Micropower 150 mA LDO Linear Regulators with ENABLE, DELAY, RESET, and Monitor Flag

The NCV8501 is a family of precision micropower voltage regulators. Their output current capability is 150 mA. The family has output voltage options for adjustable, 2.5 V, 3.3 V, 5.0 V, 8.0 V, and 10 V.

The output voltage is accurate within $\pm 2.0\%$ with a maximum dropout voltage of 0.6 V at 150 mA. Low quiescent current is a feature drawing only 90 μ A with a 100 μ A load. This part is ideal for any and all battery operated microprocessor equipment.

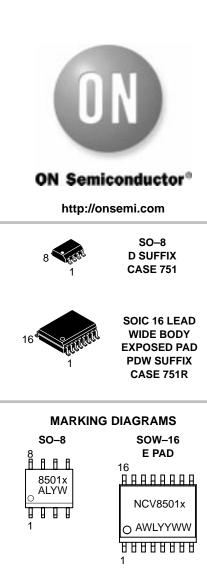

Microprocessor control logic includes an active $\overline{\text{RESET}}$ (with DELAY), and a flag monitor which can be used to provide an early warning signal to the microprocessor of a potential impending $\overline{\text{RESET}}$ signal. The use of the flag monitor allows the microprocessor to finish any signal processing before the $\overline{\text{RESET}}$ shuts the microprocessor down.

The active $\overline{\text{RESET}}$ circuit operates correctly at an output voltage as low as 1.0 V. The $\overline{\text{RESET}}$ function is activated during the power up sequence or during normal operation if the output voltage drops outside the regulation limits.

The regulator is protected against reverse battery, short circuit, and thermal overload conditions. The device can withstand load dump transients making it suitable for use in automotive environments. The device has also been optimized for EMC conditions.

Features

- Output Voltage Options: Adjustable, 2.5 V, 3.3 V, 5.0 V, 8.0 V, 10 V
- ± 2.0% Output
- Low 90 µA Quiescent Current
- Fixed or Adjustable Output Voltage
- Active RESET
- ENABLE
- 150 mA Output Current Capability
- Fault Protection
 - +60 V Peak Transient Voltage
 - -15 V Reverse Voltage
 - Short Circuit
 - Thermal Overload
- Early Warning through FLAG/MON Leads

= Voltage Ratings as Indicated Below:

- A = Adjustable 2 = 2.5 V
- 2 = 2.3 V 3 = 3.3 V
- 5 = 5.0 V
- 8 = 8.0 V
- 0 = 10 V

CIRCUIT DESCRIPTION

REGULATOR CONTROL FUNCTIONS

The NCV8501 contains the microprocessor compatible control function $\overline{\text{RESET}}$ (Figure 11).

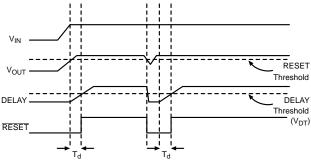

Figure 11. Reset and Delay Circuit Wave Forms

RESET Function

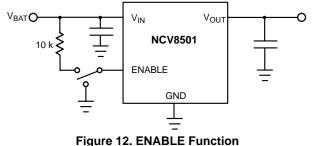

A RESET signal (low voltage) is generated as the IC powers up until V_{OUT} is within 6.0% of the regulated output voltage, or when V_{OUT} drops out of regulation, and is lower than 8.0% below the regulated output voltage. Hysteresis is included in the function to minimize oscillations.

The $\overline{\text{RESET}}$ output is an open collector NPN transistor, controlled by a low voltage detection circuit. The circuit is functionally independent of the rest of the IC thereby guaranteeing that the $\overline{\text{RESET}}$ signal is valid for V_{OUT} as low as 1.0 V.

ENABLE Function

The part stays in a low I_Q sleep mode when the ENABLE pin is held low. The part has an internal pull down if the pin is left floating. This is intended for failure modes only. An external connection (active pulldown, resistor, or switch) for normal operation is recommended.

The integrity of the ENABLE pin allows it to be tied directly to the battery line through an external resistor. It will withstand load dump potentials in this configuration.

DELAY Function

The reset delay circuit provides a programmable (by external capacitor) delay on the $\overline{\text{RESET}}$ output lead.

The DELAY lead provides source current (typically $2.5 \,\mu$ A) to the external DELAY capacitor during the following proceedings:

- 1. During Power Up (once the regulation threshold has been verified).
- 2. After a reset event has occurred and the device is back in regulation. The DELAY capacitor is discharged when the regulation (RESET threshold) has been violated. This is a latched incident. The capacitor will fully discharge and wait for the device to regulate before going through the delay time event again.

FLAG/Monitor Function

An on-chip comparator is provided to perform an early warning to the microprocessor of a possible reset signal. The reset signal typically turns the microprocessor off instantaneously. This can cause unpredictable results with the microprocessor. The signal received from the FLAG pin will allow the microprocessor time to complete its present task before shutting down. This function is performed by a comparator referenced to the bandgap reference. The actual trip point can be programmed externally using a resistor divider to the input monitor (MON) (Figure 13).

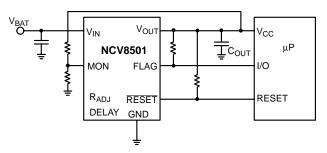

Figure 13. Flag/Monitor Function

Voltage Adjust

Figure 14 shows the device setup for a user configurable output voltage. The feedback to the V_{ADJ} pin is taken from a voltage divider referenced to the output voltage. The loop is balanced around the Unity Gain threshold (1.28 V typical).

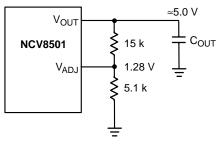

Figure 14. Adjustable Output Voltage

APPLICATION NOTES

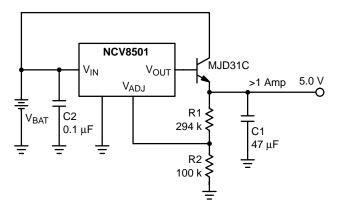

Figure 15. Additional Output Current

Adding Capability

Figure 15 shows how the adjustable version of parts can be used with an external pass transistor for additional current capability. The setup as shown will provide greater than 1 Amp of output current.

FLAG MONITOR

Figure 16 shows the FLAG Monitor waveforms as a result of the circuit depicted in Figure 13. As the output voltage falls (V_{OUT}), the Monitor threshold is crossed. This causes the voltage on the FLAG output to go low sending a warning signal to the microprocessor that a RESET signal may occur in a short period of time. T_{WARNING} is the time the microprocessor has to complete the function it is currently working on and get ready for the RESET shutdown signal.

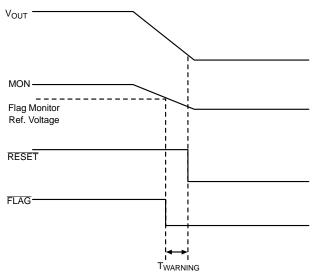

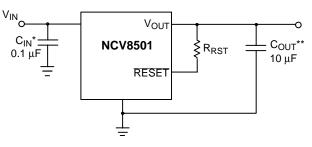

Figure 16. FLAG Monitor Circuit Waveform

*C_{IN} required if regulator is located far from the power supply filter **C_{OUT} required for stability. Capacitor must operate at minimum temperature expected

Figure 17. Test and Application Circuit Showing Output Compensation

SETTING THE DELAY TIME

The delay time is controlled by the Reset Delay Low Voltage, Delay Switching Threshold, and the Delay Charge Current. The delay follows the equation:

$${}^{t}\text{DELAY} = \frac{[C_{\text{DELAY}}(V_{\text{dt}} - \text{Reset Delay Low Voltage})]}{\text{Delay Charge Current}}$$

Example:

Using $C_{DELAY} = 33$ nF. Assume reset Delay Low Voltage = 0. Use the typical value for $V_{dt} = 1.8$ V.

Use the typical value for Delay Charge Current = $2.5 \,\mu$ A.

$$t_{\text{DELAY}} = \frac{[33 \text{ nF}(1.8 - 0)]}{2.5 \,\mu\text{A}} = 23.8 \text{ ms}$$

STABILITY CONSIDERATIONS

The output or compensation capacitor helps determine three main characteristics of a linear regulator: start–up delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. A tantalum or aluminum electrolytic capacitor is best, since a film or ceramic capacitor with almost zero ESR can cause instability. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures (-25° C to -40° C), both the value and ESR of the capacitor will vary considerably. The capacitor manufacturers data sheet usually provides this information.

The value for the output capacitor C_{OUT} shown in Figure 17 should work for most applications, however it is not necessarily the optimized solution.

CALCULATING POWER DISSIPATION IN A SINGLE OUTPUT LINEAR REGULATOR

The maximum power dissipation for a single output regulator (Figure 18) is:

$$PD(max) = [VIN(max) - VOUT(min)]IOUT(max)$$
(1)
+ VIN(max)IQ

where:

V_{IN(max)} is the maximum input voltage,

V_{OUT(min)} is the minimum output voltage,

 $I_{OUT(max)}$ is the maximum output current for the application, and

 I_Q is the quiescent current the regulator consumes at $I_{OUT(max)}$.

Once the value of $P_{D(max)}$ is known, the maximum permissible value of $R_{\Theta JA}$ can be calculated:

$$R_{\Theta}JA = \frac{150^{\circ}C - T_A}{P_D}$$
(2)

The value of $R_{\Theta JA}$ can then be compared with those in the package section of the data sheet. Those packages with $R_{\Theta JA}$'s less than the calculated value in equation 2 will keep the die temperature below 150°C.

In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heatsink will be required.

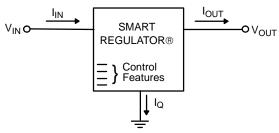

Figure 18. Single Output Regulator with Key Performance Parameters Labeled

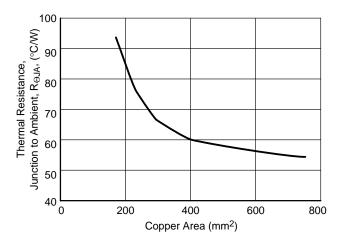

Figure 19. 16 Lead SOW (Exposed Pad), Θ JA as a Function of the Pad Copper Area (2 oz. Cu Thickness), Board Material = 0.0625" G-10/R-4

HEAT SINKS

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\Theta IA}$:

$$R_{\Theta JA} = R_{\Theta JC} + R_{\Theta CS} + R_{\Theta SA}$$
(3)

where:

 $R_{\Theta JC}$ = the junction–to–case thermal resistance,

 $R_{\Theta CS}$ = the case-to-heatsink thermal resistance, and

 $R_{\Theta SA}$ = the heatsink-to-ambient thermal resistance.

 $R_{\Theta JC}$ appears in the package section of the data sheet. Like $R_{\Theta JA}$, it too is a function of package type. $R_{\Theta CS}$ and $R_{\Theta SA}$ are functions of the package type, heatsink and the interface between them. These values appear in heat sink data sheets of heat sink manufacturers.
