 priority is given to the sub channel which means that the sub channel PIPs, if present, are placed on top of the main PIPs. If PRI0 is set to logic 1 it places the main PIPs on top of the sub PIPs. The DPAL bit sets the correct default values for PAL on the display side. The background is enlarged from 238 lines/field to 288 lines/field.

Picture-In-Picture (PIP) controller

SAB9077H

The MPAL and SPAL bits set the acquisition area. When set to logic 1 the acquisition area is enlarged from 228 lines/field (NTSC) to 276 lines/field (PAL).

The MVRPN and SVRPN bits determine the number of repeated PIP rows. There is always one row visible of each channel. If no PIPs should be visible the PIP channel must be switched off (SA 00, bit 7 or bit 6).

SA 21H AND SA 2AH: HORIZONTAL REPETITION OFFSET REGISTERS FOR ROW 0 TO 3

The horizontal repetition offsets (MHRPO and SHRPO) are strongly related to the horizontal distance (MHDIS and SHDIS bits). These bits set for each row a certain grid of possible starting points for the PIPs in that row. Every grid point has a number 0 (the most left PIP), 1, 2 or 3. The SHRPO and MHRPO bits determine the first grid number which will be displayed. This mechanism can be set for each row.

SA 22H AND SA 2BH: HORIZONTAL REPETITION NUMBER REGISTERS FOR ROW 0 TO 3

The horizontal repetition numbers (MHRPO and SHRPO) determine how many times the PIPs are repeated in a row, once the first PIP is displayed. The repeated PIPs stay in the grid determined by the SHDIS and MHDIS bits for that row. This mechanism can be set for each row independently.

SA 23H AND SA 24H; SA 2CH AND SA 2DH: PICTURE SIZE REGISTERS

The MHPIC and SHPIC bits determine the horizontal PIP size in 256 steps of 4 pixels. The MVPIC and SVPIC bits determine the vertical PIP size line in 256 steps of 1 line for NTSC or 256 steps of 2 lines for PAL.

SA 25H TO SA 29H; SA 2EH TO SA 32H: PICTURE DISTANCE REGISTERS

For each row the distance between starting points of PIPs can be set with the MHDIS and SHDIS bits in 256 steps of 4 pixels. The distance between two rows can be set with the MVDIS and SVDIS bits in 256 steps of 1 line.

Acquisition channel ADCs

Both channels convert the analog input signals to digital signals by means of two ADCs for each channel. The internal input levels of the ADCs of each channel are equal and can be set by the AV_{refT} and AV_{refB} pins.

The reference levels are made internally by means of a resistor network which divides the analog voltage to a default set of preferred levels. External capacitors are needed to filter AC components on the reference levels. The resolution of the ADCs is 8-bit; Differential Non-Linearity (DNL) is 7-bit; Integral Non-Linearity (INL) is 6-bit, and the sampling is done at the system frequency of 27 MHz for the Y-input. The U/V inputs are multiplexed and sampled at 13.5 MHz. The analog input signals are amplified to make maximum use of the dynamic range of the ADCs. A bias voltage V_{bias} is used for decoupling AC components on internal references. The inputs should be AC-coupled and an internal clamp circuit will clamp the input to AV_{refB} for the luminance channels and to

$$\frac{AV_{refT} - AV_{refB}}{2} \text{ for the chrominance channels.}$$

The clamping starts at the leading edge of the burst key pulse.

Output DACs

The digitally processed signals are converted to analog signals by means of three 8-bit DACs. The output voltages of these DACs are default set by the DAV_{refT} pin for the top level and DAV_{refB} pin for the bottom level. Default values are 1.5 V.

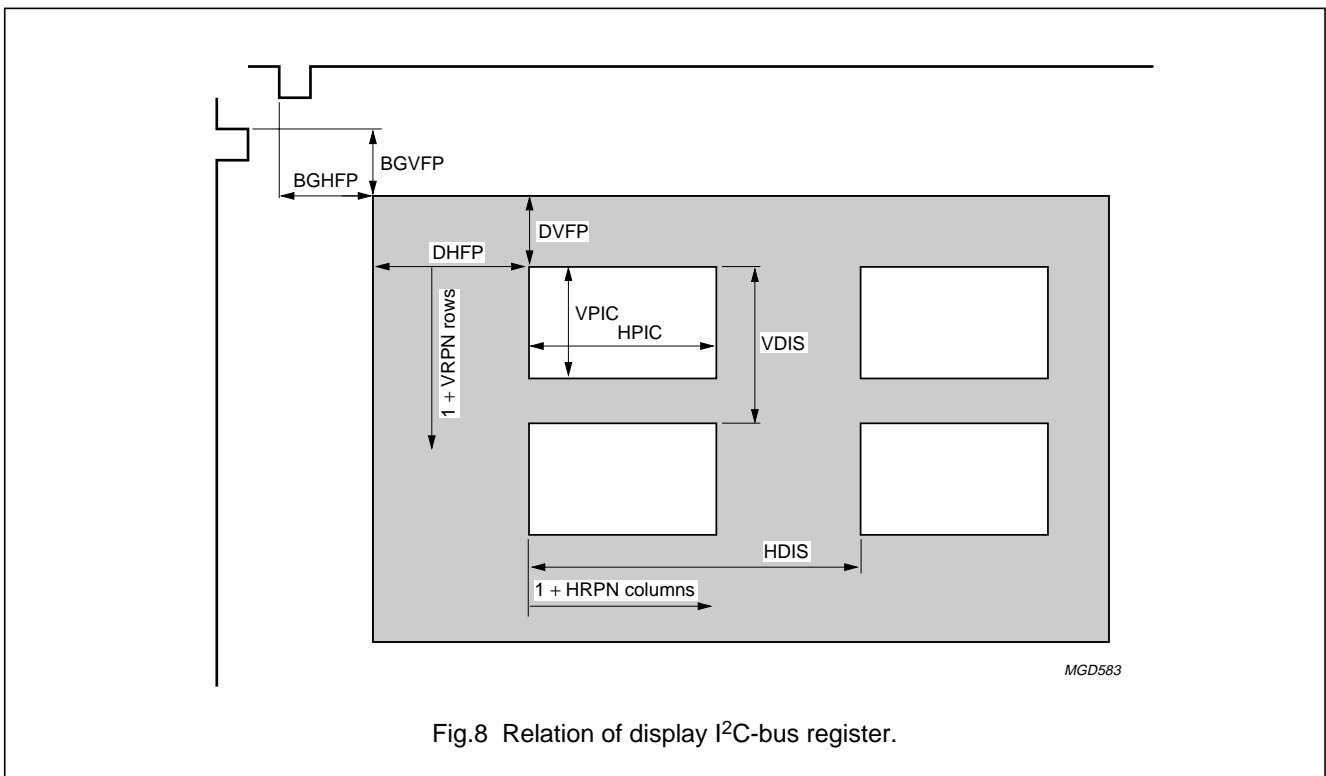

External memory

For the external memory two VDRAMs of type Mitsubishi M5M442256 are foreseen. They have a storage capacity of 262 144 words of 4-bit each and will be used in parallel.

It is also possible to use one 2 Mbit VDRAM of 262 144 words of 8-bit. An overview of the timing diagrams is given in Fig.9.

Notes

1. Digital clocks are silent, POR and TM_2 are connected to V_{DD} .
2. The V_{refT} and V_{refB} are made by a resistor division of the V_{DD} . They can be calculated with the formulas

$$V_{refT} = AV_{DD} \times \left(\frac{2.0}{5.0}\right) V \text{ and } V_{refB} = AV_{DD} \times \left(\frac{0.4}{5.0}\right) V$$
3. The internal system frequency is 1728 times the H_{sync} input frequency for both the acquisition and display PLLs.
4. The Y-channel is clamped to the V_{refB} of the ADCs.
5. The UV-channel is clamped to $1/2(V_{refT} + V_{refB} + V_{LSB})$.
6. The gain of the SAB9077H is 1 under the condition that the R_L is 220 Ω .

Picture-In-Picture (PIP) controller

TEST AND APPLICATION INFORMATION

The application diagram for 1 FH mode in a standard configuration is shown in Fig.10. Two input signals MCVBS and SCVBS of different sources are processed by the SAB9077H and inserted by the YUV/RGB switch.

The synchronization of the display PLL is derived from the deflection circuit. The main signals are also led to the deflection circuit and the YUV/RGB switch where the SAB9077H signals can be inserted. The signals for deflection can also be taken from the main channel or sub-channel decoder.

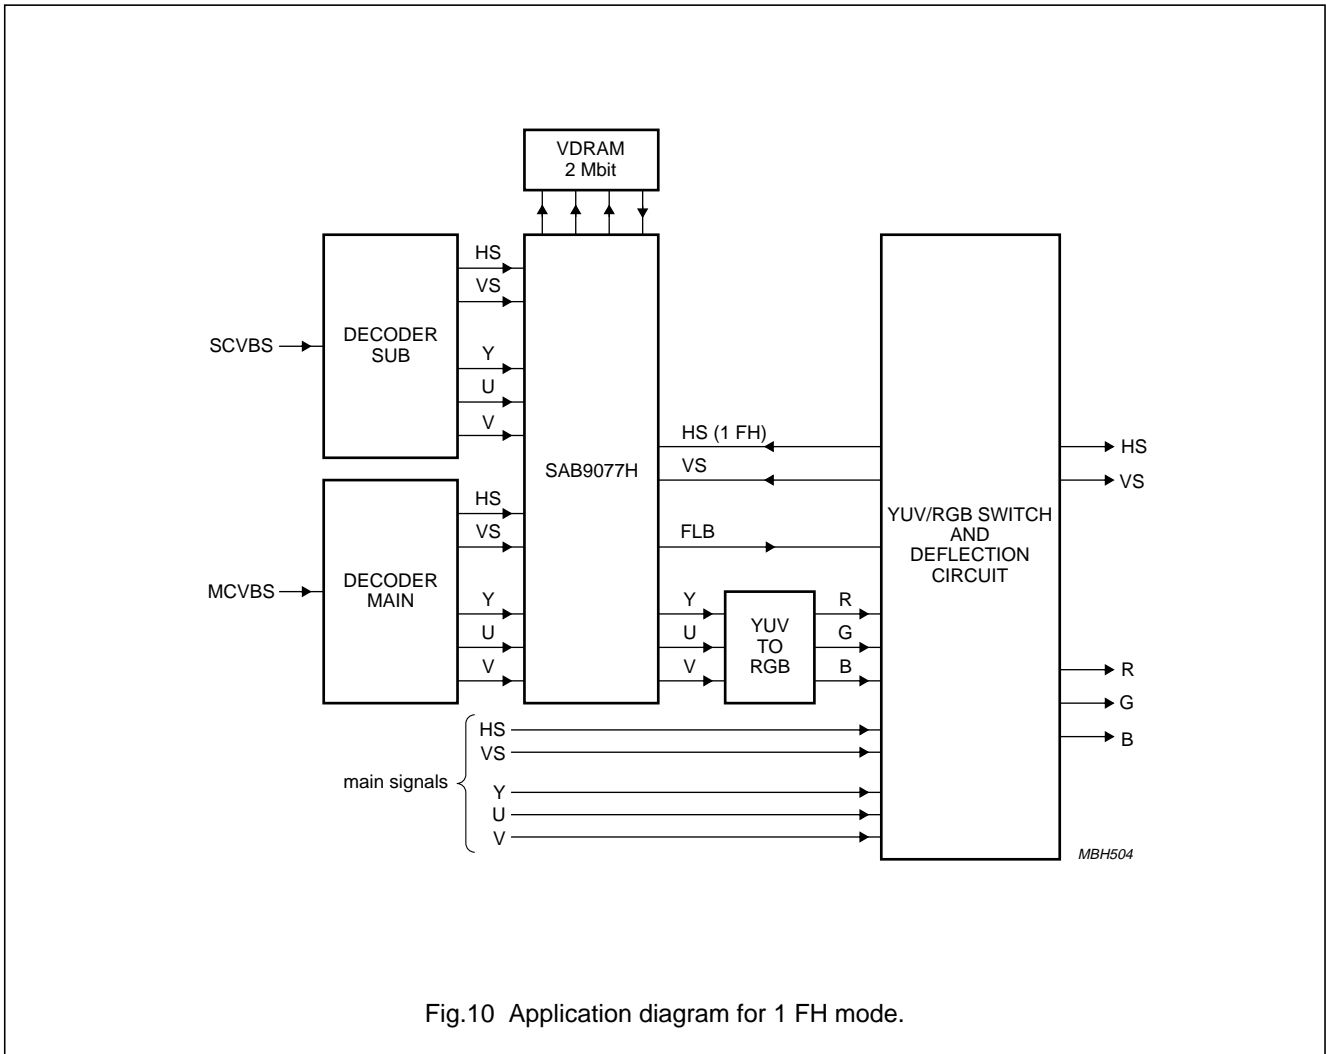

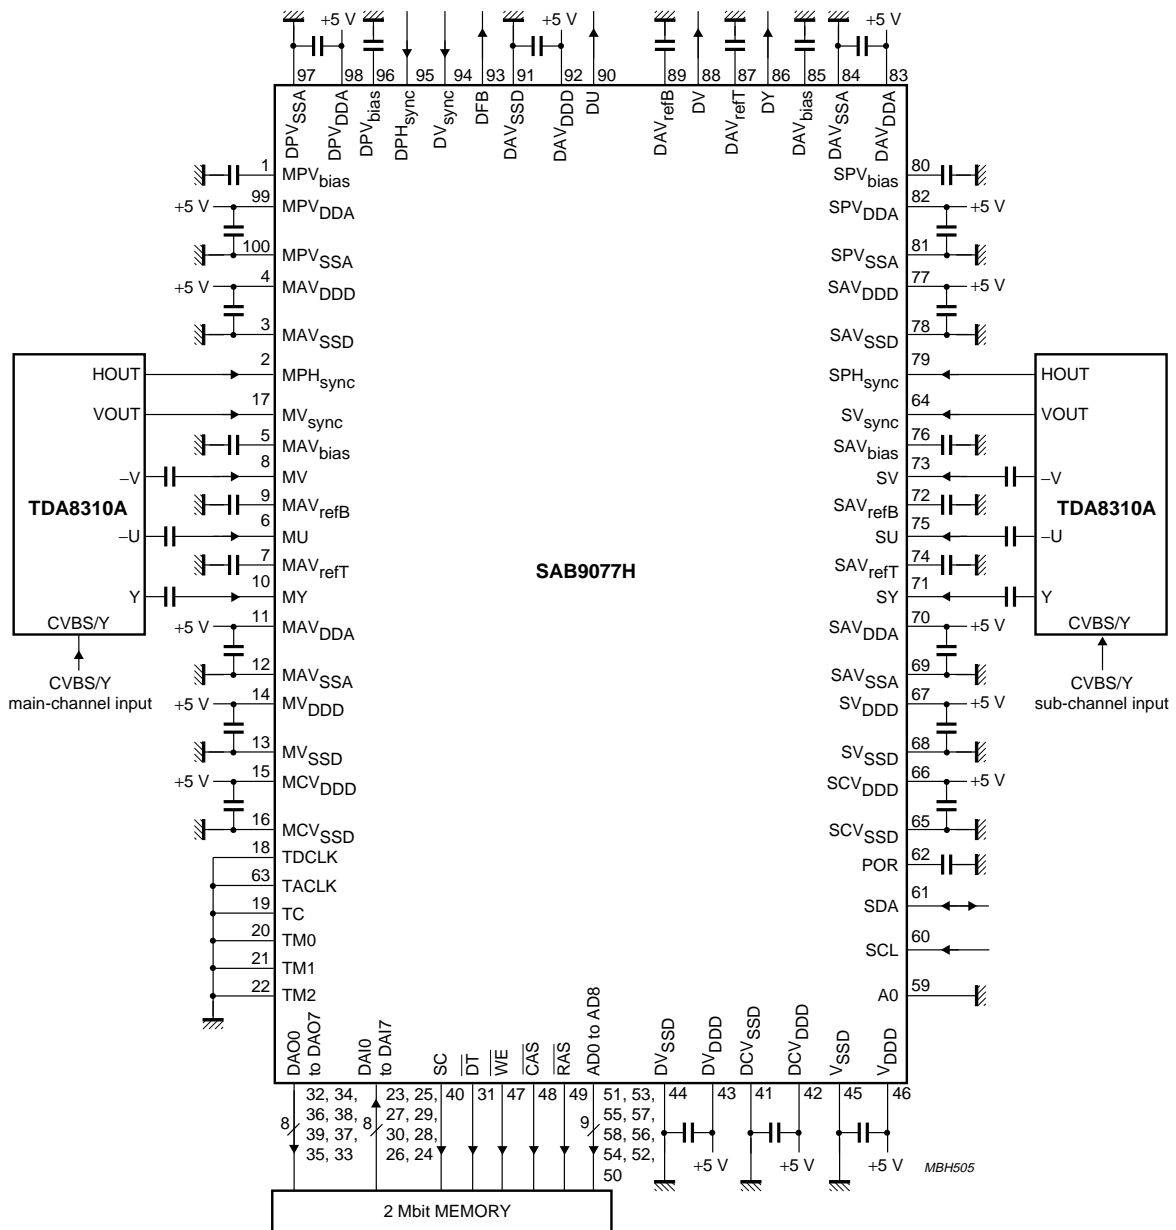

Fig.10 Application diagram for 1 FH mode.

Picture-In-Picture (PIP) controller

SAB9077H

All capacitors are 100 nF.
 On the application board a ground plane should be used.

SOLDERING

Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"IC Package Databook"* (order code 9398 652 90011).

Reflow soldering

Reflow soldering techniques are suitable for all QFP packages.

The choice of heating method may be influenced by larger plastic QFP packages (44 leads, or more). If infrared or vapour phase heating is used and the large packages are not absolutely dry (less than 0.1% moisture content by weight), vaporization of the small amount of moisture in them can cause cracking of the plastic body. For more information, refer to the Drypack chapter in our *"Quality Reference Handbook"* (order code 9397 750 00192).

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

Wave soldering

Wave soldering is **not** recommended for QFP packages. This is because of the likelihood of solder bridging due to closely-spaced leads and the possibility of incomplete solder penetration in multi-lead devices.

If wave soldering cannot be avoided, the following conditions must be observed:

- **A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.**
- **The footprint must be at an angle of 45° to the board direction and must incorporate solder thieves downstream and at the side corners.**

Even with these conditions, do not consider wave soldering the following packages: QFP52 (SOT379-1), QFP100 (SOT317-1), QFP100 (SOT317-2), QFP100 (SOT382-1) or QFP160 (SOT322-1).

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

Repairing soldered joints

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

DEFINITIONS

| | |
|---|---|
| Data sheet status | |
| Objective specification | This data sheet contains target or goal specifications for product development. |
| Preliminary specification | This data sheet contains preliminary data; supplementary data may be published later. |
| Product specification | This data sheet contains final product specifications. |
| Limiting values | |
| Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability. | |
| Application information | |
| Where application information is given, it is advisory and does not form part of the specification. | |

LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.

PURCHASE OF PHILIPS I²C COMPONENTS

Purchase of Philips I²C components conveys a license under the Philips' I²C patent to use the components in the I²C system provided the system conforms to the I²C specification defined by Philips. This specification can be ordered using the code 9398 393 40011.
