

PIC18F97J60 Family Data Sheet

64/80/100-Pin, High-Performance, 1 Mbit Flash Microcontrollers with Ethernet

© 2006 Microchip Technology Inc.

Note the following details of the code protection feature on Microchip devices:

- Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights.

Printed on recycled paper.

Microchip received ISO/TS-16949:2002 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona, Gresham, Oregon and Mountain View, California. The Company's quality system processes and procedures are for its PIC[®] 8-bit MCUs, KEELOO[®] code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.

64/80/100-Pin, High-Performance, 1-Mbit Flash Microcontrollers with Ethernet

Ethernet Features:

- IEEE 802.3 compatible Ethernet Controller
- Integrated MAC and 10Base-T PHY
- 8-Kbyte Transmit/Receive Packet Buffer SRAM
- Supports One 10Base-T Port
- Programmable Automatic Retransmit on Collision
- Programmable Padding and CRC Generation
- Programmable Automatic Rejection of Erroneous Packets
- Activity Outputs for 2 LED Indicators
- Buffer:
 - Configurable transmit/receive buffer size
 - Hardware-managed circular receive FIFO
 - Byte-wide random and sequential access
 - Internal DMA for fast memory copying
 - Hardware assisted checksum calculation for various protocols
- MAC:
 - Support for Unicast, Multicast and Broadcast packets
 - Programmable Pattern Match of up to 64 bytes within packet at user-defined offset
 - Programmable wake-up on multiple packet formats
- PHY:
 - Wave shaping output filter

Flexible Oscillator Structure:

- Selectable System Clock derived from Single 25 MHz External Source:
 - 2.778 to 41.667 MHz
- Internal 31 kHz Oscillator
- Secondary Oscillator using Timer1 @ 32 kHz
- Fail-Safe Clock Monitor:
- Allows for safe shutdown if oscillator stops
- Two-Speed Oscillator Start-up

External Memory Bus (100-pin devices only):

- · Address Capability of up to 2 Mbytes
- 8-Bit or 16-Bit Interface
- 12-Bit, 16-Bit and 20-Bit Addressing modes

Peripheral Highlights:

- High-Current Sink/Source: 25 mA/25 mA on PORTB and PORTC
- Five Timer modules (Timer0 to Timer4)
- Four External Interrupt pins
- Two Capture/Compare/PWM (CCP) modules
- Three Enhanced Capture/Compare/PWM (ECCP)
 modules:
 - One, two or four PWM outputs
 - Selectable polarity
 - Programmable dead time
 - Auto-shutdown and auto-restart
- Up to Two Master Synchronous Serial Port (MSSP) modules supporting SPI (all 4 modes) and I²C[™] Master and Slave modes
- Up to Two Enhanced USART modules:
 - Supports RS-485, RS-232 and LIN 1.2
 - Auto-wake-up on Start bit
 - Auto-Baud Detect (ABD)
- 10-Bit, Up to 16-Channel Analog-to-Digital Converter module (A/D):
 - Auto-acquisition capability
 - Conversion available during Sleep
- Dual Analog Comparators with Input Multiplexing
- Parallel Slave Port (PSP) module (100-pin devices only)

Special Microcontroller Features:

- 5.5V Tolerant Inputs (digital-only pins)
- Low-Power, High-Speed CMOS Flash Technology:
 Self-reprogrammable under software control
- C compiler Optimized Architecture for Reentrant Code
- Power Management Features:
 - Run: CPU on, peripherals on
 - Idle: CPU off, peripherals on
 - Sleep: CPU off, peripherals off
- Priority Levels for Interrupts
- 8 x 8 Single-Cycle Hardware Multiplier
- Extended Watchdog Timer (WDT):
 - Programmable period from 4 ms to 134s
- Single-Supply 3.3V In-Circuit Serial Programming[™] (ICSP[™]) via Two Pins
- In-Circuit Debug (ICD) with 3 Breakpoints via Two Pins
- Operating Voltage Range of 2.35V to 3.6V (3.1V to 3.6V using Ethernet module)
- On-Chip 2.5V Regulator

TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at **docerrors@microchip.com** or fax the **Reader Response Form** in the back of this data sheet to (480) 792-4150. We welcome your feedback.

Most Current Data Sheet

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Web site at:

http://www.microchip.com

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000A is version A of document DS30000).

Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

- Microchip's Worldwide Web site; http://www.microchip.com
- Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include literature number) you are using.

Customer Notification System

Register on our web site at www.microchip.com to receive the most current information on all of our products.

1.0 DEVICE OVERVIEW

This document contains device-specific information for the following devices:

- PIC18F66J60
 - PIC18F87J60PIC18F96J60
- PIC18F66J65PIC18F67J60
- PIC18F96J65
 DIC18F97J69
- PIC18F86J60
 PIC18F86J60
- PIC18F97J60
- PIC18F86J65

This family introduces a new line of low-voltage devices with the foremost traditional advantage of all PIC18 microcontrollers – namely, high computational performance and a rich feature set at an extremely competitive price point. These features make the PIC18F97J60 family a logical choice for many high-performance applications where cost is a primary consideration.

1.1 Core Features

1.1.1 OSCILLATOR OPTIONS AND FEATURES

All of the devices in the PIC18F97J60 family offer five different oscillator options, allowing users a range of choices in developing application hardware. These options include:

- Two Crystal modes, using crystals or ceramic resonators.
- Two External Clock modes, offering the option of a divide-by-4 clock output.
- A Phase Lock Loop (PLL) frequency multiplier, available to the external oscillator modes, which allows clock speeds of up to 41.667 MHz.
- An internal RC oscillator with a fixed 31 kHz output which provides an extremely low-power option for timing-insensitive applications.

The internal oscillator block provides a stable reference source that gives the family additional features for robust operation:

- Fail-Safe Clock Monitor: This option constantly monitors the main clock source against a reference signal provided by the internal oscillator. If a clock failure occurs, the controller is switched to the internal oscillator, allowing for continued low-speed operation or a safe application shutdown.
- **Two-Speed Start-up:** This option allows the internal oscillator to serve as the clock source from Power-on Reset, or wake-up from Sleep mode, until the primary clock source is available.

1.1.2 EXPANDED MEMORY

The PIC18F97J60 family provides ample room for application code, from 64 Kbytes to 128 Kbytes of code space. The Flash cells for program memory are rated to last 100 erase/write cycles. Data retention without refresh is conservatively estimated to be greater than 20 years.

The PIC18F97J60 family also provides plenty of room for dynamic application data with 3808 bytes of data RAM.

1.1.3 EXTERNAL MEMORY BUS

In the unlikely event that 128 Kbytes of memory are inadequate for an application, the 100-pin members of the PIC18F97J60 family also implement an External Memory Bus (EMB). This allows the controller's internal program counter to address a memory space of up to 2 Mbytes, permitting a level of data access that few 8-bit devices can claim. This allows additional memory options, including:

- Using combinations of on-chip and external memory up to the 2-Mbyte limit
- Using external Flash memory for reprogrammable application code or large data tables
- Using external RAM devices for storing large amounts of variable data

1.1.4 EXTENDED INSTRUCTION SET

The PIC18F97J60 family implements the optional extension to the PIC18 instruction set, adding eight new instructions and an Indexed Addressing mode. Enabled as a device configuration option, the extension has been specifically designed to optimize reentrant application code originally developed in high-level languages, such as C.

1.1.5 EASY MIGRATION

Regardless of the memory size, all devices share the same rich set of peripherals, allowing for a smooth migration path as applications grow and evolve.

1.2 Other Special Features

- Communications: The PIC18F97J60 family incorporates a range of serial communication peripherals, including up to two independent Enhanced USARTs and up to two Master SSP modules, capable of both SPI and I²C™ (Master and Slave) modes of operation. In addition, one of the general purpose I/O ports can be reconfigured as an 8-bit Parallel Slave Port for direct processor-to-processor communications.
- CCP Modules: All devices in the family incorporate two Capture/Compare/PWM (CCP) modules and three Enhanced CCP (ECCP) modules to maximize flexibility in control applications. Up to four different time bases may be used to perform several different operations at once. Each of the three ECCP modules offers up to four PWM outputs, allowing for a total of twelve PWMs. The ECCP modules also offer many beneficial features, including polarity selection, programmable dead time, auto-shutdown and restart and Half-Bridge and Full-Bridge Output modes.
- **10-Bit A/D Converter:** This module incorporates programmable acquisition time, allowing for a channel to be selected and a conversion to be initiated without waiting for a sampling period and thus, reducing code overhead.
- Extended Watchdog Timer (WDT): This enhanced version incorporates a 16-bit prescaler, allowing an extended time-out range. See Section 27.0 "Electrical Characteristics" for time-out periods.

1.3 Details on Individual Family Members

Devices in the PIC18F97J60 family are available in 64-pin, 80-pin and 100-pin packages. Block diagrams for the three groups are shown in Figure 1-1, Figure 1-2 and Figure 1-3.

The devices are differentiated from each other in four ways:

- Flash program memory (three sizes, ranging from 64 Kbytes for PIC18FX6J60 devices to 128 Kbytes for PIC18FX7J60 devices).
- A/D channels (eleven for 64-pin devices, fifteen for 80-pin pin devices and sixteen for 100-pin devices).
- Serial communication modules (one EUSART module and one MSSP module on 64-pin devices, two EUSART modules and one MSSP module on 80-pin devices and two EUSART modules and two MSSP modules on 100-pin devices).
- 4. I/O pins (39 on 64-pin devices, 55 on 80-pin devices and 70 on 100-pin devices).

All other features for devices in this family are identical. These are summarized in Table 1-1, Table 1-2 and Table 1-3.

The pinouts for all devices are listed in Table 1-4, Table 1-5 and Table 1-6.

2.0 OSCILLATOR CONFIGURATIONS

2.1 Overview

Devices in the PIC18F97J60 family incorporate an oscillator and microcontroller clock system that differs from standard PIC18FXXJXX devices. The addition of the Ethernet module, with its requirement for a stable 25 MHz clock source, makes it necessary to provide a primary oscillator that can provide this frequency as well as a range of different microcontroller clock speeds. An overview of the oscillator structure is shown in Figure 2-1.

Other oscillator features used in PIC18FXXJXX enhanced microcontrollers, such as the internal RC oscillator and clock switching, remain the same. They are discussed later in this chapter.

2.2 Oscillator Types

The PIC18F97J60 family of devices can be operated in five different oscillator modes:

- 1. HS High-Speed Crystal/Resonator
- 2. HSPLL High-Speed Crystal/Resonator with Software PLL Control
- 3. EC External Clock with Fosc/4 Output
- 4. ECPLL External Clock with Software PLL Control
- 5. INTRC Internal 31 kHz Oscillator

2.2.1 OSCILLATOR CONTROL

The oscillator mode is selected by programming the FOSC2:FOSC0 Configuration bits. FOSC1:FOSC0 bits select the default primary oscillator modes, while FOSC2 selects when INTRC may be invoked.

The OSCCON register (Register 2-2) selects the Active Clock mode. It is primarily used in controlling clock switching in power-managed modes. Its use is discussed in **Section 2.7.1 "Oscillator Control Register"**.

The OSCTUNE register (Register 2-1) is used to select the system clock frequency from the primary oscillator source by selecting combinations of prescaler/postscaler settings and enabling the PLL. Its use is described in **Section 2.6.1 "PLL Block"**.

FIGURE 2-1: PIC18F97J60 FAMILY CLOCK DIAGRAM

2.3 Crystal Oscillator/Ceramic Resonators (HS Modes)

In HS or HSPLL Oscillator modes, a crystal is connected to the OSC1 and OSC2 pins to establish oscillation. Figure 2-2 shows the pin connections.

The oscillator design requires the use of a crystal that is rated for parallel resonant operation.

| Note: | Use of a crystal rated for series resonant |
|-------|--|
| | operation may give a frequency out of the |
| | crystal manufacturer's specifications. |

FIGURE 2-2: CRYSTAL OSCILLATOR OPERATION (HS OR HSPLL CONFIGURATION)

TABLE 2-1:CAPACITOR SELECTION FOR
CRYSTAL OSCILLATOR

| Osc Type | Crystal Freq. | | acitor Values sted: | | |
|----------|------------------|-------|------------------------|--|--|
| | Fieq. | C1 | C2 | | |
| HS | 25 MHz | 33 pF | 33 pF | | |
| | | | | | |

Capacitor values are for design guidance only.

Different capacitor values may be required to produce acceptable oscillator operation. The user should test the performance of the oscillator over the expected VDD and temperature range for the application. Refer to the following application notes for oscillator specific information:

- AN588, "PIC[®] Microcontroller Oscillator Design Guide"
- AN826, "Crystal Oscillator Basics and Crystal Selection for rfPIC[®] and PIC[®] Devices"
- AN849, "Basic PIC® Oscillator Design"
- AN943, "Practical PIC[®] Oscillator Analysis and Design"
- AN949, "Making Your Oscillator Work"

See the notes following this table for additional information.

- **Note 1:** Higher capacitance increases the stability of the oscillator but also increases the start-up time.
 - 2: Since each crystal has its own characteristics, the user should consult the crystal manufacturer for appropriate values of external components.
 - **3:** Rs may be required to avoid overdriving crystals with low drive level specifications.
 - 4: Always verify oscillator performance over the VDD and temperature range that is expected for the application.

2.4 External Clock Input (EC Modes)

The EC and ECPLL Oscillator modes require an external clock source to be connected to the OSC1 pin. There is no oscillator start-up time required after a Power-on Reset or after an exit from Sleep mode.

In the EC Oscillator mode, the oscillator frequency divided by 4 is available on the OSC2 pin. This signal may be used for test purposes or to synchronize other logic. Figure 2-3 shows the pin connections for the EC Oscillator mode.

An external clock source may also be connected to the OSC1 pin in the HS mode, as shown in Figure 2-4. In this configuration, the OSC2 pin is left open. Current consumption in this configuration will be somewhat higher than EC mode, as the internal oscillator's feedback circuitry will be enabled (in EC mode, the feedback circuit is disabled).

FIGURE 2-4:

EXTERNAL CLOCK INPUT OPERATION (HS CONFIGURATION)

2.5 Internal Oscillator Block

The PIC18F97J60 family of devices includes an internal oscillator source (INTRC) which provides a nominal 31 kHz output. The INTRC is enabled on device power-up and clocks the device during its configuration cycle until it enters operating mode. INTRC is also enabled if it is selected as the device clock source or if any of the following are enabled:

- Fail-Safe Clock Monitor
- Watchdog Timer
- Two-Speed Start-up

These features are discussed in greater detail in Section 24.0 "Special Features of the CPU".

The INTRC can also be optionally configured as the default clock source on device start-up by setting the FOSC2 Configuration bit. This is discussed in **Section 2.7.1 "Oscillator Control Register"**.

2.6 Ethernet Operation and the Microcontroller Clock

Although devices of the PIC18F97J60 family can accept a wide range of crystals and external oscillator inputs, they must always have a 25 MHz clock source when used for Ethernet applications. No provision is made for internally generating the required Ethernet clock from a primary oscillator source of a different frequency. A frequency tolerance is specified, likely excluding the use of ceramic resonators. See **Section 27.0** "**Electrical Characteristics**", Table 27-6, parameter 5, for more details.

2.6.1 PLL BLOCK

To accommodate a range of applications and microcontroller clock speeds, a separate PLL block is incorporated into the clock system. It consists of three components:

- A configurable prescaler (1:2 or 1:3)
- A 5x PLL frequency multiplier
- A configurable postscaler (1:1, 1:2, or 1:3)

The operation of the PLL block's components is controlled by the OSCTUNE register (Register 2-1). The use of the PLL block's prescaler and postscaler, with or without the PLL itself, provides a range of system clock frequencies to choose from, including the unaltered 25 MHz of the primary oscillator. The full range of possible oscillator configurations compatible with Ethernet operation is shown in Table 2-2.

2.7 Clock Sources and Oscillator Switching

The PIC18F97J60 family of devices includes a feature that allows the device clock source to be switched from the main oscillator to an alternate clock source. These devices also offer two alternate clock sources. When an alternate clock source is enabled, the various power-managed operating modes are available.

Essentially, there are three clock sources for these devices:

- Primary oscillators
- · Secondary oscillators
- Internal oscillator block

The **primary oscillators** include the External Crystal and Resonator modes and the External Clock modes. The particular mode is defined by the FOSC2:FOSC0 Configuration bits. The details of these modes are covered earlier in this chapter. The **secondary oscillators** are those external sources not connected to the OSC1 or OSC2 pins. These sources may continue to operate even after the controller is placed in a power-managed mode. The PIC18F97J60 family of devices offers the Timer1 oscillator as a secondary oscillator. In all power-managed modes, this oscillator is often the time base for functions such as a Real-Time Clock (RTC).

Most often, a 32.768 kHz watch crystal is connected between the RC0/T1OSO/T13CKI and RC1/T1OSI pins. Loading capacitors are also connected from each pin to ground. The Timer1 oscillator is discussed in greater detail in **Section 12.3 "Timer1 Oscillator**".

In addition to being a primary clock source, the **internal oscillator** is available as a power-managed mode clock source. The INTRC source is also used as the clock source for several special features, such as the WDT and Fail-Safe Clock Monitor.

The clock sources for the PIC18F97J60 family devices are shown in Figure 2-1. See **Section 24.0** "**Special Features of the CPU**" for Configuration register details.

2.7.1 OSCILLATOR CONTROL REGISTER

The OSCCON register (Register 2-2) controls several aspects of the device clock's operation, both in full power operation and in power-managed modes.

The System Clock Select bits, SCS1:SCS0, select the clock source. The available clock sources are the primary clock (defined by the FOSC2:FOSC0 Configuration bits), the secondary clock (Timer1 oscillator) and the internal oscillator. The clock source changes after one or more of the bits are changed, following a brief clock transition interval.

The OSTS (OSCCON<3>) and T1RUN (T1CON<6>) bits indicate which clock source is currently providing the device clock. The T1RUN bit indicates when the Timer1 oscillator is providing the device clock in secondary clock modes. In power-managed modes, only one of these bits will be set at any time. If neither bit is set, the INTRC source is providing the clock, or the internal oscillator has just started and is not yet stable.

The IDLEN bit determines if the device goes into Sleep mode or one of the Idle modes when the SLEEP instruction is executed.

The use of the flag and control bits in the OSCCON register is discussed in more detail in **Section 3.0** "**Power-Managed Modes**".

- Note 1: The Timer1 oscillator must be enabled to select the secondary clock source. The Timer1 oscillator is enabled by setting the T1OSCEN bit in the Timer1 Control register (T1CON<3>). If the Timer1 oscillator is not enabled, then any attempt to select a secondary clock source will be ignored.
 - 2: It is recommended that the Timer1 oscillator be operating and stable before executing the SLEEP instruction or a very long delay may occur while the Timer1 oscillator starts.

| | |

2.7.1.1 System Clock Selection and the FOSC2 Configuration Bit

The SCS bits are cleared on all forms of Reset. In the device's default configuration, this means the primary oscillator defined by FOSC1:FOSC0 (that is, one of the HC or EC modes) is used as the primary clock source on device Resets.

The default clock configuration on Reset can be changed with the FOSC2 Configuration bit. This bit affects the clock source selection setting when SCS1:SCS0 = 00. When FOSC2 = 1 (default), the oscillator source defined by FOSC1:FOSC0 is selected whenever SCS1:SCS0 = 00. When FOSC2 = 0, the INTRC oscillator is selected whenever SCS1:SCS2 = 00. Because the SCS bits are cleared on Reset, the FOSC2 setting also changes the default oscillator mode on Reset.

Regardless of the setting of FOSC2, INTRC will always be enabled on device power-up. It will serve as the clock source until the device has loaded its configuration values from memory. It is at this point that the FOSC Configuration bits are read and the oscillator selection of operational mode is made.

Note that either the primary clock or the internal oscillator will have two bit setting options, at any given time, depending on the setting of FOSC2.

2.7.2 OSCILLATOR TRANSITIONS

PIC18F97J60 family devices contain circuitry to prevent clock "glitches" when switching between clock sources. A short pause in the device clock occurs during the clock switch. The length of this pause is the sum of two cycles of the old clock source and three to four cycles of the new clock source. This formula assumes that the new clock source is stable.

Clock transitions are discussed in greater detail in **Section 3.1.2 "Entering Power-Managed Modes**".

2.8 Effects of Power-Managed Modes on the Various Clock Sources

When PRI_IDLE mode is selected, the designated primary oscillator continues to run without interruption. For all other power-managed modes, the oscillator using the OSC1 pin is disabled. The OSC1 pin (and OSC2 pin if used by the oscillator) will stop oscillating.

In secondary clock modes (SEC_RUN and SEC_IDLE), the Timer1 oscillator is operating and providing the device clock. The Timer1 oscillator may also run in all power-managed modes if required to clock Timer1 or Timer3.

In RC_RUN and RC_IDLE modes, the internal oscillator provides the device clock source. The 31 kHz INTRC output can be used directly to provide the clock and may be enabled to support various special features, regardless of the power-managed mode (see Section 24.2 "Watchdog Timer (WDT)" through Section 24.5 "Fail-Safe Clock Monitor" for more information on WDT, Fail-Safe Clock Monitor and Two-Speed Start-up).

If the Sleep mode is selected, all clock sources are stopped. Since all the transistor switching currents have been stopped, Sleep mode achieves the lowest current consumption of the device (only leakage currents).

Enabling any on-chip feature that will operate during Sleep will increase the current consumed during Sleep. The INTRC is required to support WDT operation. The Timer1 oscillator may be operating to support a Real-Time Clock. Other features may be operating that do not require a device clock source (i.e., MSSP slave, PSP, INTx pins and others). Peripherals that may add significant current consumption are listed in Section 27.2 "DC Characteristics: Power-Down and Supply Current".

2.9 Power-up Delays

Power-up delays are controlled by two timers, so that no external Reset circuitry is required for most applications. The delays ensure that the device is kept in Reset until the device power supply is stable under normal circumstances and the primary clock is operating and stable. For additional information on power-up delays, see **Section 4.6 "Power-up Timer (PWRT)**".

The first timer is the Power-up Timer (PWRT), which provides a fixed delay on power-up (parameter 33, Table 27-12); it is always enabled.

The second timer is the Oscillator Start-up Timer (OST), intended to keep the chip in Reset until the crystal oscillator is stable (HS modes). The OST does this by counting 1024 oscillator cycles before allowing the oscillator to clock the device.

There is a delay of interval TCSD (parameter 38, Table 27-12), following POR, while the controller becomes ready to execute instructions.

| Oscillator Mode | OSC1 Pin | OSC2 Pin |
|-----------------|---|---|
| EC, ECPLL | Floating, pulled by external clock | At logic low (clock/4 output) |
| HS, HSPLL | Feedback inverter disabled at quiescent voltage level | Feedback inverter disabled at quiescent voltage level |

 TABLE 2-3:
 OSC1 AND OSC2 PIN STATES IN SLEEP MODE

Note: See Table 4-2 in Section 4.0 "Reset" for time-outs due to Sleep and MCLR Reset.

3.0 POWER-MANAGED MODES

The PIC18F97J60 family devices provide the ability to manage power consumption by simply managing clocking to the CPU and the peripherals. In general, a lower clock frequency and a reduction in the number of circuits being clocked constitutes lower consumed power. For the sake of managing power in an application, there are three primary modes of operation:

- Run mode
- Idle mode
- Sleep mode

These modes define which portions of the device are clocked and at what speed. The Run and Idle modes may use any of the three available clock sources (primary, secondary or internal oscillator block); the Sleep mode does not use a clock source.

The power-managed modes include several power-saving features offered on previous PIC[®] MCU devices. One is the clock switching feature, offered in other PIC18 devices, allowing the controller to use the Timer1 oscillator in place of the primary oscillator. Also included is the Sleep mode, offered by all PIC MCU devices, where all device clocks are stopped.

3.1 Selecting Power-Managed Modes

Selecting a power-managed mode requires two decisions: if the CPU is to be clocked or not and which clock source is to be used. The IDLEN bit (OSCCON<7>) controls CPU clocking, while the SCS1:SCS0 bits (OSCCON<1:0>) select the clock source. The individual modes, bit settings, clock sources and affected modules are summarized in Table 3-1.

3.1.1 CLOCK SOURCES

The SCS1:SCS0 bits allow the selection of one of three clock sources for power-managed modes. They are:

- The primary clock, as defined by the FOSC2:FOSC0 Configuration bits
- The secondary clock (Timer1 oscillator)
- The internal oscillator

3.1.2 ENTERING POWER-MANAGED MODES

Switching from one power-managed mode to another begins by loading the OSCCON register. The SCS1:SCS0 bits select the clock source and determine which Run or Idle mode is to be used. Changing these bits causes an immediate switch to the new clock source, assuming that it is running. The switch may also be subject to clock transition delays. These are discussed in **Section 3.1.3 "Clock Transitions and Status Indicators"** and subsequent sections.

Entry to the power-managed Idle or Sleep modes is triggered by the execution of a SLEEP instruction. The actual mode that results depends on the status of the IDLEN bit.

Depending on the current mode and the mode being switched to, a change to a power-managed mode does not always require setting all of these bits. Many transitions may be done by changing the oscillator select bits, or changing the IDLEN bit, prior to issuing a SLEEP instruction. If the IDLEN bit is already configured correctly, it may only be necessary to perform a SLEEP instruction to switch to the desired mode.

| | - | | - | | |
|----------|-------------------------------------|---------------|---------|-------------|--|
| | osco | OSCCON<7,1:0> | | e Clocking | Available Cleak and Oscillator Source |
| Mode | Mode IDLEN ⁽¹⁾ SCS1:SCS0 | | CPU | Peripherals | Available Clock and Oscillator Source |
| Sleep | 0 | N/A | Off | Off | None – All clocks are disabled |
| PRI_RUN | N/A | 10 | Clocked | Clocked | Primary – HS, EC, HSPLL, ECPLL; this is the normal, full power execution mode |
| SEC_RUN | N/A | 01 | Clocked | Clocked | Secondary – Timer1 Oscillator |
| RC_RUN | N/A | 11 | Clocked | Clocked | Internal Oscillator |
| PRI_IDLE | 1 | 10 | Off | Clocked | Primary – HS, EC, HSPLL, ECPLL |
| SEC_IDLE | 1 | 01 | Off | Clocked | Secondary – Timer1 Oscillator |
| RC_IDLE | 1 | 11 | Off | Clocked | Internal Oscillator |

TABLE 3-1: POWER-MANAGED MODES

Note 1: IDLEN reflects its value when the SLEEP instruction is executed.

3.1.3 CLOCK TRANSITIONS AND STATUS INDICATORS

The length of the transition between clock sources is the sum of two cycles of the old clock source and three to four cycles of the new clock source. This formula assumes that the new clock source is stable.

Two bits indicate the current clock source and its status: OSTS (OSCCON<3>) and T1RUN (T1CON<6>). In general, only one of these bits will be set while in a given power-managed mode. When the OSTS bit is set, the primary clock is providing the device clock. When the T1RUN bit is set, the Timer1 oscillator is providing the clock. If neither of these bits is set, INTRC is clocking the device.

| Note: | Executing a SLEEP instruction does not |
|-------|---|
| | necessarily place the device into Sleep |
| | mode. It acts as the trigger to place the |
| | controller into either the Sleep mode, or |
| | one of the Idle modes, depending on the |
| | setting of the IDLEN bit. |

3.1.4 MULTIPLE SLEEP COMMANDS

The power-managed mode that is invoked with the SLEEP instruction is determined by the setting of the IDLEN bit at the time the instruction is executed. If another SLEEP instruction is executed, the device will enter the power-managed mode specified by IDLEN at that time. If IDLEN has changed, the device will enter the new power-managed mode specified by the new setting.

3.2 Run Modes

In the Run modes, clocks to both the core and peripherals are active. The difference between these modes is the clock source.

3.2.1 PRI_RUN MODE

The PRI_RUN mode is the normal, full power execution mode of the microcontroller. This is also the default mode upon a device Reset unless Two-Speed Start-up is enabled (see **Section 24.4 "Two-Speed Start-up"** for details). In this mode, the OSTS bit is set. (see **Section 2.7.1 "Oscillator Control Register"**).

3.2.2 SEC_RUN MODE

The SEC_RUN mode is the compatible mode to the "clock switching" feature offered in other PIC18 devices. In this mode, the CPU and peripherals are clocked from the Timer1 oscillator. This gives users the option of lower power consumption while still using a high accuracy clock source.

SEC_RUN mode is entered by setting the SCS1:SCS0 bits to '01'. The device clock source is switched to the Timer1 oscillator (see Figure 3-1), the primary oscillator is shut down, the T1RUN bit (T1CON<6>) is set and the OSTS bit is cleared.

Note: The Timer1 oscillator should already be running prior to entering SEC_RUN mode. If the T1OSCEN bit is not set when the SCS1:SCS0 bits are set to '01', entry to SEC_RUN mode will not occur. If the Timer1 oscillator is enabled, but not yet running, device clocks will be delayed until the oscillator has started. In such situations, initial oscillator operation is far from stable and unpredictable operation may result.

On transitions from SEC_RUN mode to PRI_RUN, the peripherals and CPU continue to be clocked from the Timer1 oscillator while the primary clock is started. When the primary clock becomes ready, a clock switch back to the primary clock occurs (see Figure 3-2). When the clock switch is complete, the T1RUN bit is cleared, the OSTS bit is set and the primary clock is providing the clock. The IDLEN and SCS bits are not affected by the wake-up; the Timer1 oscillator continues to run.

3.2.3 RC_RUN MODE

In RC_RUN mode, the CPU and peripherals are clocked from the internal oscillator; the primary clock is shut down. This mode provides the best power conservation of all the Run modes while still executing code. It works well for user applications which are not highly timing sensitive or do not require high-speed clocks at all times.

This mode is entered by setting SCS<1:0> to '11'. When the clock source is switched to the INTRC (see Figure 3-3), the primary oscillator is shut down and the OSTS bit is cleared.

On transitions from RC_RUN mode to PRI_RUN mode, the device continues to be clocked from the INTRC while the primary clock is started. When the primary clock becomes ready, a clock switch to the primary clock occurs (see Figure 3-4). When the clock switch is complete, the OSTS bit is set and the primary clock is providing the device clock. The IDLEN and SCS bits are not affected by the switch. The INTRC source will continue to run if either the WDT or Fail-Safe Clock Monitor is enabled.

FIGURE 3-4: TRANSITION TIMING FROM RC_RUN MODE TO PRI_RUN MODE

3.3 Sleep Mode

The power-managed Sleep mode is identical to the legacy Sleep mode offered in all other PIC MCU devices. It is entered by clearing the IDLEN bit (the default state on device Reset) and executing the SLEEP instruction. This shuts down the selected oscillator (Figure 3-5). All clock source status bits are cleared.

Entering the Sleep mode from any other mode does not require a clock switch. This is because no clocks are needed once the controller has entered Sleep. If the WDT is selected, the INTRC source will continue to operate. If the Timer1 oscillator is enabled, it will also continue to run.

When a wake event occurs in Sleep mode (by interrupt, Reset or WDT time-out), the device will not be clocked until the clock source selected by the SCS1:SCS0 bits becomes ready (see Figure 3-6), or it will be clocked from the internal oscillator if either the Two-Speed Start-up or the Fail-Safe Clock Monitor is enabled (see **Section 24.0 "Special Features of the CPU"**). In either case, the OSTS bit is set when the primary clock is providing the device clocks. The IDLEN and SCS bits are not affected by the wake-up.

3.4 Idle Modes

The Idle modes allow the controller's CPU to be selectively shut down while the peripherals continue to operate. Selecting a particular Idle mode allows users to further manage power consumption.

If the IDLEN bit is set to '1' when a SLEEP instruction is executed, the peripherals will be clocked from the clock source selected using the SCS1:SCS0 bits; however, the CPU will not be clocked. The clock source status bits are not affected. Setting IDLEN and executing a SLEEP instruction provides a quick method of switching from a given Run mode to its corresponding Idle mode.

If the WDT is selected, the INTRC source will continue to operate. If the Timer1 oscillator is enabled, it will also continue to run.

Since the CPU is not executing instructions, the only exits from any of the Idle modes are by interrupt, WDT time-out or a Reset. When a wake event occurs, CPU execution is delayed by an interval of TCSD (parameter 38, Table 27-12) while it becomes ready to execute code. When the CPU begins executing code, it resumes with the same clock source for the current Idle mode. For example, when waking from RC_IDLE mode, the internal oscillator block will clock the CPU and peripherals (in other words, RC_RUN mode). The IDLEN and SCS bits are not affected by the wake-up.

While in any Idle mode or the Sleep mode, a WDT time-out will result in a WDT wake-up to the Run mode currently specified by the SCS1:SCS0 bits.

FIGURE 3-5: TRANSITION TIMING FOR ENTRY TO SLEEP MODE

© 2006 Microchip Technology Inc.

3.4.1 PRI_IDLE MODE

This mode is unique among the three low-power Idle modes in that it does not disable the primary device clock. For timing sensitive applications, this allows for the fastest resumption of device operation with its more accurate primary clock source, since the clock source does not have to "warm up" or transition from another oscillator.

PRI_IDLE mode is entered from PRI_RUN mode by setting the IDLEN bit and executing a SLEEP instruction. If the device is in another Run mode, set IDLEN first, then set the SCS<1:0> bits to '10' and execute SLEEP. Although the CPU is disabled, the peripherals continue to be clocked from the primary clock source specified by the FOSC1:FOSC0 Configuration bits. The OSTS bit remains set (see Figure 3-7).

When a wake event occurs, the CPU is clocked from the primary clock source. A delay of interval TCSD is required between the wake event and when code execution starts. This is required to allow the CPU to become ready to execute instructions. After the wake-up, the OSTS bit remains set. The IDLEN and SCS bits are not affected by the wake-up (see Figure 3-8).

3.4.2 SEC_IDLE MODE

In SEC_IDLE mode, the CPU is disabled but the peripherals continue to be clocked from the Timer1 oscillator. This mode is entered from SEC_RUN by setting the IDLEN bit and executing a SLEEP instruction. If the device is in another Run mode, set IDLEN first, then set SCS<1:0> to '01' and execute SLEEP. When the clock source is switched to the Timer1 oscillator, the primary oscillator is shut down, the OSTS bit is cleared and the T1RUN bit is set.

When a wake event occurs, the peripherals continue to be clocked from the Timer1 oscillator. After an interval of TCSD following the wake event, the CPU begins executing code being clocked by the Timer1 oscillator. The IDLEN and SCS bits are not affected by the wake-up; the Timer1 oscillator continues to run (see Figure 3-8).

Note: The Timer1 oscillator should already be running prior to entering SEC_IDLE mode. If the T1OSCEN bit is not set when the SLEEP instruction is executed, the SLEEP instruction will be ignored and entry to SEC_IDLE mode will not occur. If the Timer1 oscillator is enabled, but not yet running, peripheral clocks will be delayed until the oscillator has started. In such situations, initial oscillator operation is far from stable and unpredictable operation may result.

FIGURE 3-7: TRANSITION TIMING FOR ENTRY TO IDLE MODE

FIGURE 3-8: TRANSITION TIMING FOR WAKE FROM IDLE TO RUN MODE

3.4.3 RC_IDLE MODE

In RC_IDLE mode, the CPU is disabled but the peripherals continue to be clocked from the internal oscillator. This mode allows for controllable power conservation during Idle periods.

From RC_RUN mode, RC_IDLE mode is entered by setting the IDLEN bit and executing a SLEEP instruction. If the device is in another Run mode, first set IDLEN, then clear the SCS bits and execute SLEEP. When the clock source is switched to the INTRC, the primary oscillator is shut down and the OSTS bit is cleared.

When a wake event occurs, the peripherals continue to be clocked from the INTRC. After a delay of TCSD following the wake event, the CPU begins executing code being clocked by the INTRC. The IDLEN and SCS bits are not affected by the wake-up. The INTRC source will continue to run if either the WDT or the Fail-Safe Clock Monitor is enabled.

3.5 Exiting Idle and Sleep Modes

An exit from Sleep mode, or any of the Idle modes, is triggered by an interrupt, a Reset or a WDT time-out. This section discusses the triggers that cause exits from power-managed modes. The clocking subsystem actions are discussed in each of the power-managed modes sections (see Section 3.2 "Run Modes", Section 3.3 "Sleep Mode" and Section 3.4 "Idle Modes").

3.5.1 EXIT BY INTERRUPT

Any of the available interrupt sources can cause the device to exit from an Idle mode, or the Sleep mode, to a Run mode. To enable this functionality, an interrupt source must be enabled by setting its enable bit in one of the INTCON or PIE registers. The exit sequence is initiated when the corresponding interrupt flag bit is set.

On all exits from Idle or Sleep modes by interrupt, code execution branches to the interrupt vector if the GIE/GIEH bit (INTCON<7>) is set. Otherwise, code execution continues or resumes without branching (see Section 9.0 "Interrupts").

A fixed delay of interval TCSD following the wake event is required when leaving the Sleep and Idle modes. This delay is required for the CPU to prepare for execution. Instruction execution resumes on the first clock cycle following this delay.

3.5.2 EXIT BY WDT TIME-OUT

A WDT time-out will cause different actions depending on which power-managed mode the device is in when the time-out occurs.

If the device is not executing code (all Idle modes and Sleep mode), the time-out will result in an exit from the power-managed mode (see Section 3.2 "Run Modes" and Section 3.3 "Sleep Mode"). If the device is executing code (all Run modes), the time-out will result in a WDT Reset (see Section 24.2 "Watchdog Timer (WDT)").

The WDT timer and postscaler are cleared by one of the following events:

- Executing a SLEEP or CLRWDT instruction
- The loss of a currently selected clock source (if the Fail-Safe Clock Monitor is enabled)

3.5.3 EXIT BY RESET

Exiting an Idle or Sleep mode by Reset automatically forces the device to run from the INTRC.

3.5.4 EXIT WITHOUT AN OSCILLATOR START-UP TIMER DELAY

Certain exits from power-managed modes do not invoke the OST at all. There are two cases:

- PRI_IDLE mode, where the primary clock source is not stopped
- The primary clock source is either the EC or ECPLL mode

In these instances, the primary clock source either does not require an oscillator start-up delay since it is already running (PRI_IDLE), or normally does not require an oscillator start-up delay (EC). However, a fixed delay of interval TCSD following the wake event is still required when leaving the Sleep and Idle modes to allow the CPU to prepare for execution. Instruction execution resumes on the first clock cycle following this delay. NOTES:

4.0 RESET

The PIC18F97J60 family of devices differentiates between various kinds of Reset:

- a) MCLR Reset during normal operation
- b) MCLR Reset during power-managed modes
- c) Power-on Reset (POR)
- d) Brown-out Reset (BOR)
- e) Configuration Mismatch (CM)
- f) RESET Instruction
- g) Stack Full Reset
- h) Stack Underflow Reset
- i) Watchdog Timer (WDT) Reset during execution

This section discusses Resets generated by hard events (MCLR), power events (POR and BOR) and Configuration Mismatches (CM). It also covers the operation of the various start-up timers. Stack Reset events are covered in Section 5.1.6.4 "Stack Full and Underflow Resets". WDT Resets are covered in Section 24.2 "Watchdog Timer (WDT)".

A simplified block diagram of the on-chip Reset circuit is shown in Figure 4-1.

4.1 RCON Register

Device Reset events are tracked through the RCON register (Register 4-1). The lower six bits of the register indicate that a specific Reset event has occurred. In most cases, these bits can only be set by the event and must be cleared by the application after the event. The state of these flag bits, taken together, can be read to indicate the type of Reset that just occurred. This is described in more detail in **Section 4.7** "**Reset State of Registers**".

The RCON register also has a control bit for setting interrupt priority (IPEN). Interrupt priority is discussed in **Section 9.0 "Interrupts"**.

REGISTER 4-1: RCON: RESET CONTROL REGISTER

4.2 Master Clear (MCLR)

The MCLR pin provides a method for triggering a hard external Reset of the device. A Reset is generated by holding the pin low. PIC18 extended microcontroller devices have a noise filter in the MCLR Reset path which detects and ignores small pulses.

The $\overline{\text{MCLR}}$ pin is not driven low by any internal Resets, including the WDT.

4.3 Power-on Reset (POR)

A Power-on Reset condition is generated on-chip whenever VDD rises above a certain threshold. This allows the device to start in the initialized state when VDD is adequate for operation.

To take advantage of the POR circuitry, tie the $\overline{\text{MCLR}}$ pin through a resistor (1 k Ω to 10 k Ω) to VDD. This will eliminate external RC components usually needed to create a Power-on Reset delay. A minimum rise rate for VDD is specified (parameter D004). For a slow rise time, see Figure 4-2.

When the device starts normal operation (i.e., exits the Reset condition), device operating parameters (voltage, frequency, temperature, etc.) must be met to ensure operation. If these conditions are not met, the device must be held in Reset until the operating conditions are met.

POR events are captured by the $\overrightarrow{\text{POR}}$ bit (RCON<1>). The state of the bit is set to '0' whenever a Power-on Reset occurs; it does not change for any other Reset event. $\overrightarrow{\text{POR}}$ is not reset to '1' by any hardware event. To capture multiple events, the user manually resets the bit to '1' in software following any Power-on Reset.

4.4 Brown-out Reset (BOR)

The PIC18F97J60 family of devices incorporates a simple BOR function when the internal regulator is enabled (ENVREG pin is tied to VDD). Any drop of VDD below VBOR (parameter D005), for greater than time TBOR (parameter 35), will reset the device. A Reset may or may not occur if VDD falls below VBOR for less than TBOR. The chip will remain in Brown-out Reset until VDD rises above VBOR.

Once a BOR has occurred, the Power-up Timer will keep the chip in Reset for TPWRT (parameter 33). If VDD drops below VBOR while the Power-up Timer is running, the chip will go back into a Brown-out Reset and the Power-up Timer will be initialized. Once VDD rises above VBOR, the Power-up Timer will execute the additional time delay.

FIGURE 4-2:

EXTERNAL POWER-ON RESET CIRCUIT (FOR SLOW VDD POWER-UP)

3: <u>R1 ≥ 1 kG</u> will limit any current flowing into MCLR from external capacitor C in the event of MCLR/VPP pin breakdown, due to Electrostatic Discharge (ESD), or Electrical Overstress (EOS).

4.4.1 DETECTING BOR

The BOR bit always resets to '0' on any Brown-out Reset or Power-on Reset event. This makes it difficult to determine if a Brown-out Reset event has occurred just by reading the state of BOR alone. A more reliable method is to simultaneously check the state of both POR and BOR. This assumes that the POR bit is reset to '1' in software immediately after any Power-on Reset event. If BOR is '0' while POR is '1', it can be reliably assumed that a Brown-out Reset event has occurred.

If the voltage regulator is disabled, Brown-out Reset functionality is disabled. In this case, the BOR bit cannot be used to determine a Brown-out Reset event. The BOR bit is still cleared by a Power-on Reset event.

4.5 Configuration Mismatch (CM)

The Configuration Mismatch (CM) Reset is designed to detect and attempt to recover from random, memory corrupting events. These include Electrostatic Discharge (ESD) events which can cause widespread single-bit changes throughout the device and result in catastrophic failure.

In PIC18FXXJ Flash devices, the device Configuration registers (located in the configuration memory space) are continuously monitored during operation by comparing their values to complimentary shadow registers. If a mismatch is detected between the two sets of registers, a CM Reset automatically occurs. These events are captured by the \overline{CM} bit (RCON<5>). The state of the bit is set to '0' whenever a CM event occurs; it does not change for any other Reset event.

A CM Reset behaves similarly to a Master Clear Reset, RESET instruction, WDT time-out or Stack Event Reset. As with all hard and power Reset events, the device Configuration Words are reloaded from the Flash Configuration Words in program memory as the device restarts.

4.6 **Power-up Timer (PWRT)**

PIC18F97J60 family of devices incorporates an on-chip Power-up Timer (PWRT) to help regulate the Power-on Reset process. The PWRT is always enabled. The main function is to ensure that the device voltage is stable before code is executed.

The Power-up Timer (PWRT) of the PIC18F97J60 family devices is an 11-bit counter which uses the INTRC source as the clock input. This yields an approximate time interval of 2048 x 32 μ s = 66 ms. While the PWRT is counting, the device is held in Reset. The power-up time delay depends on the INTRC clock and will vary from chip-to-chip due to temperature and process variation. See DC parameter 33 for details.

4.6.1 TIME-OUT SEQUENCE

The PWRT time-out is invoked after the POR pulse has cleared. The total time-out will vary based on the status of the PWRT. Figure 4-3, Figure 4-4, Figure 4-5 and Figure 4-6 all depict time-out sequences on power-up.

Since the time-outs occur from the POR pulse, if MCLR is kept low long enough, the PWRT will expire. Bringing MCLR high will begin execution immediately (Figure 4-5). This is useful for testing purposes or to synchronize more than one PIC18FXXJ6X device operating in parallel.

FIGURE 4-3: TIME-OUT SEQUENCE ON POWER-UP (MCLR TIED TO VDD, VDD RISE < TPWRT)

FIGURE 4-4: TIME-OUT SEQUENCE ON POWER-UP (MCLR NOT TIED TO VDD): CASE 1

FIGURE 4-6: SLOW RISE TIME (MCLR TIED TO VDD, VDD RISE > TPWRT)

4.7 Reset State of Registers

Most registers are unaffected by a Reset. Their status is unknown on POR and unchanged by all other Resets. The other registers are forced to a "Reset state" depending on the type of Reset that occurred.

Most registers are not affected by a WDT wake-up since this is viewed as the resumption of normal operation. Status bits from the RCON register (CM, RI,

TO, PD, POR and BOR) are set or cleared differently in different Reset situations, as indicated in Table 4-1. These bits are used in software to determine the nature of the Reset.

Table 4-2 describes the Reset states for all of the Special Function Registers. These are categorized by Power-on and Brown-out Resets, Master Clear and WDT Resets and WDT wake-ups.

| TABLE 4-1: | STATUS BITS, THEIR SIGNIFICANCE AND THE INITIALIZATION CONDITION FOR |

TABLE 4-2: INITIALIZATION CONDITIONS FOR ALL REGISTERS

Legend: u = unchanged, x = unknown, - = unimplemented bit, read as '0', q = value depends on condition. Shaded cells indicate conditions do not apply for the designated device.

Note 1: When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the TOSU, TOSH and TOSL are updated with the current value of the PC. The STKPTR is modified to point to the next location in the hardware stack.

2: When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the PC is loaded with the interrupt vector (0008h or 0018h).

3: One or more bits in the INTCONx or PIRx registers will be affected (to cause wake-up).

TABLE 4-2: INITIALIZATION CONDITIONS FOR ALL REGISTERS (CONTINUED)

Note 1: When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the TOSU, TOSH and TOSL are updated with the current value of the PC. The STKPTR is modified to point to the next location in the hardware stack.

2: When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the PC is loaded with the interrupt vector (0008h or 0018h).

3: One or more bits in the INTCONx or PIRx registers will be affected (to cause wake-up).

TABLE 4-2: INITIALIZATION CONDITIONS FOR ALL REGISTERS (CONTINUED)

Legend: u = unchanged, x = unknown, - = unimplemented bit, read as '0', q = value depends on condition.

Shaded cells indicate conditions do not apply for the designated device.

Note 1: When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the TOSU, TOSH and TOSL are updated with the current value of the PC. The STKPTR is modified to point to the next location in the hardware stack.

2: When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the PC is loaded with the interrupt vector (0008h or 0018h).

3: One or more bits in the INTCONx or PIRx registers will be affected (to cause wake-up).

TABLE 4-2: INITIALIZATION CONDITIONS FOR ALL REGISTERS (CONTINUED)

Legend: u = unchanged, x = unknown, - = unimplemented bit, read as '0', q = value depends on condition. Shaded cells indicate conditions do not apply for the designated device.

Note 1: When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the TOSU, TOSH and TOSL are updated with the current value of the PC. The STKPTR is modified to point to the next location in the hardware stack.

2: When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the PC is loaded with the interrupt vector (0008h or 0018h).

3: One or more bits in the INTCONx or PIRx registers will be affected (to cause wake-up).

NOTES:

5.0 MEMORY ORGANIZATION

There are two types of memory in PIC18 Flash microcontroller devices:

- Program Memory
- Data RAM

As Harvard architecture devices, the data and program memories use separate busses. This allows for concurrent access of the two memory spaces.

Additional detailed information on the operation of the Flash program memory is provided in **Section 6.0 "Flash Program Memory"**.

5.1 Program Memory Organization

PIC18 microcontrollers implement a 21-bit program counter which is capable of addressing a 2-Mbyte program memory space. Accessing a location between the upper boundary of the physically implemented memory and the 2-Mbyte address will return all '0's (a NOP instruction).

The entire PIC18F97J60 family offers three sizes of on-chip Flash program memory, from 64 Kbytes (up to 32,764 single-word instructions) to 128 Kbytes (65,532 single-word instructions). The program memory maps for individual family members are shown in Figure 5-1.

FIGURE 5-1: MEMORY MAPS FOR PIC18F97J60 FAMILY DEVICES

5.1.1 HARD MEMORY VECTORS

All PIC18 devices have a total of three hard-coded return vectors in their program memory space. The Reset vector address is the default value to which the program counter returns on all device Resets; it is located at 0000h.

PIC18 devices also have two interrupt vector addresses for the handling of high priority and low priority interrupts. The high priority interrupt vector is located at 0008h and the low priority interrupt vector is at 0018h. Their locations in relation to the program memory map are shown in Figure 5-2.

FIGURE 5-2: HARD VECTOR AND CONFIGURATION WORD LOCATIONS FOR PIC18F97J60 FAMILY DEVICES

5.1.2 FLASH CONFIGURATION WORDS

Because the PIC18F97J60 family devices do not have persistent configuration memory, the top four words of on-chip program memory are reserved for configuration information. On Reset, the configuration information is copied into the Configuration registers.

The Configuration Words are stored in their program memory location in numerical order, starting with the lower byte of CONFIG1 at the lowest address and ending with the upper byte of CONFIG4. For these devices, only Configuration Words, CONFIG1 through CONFIG3, are used; CONFIG4 is reserved. The actual addresses of the Flash Configuration Words for devices in the PIC18F97J60 family are shown in Table 5-1. Their location in the memory map is shown with the other memory vectors in Figure 5-2.

Additional details on the device Configuration Words are provided in **Section 24.1** "Configuration Bits".

5.1.3 PIC18F9XJ60/9XJ65 PROGRAM MEMORY MODES

The 100-pin devices in this family can address up to a total of 2 Mbytes of program memory. This is achieved through the external memory bus. There are two distinct operating modes available to the controllers:

- Microcontroller (MC)
- Extended Microcontroller (EMC)

The program memory mode is determined by setting the EMB Configuration bits (CONFIG3L<5:4>), as shown in Register 5-1. (See also **Section 24.1** "**Configuration Bits**" for additional details on the device Configuration bits.)

The program memory modes operate as follows:

 The Microcontroller Mode accesses only on-chip Flash memory. Attempts to read above the top of on-chip memory causes a read of all '0's (a NOP instruction).

The Microcontroller mode is also the only operating mode available to 64-pin and 80-pin devices.

 The Extended Microcontroller Mode allows access to both internal and external program memories as a single block. The device can access its entire on-chip program memory. Above this, the device accesses external program memory up to the 2-Mbyte program space limit. Execution automatically switches between the two memories as required.

The setting of the EMB Configuration bits also controls the address bus width of the external memory bus. This is covered in more detail in **Section 7.0** "**External Memory Bus**".

In all modes, the microcontroller has complete access to data RAM.

Figure 5-3 compares the memory maps of the different program memory modes. The differences between on-chip and external memory access limitations are more fully explained in Table 5-2.

5.1.4 EXTENDED MICROCONTROLLER MODE AND ADDRESS SHIFTING

By default, devices in Extended Microcontroller mode directly present the program counter value on the external address bus for those addresses in the range of the external memory space. In practical terms, this means addresses in the external memory device below the top of on-chip memory are unavailable. To avoid this, the Extended Microcontroller mode implements an address shifting option to enable automatic address translation. In this mode, addresses presented on the external bus are shifted down by the size of the on-chip program memory and are remapped to start at 0000h. This allows the complete use of the external memory device's memory space.

TABLE 5-2: MEMORY ACCESS FOR PIC18F9XJ60/9XJ65 PROGRAM MEMORY MODES

| Extended Microcontroller | Yes | Yes | Yes | Yes | Yes | Yes |

5.1.5 PROGRAM COUNTER

The Program Counter (PC) specifies the address of the instruction to fetch for execution. The PC is 21 bits wide and is contained in three separate 8-bit registers. The low byte, known as the PCL register, is both readable and writable. The high byte, or PCH register, contains the PC<15:8> bits; it is not directly readable or writable. Updates to the PCH register are performed through the PCLATH register. The upper byte is called PCU. This register contains the PC<20:16> bits; it is also not directly readable or writable. Updates to the PCH register. Updates to the PCU register are performed through the PCLATH register contains the PC<20:16> bits; it is also not directly readable or writable. Updates to the PCU register are performed through the PCLATU register.

The contents of PCLATH and PCLATU are transferred to the program counter by any operation that writes to the PCL. Similarly, the upper two bytes of the program counter are transferred to PCLATH and PCLATU by an operation that reads PCL. This is useful for computed offsets to the PC (see **Section 5.1.8.1 "Computed GOTO**").

The PC addresses bytes in the program memory. To prevent the PC from becoming misaligned with word instructions, the Least Significant bit of PCL is fixed to a value of '0'. The PC increments by 2 to address sequential instructions in the program memory.

The CALL, RCALL, GOTO and program branch instructions write to the program counter directly. For these instructions, the contents of PCLATH and PCLATU are not transferred to the program counter.

5.1.6 RETURN ADDRESS STACK

The return address stack allows any combination of up to 31 program calls and interrupts to occur. The PC is pushed onto the stack when a CALL or RCALL instruction is executed, or an interrupt is Acknowledged. The PC value is pulled off the stack on a RETURN, RETLW or a RETFIE instruction (and on ADDULNK and SUBULNK instructions if the extended instruction set is enabled). PCLATU and PCLATH are not affected by any of the RETURN or CALL instructions. The stack operates as a 31-word by 21-bit RAM and a 5-bit Stack Pointer, STKPTR. The stack space is not part of either program or data space. The Stack Pointer is readable and writable and the address on the top of the stack is readable and writable through the Top-of-Stack Special Function Registers. Data can also be pushed to, or popped from the stack, using these registers.

A CALL type instruction causes a push onto the stack. The Stack Pointer is first incremented and the location pointed to by the Stack Pointer is written with the contents of the PC (already pointing to the instruction following the CALL). A RETURN type instruction causes a pop from the stack. The contents of the location pointed to by the STKPTR are transferred to the PC and then the Stack Pointer is decremented.

The Stack Pointer is initialized to '00000' after all Resets. There is no RAM associated with the location corresponding to a Stack Pointer value of '00000'; this is only a Reset value. Status bits indicate if the stack is full, has overflowed or has underflowed.

5.1.6.1 Top-of-Stack Access

Only the top of the return address stack (TOS) is readable and writable. A set of three registers, TOSU:TOSH:TOSL, holds the contents of the stack location pointed to by the STKPTR register (Figure 5-4). This allows users to implement a software stack if necessary. After a CALL, RCALL or interrupt (and ADDULNK and SUBULNK instructions if the extended instruction set is enabled), the software can pushed reading the value by read the TOSU:TOSH:TOSL registers. These values can be placed on a user-defined software stack. At return time, software can return these values the to TOSU:TOSH:TOSL and do a return.

The user must disable the global interrupt enable bits while accessing the stack to prevent inadvertent stack corruption.

FIGURE 5-4: RETURN ADDRESS STACK AND ASSOCIATED REGISTERS

5.1.6.2 Return Stack Pointer (STKPTR)

The STKPTR register (Register 5-2) contains the Stack Pointer value, the STKFUL (Stack Full) status bit and the STKUNF (Stack Underflow) status bit. The value of the Stack Pointer can be 0 through 31. The Stack Pointer increments before values are pushed onto the stack and decrements after values are popped off the stack. On Reset, the Stack Pointer value will be zero. The user may read and write the Stack Pointer value. This feature can be used by a Real-Time Operating System (RTOS) for return stack maintenance.

After the PC is pushed onto the stack 31 times (without popping any values off the stack), the STKFUL bit is set. The STKFUL bit is cleared by software or by a POR.

The action that takes place when the stack becomes full depends on the state of the STVREN (Stack Overflow Reset Enable) Configuration bit. (Refer to **Section 24.1 "Configuration Bits**" for a description of the device Configuration bits.) If STVREN is set (default), the 31st push will push the (PC + 2) value onto the stack, set the STKFUL bit and reset the device. The STKFUL bit will remain set and the Stack Pointer will be set to zero.

If STVREN is cleared, the STKFUL bit will be set on the 31st push and the Stack Pointer will increment to 31. Any additional pushes will not overwrite the 31st push and the STKPTR will remain at 31.

When the stack has been popped enough times to unload the stack, the next pop returns a value of zero to the PC, and sets the STKUNF bit, while the Stack Pointer remains at zero. The STKUNF bit will remain set until cleared by software or until a POR occurs.

| Note: | Returning a value of zero to the PC on an underflow has the effect of vectoring the program to the Reset vector, where the stack conditions can be verified and appropriate actions can be taken. This is not the same as a Reset, as the contents |
|-------|---|
| | of the SFRs are not affected. |

5.1.6.3 PUSH and POP Instructions

Since the Top-of-Stack is readable and writable, the ability to push values onto the stack and pull values off the stack, without disturbing normal program execution, is a desirable feature. The PIC18 instruction set includes two instructions, PUSH and POP, that permit the TOS to be manipulated under software control. TOSU, TOSH and TOSL can be modified to place data or a return address on the stack.

The PUSH instruction places the current PC value onto the stack. This increments the Stack Pointer and loads the current PC value onto the stack.

The POP instruction discards the current TOS by decrementing the Stack Pointer. The previous value pushed onto the stack then becomes the TOS value.

| bit 4-0 | SP4:SP0: Stack Pointer Location bits |

Note 1: Bit 7 and bit 6 are cleared by user software or by a POR.

5.1.6.4 Stack Full and Underflow Resets

Device Resets on stack overflow and stack underflow conditions are enabled by setting the STVREN bit in Configuration Register 1L. When STVREN is set, a full or underflow condition will set the appropriate STKFUL or STKUNF bit and then cause a device Reset. When STVREN is cleared, a full or underflow condition will set the appropriate STKFUL or STKUNF bit, but not cause a device Reset. The STKFUL or STKUNF bit is cleared by user software or a Power-on Reset.

5.1.7 FAST REGISTER STACK

A Fast Register Stack is provided for the STATUS, WREG and BSR registers to provide a "fast return" option for interrupts. This stack is only one level deep and is neither readable nor writable. It is loaded with the current value of the corresponding register when the processor vectors for an interrupt. All interrupt sources will push values into the Stack registers. The values in the registers are then loaded back into the working registers if the RETFIE, FAST instruction is used to return from the interrupt.

If both low and high priority interrupts are enabled, the Stack registers cannot be used reliably to return from low priority interrupts. If a high priority interrupt occurs while servicing a low priority interrupt, the Stack register values stored by the low priority interrupt will be overwritten. In these cases, users must save the key registers in software during a low priority interrupt.

If interrupt priority is not used, all interrupts may use the Fast Register Stack for returns from interrupt. If no interrupts are used, the Fast Register Stack can be used to restore the STATUS, WREG and BSR registers at the end of a subroutine call. To use the Fast Register Stack for a subroutine call, a CALL label, FAST instruction must be executed to save the STATUS, WREG and BSR registers to the Fast Register Stack. A RETURN, FAST instruction is then executed to restore these registers from the Fast Register Stack.

Example 5-1 shows a source code example that uses the Fast Register Stack during a subroutine call and return.

EXAMPLE 5-1: FAST REGISTER STACK CODE EXAMPLE

| CALL | SUB1, FAST • | ;STATUS, WREG, BSR ;SAVED IN FAST REGISTER ;STACK |
|------|-----------------------|---|
| SUB1 | • • RETURN FAST | ;RESTORE VALUES SAVED ;IN FAST REGISTER STACK |

5.1.8 LOOK-UP TABLES IN PROGRAM MEMORY

There may be programming situations that require the creation of data structures, or look-up tables, in program memory. For PIC18 devices, look-up tables can be implemented in two ways:

- Computed GOTO
- Table Reads

5.1.8.1 Computed GOTO

A computed GOTO is accomplished by adding an offset to the program counter. An example is shown in Example 5-2.

A look-up table can be formed with an ADDWF PCL instruction and a group of RETLW nn instructions. The W register is loaded with an offset into the table before executing a call to that table. The first instruction of the called routine is the ADDWF PCL instruction. The next instruction executed will be one of the RETLW nn instructions, that returns the value 'nn' to the calling function.

The offset value (in WREG) specifies the number of bytes that the program counter should advance and should be multiples of 2 (LSb = 0).

In this method, only one data byte may be stored in each instruction location and room on the return address stack is required.

EXAMPLE 5-2: COMPUTED GOTO USING AN OFFSET VALUE

| | MOVF | OFFSET, W |
|-------|-------|-----------|
| | CALL | TABLE |
| ORG | nn00h | |
| TABLE | ADDWF | PCL |
| | RETLW | nnh |
| | RETLW | nnh |
| | RETLW | nnh |
| | | |
| | | |
| | • | |
| | | |

5.1.8.2 Table Reads

A better method of storing data in program memory allows two bytes of data to be stored in each instruction location.

Look-up table data may be stored two bytes per program word while programming. The Table Pointer (TBLPTR) specifies the byte address and the Table Latch (TABLAT) contains the data that is read from the program memory. Data is transferred from program memory one byte at a time.

Table read operation is discussed further inSection 6.1 "Table Reads and Table Writes".

5.2 PIC18 Instruction Cycle

5.2.1 CLOCKING SCHEME

The microcontroller clock input, whether from an internal or external source, is internally divided by four to generate four non-overlapping quadrature clocks (Q1, Q2, Q3 and Q4). Internally, the program counter is incremented on every Q1. The instruction is fetched from the program memory and latched into the Instruction Register (IR) during Q4. The instruction is decoded and executed during the following Q1 through Q4. The clocks and instruction execution flow are shown in Figure 5-5.

5.2.2 INSTRUCTION FLOW/PIPELINING

An "Instruction Cycle" consists of four Q cycles, Q1 through Q4. The instruction fetch and execute are pipelined in such a manner that a fetch takes one instruction cycle, while the decode and execute take another instruction cycle. However, due to the pipelining, each instruction effectively executes in one cycle. If an instruction causes the program counter to change (e.g., GOTO), then two cycles are required to complete the instruction (Example 5-3).

A fetch cycle begins with the Program Counter (PC) incrementing in Q1.

In the execution cycle, the fetched instruction is latched into the Instruction Register (IR) in cycle Q1. This instruction is then decoded and executed during the Q2, Q3 and Q4 cycles. Data memory is read during Q2 (operand read) and written during Q4 (destination write).

FIGURE 5-5: CLOCK/INSTRUCTION CYCLE

EXAMPLE 5-3: INSTRUCTION PIPELINE FLOW

| Тсү0 | TCY1 | TCY2 | TCY3 | TCY4 | TCY5 |
|---------------------------------|-----------|-----------|-----------|-------------|---------------|
| 1. MOVLW 55h Fetch 1 | Execute 1 | | • | | |
| 2. MOVWF PORTB | Fetch 2 | Execute 2 | | _ | |
| 3. BRA SUB_1 | | Fetch 3 | Execute 3 | | |
| 4. BSF PORTA, BIT3 (Forced NOP) | | | Fetch 4 | Flush (NOP) | |
| 5. Instruction @ address SUB_1 | | | | Fetch SUB_1 | Execute SUB_1 |

All instructions are single cycle, except for any program branches. These take two cycles since the fetch instruction is "flushed" from the pipeline while the new instruction is being fetched and then executed.

5.2.3 INSTRUCTIONS IN PROGRAM MEMORY

The program memory is addressed in bytes. Instructions are stored as two bytes or four bytes in program memory. The Least Significant Byte of an instruction word is always stored in a program memory location with an even address (LSb = 0). To maintain alignment with instruction boundaries, the PC increments in steps of 2 and the LSb will always read '0' (see **Section 5.1.5** "**Program Counter**").

Figure 5-6 shows an example of how instruction words are stored in the program memory.

The CALL and GOTO instructions have the absolute program memory address embedded into the instruction. Since instructions are always stored on word boundaries, the data contained in the instruction is a word address. The word address is written to PC<20:1> which accesses the desired byte address in program memory. Instruction #2 in Figure 5-6 shows how the instruction, GOTO 0006h, is encoded in the program memory. Program branch instructions, which encode a relative address offset, operate in the same manner. The offset value stored in a branch instruction represents the number of single-word instructions that the PC will be offset by. Section 25.0 "Instruction Set Summary" provides further details of the instruction set.

| | | | | LSB = 1 | LSB = 0 | Word Address ↓ |
|----------------|--|-------|------|----------------|----------------|-------------------|
| | Program Memory Byte Locations \rightarrow | | | | | 000000h |
| | | | | | | 000002h |

| | | | | | | 000012h |
| | | | | | | 000014h |

FIGURE 5-6: INSTRUCTIONS IN PROGRAM MEMORY

5.2.4 TWO-WORD INSTRUCTIONS

The standard PIC18 instruction set has four, two-word instructions: CALL, MOVFF, GOTO and LSFR. In all cases, the second word of the instructions always has '1111' as its four Most Significant bits; the other 12 bits are literal data, usually a data memory address.

The use of '1111' in the 4 MSbs of an instruction specifies a special form of NOP. If the instruction is executed in proper sequence – immediately after the first word – the data in the second word is accessed

and used by the instruction sequence. If the first word is skipped for some reason and the second word is executed by itself, a NOP is executed instead. This is necessary for cases when the two-word instruction is preceded by a conditional instruction that changes the PC. Example 5-4 shows how this works.

| Note: | See Section 5.5 "Program Memory and |
|-------|---|
| | the Extended Instruction Set" for |
| | information on two-word instructions in the |
| | extended instruction set. |

5.3 Data Memory Organization

| Note: | The operation of some aspects of data memory are changed when the PIC18 extended instruction set is enabled. See |
|-------|--|
| | Section 5.6 "Data Memory and the Extended Instruction Set" for more information. |

The data memory in PIC18 devices is implemented as static RAM. Each register in the data memory has a 12-bit address, allowing up to 4096 bytes of addressable memory. The memory space is divided into 16 banks that contain 256 bytes each. All of the PIC18F97J60 family devices implement all available banks and provide 3808 bytes of data memory available to the user. Figure 5-7 shows the data memory organization for the devices.

The data memory contains Special Function Registers (SFRs) and General Purpose Registers (GPRs). The SFRs are used for control and status of the controller and peripheral functions, while GPRs are used for data storage and scratchpad operations in the user's application. Any read of an unimplemented location will read as '0's.

The instruction set and architecture allow operations across all banks. The entire data memory may be accessed by Direct, Indirect or Indexed Addressing modes. Addressing modes are discussed later in this section.

To ensure that commonly used registers (most SFRs and select GPRs) can be accessed in a single cycle, PIC18 devices implement an Access Bank. This is a 256-byte memory space that provides fast access to the majority of SFRs and the lower portion of GPR Bank 0 without using the BSR. **Section 5.3.2 "Access Bank**" provides a detailed description of the Access RAM.

5.3.1 BANK SELECT REGISTER

Large areas of data memory require an efficient addressing scheme to make rapid access to any address possible. Ideally, this means that an entire address does not need to be provided for each read or write operation. For PIC18 devices, this is accomplished with a RAM banking scheme. This divides the memory space into 16 contiguous banks of 256 bytes. Depending on the instruction, each location can be addressed directly by its full 12-bit address, or an 8-bit low-order address and a 4-bit Bank Pointer.

Most instructions in the PIC18 instruction set make use of the Bank Pointer, known as the Bank Select Register (BSR). This SFR holds the 4 Most Significant bits of a location's address; the instruction itself includes the 8 Least Significant bits. Only the four lower bits of the BSR are implemented (BSR3:BSR0). The upper four bits are unused; they will always read '0' and cannot be written to. The BSR can be loaded directly by using the MOVLB instruction.

The value of the BSR indicates the bank in data memory. The 8 bits in the instruction show the location in the bank and can be thought of as an offset from the bank's lower boundary. The relationship between the BSR's value and the bank division in data memory is shown in Figure 5-8.

Since up to 16 registers may share the same low-order address, the user must always be careful to ensure that the proper bank is selected before performing a data read or write. For example, writing what should be program data to an 8-bit address of F9h, while the BSR is 0Fh, will end up resetting the program counter.

While any bank can be selected, only those banks that are actually implemented can be read or written to. Writes to unimplemented banks are ignored, while reads from unimplemented banks will return '0's. Even so, the STATUS register will still be affected as if the operation was successful. The data memory map in Figure 5-7 indicates which banks are implemented.

In the core PIC18 instruction set, only the MOVFF instruction fully specifies the 12-bit address of the source and target registers. This instruction ignores the BSR completely when it executes. All other instructions include only the low-order address as an operand and must use either the BSR or the Access Bank to locate their target registers.

FIGURE 5-7: DATA MEMORY MAP FOR PIC18F97J60 FAMILY DEVICES

FIGURE 5-8: USE OF THE BANK SELECT REGISTER (DIRECT ADDRESSING)

5.3.2 ACCESS BANK

While the use of the BSR with an embedded 8-bit address allows users to address the entire range of data memory, it also means that the user must always ensure that the correct bank is selected. Otherwise, data may be read from or written to the wrong location. This can be disastrous if a GPR is the intended target of an operation but an SFR is written to instead. Verifying and/or changing the BSR for each read or write to data memory can become very inefficient.

To streamline access for the most commonly used data memory locations, the data memory is configured with an Access Bank, which allows users to access a mapped block of memory without specifying a BSR. The Access Bank consists of the first 96 bytes of memory (00h-5Fh) in Bank 0 and the last 160 bytes of memory (60h-FFh) in Bank 15. The lower block is known as the "Access RAM" and is composed of GPRs. The upper block is where the device's SFRs are mapped. These two areas are mapped contiguously in the Access Bank and can be addressed in a linear fashion by an 8-bit address (Figure 5-7).

The Access Bank is used by core PIC18 instructions that include the Access RAM bit (the 'a' parameter in the instruction). When 'a' is equal to '1', the instruction uses the BSR and the 8-bit address included in the opcode for the data memory address. When 'a' is '0', however, the instruction is forced to use the Access Bank address map; the current value of the BSR is ignored entirely.

Using this "forced" addressing allows the instruction to operate on a data address in a single cycle without updating the BSR first. For 8-bit addresses of 60h and above, this means that users can evaluate and operate on SFRs more efficiently. The Access RAM below 60h is a good place for data values that the user might need to access rapidly, such as immediate computational results or common program variables. Access RAM also allows for faster and more code efficient context saving and switching of variables.

The mapping of the Access Bank is slightly different when the extended instruction set is enabled (XINST Configuration bit = 1). This is discussed in more detail in Section 5.6.3 "Mapping the Access Bank in Indexed Literal Offset Mode".

5.3.3 GENERAL PURPOSE REGISTER FILE

PIC18 devices may have banked memory in the GPR area. This is data RAM which is available for use by all instructions. GPRs start at the bottom of Bank 0 (address 000h) and grow upwards towards the bottom of the SFR area. GPRs are not initialized by a Power-on Reset and are unchanged on all other Resets.

5.3.4 SPECIAL FUNCTION REGISTERS

The Special Function Registers (SFRs) are registers used by the CPU and peripheral modules for controlling the desired operation of the device. These registers are implemented as static RAM.

The main group of SFRs start at the top of data memory (FFFh) and extend downward to occupy more than the top half of Bank 15 (F60h to FFFh). These SFRs can be classified into two sets: those associated with the "core" device functionality (ALU, Resets and interrupts) and those related to the peripheral functions. The

Reset and Interrupt registers are described in their respective chapters, while the ALU's STATUS register is described later in this section. Registers related to the operation of the peripheral features are described in the chapter for that peripheral.

The SFRs are typically distributed among the peripherals whose functions they control. Unused SFR locations are unimplemented and read as '0's. A list of SFRs is given in Table 5-3; a full description is provided in Table 5-5.

Note 1: This is not a physical register.

2: Unimplemented registers are read as '0'.

3: This register is not available on 64-pin devices.

4: This register is not available on 64 and 80-pin devices.

5.3.5 ETHERNET SFRs

In addition to the standard SFR set in Bank 15, members of the PIC18F97J60 family have a second set of SFRs. This group, associated exclusively with the Ethernet module, occupies the top half of Bank 14 (E80h to EFFh).

Note: To improve performance, frequently accessed Ethernet registers are located in the standard SFR bank (F60h through FFFh).

A complete list of Ethernet SFRs is given in Table 5-4. All SFRs are fully described in Table 5-5

TABLE 5-4: ETHERNET SFR MAP FOR PIC18F97J60 FAMILY DEVICES

Legend: x = unknown, u = unchanged, - = unimplemented, read as '0', q = value depends on condition, r = reserved bit, do not modify. Shaded cells are unimplemented, read as '0'.

Note 1: Bit 7 and bit 6 are cleared by user software or by a POR.

2: Bit 21 of the PC is only available in Serial Programming modes.

3: Reset value is '0' when Two-Speed Start-up is enabled and '1' if disabled.

4: Alternate names and definitions for these bits when the MSSP module is operating in l^2C^{TM} Slave mode.

5: These bits and/or registers are only available in 100-pin devices; otherwise, they are unimplemented and read as '0'. Reset values shown apply only to 100-pin devices.

6: These bits and/or registers are only available in 80-pin and 100-pin devices; in 64-pin devices, they are unimplemented and read as '0'. Reset values are shown for 100-pin devices.

7: In Microcontroller mode, the bits in this register are unwritable and read as '0'.

8: PLLEN is only available when either ECPLL or HSPLL Oscillator mode is selected; otherwise, read as '0'.

8: PLLEN is only available when either ECPLL or HSPLL Oscillator mode is selected; otherwise, read as '0'.

5.3.6 STATUS REGISTER

The STATUS register, shown in Register 5-3, contains the arithmetic status of the ALU. The STATUS register can be the operand for any instruction, as with any other register. If the STATUS register is the destination for an instruction that affects the Z, DC, C, OV or N bits, then the write to these five bits is disabled.

These bits are set or cleared according to the device logic. Therefore, the result of an instruction with the STATUS register as destination may be different than intended. For example, CLRF STATUS will set the Z bit but leave the other bits unchanged. The STATUS

register then reads back as '000u u1uu'. It is recommended, therefore, that only BCF, BSF, SWAPF, MOVFF and MOVWF instructions are used to alter the STATUS register because these instructions do not affect the Z, C, DC, OV or N bits in the STATUS register.

For other instructions not affecting any Status bits, see the instruction set summaries in Table 25-2 and Table 25-3.

Note: The C and DC bits operate as a Borrow and Digit Borrow bit respectively, in subtraction.

5.4 Data Addressing Modes

| Note: | The execution of some instructions in the core PIC18 instruction set are changed when the PIC18 extended instruction set is |
|-------|---|
| | enabled. See Section 5.6 "Data Memory |
| | and the Extended Instruction Set" for more information. |

While the program memory can be addressed in only one way – through the program counter – information in the data memory space can be addressed in several ways. For most instructions, the addressing mode is fixed. Other instructions may use up to three modes, depending on which operands are used and whether or not the extended instruction set is enabled.

The addressing modes are:

- Inherent
- Literal
- Direct
- Indirect

An additional addressing mode, Indexed Literal Offset, is available when the extended instruction set is enabled (XINST Configuration bit = 1). Its operation is discussed in greater detail in **Section 5.6.1 "Indexed Addressing with Literal Offset**".

5.4.1 INHERENT AND LITERAL ADDRESSING

Many PIC18 control instructions do not need any argument at all. They either perform an operation that globally affects the device, or they operate implicitly on one register. This addressing mode is known as Inherent Addressing. Examples include SLEEP, RESET and DAW.

Other instructions work in a similar way, but require an additional explicit argument in the opcode. This is known as Literal Addressing mode because they require some literal value as an argument. Examples include ADDLW and MOVLW, which respectively, add or move a literal value to the W register. Other examples include CALL and GOTO, which include a 20-bit program memory address.

5.4.2 DIRECT ADDRESSING

Direct Addressing mode specifies all or part of the source and/or destination address of the operation within the opcode itself. The options are specified by the arguments accompanying the instruction.

In the core PIC18 instruction set, bit-oriented and byte-oriented instructions use some version of Direct Addressing by default. All of these instructions include some 8-bit literal address as their Least Significant Byte. This address specifies either a register address in one of the banks of data RAM (Section 5.3.3 "General Purpose Register File") or a location in the Access Bank (Section 5.3.2 "Access Bank") as the data source for the instruction. The Access RAM bit, 'a', determines how the address is interpreted. When 'a' is '1', the contents of the BSR (Section 5.3.1 "Bank Select Register") are used with the address to determine the complete 12-bit address of the register. When 'a' is '0', the address is interpreted as being a register in the Access Bank. Addressing that uses the Access RAM is sometimes also known as Direct Forced Addressing mode.

A few instructions, such as MOVFF, include the entire 12-bit address (either source or destination) in their opcodes. In these cases, the BSR is ignored entirely.

The destination of the operation's results is determined by the destination bit, 'd'. When 'd' is '1', the results are stored back in the source register, overwriting its original contents. When 'd' is '0', the results are stored in the W register. Instructions without the 'd' argument have a destination that is implicit in the instruction. Their destination is either the target register being operated on or the W register.

5.4.3 INDIRECT ADDRESSING

Indirect Addressing mode allows the user to access a location in data memory without giving a fixed address in the instruction. This is done by using File Select Registers (FSRs) as pointers to the locations to be read or written to. Since the FSRs are themselves located in RAM as Special Function Registers, they can also be directly manipulated under program control. This makes FSRs very useful in implementing data structures, such as tables and arrays in data memory.

The registers for Indirect Addressing are also implemented with Indirect File Operands (INDFs) that permit automatic manipulation of the pointer value with auto-incrementing, auto-decrementing or offsetting with another value. This allows for efficient code using loops, such as the example of clearing an entire RAM bank in Example 5-5. It also enables users to perform indexed addressing and other Stack Pointer operations for program memory in data memory.

EXAMPLE 5-5: HOW TO CLEAR RAM (BANK 1) USING INDIRECT ADDRESSING

| | LFSR | FSR0, | 100h | ; | |

5.4.3.1 FSR Registers and the INDF Operand

At the core of Indirect Addressing are three sets of registers: FSR0, FSR1 and FSR2. Each represents a pair of 8-bit registers: FSRnH and FSRnL. The four upper bits of the FSRnH register are not used, so each FSR pair holds a 12-bit value. This represents a value that can address the entire range of the data memory in a linear fashion. The FSR register pairs, then, serve as pointers to data memory locations.

Indirect Addressing is accomplished with a set of Indirect File Operands: INDF0 through INDF2. These can be thought of as "virtual" registers; they are mapped in the SFR space but are not physically implemented. Reading or writing to a particular INDF register actually accesses its corresponding FSR register pair. A read from INDF1, for example, reads the data at the address indicated by FSR1H:FSR1L. Instructions that use the INDF registers as operands actually use the contents of their corresponding FSR as a pointer to the instruction's target. The INDF operand is just a convenient way of using the pointer.

Because Indirect Addressing uses a full 12-bit address, data RAM banking is not necessary. Thus, the current contents of the BSR and Access RAM bit have no effect on determining the target address.

5.4.3.2 FSR Registers and POSTINC, POSTDEC, PREINC and PLUSW

In addition to the INDF operand, each FSR register pair also has four additional indirect operands. Like INDF, these are "virtual" registers that cannot be indirectly read or written to. Accessing these registers actually accesses the associated FSR register pair, but also performs a specific action on its stored value. They are:

- POSTDEC: accesses the FSR value, then automatically decrements it by '1' afterwards
- POSTINC: accesses the FSR value, then automatically increments it by '1' afterwards
- PREINC: increments the FSR value by '1', then uses it in the operation
- PLUSW: adds the signed value of the W register (range of -128 to 127) to that of the FSR and uses the new value in the operation

In this context, accessing an INDF register uses the value in the FSR registers without changing them. Similarly, accessing a PLUSW register gives the FSR value offset by the value in the W register; neither value is actually changed in the operation. Accessing the other virtual registers changes the value of the FSR registers.

Operations on the FSRs with POSTDEC, POSTINC and PREINC affect the entire register pair; that is, rollovers of the FSRnL register from FFh to 00h carry over to the FSRnH register. On the other hand, results of these operations do not change the value of any flags in the STATUS register (e.g., Z, N, OV, etc.).

The PLUSW register can be used to implement a form of Indexed Addressing in the data memory space. By manipulating the value in the W register, users can reach addresses that are fixed offsets from pointer addresses. In some applications, this can be used to implement some powerful program control structure, such as software stacks, inside of data memory.

5.4.3.3 Operations by FSRs on FSRs

Indirect Addressing operations that target other FSRs, or virtual registers, represent special cases. For example, using an FSR to point to one of the virtual registers will not result in successful operation. As a specific case, assume that the FSR0H:FSR0L pair contains FE7h, the address of INDF1. Attempts to read the value of the INDF1, using INDF0 as an operand, will return 00h. Attempts to write to INDF1, using INDF0 as the operand, will result in a NOP.

On the other hand, using the virtual registers to write to an FSR pair may not occur as planned. In these cases, the value will be written to the FSR pair but without any incrementing or decrementing. Thus, writing to INDF2 or POSTDEC2 will write the same value to the FSR2H:FSR2L pair.

Since the FSRs are physical registers mapped in the SFR space, they can be manipulated through all direct operations. Users should proceed cautiously when working on these registers, particularly if their code uses Indirect Addressing.

Similarly, operations by Indirect Addressing are generally permitted on all other SFRs. Users should exercise the appropriate caution that they do not inadvertently change settings that might affect the operation of the device.

5.5 Program Memory and the Extended Instruction Set

The operation of program memory is unaffected by the use of the extended instruction set.

Enabling the extended instruction set adds five additional two-word commands to the existing PIC18 instruction set: ADDFSR, CALLW, MOVSF, MOVSS and SUBFSR. These instructions are executed as described in Section 5.2.4 "Two-Word Instructions".

5.6 Data Memory and the Extended Instruction Set

Enabling the PIC18 extended instruction set (XINST Configuration bit = 1) significantly changes certain aspects of data memory and its addressing. Specifically, the use of the Access Bank for many of the core PIC18 instructions is different. This is due to the introduction of a new addressing mode for the data memory space. This mode also alters the behavior of Indirect Addressing using FSR2 and its associated operands.

What does not change is just as important. The size of the data memory space is unchanged, as well as its linear addressing. The SFR map remains the same. Core PIC18 instructions can still operate in both Direct and Indirect Addressing mode; inherent and literal instructions do not change at all. Indirect Addressing with FSR0 and FSR1 also remains unchanged.

5.6.1 INDEXED ADDRESSING WITH LITERAL OFFSET

Enabling the PIC18 extended instruction set changes the behavior of Indirect Addressing using the FSR2 register pair and its associated file operands. Under the proper conditions, instructions that use the Access Bank – that is, most bit-oriented and byte-oriented instructions – can invoke a form of Indexed Addressing using an offset specified in the instruction. This special addressing mode is known as Indexed Addressing with Literal Offset, or Indexed Literal Offset mode.

When using the extended instruction set, this addressing mode requires the following:

- The use of the Access Bank is forced ('a' = 0); and
- The file address argument is less than or equal to 5Fh.

Under these conditions, the file address of the instruction is not interpreted as the lower byte of an address (used with the BSR in Direct Addressing) or as an 8-bit address in the Access Bank. Instead, the value is interpreted as an offset value to an Address Pointer specified by FSR2. The offset and the contents of FSR2 are added to obtain the target address of the operation.

5.6.2 INSTRUCTIONS AFFECTED BY INDEXED LITERAL OFFSET MODE

Any of the core PIC18 instructions that can use Direct Addressing are potentially affected by the Indexed Literal Offset Addressing mode. This includes all byte-oriented and bit-oriented instructions, or almost half of the standard PIC18 instruction set. Instructions that only use Inherent or Literal Addressing modes are unaffected.

Additionally, byte-oriented and bit-oriented instructions are not affected if they use the Access Bank (Access RAM bit is '1') or include a file address of 60h or above. Instructions meeting these criteria will continue to execute as before. A comparison of the different possible addressing modes when the extended instruction set is enabled is shown in Figure 5-10.

Those who desire to use byte-oriented or bit-oriented instructions in the Indexed Literal Offset mode should note the changes to assembler syntax for this mode. This is described in more detail in **Section 25.2.1** "Extended Instruction Syntax".

PIC18F97J60 FAMILY

FIGURE 5-10: COMPARING ADDRESSING OPTIONS FOR BIT-ORIENTED AND BYTE-ORIENTED INSTRUCTIONS (EXTENDED INSTRUCTION SET ENABLED)

EXAMPLE INSTRUCTION: ADDWF, f, d, a (Opcode: 0010 01da ffff ffff)

When a = 0 and $f \ge 60h$:

The instruction executes in Direct Forced mode. 'f' is interpreted as a location in the Access RAM between 060h and FFFh. This is the same as locations F60h to FFFh (Bank 15) of data memory.

Locations below 060h are not available in this addressing mode.

The instruction executes in Indexed Literal Offset mode. " is interpreted as an offset to the address value in FSR2. The two are added together to obtain the address of the target register for the instruction. The address can be anywhere in the data memory space.

Note that in this mode, the correct syntax is now: ADDWF [k], d where 'k' is the same as 'f'.

When a = 1 (all values of f):

The instruction executes in Direct mode (also known as Direct Long mode). 'f' is interpreted as a location in one of the 16 banks of the data memory space. The bank is designated by the Bank Select Register (BSR). The address can be in any implemented bank in the data memory space.

5.6.3 MAPPING THE ACCESS BANK IN INDEXED LITERAL OFFSET MODE

The use of Indexed Literal Offset Addressing mode effectively changes how the lower part of Access RAM (00h to 5Fh) is mapped. Rather than containing just the contents of the bottom part of Bank 0, this mode maps the contents from Bank 0 and a user-defined "window" that can be located anywhere in the data memory space. The value of FSR2 establishes the lower boundary of the addresses mapped into the window, while the upper boundary is defined by FSR2 plus 95 (5Fh). Addresses in the Access RAM above 5Fh are mapped as previously described (see **Section 5.3.2** "**Access Bank**"). An example of Access Bank remapping in this addressing mode is shown in Figure 5-11. Remapping of the Access Bank applies *only* to operations using the Indexed Literal Offset mode. Operations that use the BSR (Access RAM bit is '1') will continue to use Direct Addressing as before. Any indirect or indexed operation that explicitly uses any of the indirect file operands (including FSR2) will continue to operate as standard Indirect Addressing. Any instruction that uses the Access Bank, but includes a register address of greater than 05Fh, will use Direct Addressing and the normal Access Bank map.

5.6.4 BSR IN INDEXED LITERAL OFFSET MODE

Although the Access Bank is remapped when the extended instruction set is enabled, the operation of the BSR remains unchanged. Direct Addressing, using the BSR to select the data memory bank, operates in the same manner as previously described.

FIGURE 5-11: REMAPPING THE ACCESS BANK WITH INDEXED LITERAL OFFSET ADDRESSING

NOTES:

6.0 FLASH PROGRAM MEMORY

The Flash program memory is readable, writable and erasable during normal operation over the entire VDD range.

A read from program memory is executed on one byte at a time. A write to program memory is executed on blocks of 64 bytes at a time. Program memory is erased in blocks of 1024 bytes at a time. A Bulk Erase operation may not be issued from user code.

Writing or erasing program memory will cease instruction fetches until the operation is complete. The program memory cannot be accessed during the write or erase, therefore, code cannot execute. An internal programming timer terminates program memory writes and erases.

A value written to program memory does not need to be a valid instruction. Executing a program memory location that forms an invalid instruction results in a NOP.

6.1 Table Reads and Table Writes

In order to read and write program memory, there are two operations that allow the processor to move bytes between the program memory space and the data RAM:

- Table Read (TBLRD)
- Table Write (TBLWT)

The program memory space is 16 bits wide, while the data RAM space is 8 bits wide. Table reads and table writes move data between these two memory spaces through an 8-bit register (TABLAT).

Table read operations retrieve data from program memory and place it into the data RAM space. Figure 6-1 shows the operation of a table read with program memory and data RAM.

Table write operations store data from the data memory space into holding registers in program memory. The procedure to write the contents of the holding registers into program memory is detailed in **Section 6.5** "**Writing to Flash Program Memory**". Figure 6-2 shows the operation of a table write with program memory and data RAM.

Table operations work with byte entities. A table block containing data, rather than program instructions, is not required to be word-aligned. Therefore, a table block can start and end at any byte address. If a table write is being used to write executable code into program memory, program instructions will need to be word-aligned.

FIGURE 6-1: TABLE READ OPERATION

PIC18F97J60 FAMILY

6.2 Control Registers

Several control registers are used in conjunction with the TBLRD and TBLWT instructions. These include the:

- EECON1 register
- EECON2 register
- TABLAT register
- TBLPTR registers

6.2.1 EECON1 AND EECON2 REGISTERS

The EECON1 register (Register 6-1) is the control register for memory accesses. The EECON2 register is not a physical register; it is used exclusively in the memory write and erase sequences. Reading EECON2 will read all '0's.

The FREE bit, when set, will allow a program memory erase operation. When FREE is set, the erase operation is initiated on the next WR command. When FREE is clear, only writes are enabled. The WREN bit, when set, will allow a write operation. On power-up, the WREN bit is clear. The WRERR bit is set in hardware when the WR bit is set, and cleared when the internal programming timer expires and the write operation is complete.

```
Note: During normal operation, the WRERR is
read as '1'. This can indicate that a write
operation was prematurely terminated by
a Reset, or a write operation was
attempted improperly.
```

The WR control bit initiates write operations. The bit cannot be cleared, only set, in software; it is cleared in hardware at the completion of the write operation.

REGISTER 6-1: EECON1: EEPROM CONTROL REGISTER 1

| U-0 | U-0 | U-0 | R/W-0 | R/W-x | R/W-0 | R/S-0 | U-0 |
|-------|-----|-----|-------|-------|-------|-------|-------|
| — | — | — | FREE | WRERR | WREN | WR | — |

|---------|---|
| bit 4 | FREE: Flash Row Erase Enable bit |
| | 1 = Erase the program memory row addressed by TBLPTR on the next WR command (cleared by completion of erase operation) 0 = Perform write-only |
| bit 3 | WRERR: Flash Program Error Flag bit |
| | 1 = A write operation is prematurely terminated (any Reset during self-timed programming in normal operation, or an improper write attempt) 0 = The write operation completed |
| bit 2 | WREN: Flash Program Write Enable bit |
| | 1 = Allows write cycles to Flash program memory 0 = Inhibits write cycles to Flash program memory |
| bit 1 | WR: Write Control bit |
| | 1 = Initiates a program memory erase cycle or write cycle. (The operation is self-timed and the bit is cleared by hardware once write is complete. The WR bit can only be set (not cleared) in software.) 0 = Write cycle complete |
| bit 0 | Unimplemented: Read as '0' |
| | |

6.2.2 TABLE LATCH REGISTER (TABLAT)

The Table Latch (TABLAT) is an 8-bit register mapped into the SFR space. The Table Latch register is used to hold 8-bit data during data transfers between program memory and data RAM.

6.2.3 TABLE POINTER REGISTER (TBLPTR)

The Table Pointer (TBLPTR) register addresses a byte within the program memory. The TBLPTR is comprised of three SFR registers: Table Pointer Upper Byte, Table Pointer High Byte and Table Pointer Low Byte (TBLPTRU:TBLPTRH:TBLPTRL). These three registers join to form a 22-bit wide pointer. The low-order 21 bits allow the device to address up to 2 Mbytes of program memory space. The 22nd bit allows access to the Device ID and Configuration bits.

The Table Pointer register, TBLPTR, is used by the TBLRD and TBLWT instructions. These instructions can update the TBLPTR in one of four ways based on the table operation. These operations are shown in Table 6-1. The table operations on the TBLPTR only affect the low-order 21 bits.

6.2.4 TABLE POINTER BOUNDARIES

TBLPTR is used in reads, writes and erases of the Flash program memory.

When a TBLRD is executed, all 22 bits of the TBLPTR determine which byte is read from program memory into TABLAT.

When a TBLWT is executed, the six LSbs of the Table Pointer register (TBLPTR<5:0>) determine which of the 64 program memory holding registers is written to. When the timed write to program memory begins (via the WR bit), the 15 MSbs of the TBLPTR (TBLPTR<20:6>) determine which program memory block of 64 bytes is written to. For more detail, see **Section 6.5 "Writing to Flash Program Memory"**.

When an erase of program memory is executed, the 11 MSbs of the Table Pointer register (TBLPTR<20:10>) point to the 1024-byte block that will be erased. The Least Significant bits (TBLPTR<9:0>) are ignored.

Figure 6-3 describes the relevant boundaries of TBLPTR based on Flash program memory operations.

| TABLE 6-1: | TABLE POINTER OPERATIONS WITH TBLRD AND TBLWT INSTRUCTIONS |
|------------|--|
| | |

| Example | Operation on Table Pointer | | | |
|--------------------|---|--|--|--|
| TBLRD* TBLWT* | TBLPTR is not modified | | | |
| TBLRD*+ TBLWT*+ | TBLPTR is incremented after the read/write | | | |
| TBLRD*- TBLWT*- | TBLPTR is decremented after the read/write | | | |
| TBLRD+* TBLWT+* | TBLPTR is incremented before the read/write | | | |

FIGURE 6-3: TABLE POINTER BOUNDARIES BASED ON OPERATION

6.3 Reading the Flash Program Memory

The TBLRD instruction is used to retrieve data from program memory and places it into data RAM. Table reads from program memory are performed one byte at a time.

TBLPTR points to a byte address in program space. Executing TBLRD places the byte pointed to into TABLAT. In addition, TBLPTR can be modified automatically for the next table read operation.

The internal program memory is typically organized by words. The Least Significant bit of the address selects between the high and low bytes of the word. Figure 6-4 shows the interface between the internal program memory and the TABLAT.

FIGURE 6-4: READS FROM FLASH PROGRAM MEMORY

EXAMPLE 6-1: READING A FLASH PROGRAM MEMORY WORD

| I I I I | MOVWF MOVLW MOVWF MOVLW | | | Load TBLPTR with the base address of the word |
|------------------|----------------------------------|-----------|---|--|

| | TBLRD*+ | | ; | read into TABLAT and increment |
| I | MOVFW | TABLAT, W | ; | get data |
| I | MOVF | WORD_ODD | | |

6.4 Erasing Flash Program Memory

The minimum erase block is 1024 bytes. Only through the use of an external programmer, or through ICSP control, can larger blocks of program memory be Bulk Erased. Word Erase in the Flash array is not supported.

When initiating an erase sequence from the microcontroller itself, a block of 1024 bytes of program memory is erased. The Most Significant 11 bits of the TBLPTR<20:10> point to the block being erased. TBLPTR<9:0> are ignored.

The EECON1 register commands the erase operation. The WREN bit must be set to enable write operations. The FREE bit is set to select an erase operation.

For protection, the write initiate sequence for EECON2 must be used.

A long write is necessary for erasing the internal Flash. Instruction execution is halted while in a long write cycle. The long write will be terminated by the internal programming timer.

6.4.1 FLASH PROGRAM MEMORY ERASE SEQUENCE

The sequence of events for erasing a block of internal program memory location is:

- 1. Load Table Pointer register with address of row being erased.
- 2. Set the EECON1 register for the erase operation:set WREN bit to enable writes;
 - set FREE bit to enable the erase.
- Disable interrupts.
- 4. Write 55h to EECON2.
- 5. Write 0AAh to EECON2.
- 6. Set the WR bit. This will begin the Row Erase cycle.
- 7. The CPU will stall for duration of the erase (about 2 ms using internal timer).
- 8. Re-enable interrupts.

EXAMPLE 6-2: ERASING A FLASH PROGRAM MEMORY ROW

| | MOVLW | CODE_ADDR_UPPER | ; load TBLPTR with the base |
|-----------|-------|-----------------|-------------------------------|
| | MOVWF | TBLPTRU | ; address of the memory block |

| | MOVWF | EECON2 | ; write OAAh |
| | BSF | EECON1, WR | ; start erase (CPU stall) |
| | BSF | INTCON, GIE | ; re-enable interrupts |
| | | | |

6.5 Writing to Flash Program Memory

The minimum programming block is 32 words or 64 bytes. Word or byte programming is not supported.

Table writes are used internally to load the holding registers needed to program the Flash memory. There are 64 holding registers used by the table writes for programming.

Since the Table Latch (TABLAT) is only a single byte, the TBLWT instruction may need to be executed 64 times for each programming operation. All of the table write operations will essentially be short writes because only the holding registers are written. At the end of updating the 64 holding registers, the EECON1 register must be written to in order to start the programming operation with a long write.

The long write is necessary for programming the internal Flash. Instruction execution is halted while in a long write cycle. The long write will be terminated by the internal programming timer.

The EEPROM on-chip timer controls the write time. The write/erase voltages are generated by an on-chip charge pump, rated to operate over the voltage range of the device.

- Note 1: Unlike previous PIC MCU devices, members of the PIC18F97J60 family do not reset the holding registers after a write occurs. The holding registers must be cleared or overwritten before a programming sequence.
 - 2: To maintain the endurance of the program memory cells, each Flash byte should not be programmed more than one time between erase operations. Before attempting to modify the contents of the target cell a second time, a Row Erase of the target row, or a Bulk Erase of the entire memory, must be performed.

FIGURE 6-5: TABLE WRITES TO FLASH PROGRAM MEMORY

6.5.1 FLASH PROGRAM MEMORY WRITE SEQUENCE

The sequence of events for programming an internal program memory location should be:

- 1. If the section of program memory to be written to has been programmed previously, then the memory will need to be erased before the write occurs (see Section 6.4.1 "Flash Program Memory Erase Sequence").
- 2. Write the 64 bytes into the holding registers with auto-increment.
- 3. Set the WREN bit to enable byte writes.
- 4. Disable interrupts.

- 5. Write 55h to EECON2.
- 6. Write AAh to EECON2.
- 7. Set the WR bit. This will begin the write cycle.
- 8. The CPU will stall for duration of the write (about 2 ms using internal timer).
- 9. Re-enable interrupts.
- 10. Verify the memory (table read).

An example of the required code is shown in Example 6-3.

| Note: | Before setting the WR bit, the Table | | | | | |

EXAMPLE 6-3: WRITING TO FLASH PROGRAM MEMORY

6.5.2 WRITE VERIFY

Depending on the application, good programming practice may dictate that the value written to the memory should be verified against the original value. This should be used in applications where excessive writes can stress bits near the specification limit.

6.5.3 UNEXPECTED TERMINATION OF WRITE OPERATION

If a write is terminated by an unplanned event, such as loss of power or an unexpected Reset, the memory location just programmed should be verified and reprogrammed if needed. If the write operation is interrupted by a MCLR Reset, or a WDT Time-out Reset during normal operation, the user can check the WRERR bit and rewrite the location(s) as needed.

6.5.4 PROTECTION AGAINST SPURIOUS WRITES

To protect against spurious writes to Flash program memory, the write initiate sequence must also be followed. See **Section 24.0** "**Special Features of the CPU**" for more details.

6.6 Flash Program Operation During Code Protection

See Section 24.6 "Program Verification and Code Protection" for details on code protection of Flash program memory.

NOTES:

7.0 EXTERNAL MEMORY BUS

| Note: | The | external | me | emory | bus | is | not |
|-------|----------------------|----------|----|--------|-----|----|-------|
| | implemented devices. | | on | 64-pin | and | 80 |)-pin |

The External Memory Bus (EMB) allows the device to access external memory devices (such as Flash, EPROM, SRAM, etc.) as program or data memory. It supports both 8 and 16-Bit Data Width modes, and three address widths of up to 20 bits.

The bus is implemented with 28 pins, multiplexed across four I/O ports. Three ports (PORTD, PORTE and PORTH) are multiplexed with the address/data bus for a total of 20 available lines, while PORTJ is multiplexed with the bus control signals.

A list of the pins and their functions is provided in Table 7-1.

| Name | Port | Bit | External Memory Bus Function |
|----------|-------|-----|--|
| RD0/AD0 | PORTD | 0 | Address bit 0 or Data bit 0 |
| RD1/AD1 | PORTD | 1 | Address bit 1 or Data bit 1 |
| RD2/AD2 | PORTD | 2 | Address bit 2 or Data bit 2 |

Note: For the sake of clarity, only I/O port and external bus assignments are shown here. One or more additional multiplexed features may be available on some pins.

7.1 External Memory Bus Control

The operation of the interface is controlled by the MEMCON register (Register 7-1). This register is available in all program memory operating modes except Microcontroller mode. In this mode, the register is disabled and cannot be written to.

The EBDIS bit (MEMCON<7>) controls the operation of the bus and related port functions. Clearing EBDIS enables the interface and disables the I/O functions of the ports, as well as any other functions multiplexed to those pins. Setting the bit enables the I/O ports and other functions, but allows the interface to override everything else on the pins when an external memory operation is required. By default, the external bus is always enabled and disables all other I/Os. The operation of the EBDIS bit is also influenced by the program memory mode being used. This is discussed in more detail in **Section 7.5** "**Program Memory Modes and the External Memory Bus**".

The WAIT bits allow for the addition of wait states to external memory operations. The use of these bits is discussed in **Section 7.3 "Wait States"**.

The WM bits select the particular operating mode used when the bus is operating in 16-Bit Data Width mode. These operating modes are discussed in more detail in **Section 7.6 "16-Bit Data Width Modes"**. The WM bits have no effect when an 8-Bit Data Width mode is selected.

REGISTER 7-1: MEMCON: EXTERNAL MEMORY BUS CONTROL REGISTER

| | 00 = Byte Write mode: TABLAT data copied on both MSB and LSB; WRH or WRL will activate | | | | |

7.2 Address and Data Width

The PIC18F97J60 family of devices can be independently configured for different address and data widths on the same memory bus. Both address and data widths are set by Configuration bits in the CONFIG3L register. As Configuration bits, this means that these options can only be configured by programming the device and are not controllable in software.

The BW bit selects an 8-bit or 16-bit data bus width. Setting this bit (default) selects a data width of 16 bits.

The EMB1:EMB0 bits determine both the program memory operating mode and the address bus width. The available options are 20-bit, 16-bit and 12-bit, as well as the default Microcontroller mode (external bus disabled). Selecting a 16-bit or 12-bit width makes a corresponding number of high-order lines available for I/O functions. These pins are no longer affected by the setting of the EBDIS bit. For example, selecting a 16-Bit Addressing mode (EMB1:EMB0 = 01) disables A19:A16 and allows the PORTH<3:0> bits to function without interruptions from the bus. Using the smaller address widths allows users to tailor the memory bus to the size of the external memory space for a particular design while freeing up pins for dedicated I/O operation.

Because the EMB bits have the effect of disabling pins for memory bus operations, it is important to always select an address width at least equal to the data width. If a 12-bit address width is used with a 16-bit data width, the upper four bits of data will not be available on the bus.

All combinations of address and data widths require multiplexing of address and data information on the same lines. The address and data multiplexing, as well as I/O ports made available by the use of smaller address widths, are summarized in Table 7-2.

7.2.1 ADDRESS SHIFTING ON THE EXTERNAL BUS

By default, the address presented on the external bus is the value of the PC. In practical terms, this means that addresses in the external memory device below the top of on-chip memory are unavailable to the microcontroller. To access these physical locations, the glue logic between the microcontroller and the external memory must somehow translate addresses.

To simplify the interface, the external bus offers an extension of Extended Microcontroller mode that automatically performs address shifting. This feature is controlled by the EASHFT Configuration bit. Setting this bit offsets addresses on the bus by the size of the microcontroller's on-chip program memory and sets the bottom address at 0000h. This allows the device to use the entire range of physical addresses of the external memory.

7.2.2 21-BIT ADDRESSING

As an extension of 20-bit address width operation, the external memory bus can also fully address a 2-Mbyte memory space. This is done by using the Bus Address (BA0) bit 0 control line as the Least Significant bit of the address. The UB and LB control signals may also be used with certain memory devices to select the upper and lower bytes within a 16-bit wide data word.

This addressing mode is available in both 8-Bit Data Width and certain 16-Bit Data Width modes. Additional details are provided in Section 7.6.3 "16-Bit Byte Select Mode" and Section 7.7 "8-Bit Data Width Mode".

| Data Width | Address Width | Multiplexed Data and Address Lines (and corresponding ports) | Address Only Lines (and corresponding ports) | Ports Available for I/O |
|------------|---------------|--|--|-----------------------------|
| | 12-bit | | AD11:AD8 (PORTE<3:0>) | PORTE<7:4>, All of PORTH |
| 8-bit | 16-bit | AD7:AD0 (PORTD<7:0>) | AD15:AD8 (PORTE<7:0>) | All of PORTH |
| | 20-bit | | A19:A16, AD15:AD8 (PORTH<3:0>, PORTE<7:0>) | — |
| | 16-bit | AD15:AD0 | — | All of PORTH |
| 16-bit | 20-bit | (PORTD<7:0>, PORTE<7:0>) | A19:A16 (PORTH<3:0>) | _ |

TABLE 7-2: ADDRESS AND DATA LINES FOR DIFFERENT ADDRESS AND DATA WIDTHS

© 2006 Microchip Technology Inc.

7.3 Wait States

While it may be assumed that external memory devices will operate at the microcontroller clock rate, this is often not the case. In fact, many devices require longer times to write or retrieve data than the time allowed by the execution of table read or table write operations.

To compensate for this, the external memory bus can be configured to add a fixed delay to each table operation using the bus. Wait states are enabled by setting the WAIT Configuration bit. When enabled, the amount of delay is set by the WAIT1:WAIT0 bits (MEMCON<5:4>). The delay is based on multiples of microcontroller instruction cycle time and are added following the instruction cycle when the table operation is executed. The range is from no delay to 3 Tcy (default value).

7.4 Port Pin Weak Pull-ups

With the exception of the upper address lines, A19:A16, the pins associated with the external memory bus are equipped with weak pull-ups. The pull-ups are controlled by bits located at LATA<7:6> and PORTA<7>. They are named RDPU, REPU and RJPU and control pull-ups on PORTD, PORTE and PORTJ, respectively. Setting one of these bits enables the corresponding pull-ups for that port. All pull-ups are disabled by default on all device Resets.

In Extended Microcontroller mode, the port pull-ups can be useful in preserving the memory state on the external bus while the bus is temporarily disabled (EBDIS = 1).

7.5 Program Memory Modes and the External Memory Bus

The PIC18F97J60 family of devices is capable of operating in one of two program memory modes, using combinations of on-chip and external program memory. The functions of the multiplexed port pins depend on the program memory mode selected, as well as the setting of the EBDIS bit.

In **Microcontroller Mode**, the bus is not active and the pins have their port functions only. Writes to the MEMCOM register are not permitted. The Reset value of EBDIS ('0') is ignored and the EMB pins behave as I/O ports.

In **Extended Microcontroller Mode**, the external program memory bus shares I/O port functions on the pins. When the device is fetching, or doing table read/table write operations on the external program memory space, the pins will have the external bus function.

If the device is fetching and accessing internal program memory locations only, the EBDIS control bit will change the pins from external memory to I/O port functions. When EBDIS = 0, the pins function as the external bus. When EBDIS = 1, the pins function as I/O ports.

If the device fetches or accesses external memory while EBDIS = 1, the pins will switch to the external bus. If the EBDIS bit is set by a program executing from external memory, the action of setting the bit will be delayed until the program branches into the internal memory. At that time, the pins will change from external bus to I/O ports.

If the device is executing out of internal memory when EBDIS = 0, the memory bus address/data and control pins will not be active. They will go to a state where the active address/data pins are tri-state; the \overline{CE} , \overline{OE} , WRH, WRL, UB and LB signals are '1' and ALE and BA0 are '0'. Note that only those pins associated with the current address width are forced to tri-state; the other pins continue to function as I/O. In the case of 16-bit address width, for example, only AD<15:0> (PORTD and PORTE) are affected; A19:A16 (PORTH<3:0>) continue to function as I/O.

In all external memory modes, the bus takes priority over any other peripherals that may share pins with it. This includes the Parallel Slave Port and serial communication modules which would otherwise take priority over the I/O port.

7.6 16-Bit Data Width Modes

In 16-Bit Data Width mode, the external memory interface can be connected to external memories in three different configurations:

- 16-Bit Byte Write
- 16-Bit Word Write
- 16-Bit Byte Select

The configuration to be used is determined by the WM1:WM0 bits in the MEMCON register (MEMCON<1:0>). These three different configurations allow the designer maximum flexibility in using both 8-bit and 16-bit devices with 16-bit data.

For all 16-Bit Data Width modes, the Address Latch Enable (ALE) pin indicates that the address bits, AD<15:0>, are available on the external memory interface bus. Following the address latch, the Output Enable signal (\overline{OE}) will enable both bytes of program memory at once to form a 16-bit instruction word. The Chip Enable signal (\overline{CE}) is active at any time that the microcontroller accesses external memory, whether reading or writing. It is inactive (asserted high) whenever the device is in Sleep mode.

In Byte Select mode, JEDEC standard Flash memories will require BA0 for the byte address line and one I/O line to select between Byte and Word mode. The other 16-Bit Data Width modes do not need BA0. JEDEC standard, static RAM memories will use the UB or LB signals for byte selection.

7.6.1 16-BIT BYTE WRITE MODE

Figure 7-1 shows an example of 16-Bit Byte Write mode for PIC18F97J60 family devices. This mode is used for two separate 8-bit memories connected for 16-bit operation. This generally includes basic EPROM and Flash devices. It allows table writes to byte-wide external memories. During a TBLWT instruction cycle, the TABLAT data is presented on the upper and <u>lower bytes</u> of the AD15:AD0 bus. The appropriate WRH or WRL control line is strobed on the LSb of the TBLPTR.

7.6.2 16-BIT WORD WRITE MODE

Figure 7-2 shows an example of 16-Bit Word Write mode for PIC18F97J60 devices. This mode is used for word-wide memories which include some of the EPROM and Flash type memories. This mode allows opcode fetches and table reads from all forms of 16-bit memory, and table writes to any type of word-wide external memories. This method makes a distinction between TBLWT cycles to even or odd addresses.

During a TBLWT cycle to an even address (TBLPTR<0> = 0), the TABLAT data is transferred to a holding latch and the external address data bus is tri-stated for the data portion of the bus cycle. No write signals are activated.

During a TBLWT cycle to an odd address (TBLPTR<0> = 1), the TABLAT data is presented on the upper byte of the AD15:AD0 bus. The contents of the holding latch are presented on the lower byte of the AD15:AD0 bus.

The WRH signal is strobed for each write cycle; the WRL pin is unused. The signal on the BA0 pin indicates the LSb of the TBLPTR but it is left unconnected. Instead, the UB and LB signals are active to select both bytes. The obvious limitation to this method is that the table write must be done in pairs on a specific word boundary to correctly write a word location.

FIGURE 7-2: 16-BIT WORD WRITE MODE EXAMPLE

7.6.3 16-BIT BYTE SELECT MODE

Figure 7-3 shows an example of 16-Bit Byte Select mode. This mode allows table write operations to word-wide external memories with byte selection capability. This generally includes both word-wide Flash and SRAM devices.

During a TBLWT cycle, the TABLAT data is presented on the upper and lower byte of the AD15:AD0 bus. The WRH signal is strobed for each write cycle; the WRL pin is not used. The BA0 or UB/LB signals are used to select the byte to be written based on the Least Significant bit of the TBLPTR register. Flash and SRAM devices use different control signal combinations to implement Byte Select mode. JEDEC standard Flash memories require that a controller I/O port pin be connected to the memory's BYTE/WORD pin to provide the select signal. They also use the BA0 signal from the controller as a byte address. JEDEC standard, static RAM memories, on the other hand, use the UB or LB signals to select the byte.

7.6.4 16-BIT MODE TIMING

The presentation of control signals on the external memory bus is different for the various operating modes. Typical signal timing diagrams are shown in Figure 7-4 and Figure 7-5.

FIGURE 7-5: EXTERNAL MEMORY BUS TIMING FOR SLEEP (EXTENDED MICROCONTROLLER MODE)

7.7 8-Bit Data Width Mode

In 8-Bit Data Width mode, the external memory bus operates only in Multiplexed mode; that is, data shares the eight Least Significant bits of the address bus.

Figure 7-6 shows an example of 8-Bit Multiplexed mode for 100-pin devices. This mode is used for a single 8-bit memory connected for 16-bit operation. The instructions will be fetched as two 8-bit bytes on a shared data/address bus. The two bytes are sequentially fetched within one instruction cycle (TcY). Therefore, the designer must choose external memory devices according to timing calculations based on 1/2 TcY (2 times the instruction rate). For proper memory speed selection, glue logic propagation delay times must be considered, along with setup and hold times.

The Address Latch Enable (ALE) pin indicates that the address bits, AD<15:0>, are available on the external memory interface bus. The Output Enable signal (OE)

will enable one byte of program memory for a portion of the instruction cycle, then BA0 will change and the second byte will be enabled to form the 16-bit instruction word. The Least Significant bit of the address, BA0, must be connected to the memory devices in this mode. The Chip Enable signal (\overline{CE}) is active at any time that the microcontroller accesses external memory, whether reading or writing. It is inactive (asserted high) whenever the device is in Sleep mode.

This process generally includes basic EPROM and Flash devices. It allows table writes to byte-wide external memories.

During a TBLWT instruction cycle, the TABLAT data is presented on the upper and lower bytes of the AD15:AD0 bus. The appropriate level of the BA0 control line is strobed on the LSb of the TBLPTR.

FIGURE 7-6: 8-BIT MULTIPLEXED MODE EXAMPLE

7.7.1 8-BIT MODE TIMING

The presentation of control signals on the external memory bus is different for the various operating modes. Typical signal timing diagrams are shown in Figure 7-7 and Figure 7-8.

FIGURE 7-8: EXTERNAL MEMORY BUS TIMING FOR SLEEP (EXTENDED MICROCONTROLLER MODE)

7.8 Operation in Power-Managed Modes

In alternate power-managed Run modes, the external bus continues to operate normally. If a clock source with a lower speed is selected, bus operations will run at that speed. In these cases, excessive access times for the external memory may result if wait states have been enabled and added to external memory operations. If operations in a lower power Run mode are anticipated, user applications should provide memory access time adjustments at the lower clock speeds. In Sleep and Idle modes, the microcontroller core does not need to access data; bus operations are suspended. The state of the external bus is frozen, with the address/data pins and most of the control pins holding at the same state they were in when the mode was invoked. The only potential changes are the \overline{CE} , \overline{LB} and \overline{UB} pins, which are held at logic high. NOTES:

8.0 8 x 8 HARDWARE MULTIPLIER

8.1 Introduction

All PIC18 devices include an 8 x 8 hardware multiplier as part of the ALU. The multiplier performs an unsigned operation and yields a 16-bit result that is stored in the product register pair, PRODH:PRODL. The multiplier's operation does not affect any flags in the STATUS register.

Making multiplication a hardware operation allows it to be completed in a single instruction cycle. This has the advantages of higher computational throughput and reduced code size for multiplication algorithms and allows the PIC18 devices to be used in many applications previously reserved for digital signal processors. A comparison of various hardware and software multiply operations, along with the savings in memory and execution time, is shown in Table 8-1.

8.2 Operation

Example 8-1 shows the instruction sequence for an 8 x 8 unsigned multiplication. Only one instruction is required when one of the arguments is already loaded in the WREG register.

Example 8-2 shows the sequence to do an 8 x 8 signed multiplication. To account for the sign bits of the arguments, each argument's Most Significant bit (MSb) is tested and the appropriate subtractions are done.

9.0 INTERRUPTS

Members of the PIC18F97J60 family of devices have multiple interrupt sources and an interrupt priority feature that allows most interrupt sources to be assigned a high priority level or a low priority level. The high priority interrupt vector is at 0008h and the low priority interrupt vector is at 0018h. High priority interrupt events will interrupt any low priority interrupts that may be in progress.

There are thirteen registers which are used to control interrupt operation. These registers are:

- RCON
- INTCON
- INTCON2
- INTCON3
- PIR1, PIR2, PIR3
- PIE1, PIE2, PIE3
- IPR1, IPR2, IPR3

It is recommended that the Microchip header files supplied with MPLAB[®] IDE be used for the symbolic bit names in these registers. This allows the assembler/compiler to automatically take care of the placement of these bits within the specified register.

In general, interrupt sources have three bits to control their operation. They are:

- Flag bit to indicate that an interrupt event occurred
- Enable bit that allows program execution to branch to the interrupt vector address when the flag bit is set
- **Priority bit** to select high priority or low priority

The interrupt priority feature is enabled by setting the IPEN bit (RCON<7>). When interrupt priority is enabled, there are two bits which enable interrupts globally. Setting the GIEH bit (INTCON<7>) enables all interrupts that have the priority bit set (high priority). Setting the GIEL bit (INTCON<6>) enables all interrupts that have the priority bit cleared (low priority). When the interrupt flag, enable bit and appropriate global interrupt enable bit are set, the interrupt will vector immediately to address 0008h or 0018h, depending on the priority bit setting. Individual interrupts can be disabled through their corresponding enable bits.

When the IPEN bit is cleared (default state), the interrupt priority feature is disabled and interrupts are compatible with PIC[®] mid-range devices. In Compatibility mode, the interrupt priority bits for each source have no effect. INTCON<6> is the PEIE bit which enables/disables all peripheral interrupt sources. INTCON<7> is the GIE bit which enables/disables all interrupt sources. All interrupts branch to address 0008h in Compatibility mode.

When an interrupt is responded to, the global interrupt enable bit is cleared to disable further interrupts. If the IPEN bit is cleared, this is the GIE bit. If interrupt priority levels are used, this will be either the GIEH or GIEL bit. High priority interrupt sources can interrupt a low priority interrupt. Low priority interrupts are not processed while high priority interrupts are in progress.

The return address is pushed onto the stack and the PC is loaded with the interrupt vector address (0008h or 0018h). Once in the Interrupt Service Routine, the source(s) of the interrupt can be determined by polling the interrupt flag bits. The interrupt flag bits must be cleared in software before re-enabling interrupts to avoid recursive interrupts.

The "return from interrupt" instruction, RETFIE, exits the interrupt routine and sets the GIE bit (GIEH or GIEL if priority levels are used) which re-enables interrupts.

For external interrupt events, such as the INTx pins or the PORTB input change interrupt, the interrupt latency will be three to four instruction cycles. The exact latency is the same for one or two-cycle instructions. Individual interrupt flag bits are set regardless of the status of their corresponding enable bit or the GIE bit.

Note: Do not use the MOVFF instruction to modify any of the interrupt control registers while **any** interrupt is enabled. Doing so may cause erratic microcontroller behavior.

9.1 INTCON Registers

The INTCON registers are readable and writable registers which contain various enable, priority and flag bits.

Note: Interrupt flag bits are set when an interrupt condition occurs regardless of the state of its corresponding enable bit or the global interrupt enable bit. User software should ensure the appropriate interrupt flag bits are clear prior to enabling an interrupt. This feature allows for software polling.

9.2 PIR Registers

The PIR registers contain the individual flag bits for the peripheral interrupts. Due to the number of peripheral interrupt sources, there are three Peripheral Interrupt Request (Flag) registers (PIR1, PIR2, PIR3).

- Note 1: Interrupt flag bits are set when an interrupt condition occurs regardless of the state of its corresponding enable bit or the Global Interrupt Enable bit, GIE (INTCON<7>).
 - 2: User software should ensure the appropriate interrupt flag bits are cleared prior to enabling an interrupt and after servicing that interrupt.

REGISTER 9-9: PIE3: PERIPHERAL INTERRUPT ENABLE REGISTER 3

2: Implemented in 80-pin and 100-pin devices only.

9.4 IPR Registers

The IPR registers contain the individual priority bits for the peripheral interrupts. Due to the number of peripheral interrupt sources, there are three Peripheral Interrupt Priority registers (IPR1, IPR2, IPR3). Using the priority bits requires that the Interrupt Priority Enable (IPEN) bit be set.

9.6 INTx Pin Interrupts

External interrupts on the RB0/INT0/FLT0, RB1/INT1, RB2/INT2 and RB3/INT3 pins are edge-triggered. If the corresponding INTEDGx bit in the INTCON2 register is set (= 1), the interrupt is triggered by a rising edge; if the bit is clear, the trigger is on the falling edge. When a valid edge appears on the RBx/INTx pin, the corresponding flag bit, INTxIF, is set. This interrupt can be disabled by clearing the corresponding enable bit, INTxIE. Flag bit, INTxIF, must be cleared in software in the Interrupt Service Routine before re-enabling the interrupt.

All external interrupts (INT0, INT1, INT2 and INT3) can wake-up the processor from the power-managed modes if bit INTxIE was set prior to going into the power-managed modes. If the Global Interrupt Enable bit, GIE, is set, the processor will branch to the interrupt vector following wake-up.

Interrupt priority for INT1, INT2 and INT3 is determined by the value contained in the Interrupt Priority bits, INT1IP (INTCON3<6>), INT2IP (INTCON3<7>) and INT3IP (INTCON2<1>). There is no priority bit associated with INT0. It is always a high priority interrupt source.

9.7 TMR0 Interrupt

In 8-bit mode (which is the default), an overflow in the TMR0 register (FFh \rightarrow 00h) will set flag bit, TMR0IF. In 16-bit mode, an overflow in the TMR0H:TMR0L register pair (FFFFh \rightarrow 0000h) will set TMR0IF. The interrupt can be enabled/disabled by setting/clearing enable bit, TMR0IE (INTCON<5>). Interrupt priority for Timer0 is determined by the value contained in the interrupt priority bit, TMR0IP (INTCON2<2>). See Section 11.0 "Timer0 Module" for further details on the Timer0 module.

9.8 PORTB Interrupt-on-Change

An input change on PORTB<7:4> sets flag bit, RBIF (INTCON<0>). The interrupt can be enabled/disabled by setting/clearing enable bit, RBIE (INTCON<3>). Interrupt priority for PORTB interrupt-on-change is determined by the value contained in the interrupt priority bit, RBIP (INTCON2<0>).

9.9 Context Saving During Interrupts

During interrupts, the return PC address is saved on the stack. Additionally, the WREG, STATUS and BSR registers are saved on the fast return stack. If a fast return from interrupt is not used (see **Section 5.3 "Data Memory Organization"**), the user may need to save the WREG, STATUS and BSR registers on entry to the Interrupt Service Routine. Depending on the user's application, other registers may also need to be saved. Example 9-1 saves and restores the WREG, STATUS and BSR registers during an Interrupt Service Routine.

| MOVWF MOVFF MOVFF | W_TEMP STATUS, STATUS_TEMP BSR, BSR_TEMP | ; W_TEMP is in virtual bank ; STATUS_TEMP located anywhere ; BSR_TMEP located anywhere |

| | | |

EXAMPLE 9-1: SAVING STATUS, WREG AND BSR REGISTERS IN RAM

10.0 I/O PORTS

Depending on the device selected and features enabled, there are up to nine ports available. Some pins of the I/O ports are multiplexed with an alternate function from the peripheral features on the device. In general, when a peripheral is enabled, that pin may not be used as a general purpose I/O pin.

Each port has three registers for its operation. These registers are:

- TRIS register (Data Direction register)
- PORT register (reads the levels on the pins of the device)
- LAT register (Output Latch register)

The Output Latch (LAT register) is useful for read-modify-write operations on the value that the $\mbox{I/O}$ pins are driving.

A simplified model of a generic I/O port, without the interfaces to other peripherals, is shown in Figure 10-1.

FIGURE 10-1: GENERIC I/O PORT OPERATION

10.1 I/O Port Pin Capabilities

When developing an application, the capabilities of the port pins must be considered. Outputs on some pins have higher output drive strength than others. Similarly, some pins can tolerate higher than VDD input levels.

10.1.1 PIN OUTPUT DRIVE

The output pin drive strengths vary for groups of pins intended to meet the needs for a variety of applications. PORTB and PORTC are designed to drive higher loads, such as LEDs. The external memory interface ports (PORTD, PORTE and PORTJ) are designed to drive medium loads. All other ports are designed for small loads, typically indication only. Table 10-1 summarizes the output capabilities. Refer to **Section 27.0 "Electrical Characteristics"** for more details.

| TABLE 10-1: | OUTPUT DRIVE LEVELS |
|-------------|---------------------|
|-------------|---------------------|

| Port | Drive | Description |
|----------------------|---------|-------------------------------|
| PORTA ⁽¹⁾ | Minimum | Intended for indication. |
| PORTF ⁽²⁾ | | |
| PORTG ⁽²⁾ | | |
| PORTH ⁽³⁾ | | |
| PORTD ⁽²⁾ | Medium | Sufficient drive levels for |
| PORTE | | external memory interfacing, |
| PORTJ ⁽³⁾ | | as well as indication. |
| PORTB | High | Suitable for direct LED drive |
| PORTC | | levels. |

Note 1: The exceptions are RA0:RA1, which are capable of directly driving LEDs.

2: Partially implemented on 64-pin and 80-pin devices; fully implemented on 100-pin devices.

^{3:} Unimplemented on 64-pin devices.

10.1.2 INPUT PINS AND VOLTAGE CONSIDERATIONS

The voltage tolerance of pins used as device inputs is dependent on the pin's input function. Pins that are used as digital only inputs are able to handle DC voltages up to 5.5V, a level typical for digital logic circuits. In contrast, pins that also have analog input functions of any kind can only tolerate voltages up to VDD. Voltage excursions beyond VDD on these pins are always to be avoided. Table 10-2 summarizes the input capabilities. Refer to **Section 27.0 "Electrical Characteristics"** for more details.

| Port or Pin | Tolerated Input | Description |
|---------------------------|--------------------|------------------------|
| PORTA<5:0> | Vdd | Only VDD input levels |
| PORTF<6:1> ⁽¹⁾ | | tolerated. |
| PORTH<7:4>(2) | | |
| PORTB<7:0> | 5.5V | Tolerates input levels |
| PORTC<7:0> | | above VDD, useful for |
| PORTD<7:0>(1) | | most standard logic. |
| PORTE<7:0> | | |
| PORTF<7> | | |
| PORTG<7:0>(1) | | |
| PORTH<3:0> ⁽²⁾ | | |
| PORTJ<7:0> ⁽²⁾ | | |

TABLE 10-2: INPUT VOLTAGE LEVELS

- Note 1: Partially implemented on 64-pin and 80-pin devices; fully implemented on 100-pin devices.
 - **2:** Unavailable on 64-pin devices.

10.2 PORTA, TRISA and LATA Registers

PORTA is a 6-bit wide, bidirectional port; it is fully implemented on all devices. The corresponding Data Direction register is TRISA. Setting a TRISA bit (= 1) will make the corresponding PORTA pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISA bit (= 0) will make the corresponding PORTA pin an output (i.e., put the contents of the output latch on the selected pin).

Reading the PORTA register reads the status of the pins, whereas writing to it, will write to the port latch.

The Output Latch register (LATA) is also memory mapped. Read-modify-write operations on the LATA register read and write the latched output value for PORTA.

The RA4 pin is multiplexed with the Timer0 module clock input to become the RA4/T0CKI pin. The other PORTA pins are multiplexed with the analog VREF+ and VREF- inputs. The operation of pins RA5:RA0 as A/D converter inputs is selected by clearing or setting the PCFG3:PCFG0 control bits in the ADCON1 register.

| Note: | RA5 and RA3:RA0 are configured as |
|-------|---|
| | analog inputs on any Reset and are read |
| | as '0'. RA4 is configured as a digital input. |

The RA4/T0CKI pin is a Schmitt Trigger input. All other PORTA pins have TTL input levels and full CMOS output drivers.

The TRISA register controls the direction of the PORTA pins, even when they are being used as analog inputs. The user must ensure the bits in the TRISA register are maintained set when using them as analog inputs.

The RA0 and RA1 pins can also be configured as the outputs for the two Ethernet LED indicators. When configured, these two pins are the only pins on PORTA that are capable of high output drive levels.

Although the port is only six bits wide, PORTA<7> is implemented as RJPU, the weak pull-up control bit for PORTJ. In a similar fashion, the LATA<7:6> bits are implemented, not as latch bits, but the pull-up control bits, RDPU and REPU, for PORTD and PORTE. Setting these bits enables the pull-ups for the corresponding port. Because their port pins are not used, the TRISA<7:6> bits are not implemented.

Legend: — = unimplemented, read as '0'. Shaded cells are not used by PORTA.

Note 1: Implemented in 80-pin and 100-pin devices only.

10.3 PORTB, TRISB and LATB Registers

PORTB is an 8-bit wide, bidirectional port; it is fully implemented on all devices. The corresponding Data Direction register is TRISB. Setting a TRISB bit (= 1) will make the corresponding PORTB pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISB bit (= 0) will make the corresponding PORTB pin an output (i.e., put the contents of the output latch on the selected pin). All pins on PORTB are digital only and tolerate voltages up to 5.5V.

The Output Latch register (LATB) is also memory mapped. Read-modify-write operations on the LATB register read and write the latched output value for PORTB.

EXAMPLE 10-2: INITIALIZING PORTB

| CLRF | PORTB | ; Initialize PORTB by ; clearing output |
|-------|-------|---|
| CLRF | LATB | ; data latches ; Alternate method ; to clear output ; data latches |
| MOVLW | 0CFh | ; Value used to ; initialize data ; direction |
| MOVWF | TRISB | ; Set RB<3:0> as inputs ; RB<5:4> as outputs ; RB<7:6> as inputs |

Each of the PORTB pins has a weak internal pull-up. A single control bit can turn on all of the pull-ups. This is performed by clearing bit, RBPU (INTCON2<7>). The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on all Resets.

Four of the PORTB pins (RB7:RB4) have an interrupt-on-change feature. Only pins configured as inputs can cause this interrupt to occur (i.e., any RB7:RB4 pin configured as an output is excluded from the interrupt-on-change comparison). The input pins (of RB7:RB4) are compared with the old value latched on the last read of PORTB. The "mismatch" outputs of RB7:RB4 are ORed together to generate the RB Port Change Interrupt with Flag bit, RBIF (INTCON<0>).

This interrupt can wake the device from power-managed modes. The user, in the Interrupt Service Routine, can clear the interrupt in the following manner:

- a) Any read or write of PORTB (except with the MOVFF (ANY), PORTB instruction). This will end the mismatch condition.
- b) Clear flag bit, RBIF.

A mismatch condition will continue to set flag bit, RBIF. Reading PORTB will end the mismatch condition and allow flag bit, RBIF, to be cleared.

The interrupt-on-change feature is recommended for wake-up on key depression operation and operations where PORTB is only used for the interrupt-on-change feature. Polling of PORTB is not recommended while using the interrupt-on-change feature.

For 100-pin devices operating in Extended Microcontroller mode, RB3 can be configured as the alternate peripheral pin for the ECCP2 module and Enhanced PWM output 2A by clearing the CCP2MX Configuration bit. If the devices are in Microcontroller mode, the alternate assignment for ECCP2 is RE7. As with other ECCP2 configurations, the user must ensure that the TRISB<3> bit is set appropriately for the intended operation.

| Pin Name | Function | TRIS Setting | I/O | I/O Type | Description |
|---------------|----------------------|-----------------|-----|-------------|---|
| RB0/INT0/FLT0 | RB0 | 0 | 0 | DIG | LATB<0> data output. |

TABLE 10-6: SUMMARY OF REGISTERS ASSOCIATED WITH PORTB

Legend: Shaded cells are not used by PORTB.

10.4 PORTC, TRISC and LATC Registers

PORTC is an 8-bit wide, bidirectional port; it is fully implemented on all devices. The corresponding Data Direction register is TRISC. Setting a TRISC bit (= 1) will make the corresponding PORTC pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISC bit (= 0) will make the corresponding PORTC pin an output (i.e., put the contents of the output latch on the selected pin). Only PORTC pins, RC2 through RC7, are digital only pins and can tolerate input voltages up to 5.5V.

The Output Latch register (LATC) is also memory mapped. Read-modify-write operations on the LATC register read and write the latched output value for PORTC.

PORTC is multiplexed with several peripheral functions (Table 10-7). The pins have Schmitt Trigger input buffers. RC1 is normally configured by Configuration bit, CCP2MX, as the default peripheral pin for the ECCP2 module and Enhanced PWM output P2A (default state, CCP2MX = 1).

When enabling peripheral functions, care should be taken in defining TRIS bits for each PORTC pin. Some peripherals override the TRIS bit to make a pin an output, while other peripherals override the TRIS bit to make a pin an input. The user should refer to the corresponding peripheral section for the correct TRIS bit settings. Note: These pins are configured as digital inputs on any device Reset.

The contents of the TRISC register are affected by peripheral overrides. Reading TRISC always returns the current contents, even though a peripheral device may be overriding one or more of the pins.

TABLE 10-8: SUMMARY OF REGISTERS ASSOCIATED WITH PORTC

10.5 PORTD, TRISD and LATD Registers

PORTD is implemented as a bidirectional port in two ways:

- 64-pin and 80-pin devices: 3 bits (RD<2:0>)
- 100-pin devices: 8 bits (RD<7:0>)

The corresponding Data Direction register is TRISD. Setting a TRISD bit (= 1) will make the corresponding PORTD pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISD bit (= 0) will make the corresponding PORTD pin an output (i.e., put the contents of the output latch on the selected pin). All pins on PORTD are digital only and tolerate voltages up to 5.5V.

The Output Latch register (LATD) is also memory mapped. Read-modify-write operations on the LATD register read and write the latched output value for PORTD.

All pins on PORTD are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output.

| Note: | These pins are configured as digital inputs |
|-------|---|
| | on any device Reset. |

On 100-pin devices, PORTD is multiplexed with the system bus as part of the external memory interface. I/O port and other functions are only available when the interface is disabled by setting the EBDIS bit (MEMCON<7>). When the interface is enabled, PORTD is the low-order byte of the multiplexed address/data bus (AD7:AD0). The TRISD bits are also overridden.

Each of the PORTD pins has a weak internal pull-up. A single control bit can turn on all of the pull-ups. This is performed by setting the RDPU bit (LATA<7>). The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on all device Resets.

On 100-pin devices, PORTD can also be configured to function as an 8-bit wide, parallel microprocessor port by setting the PSPMODE control bit (PSPCON<4>). In this mode, parallel port data takes priority over other digital I/O (but not the external memory interface). When the parallel port is active, the input buffers are TTL. For more information, refer to **Section 10.11** "**Parallel Slave Port**".

Legend: Shaded cells are not used by PORTD.

Note 1: Unimplemented on 64-pin and 80-pin devices; read as '0'.

10.6 PORTE, TRISE and LATE Registers

PORTE is implemented as a bidirectional port in two different ways:

- 64-pin devices: 6 bits wide (RE<5:0>)
- 80-pin and 100-pin devices: 8 bits wide (RE<7:0>)

The corresponding Data Direction register is TRISE. Setting a TRISE bit (= 1) will make the corresponding PORTE pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISE bit (= 0) will make the corresponding PORTE pin an output (i.e., put the contents of the output latch on the selected pin). All pins on PORTE are digital only and tolerate voltages up to 5.5V.

The Output Latch register (LATE) is also memory mapped. Read-modify-write operations on the LATE register read and write the latched output value for PORTE.

All pins on PORTE are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output.

| Note: | These pins are configured as digital inputs | |
|-------|---|--|
| | on any device Reset. | |

On 100-pin devices, PORTE is multiplexed with the system bus as part of the external memory interface. I/O port and other functions are only available when the interface is disabled by setting the EBDIS bit (MEMCON<7>). When the interface is enabled, PORTE is the high-order byte of the multiplexed address/data bus (AD15:AD8). The TRISE bits are also overridden.

Each of the PORTE pins has a weak internal pull-up. A single control bit can turn on all of the pull-ups. This is performed by setting bit REPU (LATA<6>). The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on all device Resets.

PORTE is also multiplexed with Enhanced PWM outputs B and C for ECCP1 and ECCP3 and outputs B, C and D for ECCP2. For 80-pin and 100-pin devices, their default assignments are on PORTE<6:0>. For 64-pin devices, their default assignments are on PORTE<5:0> and PORTD<0>. On 80-pin and 100-pin devices, the multiplexing for the outputs of ECCP1 and ECCP3 is controlled by the ECCPMX Configuration bit. Clearing this bit reassigns the P1B/P1C and P3B/P3C outputs to PORTH.

For 80-pin and 100-pin devices operating in Microcontroller mode, pin RE7 can be configured as the alternate peripheral pin for the ECCP2 module and Enhanced PWM output 2A. This is done by clearing the CCP2MX Configuration bit.

When the Parallel Slave Port is active on PORTD, three of the PORTE pins (RE0, RE1 and RE2) are configured as digital control inputs for the port. The control functions are summarized in Table 10-11. The reconfiguration occurs automatically when the PSPMODE control bit (PSPCON<4>) is set. Users must still make certain the corresponding TRISE bits are set to configure these pins as digital inputs.

10.7 PORTF, LATF and TRISF Registers

PORTF is implemented as a bidirectional port in two different ways:

- 64-pin and 80-pin devices: 7 bits wide (RF<7:1>)
- 100-pin devices: 8 bits wide (RF<7:0>)

The corresponding Data Direction register is TRISF. Setting a TRISF bit (= 1) will make the corresponding PORTF pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISF bit (= 0) will make the corresponding PORTF pin an output (i.e., put the contents of the output latch on the selected pin). Only pin 7 of PORTF has no analog input; it is the only pin that can tolerate voltages up to 5.5V.

The Output Latch register (LATF) is also memory mapped. Read-modify-write operations on the LATF register read and write the latched output value for PORTF.

All pins on PORTF are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output.

PORTF is multiplexed with several analog peripheral functions, including the A/D converter and comparator inputs, as well as the comparator outputs. Pins RF1 through RF6 may be used as comparator inputs or outputs by setting the appropriate bits in the CMCON register. To use RF6:RF1 as digital inputs, it is also necessary to turn off the comparators.

- Note 1: On device Resets, pins RF6:RF1 are configured as analog inputs and are read as '0'.
 - **2:** To configure PORTF as digital I/O, turn off comparators and set ADCON1 value.

10.8 PORTG, TRISG and LATG Registers

Depending on the particular device, PORTG is implemented as a bidirectional port in one of three ways:

- 64-pin devices: 1 bit wide (RG<4>)
- 80-pin devices: 5 bits wide (RG<4:0>)
- 100-pin devices: 8 bits wide (RG<7:0>)

The corresponding Data Direction register is TRISG. Setting a TRISG bit (= 1) will make the corresponding PORTG pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISG bit (= 0) will make the corresponding PORTG pin an output (i.e., put the contents of the output latch on the selected pin). All pins on PORTG are digital only and tolerate voltages up to 5.5V.

The Output Latch register (LATG) is also memory mapped. Read-modify-write operations on the LATG register read and write the latched output value for PORTG.

PORTG is multiplexed with EUSART2 functions on 80-pin and 100-pin devices (Table 10-15). PORTG pins have Schmitt Trigger input buffers.

When enabling peripheral functions, care should be taken in defining TRIS bits for each PORTG pin. Some peripherals override the TRIS bit to make a pin an output, while other peripherals override the TRIS bit to make a pin an input. The user should refer to the corresponding peripheral section for the correct TRIS bit settings. The pin override value is not loaded into the TRIS register. This allows read-modify-write of the TRIS register without concern due to peripheral overrides.

TABLE 10-16: SUMMARY OF REGISTERS ASSOCIATED WITH PORTG

Note 1: Implemented on 100-pin devices only.

2: Implemented on 80-pin and 100-pin devices only.

10.9 PORTH, LATH and TRISH Registers

| Note: | PORTH is available only on 80-pin and |
|-------|---------------------------------------|
| | 100-pin devices. |

PORTH is an 8-bit wide, bidirectional I/O port; it is fully implemented on 80-pin and 100-pin devices. The corresponding Data Direction register is TRISH. Setting a TRISH bit (= 1) will make the corresponding PORTH pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISH bit (= 0) will make the corresponding PORTH pin an output (i.e., put the contents of the output latch on the selected pin). PORTH<3:0> pins are digital only and tolerate voltages up to 5.5V.

The Output Latch register (LATH) is also memory mapped. Read-modify-write operations on the LATH register read and write the latched output value for PORTH.

All pins on PORTH are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output. When the external memory interface is enabled, four of the PORTH pins function as the high-order address lines for the interface. The address output from the interface takes priority over other digital I/O. The corresponding TRISH bits are also overridden.

PORTH pins, RH4 through RH7, are multiplexed with analog converter inputs. The operation of these pins as analog inputs is selected by clearing or setting the PCFG3:PCFG0 control bits in the ADCON1 register.

PORTH can also be configured as the alternate Enhanced PWM output channels B and C for the ECCP1 and ECCP3 modules. This is done by clearing the ECCPMX Configuration bit.

TABLE 10-18: SUMMARY OF REGISTERS ASSOCIATED WITH PORTH

10.10 PORTJ, TRISJ and LATJ Registers

| Note: | PORTJ is available only on 80-p | in and |
|-------|---------------------------------|--------|
| | 100-pin devices. | |

PORTJ is implemented as a bidirectional port in two different ways:

- 80-pin devices: 2 bits wide (RJ<5:4>)
- 100-pin devices: 8 bits wide (RJ<7:0>)

The corresponding Data Direction register is TRISJ. Setting a TRISJ bit (= 1) will make the corresponding PORTJ pin an input (i.e., put the corresponding output driver in a high-impedance mode). Clearing a TRISJ bit (= 0) will make the corresponding PORTJ pin an output (i.e., put the contents of the output latch on the selected pin). All pins on PORTJ are digital only and tolerate voltages up to 5.5V.

The Output Latch register (LATJ) is also memory mapped. Read-modify-write operations on the LATJ register read and write the latched output value for PORTJ.

All pins on PORTJ are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output.

| Note: | These pins are configured as digital inputs |
|-------|---|
| | on any device Reset. |

When the external memory interface is enabled, all of the PORTJ pins function as control outputs for the interface. This occurs automatically when the interface is enabled by clearing the EBDIS control bit (MEMCON<7>). The TRISJ bits are also overridden.

Each of the PORTJ pins has a weak internal pull-up. A single control bit can turn on all the pull-ups. This is performed by setting bit, RJPU (PORTA<7>). The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on all device Resets.

10.11 Parallel Slave Port

| Note: | The Parallel Slave Port is only implemented |
|-------|---|
| | in 100-pin devices. |

PORTD can also function as an 8-bit wide, Parallel Slave Port, or microprocessor port, when control bit, PSPMODE (PSPCON<4>), is set. It is asynchronously readable and writable by the external world through the RD control input pin, RE0/AD8/RD/P2D and WR control input pin, RE1/AD9//WR/P2C.

| Note: | The Parallel Slave Port is available only in |
|-------|--|
| | Microcontroller mode. |

The PSP can directly interface to an 8-bit microprocessor data bus. The external microprocessor can read or write the PORTD latch as an 8-bit latch. Setting bit, PSPMODE, enables port pin RE0/AD8/RD/P2D to be the RD input, RE1/AD9//WR/P2C to be the WR input and RE2/AD10//CS/P2B to be the CS (Chip Select) input. For this functionality, the corresponding data direction bits of the TRISE register (TRISE<2:0>) must be configured as inputs (set).

A write to the PSP occurs when both the \overline{CS} and \overline{WR} lines are first detected low and ends when either are detected high. The PSPIF and IBF flag bits are both set when the write ends.

A read from the PSP occurs when both the \overline{CS} and \overline{RD} lines are first detected low. The data in PORTD is read out and the OBF bit is set. If the user writes new data to PORTD to set OBF, the data is immediately read out; however, the OBF bit is not set.

When either the \overline{CS} or \overline{RD} lines is detected high, the PORTD pins return to the input state and the PSPIF bit is set. User applications should wait for PSPIF to be set before servicing the PSP. When this happens, the IBF and OBF bits can be polled and the appropriate action taken.

The timing for the control signals in Write and Read modes is shown in Figure 10-3 and Figure 10-4, respectively.

NOTES:

11.0 TIMER0 MODULE

The Timer0 module incorporates the following features:

- Software selectable operation as a timer or counter in both 8-bit or 16-bit modes
- Readable and writable registers
- Dedicated, 8-bit, software programmable prescaler
- Selectable clock source (internal or external)
- Edge select for external clock
- · Interrupt on overflow

The T0CON register (Register 11-1) controls all aspects of the module's operation, including the prescale selection. It is both readable and writable.

A simplified block diagram of the Timer0 module in 8-bit mode is shown in Figure 11-1. Figure 11-2 shows a simplified block diagram of the Timer0 module in 16-bit mode.

11.1 Timer0 Operation

Timer0 can operate as either a timer or a counter; the mode is selected with the TOCS bit (TOCON<5>). In Timer mode (TOCS = 0), the module increments on every clock by default unless a different prescaler value is selected (see **Section 11.3 "Prescaler"**). If the TMR0 register is written to, the increment is inhibited for the following two instruction cycles. The user can work around this by writing an adjusted value to the TMR0 register.

The Counter mode is selected by setting the T0CS bit (= 1). In this mode, Timer0 increments either on every rising or falling edge of pin RA4/T0CKI. The incrementing edge is determined by the Timer0 Source Edge Select bit, T0SE (T0CON<4>); clearing this bit selects the rising edge. Restrictions on the external clock input are discussed below.

An external clock source can be used to drive Timer0; however, it must meet certain requirements to ensure that the external clock can be synchronized with the internal phase clock (Tosc). There is a delay between synchronization and the onset of incrementing the timer/counter.

11.2 Timer0 Reads and Writes in 16-Bit Mode

TMR0H is not the actual high byte of Timer0 in 16-bit mode. It is actually a buffered version of the real high byte of Timer0 which is not directly readable nor writable (refer to Figure 11-2). TMR0H is updated with the contents of the high byte of Timer0 during a read of TMR0L. This provides the ability to read all 16 bits of Timer0 without having to verify that the read of the high and low byte were valid, due to a rollover between successive reads of the high and low byte.

Similarly, a write to the high byte of Timer0 must also take place through the TMR0H Buffer register. The high byte is updated with the contents of TMR0H when a write occurs to TMR0L. This allows all 16 bits of Timer0 to be updated at once.

FIGURE 11-1: TIMER0 BLOCK DIAGRAM (8-BIT MODE)

FIGURE 11-2: TIMER0 BLOCK DIAGRAM (16-BIT MODE)

11.3 Prescaler

An 8-bit counter is available as a prescaler for the Timer0 module. The prescaler is not directly readable or writable. Its value is set by the PSA and T0PS2:T0PS0 bits (T0CON<3:0>) which determine the prescaler assignment and prescale ratio.

Clearing the PSA bit assigns the prescaler to the Timer0 module. When it is assigned, prescale values from 1:2 through 1:256 in power-of-2 increments are selectable.

When assigned to the Timer0 module, all instructions writing to the TMR0 register (e.g., CLRF TMR0, MOVWF TMR0, BSF TMR0, etc.) clear the prescaler count.

| Note: | Writing to TMR0 when the prescaler is |
|-------|---|
| | assigned to Timer0 will clear the prescaler |
| | count but will not change the prescaler |
| | assignment. |

11.3.1 SWITCHING PRESCALER ASSIGNMENT

The prescaler assignment is fully under software control and can be changed "on-the-fly" during program execution.

11.4 Timer0 Interrupt

The TMR0 interrupt is generated when the TMR0 register overflows from FFh to 00h in 8-bit mode, or from FFFFh to 0000h in 16-bit mode. This overflow sets the TMR0IF flag bit. The interrupt can be masked by clearing the TMR0IE bit (INTCON<5>). Before re-enabling the interrupt, the TMR0IF bit must be cleared in software by the Interrupt Service Routine.

Since Timer0 is shut down in Sleep mode, the TMR0 interrupt cannot awaken the processor from Sleep.

NOTES:

12.0 TIMER1 MODULE

The Timer1 timer/counter module incorporates these features:

- Software selectable operation as a 16-bit timer or counter
- Readable and writable 8-bit registers (TMR1H and TMR1L)
- Selectable clock source (internal or external) with device clock or Timer1 oscillator internal options
- Interrupt on overflow
- Reset on ECCP Special Event Trigger
- Device clock status flag (T1RUN)

A simplified block diagram of the Timer1 module is shown in Figure 12-1. A block diagram of the module's operation in Read/Write mode is shown in Figure 12-2.

The module incorporates its own low-power oscillator to provide an additional clocking option. The Timer1 oscillator can also be used as a low-power clock source for the microcontroller in power-managed operation.

Timer1 can also be used to provide Real-Time Clock (RTC) functionality to applications with only a minimal addition of external components and code overhead.

Timer1 is controlled through the T1CON Control register (Register 12-1). It also contains the Timer1 Oscillator Enable bit (T1OSCEN). Timer1 can be enabled or disabled by setting or clearing control bit, TMR10N (T1CON<0>).

12.1 Timer1 Operation

Timer1 can operate in one of these modes:

- Timer
- Synchronous Counter
- Asynchronous Counter

The operating mode is determined by the clock select bit, TMR1CS (T1CON<1>). When TMR1CS is cleared (= 0), Timer1 increments on every internal instruction

FIGURE 12-2: TIMER1 BLOCK DIAGRAM (16-BIT READ/WRITE MODE)

FIGURE 12-1: TIMER1 BLOCK DIAGRAM

cycle (FOSC/4). When the bit is set, Timer1 increments on every rising edge of the Timer1 external clock input or the Timer1 oscillator, if enabled.

When Timer1 is enabled, the RC1/T1OSI and RC0/T1OSO/T13CKI pins become inputs. This means the values of TRISC<1:0> are ignored and the pins are read as '0'.

12.2 Timer1 16-Bit Read/Write Mode

Timer1 can be configured for 16-bit reads and writes (see Figure 12-2). When the RD16 control bit (T1CON<7>) is set, the address for TMR1H is mapped to a buffer register for the high byte of Timer1. A read from TMR1L will load the contents of the high byte of Timer1 into the Timer1 High Byte Buffer register. This provides the user with the ability to accurately read all 16 bits of Timer1 without having to determine whether a read of the high byte, followed by a read of the low byte, has become invalid due to a rollover between reads.

A write to the high byte of Timer1 must also take place through the TMR1H Buffer register. The Timer1 high byte is updated with the contents of TMR1H when a write occurs to TMR1L. This allows a user to write all 16 bits to both the high and low bytes of Timer1 at once.

The high byte of Timer1 is not directly readable or writable in this mode. All reads and writes must take place through the Timer1 High Byte Buffer register. Writes to TMR1H do not clear the Timer1 prescaler. The prescaler is only cleared on writes to TMR1L.

12.3 Timer1 Oscillator

An on-chip crystal oscillator circuit is incorporated between pins T1OSI (input) and T1OSO (amplifier output). It is enabled by setting the Timer1 Oscillator Enable bit, T1OSCEN (T1CON<3>). The oscillator is a low-power circuit rated for 32 kHz crystals. It will continue to run during all power-managed modes. The circuit for a typical LP oscillator is shown in Figure 12-3. Table 12-1 shows the capacitor selection for the Timer1 oscillator.

The user must provide a software time delay to ensure proper start-up of the Timer1 oscillator.

FIGURE 12-3: EXTERNAL COMPONENTS FOR THE TIMER1 OSCILLATOR

TABLE 12-1: CAPACITOR SELECTION FOR THETIMEROSCILLATOR^(2,3,4)

| Oscillator Type | Freq. | C1 | C2 | | | | | | |

| (| Higher capacitance increases the stability of the oscillator but also increases the start-up time. | | | | | | | | |
| t t | Since each resonator/crystal has its own characteristics, the user should consult the resonator/crystal manufacturer for appropriate values of external components. | | | | | | | | |
| | Capacitor values are for design guida only. | | | | | | | | |

12.3.1 USING TIMER1 AS A CLOCK SOURCE

The Timer1 oscillator is also available as a clock source in power-managed modes. By setting the Clock Select bits, SCS1:SCS0 (OSCCON<1:0>), to '01', the device switches to SEC_RUN mode; both the CPU and peripherals are clocked from the Timer1 oscillator. If the IDLEN bit (OSCCON<7>) is cleared and a SLEEP instruction is executed, the device enters SEC_IDLE mode. Additional details are available in **Section 3.0 "Power-Managed Modes"**.

Whenever the Timer1 oscillator is providing the clock source, the Timer1 system clock status flag, T1RUN (T1CON<6>), is set. This can be used to determine the controller's current clocking mode. It can also indicate the clock source being currently used by the Fail-Safe Clock Monitor. If the Clock Monitor is enabled and the Timer1 oscillator fails while providing the clock, polling the T1RUN bit will indicate whether the clock is being provided by the Timer1 oscillator or another source.

12.3.2 TIMER1 OSCILLATOR LAYOUT CONSIDERATIONS

The Timer1 oscillator circuit draws very little power during operation. Due to the low-power nature of the oscillator, it may also be sensitive to rapidly changing signals in close proximity.

The oscillator circuit, shown in Figure 12-3, should be located as close as possible to the microcontroller. There should be no circuits passing within the oscillator circuit boundaries other than VSS or VDD.

If a high-speed circuit must be located near the oscillator (such as the ECCP1 pin in Output Compare or PWM mode, or the primary oscillator using the OSC2 pin), a grounded guard ring around the oscillator circuit, as shown in Figure 12-4, may be helpful when used on a single-sided PCB or in addition to a ground plane.

FIGURE 12-4: OSCILLATOR CIRCUIT WITH GROUNDED GUARD RING

12.4 Timer1 Interrupt

The TMR1 register pair (TMR1H:TMR1L) increments from 0000h to FFFFh and rolls over to 0000h. The Timer1 interrupt, if enabled, is generated on overflow which is latched in interrupt flag bit, TMR1IF (PIR1<0>). This interrupt can be enabled or disabled by setting or clearing the Timer1 Interrupt Enable bit, TMR1IE (PIE1<0>).

12.5 Resetting Timer1 Using the ECCPx Special Event Trigger

If ECCP1 or ECCP2 is configured to use Timer1 and to generate a Special Event Trigger in Compare mode (CCPxM3:CCPxM0 = 1011), this signal will reset Timer3. The trigger from ECCP2 will also start an A/D conversion if the A/D module is enabled (see **Section 17.2.1 "Special Event Trigger"** for more information).

The module must be configured as either a timer or a synchronous counter to take advantage of this feature. When used this way, the CCPRxH:CCPRxL register pair effectively becomes a Period register for Timer1.

If Timer1 is running in Asynchronous Counter mode, this Reset operation may not work.

In the event that a write to Timer1 coincides with a Special Event Trigger, the write operation will take precedence.

Note: The Special Event Triggers from the ECCPx module will not set the TMR1IF interrupt flag bit (PIR1<0>).

12.6 Using Timer1 as a Real-Time Clock

Adding an external LP oscillator to Timer1 (such as the one described in **Section 12.3 "Timer1 Oscillator**") gives users the option to include RTC functionality to their applications. This is accomplished with an inexpensive watch crystal to provide an accurate time base and several lines of application code to calculate the time. When operating in Sleep mode and using a battery or supercapacitor as a power source, it can completely eliminate the need for a separate RTC device and battery backup.

The application code routine, RTCisr, shown in Example 12-1, demonstrates a simple method to increment a counter at one-second intervals using an Interrupt Service Routine. Incrementing the TMR1 register pair to overflow triggers the interrupt and calls the routine which increments the seconds counter by one. Additional counters for minutes and hours are incremented as the previous counter overflows.

Since the register pair is 16 bits wide, counting up to overflow the register directly from a 32.768 kHz clock would take 2 seconds. To force the overflow at the required one-second intervals, it is necessary to preload it. The simplest method is to set the MSb of TMR1H with a BSF instruction. Note that the TMR1L register is never preloaded or altered; doing so may introduce cumulative error over many cycles.

For this method to be accurate, Timer1 must operate in Asynchronous mode and the Timer1 overflow interrupt must be enabled (PIE1<0> = 1), as shown in the routine, RTCinit. The Timer1 oscillator must also be enabled and running at all times.

12.7 Considerations in Asynchronous Counter Mode

Following a Timer1 interrupt and an update to the TMR1 registers, the Timer1 module uses a falling edge on its clock source to trigger the next register update on the rising edge. If the update is completed after the clock input has fallen, the next rising edge will not be counted.

If the application can reliably update TMR1 before the timer input goes low, no additional action is needed. Otherwise, an adjusted update can be performed following a later Timer1 increment. This can be done by monitoring TMR1L within the interrupt routine until it increments, and then updating the TMR1H:TMR1L register pair while the clock is low, or one-half of the period of the clock source. Assuming that Timer1 is being used as a Real-Time Clock, the clock source is a 32.768 kHz crystal oscillator. In this case, one-half period of the clock is 15.25 μ s.

The Real-Time Clock application code in Example 12-1 shows a typical ISR for Timer1, as well as the optional code required if the update cannot be done reliably within the required interval.

NOTES:

13.0 TIMER2 MODULE

The Timer2 timer module incorporates the following features:

- 8-Bit Timer and Period registers (TMR2 and PR2, respectively)
- Readable and writable (both registers)
- Software programmable prescaler (1:1, 1:4 and 1:16)
- Software programmable postscaler (1:1 through 1:16)
- · Interrupt on TMR2 to PR2 match
- Optional use as the shift clock for the MSSPx modules

The module is controlled through the T2CON register (Register 13-1) which enables or disables the timer and configures the prescaler and postscaler. Timer2 can be shut off by clearing control bit, TMR2ON (T2CON<2>), to minimize power consumption.

A simplified block diagram of the module is shown in Figure 13-1.

13.1 Timer2 Operation

In normal operation, TMR2 is incremented from 00h on each clock (Fosc/4). A 4-bit counter/prescaler on the clock input gives direct input, divide-by-4 and divide-by-16 prescale options. These options are selected by the prescaler control bits, T2CKPS1:T2CKPS0 (T2CON<1:0>). The value of TMR2 is compared to that of the Period register, PR2, on each clock cycle. When the two values match, the comparator generates a match signal as the timer output. This signal also resets the value of TMR2 to 00h on the next cycle and drives the output counter/postscaler (see Section 13.2 "Timer2 Interrupt").

The TMR2 and PR2 registers are both directly readable and writable. The TMR2 register is cleared on any device Reset, while the PR2 register initializes at FFh. Both the prescaler and postscaler counters are cleared on the following events:

- a write to the TMR2 register
- a write to the T2CON register
- any device Reset (Power-on Reset, MCLR Reset, Watchdog Timer Reset or Brown-out Reset)

TMR2 is not cleared when T2CON is written.

13.2 Timer2 Interrupt

Timer2 can also generate an optional device interrupt. The Timer2 output signal (TMR2 to PR2 match) provides the input for the 4-bit output counter/postscaler. This counter generates the TMR2 match interrupt flag which is latched in TMR2IF (PIR1<1>). The interrupt is enabled by setting the TMR2 Match Interrupt Enable bit, TMR2IE (PIE1<1>).

A range of 16 postscale options (from 1:1 through 1:16 inclusive) can be selected with the postscaler control bits, T2OUTPS3:T2OUTPS0 (T2CON<6:3>).

13.3 Timer2 Output

The unscaled output of TMR2 is available primarily to the CCP modules, where it is used as a time base for operations in PWM mode.

Timer2 can be optionally used as the shift clock source for the MSSPx modules operating in SPI mode. Additional information is provided in **Section 19.0 "Master Synchronous Serial Port (MSSP) Module"**.

14.0 TIMER3 MODULE

The Timer3 timer/counter module incorporates these features:

- Software selectable operation as a 16-bit timer or counter
- Readable and writable 8-bit registers (TMR3H and TMR3L)
- Selectable clock source (internal or external) with device clock or Timer1 oscillator internal options
- Interrupt on overflow
- Module Reset on CCPx/ECCPx Special Event Trigger

A simplified block diagram of the Timer3 module is shown in Figure 14-1. A block diagram of the module's operation in Read/Write mode is shown in Figure 14-2.

The Timer3 module is controlled through the T3CON register (Register 14-1). It also selects the clock source options for the CCPx and ECCPx modules; see **Section 16.1.1 "CCPx/ECCPx Modules and Timer Resources"** for more information.

| | 1 = Enable 0 = Stops | | | | | | | | | |

14.1 Timer3 Operation

Timer3 can operate in one of three modes:

- Timer
- Synchronous Counter
- Asynchronous Counter

The operating mode is determined by the clock select bit, TMR3CS (T3CON<1>). When TMR3CS is cleared (= 0), Timer3 increments on every internal instruction cycle (Fosc/4). When the bit is set, Timer3 increments on every rising edge of the Timer1 external clock input or the Timer1 oscillator, if enabled.

As with Timer1, the RC1/T1OSI and RC0/T1OSO/T13CKI pins become inputs when the Timer1 oscillator is enabled. This means the values of TRISC<1:0> are ignored and the pins are read as '0'.

FIGURE 14-2: TIMER3 BLOCK DIAGRAM (16-BIT READ/WRITE MODE)

14.2 Timer3 16-Bit Read/Write Mode

Timer3 can be configured for 16-bit reads and writes (see Figure 14-2). When the RD16 control bit (T3CON<7>) is set, the address for TMR3H is mapped to a buffer register for the high byte of Timer3. A read from TMR3L will load the contents of the high byte of Timer3 into the Timer3 High Byte Buffer register. This provides the user with the ability to accurately read all 16 bits of Timer1 without having to determine whether a read of the high byte, followed by a read of the low byte, has become invalid due to a rollover between reads.

A write to the high byte of Timer3 must also take place through the TMR3H Buffer register. The Timer3 high byte is updated with the contents of TMR3H when a write occurs to TMR3L. This allows a user to write all 16 bits to both the high and low bytes of Timer3 at once.

The high byte of Timer3 is not directly readable or writable in this mode. All reads and writes must take place through the Timer3 High Byte Buffer register.

Writes to TMR3H do not clear the Timer3 prescaler. The prescaler is only cleared on writes to TMR3L.

14.3 Using the Timer1 Oscillator as the Timer3 Clock Source

The Timer1 internal oscillator may be used as the clock source for Timer3. The Timer1 oscillator is enabled by setting the T1OSCEN (T1CON<3>) bit. To use it as the Timer3 clock source, the TMR3CS bit must also be set. As previously noted, this also configures Timer3 to increment on every rising edge of the oscillator source.

The Timer1 oscillator is described in Section 12.0 "Timer1 Module".

14.4 Timer3 Interrupt

The TMR3 register pair (TMR3H:TMR3L) increments from 0000h to FFFFh and overflows to 0000h. The Timer3 interrupt, if enabled, is generated on overflow and is latched in interrupt flag bit, TMR3IF (PIR2<1>). This interrupt can be enabled or disabled by setting or clearing the Timer3 Interrupt Enable bit, TMR3IE (PIE2<1>).

14.5 Resetting Timer3 Using the ECCPx Special Event Trigger

If ECCP1 or ECCP2 is configured to use Timer3 and to generate a Special Event Trigger in Compare mode (CCPxM3:CCPxM0 = 1011), this signal will reset Timer3. The trigger from ECCP2 will also start an A/D conversion if the A/D module is enabled (see **Section 17.2.1 "Special Event Trigger**" for more information).

The module must be configured as either a timer or synchronous counter to take advantage of this feature. When used this way, the CCPRxH:CCPRxL register pair effectively becomes a Period register for Timer3.

If Timer3 is running in Asynchronous Counter mode, the Reset operation may not work.

In the event that a write to Timer3 coincides with a Special Event Trigger from an ECCPx module, the write will take precedence.

Note: The Special Event Triggers from the ECCPx module will not set the TMR3IF interrupt flag bit (PIR2<1>).

 TABLE 14-1:
 REGISTERS ASSOCIATED WITH TIMER3 AS A TIMER/COUNTER

Legend: — = unimplemented, read as '0', r = reserved. Shaded cells are not used by the Timer3 module.

NOTES:

15.0 TIMER4 MODULE

The Timer4 module has the following features:

- 8-Bit Timer register (TMR4)
- 8-Bit Period register (PR4)
- Readable and writable (both registers)
- Software programmable prescaler (1:1, 1:4, 1:16)
- Software programmable postscaler (1:1 to 1:16)
- Interrupt on TMR4 match of PR4

Timer4 has a control register shown in Register 15-1. Timer4 can be shut off by clearing control bit, TMR4ON (T4CON<2>), to minimize power consumption. The prescaler and postscaler selection of Timer4 are also controlled by this register. Figure 15-1 is a simplified block diagram of the Timer4 module.

15.1 Timer4 Operation

Timer4 can be used as the PWM time base for the PWM mode of the CCP module. The TMR4 register is readable and writable and is cleared on any device Reset. The input clock (Fosc/4) has a prescale option of 1:1, 1:4 or 1:16, selected by control bits T4CKPS1:T4CKPS0 (T4CON<1:0>). The match output of TMR4 goes through a 4-bit postscaler (which gives a 1:1 to 1:16 scaling inclusive) to generate a TMR4 interrupt, latched in flag bit, TMR4IF (PIR3<3>).

The prescaler and postscaler counters are cleared when any of the following occurs:

- a write to the TMR4 register
- a write to the T4CON register
- any device Reset (Power-on Reset, MCLR Reset, Watchdog Timer Reset or Brown-out Reset)

TMR4 is not cleared when T4CON is written.

15.2 Timer4 Interrupt

The Timer4 module has an 8-Bit Period register, PR4, which is both readable and writable. Timer4 increments from 00h until it matches PR4 and then resets to 00h on the next increment cycle. The PR4 register is initialized to FFh upon Reset.

FIGURE 15-1: TIMER4 BLOCK DIAGRAM

15.3 Output of TMR4

The output of TMR4 (before the postscaler) is used only as a PWM time base for the CCPx/ECCPx modules. It is not used as a baud rate clock for the MSSPx modules as is the Timer2 output.

16.0 CAPTURE/COMPARE/PWM (CCP) MODULES

Members of the PIC18F97J60 family of devices all have a total of five CCP (Capture/Compare/PWM) modules. Two of these (CCP4 and CCP5) implement standard Capture, Compare and Pulse-Width Modulation (PWM) modes and are discussed in this section. The other three modules (ECCP1, ECCP2, ECCP3) implement standard Capture and Compare modes, as well as Enhanced PWM modes. These are discussed in Section 17.0 "Enhanced Capture/Compare/PWM (ECCP) Modules".

Each CCPx/ECCPx module contains a 16-bit register which can operate as a 16-Bit Capture register, a 16-Bit Compare register or a PWM Master/Slave Duty Cycle register. For the sake of clarity, all CCPx module operation in the following sections is described with respect to CCP4, but is equally applicable to CCP5.

Capture and Compare operations described in this chapter apply to all standard and Enhanced CCPx modules. The operations of PWM mode, described in **Section 16.4 "PWM Mode"**, apply to CCP4 and CCP5 only.

Note: Throughout this section and Section 17.0 "Enhanced Capture/Compare/PWM (ECCP) Modules", references to register and bit names that may be associated with a specific CCP module are referred to generically by the use of 'x' or 'y' in place of the specific module number. Thus, "CCPxCON" might refer to the control register for ECCP1, ECCP2, ECCP3, CCP4 or CCP5.

16.1 CCPx Module Configuration

Each Capture/Compare/PWM module is associated with a control register (generically, CCPxCON) and a data register (CCPRx). The data register, in turn, is comprised of two 8-bit registers: CCPRxL (low byte) and CCPRxH (high byte). All registers are both readable and writable.

16.1.1 CCPx/ECCPx MODULES AND TIMER RESOURCES

The CCPx/ECCPx modules utilize Timers 1, 2, 3 or 4, depending on the mode selected. Timer1 and Timer3 are available to modules in Capture or Compare modes, while Timer2 and Timer4 are available for modules in PWM mode.

TABLE 16-1: CCPx/ECCPx MODE – TIMER RESOURCE

| CCPx/ECCPx Mode | Timer Resource |
|-----------------|------------------|
| Capture | Timer1 or Timer3 |
| Compare | Timer1 or Timer3 |
| PWM | Timer2 or Timer4 |

The assignment of a particular timer to a module is determined by the timer to CCPx enable bits in the T3CON register (Register 14-1, page 175). Depending on the configuration selected, up to four timers may be active at once, with modules in the same configuration (Capture/Compare or PWM) sharing timer resources. The possible configurations are shown in Figure 16-1.

16.1.2 ECCP2 PIN ASSIGNMENT

The pin assignment for ECCP2 (Capture input, Compare and PWM output) can change based on device configuration. The CCP2MX Configuration bit determines which pin ECCP2 is multiplexed to. By default, it is assigned to RC1 (CCP2MX = 1). If the Configuration bit is cleared, ECCP2 is multiplexed with RE7 on 80-pin and 100-pin devices in Microcontroller mode and RB3 on 100-pin devices in Extended Microcontroller mode.

Changing the pin assignment of ECCP2 does not automatically change any requirements for configuring the port pin. Users must always verify that the appropriate TRIS register is configured correctly for ECCP2 operation regardless of where it is located.

FIGURE 16-1: CCPx/ECCPx AND TIMER INTERCONNECT CONFIGURATIONS

TMR1 TMR3 ECCP1 ECCP2 ECCP3 CCP4 CCP5 TMR2 TMR4

T3CCP<2:1> = 01

Timer1 is used for all Capture and Compare operations for all CCPx modules. Timer2 is used for PWM operations for all CCPx modules. Modules may share either timer resource as a common time base.

Timer3 and Timer4 are not available.

Timer1 and Timer2 are used for Capture and Compare or PWM operations for ECCP1 only (depending on selected mode).

All other modules use either Timer3 or Timer4. Modules may share either timer resource as a common time base if they are in Capture/Compare or PWM modes. Timer1 and Timer2 are used for Capture and Compare or PWM operations for ECCP1 and ECCP2 only (depending on the mode selected for each module). Both modules may use a timer as a common time base if they are both in Capture/Compare or PWM modes.

resource as a common time

base.

16.2 Capture Mode

In Capture mode, the CCPRxH:CCPRxL register pair captures the 16-bit value of the TMR1 or TMR3 registers when an event occurs on the corresponding CCPx pin. An event is defined as one of the following:

- every falling edge
- every rising edge
- every 4th rising edge
- every 16th rising edge

The event is selected by the mode select bits, CCPxM3:CCPxM0 (CCPxCON<3:0>). When a capture is made, the interrupt request flag bit, CCPxIF, is set; it must be cleared in software. If another capture occurs before the value in register CCPRx is read, the old captured value is overwritten by the new captured value.

16.2.1 CCPx PIN CONFIGURATION

In Capture mode, the appropriate CCPx pin should be configured as an input by setting the corresponding TRIS direction bit.

Note: If RG4/CCP5/P1D is configured as an output, a write to the port can cause a capture condition.

16.2.2 TIMER1/TIMER3 MODE SELECTION

The timers that are to be used with the capture feature (Timer1 and/or Timer3) must be running in Timer mode or Synchronized Counter mode. In Asynchronous Counter mode, the capture operation will not work. The timer to be used with each CCPx module is selected in the T3CON register (see Section 16.1.1 "CCPx/ECCPx Modules and Timer Resources").

16.2.3 SOFTWARE INTERRUPT

When the Capture mode is changed, a false capture interrupt may be generated. The user should keep the CCPxIE interrupt enable bit clear to avoid false interrupts. The interrupt flag bit, CCPxIF, should also be cleared following any such change in operating mode.

16.2.4 CCPx PRESCALER

There are four prescaler settings in Capture mode. They are specified as part of the operating mode selected by the mode select bits (CCPxM3:CCPxM0). Whenever the CCPx module is turned off or Capture mode is disabled, the prescaler counter is cleared. This means that any Reset will clear the prescaler counter.

Switching from one capture prescaler to another may generate an interrupt. Also, the prescaler counter will not be cleared; therefore, the first capture may be from a non-zero prescaler. Example 16-1 shows the recommended method for switching between capture prescalers. This example also clears the prescaler counter and will not generate the "false" interrupt.

EXAMPLE 16-1: CHANGING BETWEEN CAPTURE PRESCALERS (CCP5 SHOWN)

| | | ; | this value |
| | | | |

FIGURE 16-2: CAPTURE MODE OPERATION BLOCK DIAGRAM

16.3 Compare Mode

In Compare mode, the 16-bit CCPRx register value is constantly compared against either the TMR1 or TMR3 register pair value. When a match occurs, the CCPx pin:

- can be driven high
- · can be driven low
- can be toggled (high-to-low or low-to-high)
- remains unchanged (that is, reflects the state of the I/O latch)

The action on the pin is based on the value of the mode select bits (CCPxM3:CCPxM0). At the same time, the interrupt flag bit, CCPxIF, is set.

16.3.1 CCPx PIN CONFIGURATION

The user must configure the CCPx pin as an output by clearing the appropriate TRIS bit.

Note: Clearing the CCP5CON register will force the RG4 compare output latch (depending on device configuration) to the default low level. This is not the PORTB or PORTC I/O data latch.

16.3.2 TIMER1/TIMER3 MODE SELECTION

Timer1 and/or Timer3 must be running in Timer mode or Synchronized Counter mode if the CCPx module is using the compare feature. In Asynchronous Counter mode, the compare operation may not work.

16.3.3 SOFTWARE INTERRUPT MODE

When the Generate Software Interrupt mode is chosen (CCPxM3:CCPxM0 = 1010), the corresponding CCPx pin is not affected. Only a CCPx interrupt is generated, if enabled and the CCPxIE bit is set.

TABLE 16-2: REGISTERS ASSOCIATED WITH CAPTURE, COMPARE, TIMER1 AND TIMER3

Legend: — = unimplemented, read as '0', r = reserved. Shaded cells are not used by Capture/Compare, Timer1 or Timer3.

Note 1: This bit is only available in 80-pin and 100-pin devices; otherwise, it is unimplemented and reads as '0'.

16.4 PWM Mode

In Pulse-Width Modulation (PWM) mode, the CCPx pin produces up to a 10-bit resolution PWM output. Since the CCP4 and CCP5 pins are multiplexed with a PORTG data latch, the appropriate TRISG bit must be cleared to make the CCP4 or CCP5 pin an output.

| Note: | Clearing the CCP4CON or CCP5CON register will force the RG3 or RG4 output latch (depending on device configuration) |
|-------|---|
| | to the default low level. This is not the PORTG I/O data latch. |

Figure 16-4 shows a simplified block diagram of the CCPx module in PWM mode.

For a step-by-step procedure on how to set up a CCPx module for PWM operation, see **Section 16.4.3 "Setup for PWM Operation"**.

FIGURE 16-4: SIMPLIFIED PWM BLOCK DIAGRAM

A PWM output (Figure 16-5) has a time base (period) and a time that the output stays high (duty cycle). The frequency of the PWM is the inverse of the period (1/period).

FIGURE 16-5: PWM OUTPUT

16.4.1 PWM PERIOD

The PWM period is specified by writing to the PR2 (PR4) register. The PWM period can be calculated using Equation 16-1:

EQUATION 16-1:

 $PWM Period = [(PR2) + 1] \bullet 4 \bullet TOSC \bullet$ (TMR2 Prescale Value)

PWM frequency is defined as 1/[PWM period].

When TMR2 (TMR4) is equal to PR2 (PR4), the following three events occur on the next increment cycle:

- TMR2 (TMR4) is cleared
- The CCPx pin is set (exception: if PWM duty cycle = 0%, the CCPx pin will not be set)
- The PWM duty cycle is latched from CCPRxL into CCPRxH

| Note: | The Timer2 and Timer4 postscalers (see |
|-------|--|
| | Section 13.0 "Timer2 Module" and |
| | Section 15.0 "Timer4 Module") are not |
| | used in the determination of the PWM |
| | frequency. The postscaler could be used |
| | to have a servo update rate at a different |
| | frequency than the PWM output. |

16.4.2 PWM DUTY CYCLE

The PWM duty cycle is specified by writing to the CCPRxL register and to the CCPxCON<5:4> bits. Up to 10-bit resolution is available. The CCPRxL contains the eight MSbs and the CCPxCON<5:4> contains the two LSbs. This 10-bit value is represented by CCPRxL:CCPxCON<5:4>. Equation 16-2 is used to calculate the PWM duty cycle in time.

EQUATION 16-2:

PWM Duty Cycle = (CCPRxL:CCPxCON<5:4>) • Tosc • (TMRx Prescale Value)

CCPRxL and CCPxCON<5:4> can be written to at any time, but the duty cycle value is not latched into CCPRxH until after a match between PR2 (PR4) and TMR2 (TMR4) occurs (i.e., the period is complete). In PWM mode, CCPRxH is a read-only register. The CCPRxH register and a 2-bit internal latch are used to double-buffer the PWM duty cycle. This double-buffering is essential for glitchless PWM operation.

When the CCPRxH and 2-bit latch match TMR2 (TMR4), concatenated with an internal 2-bit Q clock or 2 bits of the TMR2 (TMR4) prescaler, the CCPx pin is cleared.

The maximum PWM resolution (bits) for a given PWM frequency is given by Equation 16-3:

EQUATION 16-3:

PWM Resolution (max) =
$$\frac{\log(\frac{FOSC}{FPWM})}{\log(2)}$$
 bits

Note: If the PWM duty cycle value is longer than the PWM period, the CCPx pin will not be cleared.

16.4.3 SETUP FOR PWM OPERATION

The following steps should be taken when configuring the CCPx module for PWM operation:

- 1. Set the PWM period by writing to the PR2 (PR4) register.
- 2. Set the PWM duty cycle by writing to the CCPRxL register and CCPxCON<5:4> bits.
- 3. Make the CCPx pin an output by clearing the appropriate TRIS bit.
- 4. Set the TMR2 (TMR4) prescale value, then enable Timer2 (Timer4) by writing to T2CON (T4CON).
- 5. Configure the CCPx module for PWM operation.

TABLE 16-3: EXAMPLE PWM FREQUENCIES AND RESOLUTIONS AT 40 MHz

TABLE 16-4: REGISTERS ASSOCIATED WITH PWM, TIMER2 AND TIMER4

Legend: — = unimplemented, read as '0'. Shaded cells are not used by PWM, Timer2 or Timer4.

Note 1: This bit is only available in 80-pin and 100-pin devices; otherwise, it is unimplemented and reads as '0'.

17.0 ENHANCED CAPTURE/ COMPARE/PWM (ECCP) MODULES

In the PIC18F97J60 family of devices, three of the CCP modules are implemented as standard CCP modules with Enhanced PWM capabilities. These include the provision for 2 or 4 output channels, user-selectable polarity, dead-band control and automatic shutdown and restart. The Enhanced features are discussed in detail in **Section 17.4** "Enhanced PWM Mode". Capture, Compare and single-output PWM functions of the ECCPx modules are the same as described for the standard CCPx modules.

The control register for the Enhanced CCPx module is shown in Register 17-1. It differs from the CCP4CON/ CCP5CON registers in that the two Most Significant bits are implemented to control PWM functionality.

In addition to the expanded range of modes available through the Enhanced CCPxCON register, the ECCPx modules each have two additional registers associated with Enhanced PWM operation and auto-shutdown features. They are:

- ECCPxDEL (Dead-Band Delay)
- ECCPxAS (Auto-Shutdown Configuration)

17.1 ECCPx Outputs and Configuration

Each of the Enhanced CCPx modules may have up to four PWM outputs, depending on the selected operating mode. These outputs, designated PxA through PxD, are multiplexed with various I/O pins. Some ECCPx pin assignments are constant, while others change based on device configuration. For those pins that do change, the controlling bits are:

- CCP2MX Configuration bit (80-pin and100-pin devices only)
- ECCPMX Configuration bit (80-pin and100-pin devices only)
- Program memory operating mode set by the EMB Configuration bits (100-pin devices only)

The pin assignments for the Enhanced CCPx modules are summarized in Table 17-1, Table 17-2 and Table 17-3. To configure the I/O pins as PWM outputs, the proper PWM mode must be selected by setting the PxMx and CCPxMx bits (CCPxCON<7:6> and <3:0>, respectively). The appropriate TRIS direction bits for the corresponding port pins must also be set as outputs.

17.1.1 ECCP1/ECCP3 OUTPUTS AND PROGRAM MEMORY MODE

In 100-pin devices, the use of Extended Microcontroller mode has an indirect effect on the ECCP1 and ECCP3 pins in Enhanced PWM modes. By default, PWM outputs, P1B/P1C and P3B/P3C, are multiplexed to PORTE pins, along with the high-order byte of the external memory bus. When the bus is active in Extended Microcontroller mode, it overrides the Enhanced CCPx outputs and makes them unavailable. Because of this, ECCP1 and ECCP3 can only be used in compatible (single output) PWM modes when the device is in Extended Microcontroller mode and default pin configuration.

An exception to this configuration is when a 12-bit address width is selected for the external bus (EMB1:EMB0 Configuration bits = 10). In this case, the upper pins of PORTE continue to operate as digital I/O, even when the external bus is active. P1B/P1C and P3B/P3C remain available for use as Enhanced PWM outputs.

If an application requires the use of additional PWM outputs during Extended Microcontroller mode, the P1B/P1C and P3B/P3C outputs can be reassigned to the upper bits of PORTH. This is done by clearing the ECCPMX Configuration bit.

17.1.2 ECCP2 OUTPUTS AND PROGRAM MEMORY MODES

For 100-pin devices, the program memory mode of the device (Section 5.1.3 "PIC18F9XJ60/9XJ65 Program Memory Modes") also impacts pin multiplexing for the module.

The ECCP2 input/output (ECCP2/P2A) can be multiplexed to one of three pins. The default assignment (CCP2MX Configuration bit is set) for all devices is RC1. Clearing CCP2MX reassigns ECCP2/P2A to RE7 in 80-pin and 100-pin devices.

An additional option exists for 100-pin devices. When these devices are operating in Microcontroller mode, the multiplexing options described above still apply. In Extended Microcontroller mode, clearing CCP2MX reassigns ECCP2/P2A to RB3.

17.1.3 USE OF CCP4 AND CCP5 WITH ECCP1 AND ECCP3

Only the ECCP2 module has four dedicated output pins that are available for use. Assuming that the I/O ports or other multiplexed functions on those pins are not needed, they may be used without interfering with any other CCPx module.

ECCP1 and ECCP3, on the other hand, only have three dedicated output pins: ECCPx/PxA, PxB and PxC. Whenever these modules are configured for Quad PWM mode, the pin normally used for CCP4 or CCP5 becomes the PxD output pin for ECCP3 and ECCP1, respectively. The CCP4 and CCP5 modules remain functional but their outputs are overridden.

17.1.4 ECCPx MODULES AND TIMER RESOURCES

Like the standard CCPx modules, the ECCPx modules can utilize Timers 1, 2, 3 or 4, depending on the mode selected. Timer1 and Timer3 are available for modules in Capture or Compare modes, while Timer2 and Timer4 are available for modules in PWM mode. Additional details on timer resources are provided in Section 16.1.1 "CCPx/ECCPx Modules and Timer Resources".

17.2 Capture and Compare Modes

Except for the operation of the Special Event Trigger discussed below, the Capture and Compare modes of the ECCPx modules are identical in operation to that of CCP4. These are discussed in detail in Section 16.2 "Capture Mode" and Section 16.3 "Compare Mode".

17.2.1 SPECIAL EVENT TRIGGER

ECCP1 and ECCP2 incorporate an internal hardware trigger that is generated in Compare mode on a match between the CCPRx register pair and the selected timer. This can be used in turn to initiate an action. This mode is selected by setting CCPxCON<3:0> to '1011'.

The Special Event Trigger output of either ECCP1 or ECCP2 resets the TMR1 or TMR3 register pair, depending on which timer resource is currently selected. This allows the CCPRx register to effectively be a 16-Bit Programmable Period register for Timer1 or Timer3. In addition, the ECCP2 Special Event Trigger will also start an A/D conversion if the A/D module is enabled.

Special Event Triggers are not implemented for ECCP3, CCP4 or CCP5. Selecting the Special Event Trigger mode for these modules has the same effect as selecting the Compare with Software Interrupt mode (CCPxM3:CCPxM0 = 1010).

The Special Event Trigger from ECCP2 Note: will not set the Timer1 or Timer3 interrupt flag bits.

17.3 Standard PWM Mode

When configured in Single Output mode, the ECCPx modules function identically to the standard CCPx modules in PWM mode, as described in Section 16.4 "PWM Mode". This is also sometimes referred to as "Compatible CCP" mode, as in Tables 17-1 through 17-3.

Note: When setting up single output PWM operations, users are free to use either of the processes described in Section 16.4.3 "Setup for PWM Operation" or Section 17.4.9 "Setup for PWM Operation". The latter is more generic but will work for either single or multi-output PWM.

17.4 Enhanced PWM Mode

The Enhanced PWM mode provides additional PWM output options for a broader range of control applications. The module is a backward compatible version of the standard CCPx modules and offers up to four outputs, designated PxA through PxD. Users are also able to select the polarity of the signal (either active-high or active-low). The module's output mode and polarity are configured by setting the PxM1:PxM0 and CCPxM3CCPxM0 bits of the CCPxCON register (CCPxCON<7:6> and <3:0>, respectively).

For the sake of clarity, Enhanced PWM mode operation is described generically throughout this section with respect to ECCP1 and TMR2 modules. Control register names are presented in terms of ECCP1. All three Enhanced modules, as well as the two timer resources, can be used interchangeably and function identically. TMR2 or TMR4 can be selected for PWM operation by selecting the proper bits in T3CON.

Figure 17-1 shows a simplified block diagram of PWM operation. All control registers are double-buffered and are loaded at the beginning of a new PWM cycle (the period boundary when Timer2 resets) in order to prevent glitches on any of the outputs. The exception is the ECCP1 Dead-Band Delay register, ECCP1DEL, which is loaded at either the duty cycle boundary or the boundary period (whichever comes first). Because of the buffering, the module waits until the assigned timer resets instead of starting immediately. This means that

Enhanced PWM waveforms do not exactly match the standard PWM waveforms, but are instead, offset by one full instruction cycle (4 Tosc).

As before, the user must manually configure the appropriate TRIS bits for output.

17.4.1 PWM PERIOD

The PWM period is specified by writing to the PR2 register. The PWM period can be calculated using the following equation:

EQUATION 17-1:

 $PWM Period = [(PR2) + 1] \bullet 4 \bullet TOSC \bullet$ (TMR2 Prescale Value)

PWM frequency is defined as 1/[PWM period]. When TMR2 is equal to PR2, the following three events occur on the next increment cycle:

- TMR2 is cleared
- The ECCP1 pin is set (if PWM duty cycle = 0%, the ECCP1 pin will not be set)
- The PWM duty cycle is copied from CCPR1L into CCPR1H

Note: The Timer2 postscaler (see Section 13.0 "Timer2 Module") is not used in the determination of the PWM frequency. The postscaler could be used to have a servo update rate at a different frequency than the PWM output.

FIGURE 17-1: SIMPLIFIED BLOCK DIAGRAM OF THE ENHANCED PWM MODULE

© 2006 Microchip Technology Inc.

17.4.2 PWM DUTY CYCLE

The PWM duty cycle is specified by writing to the CCPR1L register and to the CCP1CON<5:4> bits. Up to 10-bit resolution is available. The CCPR1L contains the eight MSbs and the CCP1CON<5:4> bits contain the two LSbs. This 10-bit value is represented by CCPR1L:CCP1CON<5:4>. The PWM duty cycle is calculated by the equation:

EQUATION 17-2:

PWM Duty Cycle = (CCPR1L:CCP1CON<5:4>) • Tosc • (TMR2 Prescale Value)

CCPR1L and CCP1CON<5:4> can be written to at any time but the duty cycle value is not copied into CCPR1H until a match between PR2 and TMR2 occurs (i.e., the period is complete). In PWM mode, CCPR1H is a read-only register.

The CCPR1H register and a 2-bit internal latch are used to double-buffer the PWM duty cycle. This double-buffering is essential for glitchless PWM operation. When the CCPR1H and 2-bit latch match TMR2, concatenated with an internal 2-bit Q clock or two bits of the TMR2 prescaler, the ECCP1 pin is cleared. The maximum PWM resolution (bits) for a given PWM frequency is given by the following equation:

EQUATION 17-3:

PWM Resolution (max) =
$$\frac{\log\left(\frac{FOSC}{FPWM}\right)}{\log(2)}$$
 bits

Note: If the PWM duty cycle value is longer than the PWM period, the ECCP1 pin will not be cleared.

17.4.3 PWM OUTPUT CONFIGURATIONS

The P1M1:P1M0 bits in the CCP1CON register allow one of four configurations:

- Single Output
- Half-Bridge Output
- Full-Bridge Output, Forward mode
- Full-Bridge Output, Reverse mode

The Single Output mode is the standard PWM mode discussed in **Section 17.4 "Enhanced PWM Mode**". The Half-Bridge and Full-Bridge Output modes are covered in detail in the sections that follow.

The general relationship of the outputs in all configurations is summarized in Figure 17-2.

| TABLE 17-4: | EXAMPLE PWM FREQUENCIES AND RESOLUTIONS AT 40 MHz |

17.4.4 HALF-BRIDGE MODE

In the Half-Bridge Output mode, two pins are used as outputs to drive push-pull loads. The PWM output signal is output on the P1A pin, while the complementary PWM output signal is output on the P1B pin (Figure 17-4). This mode can be used for half-bridge applications, as shown in Figure 17-5, or for full-bridge applications, where four power switches are being modulated with two PWM signals.

In Half-Bridge Output mode, the programmable dead-band delay can be used to prevent shoot-through current in half-bridge power devices. The value of bits, P1DC6:P1DC0, sets the number of instruction cycles before the output is driven active. If the value is greater than the duty cycle, the corresponding output remains inactive during the entire cycle. See **Section 17.4.6** "**Programmable Dead-Band Delay**" for more details on dead-band delay operations.

Since the P1A and P1B outputs are multiplexed with the PORTC<2> and PORTE<6> data latches, the TRISC<2> and TRISE<6> bits must be cleared to configure P1A and P1B as outputs.

FIGURE 17-4: HALF-BRIDGE PWM OUTPUT

FIGURE 17-5: EXAMPLES OF HALF-BRIDGE OUTPUT MODE APPLICATIONS

17.4.5 FULL-BRIDGE MODE

In Full-Bridge Output mode, four pins are used as outputs; however, only two outputs are active at a time. In the Forward mode, pin P1A is continuously active and pin P1D is modulated. In the Reverse mode, pin P1C is continuously active and pin P1B is modulated. These are illustrated in Figure 17-6. P1A, P1B, P1C and P1D outputs are multiplexed with the data latches of the port pins listed in Table 17-1 and Table 17-3. The corresponding TRIS bits must be cleared to make the P1A, P1B, P1C and P1D pins outputs.

PIC18F97J60 FAMILY

FIGURE 17-7: EXAMPLE OF FULL-BRIDGE APPLICATION

17.4.5.1 Direction Change in Full-Bridge Mode

In the Full-Bridge Output mode, the P1M1 bit in the CCP1CON register allows users to control the forward/ reverse direction. When the application firmware changes this direction control bit, the module will assume the new direction on the next PWM cycle.

Just before the end of the current PWM period, the modulated outputs (P1B and P1D) are placed in their inactive state, while the unmodulated outputs (P1A and P1C) are switched to drive in the opposite direction. This occurs in a time interval of (4 Tosc * (Timer2 Prescale Value) before the next PWM period begins. The Timer2 prescaler will be either 1, 4 or 16, depending on the value of the T2CKPS bits (T2CON<1:0>). During the interval from the switch of the unmodulated outputs to the beginning of the next period, the modulated outputs (P1B and P1D) remain inactive. This relationship is shown in Figure 17-8.

Note that in Full-Bridge Output mode, the ECCP1 module does not provide any dead-band delay. In general, since only one output is modulated at all times, dead-band delay is not required. However, there is a situation where a dead-band delay might be required. This situation occurs when both of the following conditions are true:

- 1. The direction of the PWM output changes when the duty cycle of the output is at or near 100%.
- 2. The turn-off time of the power switch, including the power device and driver circuit, is greater than the turn-on time.

Figure 17-9 shows an example where the PWM direction changes from forward to reverse at a near 100% duty cycle. At time t1, the outputs, P1A and P1D, become inactive, while output, P1C, becomes active. In this example, since the turn-off time of the power devices is longer than the turn-on time, a shoot-through current may flow through power devices, QC and QD (see Figure 17-7), for the duration of 't'. The same phenomenon will occur to power devices, QA and QB, for PWM direction change from reverse to forward.

If changing PWM direction at high duty cycle is required for an application, one of the following requirements must be met:

- 1. Reduce PWM for a PWM period before changing directions.
- 2. Use switch drivers that can drive the switches off faster than they can drive them on.

Other options to prevent shoot-through current may exist.

© 2006 Microchip Technology Inc.

17.4.6 PROGRAMMABLE DEAD-BAND DELAY

In half-bridge applications, where all power switches are modulated at the PWM frequency at all times, the power switches normally require more time to turn off than to turn on. If both the upper and lower power switches are switched at the same time (one turned on and the other turned off), both switches may be on for a short period of time until one switch completely turns off. During this brief interval, a very high current (*shoot-through current*) may flow through both power switches, shorting the bridge supply. To avoid this potentially destructive shoot-through current from flowing during switching, turning on either of the power switches is normally delayed to allow the other switch to completely turn off.

In the Half-Bridge Output mode, a digitally programmable dead-band delay is available to avoid shoot-through current from destroying the bridge power switches. The delay occurs at the signal transition from the non-active state to the active state. See Figure 17-4 for illustration. The lower seven bits of the ECCP1DEL register (Register 17-2) set the delay period in terms of microcontroller instruction cycles (TcY or 4 Tosc).

17.4.7 ENHANCED PWM AUTO-SHUTDOWN

When the ECCP1 is programmed for any of the Enhanced PWM modes, the active output pins may be configured for auto-shutdown. Auto-shutdown immediately places the Enhanced PWM output pins into a defined shutdown state when a shutdown event occurs.

A shutdown event can be caused by either of the two comparator modules or the FLT0 pin (or any combination of these three sources). The comparators may be used to monitor a voltage input proportional to a current being monitored in the bridge circuit. If the voltage exceeds a threshold, the comparator switches state and triggers a shutdown. Alternatively, a low-level digital signal on the FLT0 pin can also trigger a shutdown. The auto-shutdown feature can be disabled by not selecting any auto-shutdown sources. The auto-shutdown sources to be used are selected using the ECCP1AS2:ECCP1AS0 bits (ECCP1AS<6:4>).

When a shutdown occurs, the output pins are asynchronously placed in their shutdown states, specified by the PSS1AC1:PSS1AC0 and PSS1BD1:PSS1BD0 bits (ECCP1AS<3:0>). Each pin pair (P1A/P1C and P1B/P1D) may be set to drive high, drive low or be tri-stated (not driving). The ECCP1ASE bit (ECCP1AS<7>) is also set to hold the Enhanced PWM outputs in their shutdown states.

The ECCP1ASE bit is set by hardware when a shutdown event occurs. If automatic restarts are not enabled, the ECCP1ASE bit is cleared by firmware when the cause of the shutdown clears. If automatic restarts are enabled, the ECC1PASE bit is automatically cleared when the cause of the auto-shutdown has cleared.

If the ECCP1ASE bit is set when a PWM period begins, the PWM outputs remain in their shutdown state for that entire PWM period. When the ECCP1ASE bit is cleared, the PWM outputs will return to normal operation at the beginning of the next PWM period.

Note: Writing to the ECCP1ASE bit is disabled while a shutdown condition is active.

1x = Pins B and D tri-state

17.4.7.1 Auto-Shutdown and Automatic Restart

The auto-shutdown feature can be configured to allow automatic restarts of the module following a shutdown event. This is enabled by setting the P1RSEN bit of the ECCP1DEL register (ECCP1DEL<7>).

In Shutdown mode with P1RSEN = 1 (Figure 17-10), the ECCP1ASE bit will remain set for as long as the cause of the shutdown continues. When the shutdown condition clears, the ECCP1ASE bit is cleared. If P1RSEN = 0 (Figure 17-11), once a shutdown condition occurs, the ECCP1ASE bit will remain set until it is cleared by firmware. Once ECCP1ASE is cleared, the Enhanced PWM will resume at the beginning of the next PWM period.

| Note: | Writing to the ECCP1ASE bit is disabled |
|-------|---|
| | while a shutdown condition is active. |

Independent of the P1RSEN bit setting, if the auto-shutdown source is one of the comparators, the shutdown condition is a level. The ECCP1ASE bit cannot be cleared as long as the cause of the shutdown persists.

The Auto-Shutdown mode can be forced by writing a '1' to the ECCP1ASE bit.

17.4.8 START-UP CONSIDERATIONS

When the ECCP1 module is used in the PWM mode, the application hardware must use the proper external pull-up and/or pull-down resistors on the PWM output pins. When the microcontroller is released from Reset, all of the I/O pins are in the high-impedance state. The external circuits must keep the power switch devices in the OFF state until the microcontroller drives the I/O pins with the proper signal levels, or activates the PWM output(s).

The CCP1M1:CCP1M0 bits (CCP1CON<1:0>) allow the user to choose whether the PWM output signals are active-high or active-low for each pair of PWM output pins (P1A/P1C and P1B/P1D). The PWM output polarities must be selected before the PWM pins are configured as outputs. Changing the polarity configuration while the PWM pins are configured as outputs is not recommended since it may result in damage to the application circuits. The P1A, P1B, P1C and P1D output latches may not be in the proper states when the PWM module is initialized. Enabling the PWM pins for output at the same time as the ECCP1 module may cause damage to the application circuit. The ECCP1 module must be enabled in the proper output mode and complete a full PWM cycle before configuring the PWM pins as outputs. The completion of a full PWM cycle is indicated by the TMR2IF bit being set as the second PWM period begins.

FIGURE 17-10: PWM AUTO-SHUTDOWN (P1RSEN = 1, AUTO-RESTART ENABLED)

FIGURE 17-11: PWM AUTO-SHUTDOWN (P1RSEN = 0, AUTO-RESTART DISABLED)

17.4.9 SETUP FOR PWM OPERATION

The following steps should be taken when configuring the ECCP1 module for PWM operation:

- 1. Configure the PWM pins P1A and P1B (and P1C and P1D, if used) as inputs by setting the corresponding TRIS bits.
- 2. Set the PWM period by loading the PR2 (PR4) register.
- 3. Configure the ECCP1 module for the desired PWM mode and configuration by loading the CCP1CON register with the appropriate values:
 - Select one of the available output configurations and direction with the P1M1:P1M0 bits.
 - Select the polarities of the PWM output signals with the CCP1M3:CCP1M0 bits.
- 4. Set the PWM duty cycle by loading the CCPR1L register and the CCP1CON<5:4> bits.
- 5. For auto-shutdown:
 - Disable auto-shutdown; ECCP1ASE = 0
 - Configure auto-shutdown source
 - Wait for Run condition
- 6. For Half-Bridge Output mode, set the dead-band delay by loading ECCP1DEL<6:0> with the appropriate value.
- 7. If auto-shutdown operation is required, load the ECCP1AS register:
 - Select the auto-shutdown sources using the ECCP1AS2:ECCP1AS0 bits.
 - Select the shutdown states of the PWM output pins using PSS1AC1:PSS1AC0 and PSS1BD1:PSS1BD0 bits.
 - Set the ECCP1ASE bit (ECCP1AS<7>).

- 8. If auto-restart operation is required, set the P1RSEN bit (ECCP1DEL<7>).
- 9. Configure and start TMR2 (TMR4):
 - Clear the TMRx interrupt flag bit by clearing the TMRxIF bit (PIR1<1> for Timer2 or PIR3<3> for Timer4).
 - Set the TMRx prescale value by loading the TxCKPS bits (T2CON<1:0> for Timer2 or T4CON<1:0> for Timer4).
 - Enable Timer2 (or Timer4) by setting the TMRxON bit (T2CON<2> for Timer2 or T4CON<2> for Timer4).
- 10. Enable PWM outputs after a new PWM cycle has started:
 - Wait until TMR2 (TMR4) overflows (TMRxIF bit is set).
 - Enable the ECCP1/P1A, P1B, P1C and/or P1D pin outputs by clearing the respective TRIS bits.
 - Clear the ECCP1ASE bit (ECCP1AS<7>).

17.4.10 EFFECTS OF A RESET

Both Power-on Reset and subsequent Resets will force all ports to Input mode and the CCPx/ECCPx registers to their Reset states.

This forces the Enhanced CCPx modules to reset to a state compatible with the standard CCPx modules.

TABLE 17-5: REGISTERS ASSOCIATED WITH ECCPx MODULES AND TIMER1 TO TIMER4

Legend: — = unimplemented, read as '0', r = reserved. Shaded cells are not used during ECCPx operation.

Note 1: Applicable to 64-pin devices only.

2: Registers and/or specific bits are unimplemented on 64-pin devices.

3: Generic term for all of the identical registers of this name for all Enhanced CCPx modules, where 'x' identifies the individual module (ECCP1, ECCP2 or ECCP3). Bit assignments and Reset values for all registers of the same generic name are identical.

18.0 ETHERNET MODULE

All members of the PIC18F97J60 family of devices feature an embedded Ethernet controller module. This is a complete connectivity solution, including full implementations of both Media Access Control (MAC) and Physical Layer transceiver (PHY) modules. Two pulse transformers and a few passive components are all that are required to connect the microcontroller directly to an Ethernet network.

The Ethernet module meets all of the IEEE 802.3 specifications for 10-BaseT connectivity to a twisted-pair network. It incorporates a number of packet filtering schemes to limit incoming packets. It also provides an internal DMA module for fast data throughput and hardware assisted IP checksum calculations. Provisions are also made for two LED outputs to indicate link and network activity.

A simple block diagram of the module is shown in Figure 18-1.

The Ethernet module consists of five major functional blocks:

- The PHY transceiver module that encodes and decodes the analog data that is present on the twisted-pair interface and sends or receives it over the network.
- 2. The MAC module that implements IEEE 802.3 compliant MAC logic and provides Media Independent Interface Management (MIIM) to control the PHY.
- 3. An independent, 8-Kbyte RAM buffer for storing packets that have been received and packets that are to be transmitted.
- 4. An arbiter to control access to the RAM buffer when requests are made from the microcontroller core, DMA, transmit and receive blocks.
- 5. The register interface that functions as an interpreter of commands and internal status signals between the module and the microcontroller's SFRs.

FIGURE 18-1: ETHERNET MODULE BLOCK DIAGRAM

18.1 Physical Interfaces and External Connections

18.1.1 SIGNAL AND POWER INTERFACES

PIC18F97J60 family devices all provide a dedicated 4-pin signal interface for the Ethernet module. No other microcontroller or peripheral functions are multiplexed with these pins, so potential device configuration conflicts do not need to be considered. The pins are:

- TPIN+: Differential plus twisted-pair input
- TPIN-: Differential minus twisted-pair input
- TPOUT+: Differential plus twisted-pair output
- TPOUT-: Differential minus twisted-pair output

No provisions are made for providing or receiving digital Ethernet data from an external Ethernet PHY.

In addition to the signal connections, the Ethernet module has its own independent voltage source and ground connections for the PHY module. Separate connections are provided for the receiver (VDDRx and VSSRx), the transmitter (VDDTx and VSSTx) and the transmitter's internal PLL (VDDPLL and VSSPLL). Although the voltage requirements are the same as VDD and VSS for the microcontroller, the pins are not internally connected. For the Ethernet module to operate properly, supply voltage and ground must be connected to these pins. All of the microcontroller's power and ground supply pins should be externally connected to the same power source or ground node, with no inductors or other filter components between the microcontroller and Ethernet module's VDD pins.

Besides the independent voltage connections, the PHY module has a separate bias current input pin, RBIAS. A bias current, derived from an external resistor, must be applied to RBIAS for proper transceiver operation.

18.1.2 LED CONFIGURATION

The PHY module provides separate outputs to drive the standard Ethernet indicators, LEDA and LEDB. The LED outputs are multiplexed with PORTA pins RA0 and RA1. Their use as LED outputs is enabled by setting the Configuration bit, ETHLED (Register 24-6, CONFIG3H<2>). When configured as LED outputs, RA0/LEDA and RA1/LEDB have sufficient drive capacity (8 mA) to directly power the LEDs. The pins must always be configured to supply (source) current to the LEDs. Users must also configure the pins as outputs by clearing TRISA<1:0>.

The LEDs can be individually configured to automatically display link status, RX/TX activity, etc. A configurable stretch capability prolongs the LED blink duration for short events, such as a single packet transmit, allowing human perception. The options are controlled by the PHLCON register (Register 18-13). Typical values for blink stretch are listed in Table 18-1.

TABLE 18-1: LED BLINK STRETCH LENGTH

| Stretch Length | Typical Stretch (ms) |
|------------------|----------------------|
| TNSTRCH (normal) | 40 |
| Тмstrch (medium) | 70 |
| TLSTRCH (long) | 140 |

18.1.3 OSCILLATOR REQUIREMENTS

The Ethernet module is designed to operate at 25 MHz. This is provided by the primary microcontroller clock, either with a 25 MHz crystal connected to the OSC1 and OSC2 pins or an external clock source connected to the OSC1 pin. No provision is made to clock the module from a different source.

To maintain the required clock frequency, the microcontroller can operate only from the primary oscillator source (PRI_RUN or PRI_IDLE modes) while the Ethernet module is enabled. Using any other power-managed mode will require that the Ethernet module be disabled.

18.1.3.1 Start-up Timer

The Ethernet module contains a start-up timer, independent of the microcontroller's OST, to ensure that the PHY module's PLL has stabilized before operation. Clearing the module enable bit, ETHEN (ECON2<5>), clears the PHYRDY status bit (ESTAT<0>). Setting the ETHEN bit causes this start-up timer to start counting. When the timer expires, after 1 ms, the PHYRDY bit will be automatically set.

After enabling the module by setting the ETHEN bit, the application software should always poll PHYRDY to determine when normal Ethernet operation can begin.

18.1.4 MAGNETICS, TERMINATION AND OTHER EXTERNAL COMPONENTS

To complete the Ethernet interface, the Ethernet module requires several standard components to be installed externally. These components should be connected as shown in Figure 18-2.

The internal analog circuitry in the PHY module requires that an external resistor (2.26 k Ω) be attached from RBIAS to ground. The resistor influences the TPOUT+/-signal amplitude. It should be placed as close as possible to the chip with no immediately adjacent signal traces to prevent noise capacitively coupling into the pin and affecting the transmit behavior. It is recommended that the resistor be a surface mount type.

On the TPIN+/TPIN- and TPOUT+/TPOUT- pins, 1:1 center-tapped pulse transformers rated for Ethernet operations (10/100 or 10/100/1000) are required. When the Ethernet module is enabled, current is continually sunk through both TPOUT pins. When the PHY is actively transmitting, a differential voltage is created on the Ethernet cable by varying the relative current sunk by TPOUT+ compared to TPOUT-.

A common-mode choke on the PHY side of the interface (i.e., between the microcontrollers's TPOUT pins and the Ethernet transformer) is not recommend. If a common-mode choke is used to reduce EMI emissions, it should be placed between the Ethernet transformer and pins 1 and 2 of the RJ-45 connector. Many Ethernet transformer modules include common-mode chokes inside the same device package. The transformers should have at least the isolation rating specified in Table 27-28 to protect against static voltages and meet IEEE 802.3 isolation requirements (see Section 27.5 "Ethernet Specifications and Requirements" for specific transformer requirements). Both transmit and receive interfaces additionally require two resistors and a capacitor to properly terminate the transmission line, minimizing signal reflections.

All power supply pins must be externally connected to the same power source. Similarly, all ground references must be externally connected to the same ground node. Each VDD and Vss pin pair should have a 0.1 μ F ceramic bypass capacitor placed as close to the pins as possible.

Since relatively high currents are necessary to operate the twisted-pair interface, all wires should be kept as short as possible. Reasonable wire widths should be used on power wires to reduce resistive loss. If the differential data lines cannot be kept short, they should be routed in such a way as to have a 100Ω characteristic impedance.

FIGURE 18-2: EXTERNAL COMPONENTS REQUIRED FOR ETHERNET OPERATION

18.2 Ethernet Buffer and Register Spaces

The Ethernet module uses three independent memory spaces for its operations:

- An Ethernet RAM buffer which stores packet data as it is received and being prepared for transmission.
- A set of 8-bit Special Function Registers (SFRs), used to control the module and pass data back and forth between the module and microcontroller core.
- A separate set of 16-bit PHY registers used specifically for PHY control and status reporting.

The Ethernet buffer and PHY control registers are contained entirely within the Ethernet module and cannot be accessed directly by the microcontroller. Data is transferred between the Ethernet and microcontroller by using buffer and pointer registers mapped in the microcontroller's SFR space. The relationships between the SFRs and the Ethernet module's memory spaces are shown in Figure 18-3.

FIGURE 18-3: RELATIONSHIP BETWEEN MICROCONTROLLER AND ETHERNET MEMORY SPACES

18.2.1 ETHERNET BUFFER AND BUFFER POINTER REGISTERS

The Ethernet buffer contains the transmit and receive memory used by the Ethernet controller. The entire buffer is 8 Kbytes, divided into separate receive and transmit buffer spaces. The sizes and locations of transmit and receive memory are fully definable using the pointers in the Ethernet SFR space. The organization of the memory space and the relationships of the pointers are shown in Figure 18-4.

The buffer is always accessible through the EDATA and Ethernet Pointer SFRs, regardless of whether or not the Ethernet module is enabled. This makes the buffer potentially useful for applications requiring large amounts of RAM and that do not require Ethernet communication. In these instances, disabling the Ethernet module reduces overall power usage but does not prevent buffer access.

18.2.1.1 Reading and Writing to the Buffer

The Ethernet buffer contents are accessed through the EDATA register, which acts as a window from the microcontroller data bus into the buffer. The location of

that window is determined by either the ERDPT or EWRPT Pointers, depending on the operation being performed. For example, writing to EDATA causes a write to the Ethernet buffer at the address currently indicated by EWRPT register pair. Similarly, moving the contents of EDATA to another register actually moves the buffer contents at the address indicated by the ERDPT Pointer.

When the AUTOINC bit (ECON2<7>) is set, the associated Read or Write Pointer increments by one address following each read or write operation. This eliminates the need to constantly update a pointer after each read or write, simplifying multiple sequential operations. By default, the AUTOINC bit is set.

While sequentially reading from the receive buffer, a wrapping condition will occur at the end of the receive buffer. A read of EDATA from the address programmed into the ERXND Pointers will cause the ERDPT registers to be incremented to the value contained in the ERXST Pointers. Writing to the buffer, on the other hand, does not result in automatic wrapping.

FIGURE 18-4: ETHERNET BUFFER ORGANIZATION

18.2.1.2 Receive Buffer

The receive buffer constitutes a circular FIFO buffer managed by hardware. The register pairs, ERXSTH:ERXSTL and ERXNDH:ERXNDL, serve as pointers to define the buffer's size and location within the memory. The byte pointed to by the ERXST pair and the byte pointed to by the ERXND pair are both included in the FIFO buffer.

As bytes of data are received from the Ethernet interface, they are written into the receive buffer sequentially. However, after the memory pointed to by the ERXND Pointers is written to, the hardware will automatically write the next byte of received data to the memory pointed to by the ERXST pair. As a result, the receive hardware will never write outside the boundaries of the FIFO.

The user may program the ERXST and ERXND Pointers while the receive logic is disabled. The pointers must not be modified while the receive logic is enabled (ERXEN (ECON1<2>) is set).

The buffer hardware uses an Internal Pointer (not mapped to any user-accessible registers) to determine where unvalidated incoming data is to be written. When a packet has been completely received and validated, the read-only ERXWRPTH:ERXWRPTL registers are updated with the Internal Pointer's value. Thus, the ERXWRPT registers define the general area in the receive buffer where data is currently being written. This makes it useful for determining how much free space is available within the FIFO.

The ERXRDPT registers define a location within the FIFO where the receive hardware is forbidden to write to. In normal operation, the receive hardware will write data up to, but not including, the memory pointed to by the ERXRDPT registers. If the FIFO fills up with data and new data continues to arrive, the hardware will not overwrite the previously received data. Instead, the incoming data will be thrown away and the old data will be preserved. In order to continuously receive new data, the application must periodically advance this pointer whenever it finishes processing some, or all, of the old received data.

An example of how the Receive Buffer Pointers and packet data are related in the circular buffer scheme is shown in Figure 18-5. Note that while four packets are shown in this example, the actual number of packets may be greater or lesser.

FIGURE 18-5: CIRCULAR FIFO BUFFER AND THE RELATIONSHIPS OF THE POINTERS

18.2.1.3 Transmit Buffer

Any space within the 8-Kbyte memory which is not programmed as part of the receive FIFO buffer is considered to be the transmit buffer. The responsibility of managing where packets are located in the transmit buffer belongs to the application. Whenever the application decides to transmit a packet, the ETXST and ETXND Pointers are programmed with addresses specifying where, within the transmit buffer, the particular packet to transmit is located. The hardware does not check that the start and end addresses do not overlap with the receive buffer. To prevent buffer corruption, the firmware must not transmit a packet while the ETXST and ETXND Pointers are overlapping the receive buffer, or while the ETXND Pointers are too close to the receive buffer. See Section 18.5.2 "Transmitting Packets" for more information.

18.2.1.4 Buffer Arbiter and Access Arbitration

The Ethernet buffer is clocked at one-half of the microcontroller clock rate. Varying amounts of memory access bandwidth are available depending on the clock speed. The total bandwidth available, in bytes per second, is equal to twice the instruction rate (2 * FCY, or FOSC/2). For example, at a system clock speed of 41.667 MHz, the total available memory bandwidth that is available is 20.834 Mbyte/s. At an Ethernet signaling rate of 10 Mbit/s, the Ethernet RX engine requires 1.25 Mbyte/s of buffer memory bandwidth to operate without causing an overrun. If Full-Duplex mode is used, an additional 1.25 Mbyte/s is required to allow for simultaneous RX and TX activity.

Because of the finite available memory bandwidth, a three-channel arbiter is used to allocate bandwidth between the RX engine, the TX and DMA engines, and the microcontroller's CPU (i.e., the application access-

ing EDATA). The arbiter gives the EDATA register accesses first priority, while all remaining bandwidth is shared between the RX and TX/DMA blocks.

With arbitration, bandwidth limitations require that some care be taken in balancing the needs of the module's hardware with that of the application. Accessing the EDATA register too often may result in the RX or TX blocks causing a buffer overrun or underrun, respectively. If such a memory access failure occurs, the BUFER bit (ESTAT<6>) and either the TXERIF or RXERIF interrupt flag becomes set, and a TX or RX interrupt occurs (if enabled). In either case, the current packet will be lost or aborted.

To eliminate the risk of lost packets, run the microcontroller core at higher speeds. Following the arbitration restrictions shown in Table 18-2 will prevent memory access failures from occurring. Also, avoid using segments of application code which perform back-to-back accesses of the EDATA register. Instead, insert one or more instructions (including NOP instructions) between each read or write to EDATA.

18.2.1.5 DMA Access to the Buffer

The integrated DMA controller must read from the buffer when calculating a checksum, and it must read and write to the buffer when copying memory. The DMA follows the same wrapping rules as previously described for the receive buffer. While it sequentially reads, it will be subject to a wrapping condition at the end of the receive buffer. All writes it does will not be subject to any wrapping conditions. See Section 18.9 "Direct Memory Access Controller" for more information.

| Fosc | Fcy | | | (Mbyte/s) | Application Restrictions |
|--------|-------|-------|-------|-----------|---|
| (MHz) | (MHz) | | | After TX | to Prevent Underrun/Overrun |
| 41.667 | 10.42 | 20.83 | 19.58 | 18.33 | Access EDATA no more than once every 2 Tcy |
| 31.250 | 7.81 | 15.63 | 14.38 | 13.13 | Access EDATA no more than once every 2 TCY |
| 25.000 | 6.25 | 12.50 | 11.25 | 10.00 | Access EDATA no more than once every 2 TCY |
| 20.833 | 5.21 | 10.42 | 9.17 | 7.92 | Access EDATA no more than once every 2 TCY |
| 13.889 | 3.47 | 6.94 | 5.69 | 4.44 | Access EDATA no more than once every 2 TCY |
| 12.500 | 3.13 | 6.25 | 5.00 | 3.75 | Access EDATA no more than once every 2 TCY |
| 8.333 | 2.08 | 4.17 | 2.92 | 1.67 | Access EDATA no more than once every 3 TCY |
| 6.250 | 1.56 | 3.13 | 1.88 | 0.63 | Access EDATA no more than once every 5 TCY |
| 4.167 | 1.04 | 2.08 | 0.83 | < 0 | Do not use DMA, do not use full duplex, access EDATA no more than once every 3 Tcy |
| 2.778 | 0.69 | 1.39 | 0.14 | < 0 | Do not use DMA, do not use full duplex, access EDATA no more than once every 10 Tcy |

TABLE 18-2: BUFFER ARBITRATION RESTRICTIONS VS. CLOCK SPEED

18.2.2 SFRs AND THE ETHERNET MODULE

Like other peripherals, direct control of the Ethernet module is accomplished through a set of SFRs. Because of their large number, the majority of these registers are located in the bottom half of Bank 14 of the microcontroller's data memory space.

Five key SFRs for the Ethernet module are located in the microcontroller's regular SFR area in Bank 15, where fast access is possible. They are:

- ECON1
- EDATA
- EIR
- The Ethernet Buffer Read Pointer pair (ERDPTH and ERDPTL)

ECON1 is described along with other Ethernet control registers in the following section. EDATA and ERDPTH:ERDPTL are the Ethernet Data Buffer registers and its pointers during read operations (see Section 18.2.1 "Ethernet Buffer and Buffer Pointer Registers"). EIR is part of the Ethernet interrupt structure and is described in Section 18.3 "Ethernet Interrupts".

Many of the Ethernet SFRs in Bank 14 serve as pointer registers to indicate addresses within the dedicated Ethernet buffer for storage and retrieval of packet data. Others store information for packet pattern masks or checksum operations. Several are used for controlling overall module operations, as well as specific MAC and PHY functions.

18.2.3 ETHERNET CONTROL REGISTERS

The ECON1 register (Register 18-1) is used to control the main functions of the module. Receive enable, transmit request and DMA control bits are all located here. The ECON2 register (Register 18-2) is used to control other top level functions of the module. The ESTAT register (Register 18-3) is used to report the high-level status of the module and Ethernet communications.

The Ethernet SFRs with the 'E' prefix are always accessible, regardless of whether or not the module is enabled.

18.2.4 MAC AND MII REGISTERS

These SFRs are used to control the operations of the MAC and, through the MIIM, the PHY. The MAC and MII registers occupy data addresses E80h-E85h, E8Ah, and EA0h through EB9h.

Although MAC and MII registers appear in the general memory map of the microcontroller, these registers are embedded inside the MAC module. Host interface logic translates the microcontroller data/address bus data to be able to access these registers. The host interface logic imposes restrictions on how firmware is able to access the MAC and MII SFRs. See the following notes.

- **Note 1:** Do not access the MAC and MII SFRs unless the Ethernet module is enabled (ETHEN = 1).
 - 2: Back-to-back accesses of MAC or MII registers are not supported. Between any instruction which addresses a MAC or MII register, at least one NOP or other instruction must be executed.

The three MACON registers control specific MAC operations and packet configuration operations. They are shown in Register 18-4 through Register 18-6.

The MII registers are used to control the MIIM interface and serve as the communication channel with the PHY registers. They are shown in Register 18-7 and Register 18-8.

18.2.5 PHY REGISTERS

The PHY registers provide configuration and control of the PHY module, as well as status information about its operation. All PHY registers are 16 bits in width.

PHY registers are accessed with a 5-bit address, for a total of 32 possible registers; of these, only 7 addresses are implemented. The implemented registers are listed in Table 18-3. The main PHY Control registers are described in Register 18-9 through Register 18-13. The other PHY Control and Status registers are described later in this chapter.

Unimplemented registers must never be written to; reading these locations will return indeterminate data. Within implemented registers, all reserved bit locations that are listed as writable must always be written with the value provided in the register description. When read, these reserved bits can be ignored.

Thy PHY registers are only accessible through the MII Management interface. They must not be read or written to until the PHY start-up timer has expired and the PHYRDY bit (ESTAT<0>) is set.

18.2.5.1 PHSTAT Registers

The PHSTAT1 and PHSTAT2 registers contain read-only bits that show the current status of the PHY module's operations, particularly the conditions of the communications link to the rest of the network.

The PHSTAT1 register (Register 18-10) contains the LLSTAT bit; it clears and latches low if the physical layer link has gone down since the last read of the register. The application can periodically poll LLSTAT to determine exactly when the link fails. It may be particularly useful if the link change interrupt is not used.

The PHSTAT2 register (Register 18-12) contains status bits which report if the PHY module is linked to the network and whether or not it is transmitting or receiving.

18.2.5.2 Accessing PHY Registers

As already mentioned, the PHY registers exist in a different memory space and are not directly accessible by the microcontroller. Instead, they are addressed through a special set of MII registers in the Ethernet SFR bank that implement a Media Independent Interface Management (MIIM).

Access is similar to that of the Ethernet buffer, but uses separate read and write buffers (MIRDH:MIRDL and MIWRH:MIWRL) and a 5-bit address register (MIREGADR). In addition, the MICMD and MISTAT registers are used to control read and write operations. To read from a PHY register:

- 1. Write the address of the PHY register to be read into the MIREGADR register.
- Set the MIIRD bit (MICMD<0>). The read operation begins and the BUSY bit (MISTAT<0>) is set.
- Wait 10.24 μs, then poll the BUSY bit to be certain that the operation is complete. When the MAC has obtained the register contents, the BUSY bit will clear itself. While BUSY is set, the user application should not start any MIISCAN operations or write to the MIWRH register.
- 4. Clear the MIIRD bit.
- 5. Read the entire 16 bits of the PHY register from the MIRDL and MIRDH registers.

To write to a PHY register:

- 1. Write the address of the PHY register to be written into the MIREGADR register.
- 2. Write the lower 8 bits of data to write into the MIWRL register.
- 3. Write the upper 8 bits of data to write into the MIWRH register. Writing to this register automatically begins the MII transaction, so it must be written to after MIWRL. The BUSY bit is set automatically.

The PHY register is written after the MII operation completes, which takes 10.24 $\mu s.$ When the write operation has completed, the BUSY bit will clear itself. The application should not start any MII scan or read operations while busy.

When a PHY register is written to, the entire 16 bits is written at once; selective bit and/or byte writes are not implemented. If it is necessary to reprogram only select bits in the register, the controller must first read the PHY register, modify the resulting data and then write the data back to the PHY register. The MAC can also be configured to perform automatic back-to-back read operations on a PHY register. To perform this scan operation:

- 1. Write the address of the PHY register to be scanned into the MIREGADR register.
- 2. Set the MIISCAN bit (MICMD<1>). The scan operation begins and the BUSY bit is set.

After MIISCAN is set, the NVALID (MISTAT<2>), SCAN and BUSY bits are also set. The first read operation will complete after 10.24 μ s. Subsequent reads will be done and the MIRDL and MIRDH registers will be continuously updated automatically at the same interval until the operation is cancelled. The NVALID bit may be polled to determine when the first read operation is complete.

There is no status information which can be used to determine when the MIRD registers are updated. Since only one MII register can be read at a time, it must not be assumed that the values of MIRDL and MIRDH were read from the PHY at exactly the same time during a scan operation.

MIISCAN should remain set as long as the scan operation is desired. The BUSY and SCAN bits are automatically cleared after MIISCAN is set to '0' and the last read sequence is completed. MIREGADR should not be updated while MIISCAN is set.

Starting new PHY operations, such as a read operation or writing to the MIWRH register, must not be done while a scan is underway. The operation can be cancelled by clearing the MIISCAN bit and then polling the BUSY bit. New operations may be started after the BUSY bit is cleared.

18.3 Ethernet Interrupts

The Ethernet module can generate multiple interrupt conditions. To accommodate all of these sources, the module has its own interrupt logic structure, similar to that of the microcontroller. Separate sets of registers are used to enable and flag different interrupt conditions.

The EIE register contains the individual interrupt enable bits for each source, while the EIR register contains the corresponding interrupt flag bits. When an interrupt occurs, the interrupt flag is set. If the interrupt is enabled in the EIE register, and the corresponding ETHIE global interrupt enable bit is set, the microcontroller's master Ethernet Interrupt Flag (ETHIF) is set, as appropriate (see Figure 18-6). Note: Except for the LINKIF interrupt flag, interrupt flag bits are set when an interrupt condition occurs, regardless of the state of its corresponding enable bit or the associated global enable bit. User software should ensure the appropriate interrupt flag bits are clear prior to enabling an interrupt. This feature allows for software polling.

18.3.1 CONTROL INTERRUPT (ETHIE)

The four registers associated with the control interrupts are shown in Register 18-14 through Register 18-17.

18.3.1.1 Receive Error Interrupt (RXERIF)

The receive error interrupt is used to indicate that a packet being received was aborted due to an error condition. Three errors are possible:

- 1. No buffer space is available to store the incoming packet (buffer overflow);
- Receiving another packet would cause the EPKTCNT counter to overflow, because it already contains the value 255; or
- 3. The Ethernet RX hardware was not allocated enough memory bandwidth to write the incoming data to the buffer.

When a packet is being received and the receive error occurs, the packet being received will be aborted (permanently lost) and the RXERIF bit will be set to '1'. Once set, RXERIF can only be cleared by firmware or by a Reset condition. If the receive error interrupt and Ethernet interrupt are enabled (both RXERIE and ETHIE are set), an Ethernet interrupt is generated. If the receive error interrupt is not enabled (either RXERIE or ETHIE are cleared), the application may poll RXERIF and take appropriate action.

Normally, upon the first two receive error conditions (buffer overflow or potential EPKTCNT overflow), the application would process any packets pending from the receive buffer and then make additional room for future packets by advancing the ERXRDPT registers (low byte first) and decrementing the EPKTCNT register. See Section 18.5.3.3 "Freeing Receive Buffer Space" for more information on processing packets. Once processed, the application should clear the RXERIF bit.

The third condition (insufficient RX memory bandwidth) can be identified by checking if the BUFER bit (ESTAT<6>) has been set. Memory access errors that set BUFER are generally transient in nature, and do not require run-time resolution. Adjustments to the application and its allocation of buffer memory bandwidth may be necessary if BUFER errors are frequent or persistent.

18.3.1.2 Transmit Error Interrupt (TXERIF)

The transmit error interrupt is used to indicate that a transmit abort has occurred. An abort can occur because of any of the following conditions:

- 1. More than 15 collisions occurred while attempting to transmit a given packet.
- 2. A late collision (collision after 64 bytes of a packet had been transmitted) has occurred.
- The transmission was unable to gain an opportunity to transmit the packet because the medium was constantly occupied for too long. The deferral limit was reached and the DEFER bit (MACON4<6>) was clear.

- 4. An attempt to transmit a packet larger than the maximum frame length defined by the MAMXFL registers was made without setting the HFRMEN bit (MACON3<2>) or per-packet POVERRIDE and PHUGEEN bits.
- 5. The Ethernet buffer did not have enough memory bandwidth to maintain the required 10 Mbit/s transfer rate (buffer underrun).

Upon any of these conditions, the TXERIF flag is set to '1'. Once set, it can only be cleared by firmware or by a Reset condition. If the transmit error interrupt is enabled (TXERIE and ETHIE are both set), an Ethernet interrupt is generated. If the transmit error interrupt is not enabled (either TXERIE or ETHIE is cleared), the application may poll TXERIF and take appropriate action. Once the interrupt is processed, the flag bit should be cleared.

After a transmit abort, the TXRTS bit (ECON1<3>) will be cleared, the TXABRT bit (ESTAT<1>) becomes set and the transmit status vector will be written at the ETXND registers + 1. The MAC will not automatically attempt to retransmit the packet. The application may wish to read the transmit status vector and BUFER bit to determine the cause of the abort. After determining the problem and solution, the application should clear the BUFER (if set) and TXABRT bits so that future aborts can be detected accurately.

In Full-Duplex mode, conditions 4 and 5 are the only ones that should cause this interrupt. Condition 5 can be further distinguished as it also sets the BUFER bit. Collisions and other problems related to sharing the network are not possible on full-duplex networks. The conditions which cause the transmit error interrupt meet the requirements of the transmit interrupt. As a result, when this interrupt occurs, TXIF will also be simultaneously set.

18.3.1.3 Transmit Interrupt (TXIF)

The transmit interrupt is used to indicate that the requested packet transmission has ended (the TXRTS bit has transitioned from '1' to '0'). Upon transmission completion, abort, or transmission cancellation by the application, the TXIF flag will be set to '1'. If the application did not clear the TXRTS bit, and the TXABRT bit is not set, the packet was successfully transmitted. Once TXIF is set, it can only be cleared in software or by a Reset condition. If the transmit interrupt is generated. If the transmit interrupt is not enabled (either TXIE or ETHIE is cleared), the application may poll the TXIF bit and take appropriate action.

18.3.1.4 Link Change Interrupt (LINKIF)

The LINKIF indicates that the link status has changed. The actual current link status can be obtained from the LLSTAT (PHSTAT1<2>) or LSTAT (PHSTAT2<10>) bits (see Register 18-10 and Register 18-12). Unlike other interrupt sources, the link status change interrupt is created in the integrated PHY module; additional steps must be taken to enable it.

By Reset default, LINKIF is never set for any reason. To receive it, both the PLNKIE and PGEIE bits must be set. When the interrupt is enabled, the LINKIF bit will shadow the contents of the PGIF bit. The PHY only supports one interrupt, so the PGIF bit will always be the same as the PLNKIF bit (when both PHY enable bits are set).

Once LINKIF is set, it can only be cleared in software or by a Reset. If the link change interrupt is enabled (LINKIE, PLNKIE, PGEIE and ETHIE are all set), an interrupt is generated. If the link change interrupt is not enabled (LINKIE, PLNKIE, PGEIE or ETHIE are cleared), the user application may poll the PLNKIF flag and take appropriate action.

The LINKIF bit is read-only. Because reading PHY registers requires a non-negligible period of time, the application may instead set PLNKIE and PGEIE, then poll the LINKIF flag bit. Performing an MII read on the PHIR register will clear the LINKIF, PGIF and PLNKIF bits automatically and allow for future link status change interrupts. See **Section 18.2.5 "PHY Registers"** for information on accessing the PHY registers.

18.3.1.5 DMA Interrupt (DMAIF)

The DMA interrupt indicates that the DMA module has completed its memory copy or checksum calculation (the DMAST bit has transitioned from '1' to '0'). Additionally, this interrupt will be caused if the application cancels a DMA operation by manually clearing the DMAST bit. Once set, DMAIF can only be cleared by the firmware or by a Reset condition. If the DMA interrupt is enabled, an Ethernet interrupt is generated. If the DMA interrupt is not enabled, the user application may poll the DMAIF flag status and take appropriate action. Once processed, the flag bit should be cleared.

18.3.1.6 Receive Packet Pending Interrupt (PKTIF)

The receive packet pending interrupt is used to indicate the presence of one or more data packets in the receive buffer and to provide a notification means for the arrival of new packets. When the receive buffer has at least one packet in it, the PKTIF flag bit is set. In other words, this interrupt flag will be set any time the Ethernet Packet Count register (EPKTCNT) is non-zero. When the receive packet pending interrupt is enabled (both PKTIE and ETHIE are set), an Ethernet interrupt is generated whenever a new packet is successfully received and written into the receive buffer. If the receive packet pending interrupt is not enabled (either PKTIE or ETHIE is cleared), the user application may poll the PKTIF bit and take appropriate action.

The PKTIF bit can only be cleared indirectly in software, by decrementing the EPKTCNT register to '0', or by a Reset condition. See **Section 18.5.3** "**Receiving Packets**" for more information about clearing the EPKTCNT register. When the last data packet in the receive buffer is processed, EPKTCNT becomes zero and the PKTIF bit is automatically cleared.

18.3.2 ETHERNET INTERRUPTS AND WAKE-ON-LAN

The Ethernet interrupt structure implements a version of Wake-on-LAN, also called Remote Wake-up, using a Magic Packet data packet. This allows the application to conserve power in Idle mode, and then return to full-power operation only when a specific wake-up packet is received.

For Remote Wake-up to work, the Ethernet module must remain enabled at all times. It also necessary to configure the receive filters to select for Magic Packets. For more information on filter configuration, see **Section 18.8 "Receive Filters"**.

To configure the microcontroller for Remote Wake-up:

- With the Ethernet module enabled and in normal operating configuration, enable the CRC post-filter and Magic Packets filter (ERXFCON<5,3> = 1).
- 2. Finish processing any pending packets in the Ethernet buffer.
- 3. Enable Ethernet interrupts at the microcontroller level (PIE2<5> = 1), and the receive packet pending interrupt at the module level (EIE<6> = 1).
- Place the microcontroller in PRI_IDLE mode (with the primary clock source selected and OSCCON<7> = 1, execute the SLEEP instruction).

In this configuration, the receipt of a Magic Packet data packet will cause a receive packet pending interrupt; this in turn will cause the microcontroller to wake-up from the interrupt.

18.4 Module Initialization

Before the Ethernet module can be used to transmit and receive packets, certain device settings must be initialized. Depending on the application, some configuration options may need to be changed. Normally, these tasks may be accomplished once after Reset and do not need to be changed thereafter.

Before any other configuration actions are taken, it is recommended that the module be enabled by setting the ETHEN bit (ECON2<5>). This reduces the Idle time that might otherwise result while waiting for the PHYRDY flag to become set.

18.4.1 RECEIVE BUFFER

Before receiving any packets, the receive buffer must be initialized by setting the ERXST and ERXND Pointers. All memory between and including the ERXST and ERXND addresses will be dedicated to the receive hardware. The ERXST Pointers must be programmed with an even address while the ERXND Pointers must be programmed with an odd address.

Applications expecting large amounts of data and frequent packet delivery may wish to allocate most of the memory as the receive buffer. Applications that may need to save older packets, or have several packets ready for transmission, should allocate less memory.

When programming the ERXST or ERXND Pointers, the ERXWRPT Pointer registers will automatically be updated with the value in the ERXST registers. The address in the ERXWRPT registers will be used as the starting location when the receive hardware begins writing received data. When the ERXST and ERXND Pointers are initialized, the ERXRDPT registers should additionally be programmed with the value of the ERXND registers. To program the ERXRDPT registers, write to ERXRDPTL first, followed by ERXRDPTH. See **Section 18.5.3.3 "Freeing Receive Buffer Space**" for more information.

18.4.2 TRANSMISSION BUFFER

All memory which is not used by the receive buffer is considered to be transmission buffer. Data which is to be transmitted should be written into any unused space. After a packet is transmitted, however, the hardware will write a 7-byte status vector into memory after the last byte in the packet. Therefore, the application should leave at least 7 bytes between each packet and the beginning of the receive buffer.

18.4.3 RECEIVE FILTERS

The appropriate receive filters should be enabled or disabled by writing to the ERXFCON register. See **Section 18.8 "Receive Filters"** for information on how to configure it.

18.4.4 WAITING FOR THE PHY START-UP TIMER

If the initialization procedure is being executed immediately after enabling the module (setting the ETHEN bit to '1'), the PHYRDY bit should be polled to make certain that enough time (1 ms) has elapsed before proceeding to modify the PHY registers. For more information on the PHY start-up timer, see **Section 18.1.3.1 "Start-up Timer**".

18.4.5 MAC INITIALIZATION SETTINGS

Several of the MAC registers require configuration during initialization. This only needs to be done once during initialization; the order of programming is unimportant.

- Set the MARXEN bit (MACON1<0>) to enable the MAC to receive frames. If using full duplex, most applications should also set TXPAUS and RXPAUS to allow IEEE defined flow control to function.
- 2. Configure the PADCFG<2:0>, TXCRCEN and FULDPX bits in the MACON3 register. Most applications should enable automatic padding to at least 60 bytes and always append a valid CRC. For convenience, many applications may wish to set the FRMLNEN bit as well to enable frame length status reporting. The FULDPX bit should be set if the application will be connected to a full-duplex configured remote node; otherwise leave it clear.
- Configure the bits in MACON4. For maintaining compliance with IEEE 802.3, be certain to set the DEFER bit (MACON4<6>).
- Program the MAMXFL registers with the maximum frame length to be permitted to be received or transmitted. Normal network nodes are designed to handle packets that are 1518 bytes or less; larger packets are not supported by IEEE 802.3.
- Configure the MAC Back-to-Back Inter-Packet Gap register, MABBIPG, with 15h (when Full-Duplex mode is used) or 12h (when Half-Duplex mode is used). Refer to Register 18-18 for a more detailed description of configuring the inter-packet gap.
- 6. Configure the MAC Non Back-to-Back Inter-Packet Gap Low Byte register, MAIPGL, with 12h.
- 7. If half duplex is used, configure the MAC Non Back-to-Back Inter-Packet Gap High Byte register, MAIPGH, with 0Ch.
- 8. Program the local MAC address into the MAADR1:MAADR6 registers.

REGISTER 18-18: MABBIPG: MAC BACK-TO-BACK INTER-PACKET GAP REGISTER

| U-0 | R/W-0 |

| -n = Value at POR | '1' = Bit is set | '0' = Bit is cleared | x = Bit is unknown |

bit 7 Unimplemented: Read as '0'

bit 6-0 **BBIPG6:BBIPG0:** Back-to-Back Inter-Packet Gap Delay Time bits

When FULDPX (MACON3<0>) = 1:

Nibble time offset delay between the end of one transmission and the beginning of the next in a back-to-back sequence. The register value should be programmed to the desired period in nibble times minus 3. The recommended setting is 15h which represents the minimum IEEE specified Inter-Packet Gap (IPG) of 9.6 μ s.

When FULDPX (MACON3<0>) = 0:

Nibble time offset delay between the end of one transmission and the beginning of the next in a back-to-back sequence. The register value should be programmed to the desired period in nibble times minus 6. The recommended setting is 12h which represents the minimum IEEE specified Inter-Packet Gap (IPG) of 9.6 μ s.

18.4.6 PHY INITIALIZATION SETTINGS

Depending on the application, bits in three of the PHY module's registers may also require configuration.

The PDPXMD bit (PHCON1<8>) controls the PHY half/full-duplex configuration. The application must program the bit properly, along with the FULDPX bit (MACON3<0>).

The HDLDIS bit (PHCON2<8>) disables automatic loopback of data. For proper operation, always set both HDLDIS and RXAPDIS (PHCON2<4>).

The PHY register, PHLCON (Register 18-13), controls the outputs of LEDA and LEDB. If an application requires a LED configuration other than the default, alter this register to match the new requirements. The settings for LED operation are discussed in **Section 18.1.2 "LED Configuration"**.

18.4.7 DISABLING THE ETHERNET MODULE

There may be circumstances during which the Ethernet module is not needed for prolonged periods. For example, in situations where the application only needs to transmit or receive Ethernet packets on the occurrence of a particular event. In these cases, the module can be selectively powered down.

To selectively disable the module:

- 1. Turn off packet reception by clearing the RXEN bit.
- Wait for any in-progress packets to finish being received by polling the RXBUSY bit (ESTAT<2>). This bit should be clear before proceeding.
- 3. Wait for any current transmissions to end by confirming that the TXRTS bit (ECON1<3>) is clear.
- 4. Clear the ETHEN bit. This removes power and clock sources from the module, and makes the PHY registers inaccessible. The PHYRDY bit is also cleared automatically.

18.5 Transmitting and Receiving Data

The Ethernet protocol (IEEE Standard 802.3) provides an extremely detailed description of the 10 Mbps, frame-based serial communications system. Before discussing the actual use of the Ethernet module, a brief review of the structure of a typical Ethernet data frame may be appropriate. It is assumed that users already have some familiarity with IEEE 802.3. Those requiring more information should refer to the official standard, or other Ethernet reference texts, for a more comprehensive explanation.

18.5.1 PACKET FORMAT

Normal IEEE 802.3 compliant Ethernet frames are between 64 and 1518 bytes long. They are made up of five or six different fields: a destination MAC address, a source MAC address, a type/length field, data payload, an optional padding field and a Cyclic Redundancy Check (CRC). Additionally, when transmitted on the Ethernet medium, a 7-byte preamble field and Start-of-Frame delimiter byte are appended to the beginning of the Ethernet packet. Thus, traffic seen on the twisted-pair cabling will appear as shown in Figure 18-7.

18.5.1.1 Preamble/Start-of-Frame Delimiter

When transmitting and receiving data with the Ethernet module, the preamble and Start-of-Frame delimiter bytes are automatically generated, or stripped from the packets, when they are transmitted or received. It can also automatically generate CRC fields and padding as needed on transmission, and verify CRC data on reception. The user application does not need to create or process these fields, or manually verify CRC data. However, the padding and CRC fields are written into the receive buffer when packets arrive, so they may be evaluated by the user application as needed.

FIGURE 18-7: ETHERNET PACKET FORMAT

18.5.1.2 Destination Address

The destination address field is a 6-byte field filled with the MAC address of the device that the packet is directed to. If the Least Significant bit in the first byte of the MAC address is set, the address is a Multicast destination. For example, 01-00-00-00-F0-00 and 33-45-67-89-AB-CD are Multicast addresses, while 00-00-00-00-F0-00 and 32-45-67-89-AB-CD are not.

Packets with Multicast destination addresses are designed to arrive and be important to a selected group of Ethernet nodes. If the destination address field is the reserved Multicast address, FF-FF-FF-FF-FF, the packet is a Broadcast packet and it will be directed to everyone sharing the network. If the Least Significant bit in the first byte of the MAC address is clear, the address is a Unicast address and will be designed for usage by only the addressed node.

The Ethernet module incorporates receive filters which can be used to discard or accept packets with Multicast, Broadcast and/or Unicast destination addresses. When transmitting packets, the application is responsible for writing the desired destination address into the transmit buffer.

18.5.1.3 Source Address

The source address field is a 6-byte field filled with the MAC address of the node which created the Ethernet packet. Users of the Ethernet module must generate a unique MAC address for each and every microcontroller used.

MAC addresses consist of two portions. The first three bytes are known as the Organizationally Unique Identifier (OUI). OUIs are distributed by the IEEE. The last three bytes are address bytes at the discretion of the company that purchased the OUI.

When transmitting packets, the assigned source MAC address must be written into the transmit buffer by the application. The module will not automatically transmit the contents of the MAADR registers which are used for the Unicast receive filter.

18.5.1.4 Type/Length

The type/length field is a 2-byte field which defines which protocol the following packet data belongs to. Alternately, if the field is filled with the contents of 05DCh (1500) or any smaller number, the field is considered a length field, and it specifies the amount of non-padding data which follows in the data field. Users implementing proprietary networks may choose to treat this field as a length field, while applications implementing protocols such as the Internet Protocol (IP), or Address Resolution Protocol (ARP), should program this field with the appropriate type defined by the protocol's specification when transmitting packets.

18.5.1.5 Data

The data field is a variable length field anywhere from 0 to 1500 bytes. Larger data packets will violate Ethernet standards and will be dropped by most Ethernet nodes. The Ethernet module, however, is capable of transmitting and receiving larger packets when the Huge Frame Enable bit, HFRMEN, is set (MACON3<2> = 1).

18.5.1.6 Padding

The padding field is a variable length field added to meet IEEE 802.3 specification requirements when small data payloads are used. The destination, source, type, data and padding of an Ethernet packet must be no smaller than 60 bytes. Adding the required 4-byte CRC field, packets must be no smaller than 64 bytes. If the data field is less than 46 bytes long, a padding field is required.

When transmitting packets, the Ethernet module automatically generates zero-padding if the PADCFG2:PADCFG0 bits (MACON3<7:5>) are configured for this. Otherwise, the user application will need to add any padding to the packet before transmitting it. The module will not prevent the transmission of undersized packets should the application command such an action.

When receiving packets, the module automatically rejects packets which are less than 18 bytes. All packets, 18 bytes and larger, will be subject to the standard receive filtering criteria and may be accepted as normal traffic. Since the module only rejects packets smaller than 18 bytes, it is important that the firmware check the length of every received packet and reject packets which are smaller than 64 bytes to meet IEEE 802.3 specification requirements.

18.5.1.7 CRC

The CRC field is a 4-byte field which contains an industry standard, 32-bit CRC, calculated with the data from the destination, source, type, data and padding fields. It provides a way of detecting corrupted Ethernet frames, as well as junk data fragments resulting from packet collisions or another host's aborted transmissions.

When receiving packets, the Ethernet module will check the CRC of each incoming packet. If the CRCEN bit is set, packets with invalid CRCs will automatically be discarded. If CRCEN is clear and the packet meets all other receive filtering criteria, the packet will be written into the receive buffer and the application will be able to determine if the CRC was valid by reading the receive status vector (see Section 18.5.3 "Receiving Packets").

When transmitting packets, the module automatically generates a valid CRC and transmits it if the PADCFG2:PADCFG0 bits are configured for this. Otherwise, the user application must generate the CRC and place it in the transmit buffer. Given the complexity of calculating a CRC, it is highly recommended to allow the module to automatically calculate and include the CRC.

18.5.2 TRANSMITTING PACKETS

The Ethernet module's MAC will automatically generate the preamble and Start-of-Frame (SOF) delimiter fields when transmitting. Additionally, the MAC can generate any padding (if needed) and the CRC if configured to do so. The application must generate and write all other frame fields into the buffer memory for transmission.

In addition, the Ethernet module requires a single per-packet control byte to precede the packet for transmission. The control byte is organized as shown in Figure 18-8. Before transmitting packets, the MAC registers, which alter the transmission characteristics, should be initialized as documented in **Section 18.4 "Module Initialization"**.

An example of how the entire assembled transmit packet looks in memory is shown in Figure 18-9. To construct and transmit a packet in this fashion:

- 1. Set the ETXST Pointers to an appropriate unused location in the buffer. This will be the location of the per-packet control byte. In the example, it would be 0120h. It is recommended that an even address be used for the ETXST Pointers.
- 2. Using EDATA and the EWRPT registers, sequentially write the packet data to the Ethernet buffer. In order, write the data for the per-packet control byte, the destination address, the source MAC address, the type/length and the data payload.
- 3. Set the ETXND Pointers to point to the last byte in the data payload. In the example, it would be programmed to 0156h.
- 4. Clear the TXIF flag bit (EIR<3>), and set the TXIE (EIE<3>) and ETHIE bits to enable an interrupt when done (if desired).
- 5. Start the transmission process by setting the TXRTS bit (ECON1<3>).

If a DMA operation was in progress while the TXRTS bit was set, the module will wait until the DMA operation is complete before attempting to transmit the packet. This possible delay is required because the DMA and transmission engine share the same memory arbiter channel. Similarly, if the DMAST bit is set after TXRTS is already set, the DMA will wait until the TXRTS bit becomes clear before doing anything.

While the transmission is in progress, the ETXST and ETXND Pointers should not be modified. If it is necessary to cancel the transmission, clear the TXRTS bit.

When the packet is finished transmitting, or was aborted due to an error/cancellation, several things occur:

- The TXRTS bit is cleared.
- A 7-byte transmit status vector is written to the buffer at the location pointed to by the ETXND Pointers + 1.
- The TXIF flag is set
- · An interrupt will be generated (if enabled)
- The ETXST and ETXND Pointers will not be modified.

To check if the packet was successfully transmitted, read the TXABRT bit. If it has been set, poll the BUFER bit in addition to the various fields in the transmit status vector to determine the cause. The transmit status vector is organized as shown in Table 18-4. Multi-byte fields are written in little-endian format.

FIGURE 18-9: SAMPLE TRANSMIT PACKET LAYOUT

| Bit | Field | Description |
|-------|---------------------------------|---|
| 55-52 | Zero | 0 |
| 51 | Transmit VLAN Tagged Frame | Frame's length/type field contained 8100h which is the VLAN protocol identifier. |
| 50 | Backpressure Applied | Reserved, do not use. |
| 49 | Transmit Pause Control Frame | The frame transmitted was a control frame with a valid pause opcode. |
| 48 | Transmit Control Frame | The frame transmitted was a control frame. |
| 47-32 | Total Bytes Transmitted on Wire | Total bytes transmitted on the wire for the current packet, including all bytes from collided attempts. |
| 31 | Transmit Underrun | The transmission was aborted due to insufficient buffer memory bandwidth to sustain the 10 Mbit/s transmit rate. |
| 30 | Transmit Giant | Byte count for frame was greater than the MAMXFL registers. |
| 29 | Transmit Late Collision | Collision occurred after 64 bytes had already been transmitted. |
| 28 | Transmit Excessive Collision | Packet was aborted after the number of collisions exceeded 15, the retransmission maximum. |
| 27 | Transmit Excessive Defer | Packet was deferred in excess of 24,287 bit times (2.4287 ms), due to a continuously-occupied medium. |
| 26 | Transmit Packet Defer | Packet was deferred for at least one attempt but less than an excessive defer. |
| 25 | Transmit Broadcast | Packet's destination address was a Broadcast address. |
| 24 | Transmit Multicast | Packet's destination address was a Multicast address. |
| 23 | Transmit Done | Transmission of the packet was completed successfully. |
| 22 | Transmit Length Out of Range | Indicates that frame type/length field was larger than 1500 bytes (type field). |
| 21 | Transmit Length Check Error | Indicates that frame length field value in the packet does not match the actual data byte length and is not a type field. The FRMLNEN bit (MACON3<1>) must be set to get this error. |
| 20 | Transmit CRC Error | The attached CRC in the packet did not match the internally generated CRC. |
| 19-16 | Transmit Collision Count | Number of collisions the current packet incurred during transmission attempts. It applies to successfully transmitted packets and as such, will not show the possible maximum count of 16 collisions. |
| 15-0 | Transmit Byte Count | Total bytes in frame not counting collided bytes. |

TABLE 18-4: TRANSMIT STATUS VECTORS

18.5.3 RECEIVING PACKETS

Assuming that the receive buffer has been initialized, the MAC has been properly configured and the receive filters have been configured, the application should perform these steps to receive Ethernet packets:

- 1. Set the PKTIE and ETHIE bits to generate an Ethernet interrupt whenever a packet is received (if desired).
- Clear the RXERIF flag and set both RXERIE and ETHIE to generate an interrupt whenever a packet is dropped due to insufficient buffer space or memory access bandwidth (if desired).
- 3. Enable reception by setting the RXEN bit (ECON1<2>).

After setting RXEN, the Duplex mode and the Receive Buffer Start and End Pointers should not be modified. Additionally, to prevent unexpected packets from arriving, it is recommended that RXEN be cleared before altering the receive filter configuration (ERXFCON) and MAC address.

After reception is enabled, packets which are not filtered out will be written into the circular receive buffer. Any packet which does not meet the necessary filter

criteria will be discarded and the application will not have any means of identifying that a packet was thrown away. When a packet is accepted and completely written into the buffer:

- the EPKTCNT register is incremented,
- the PKTIF bit is set,
- an interrupt is generated (if enabled), and
- the Hardware Write Pointers, ERXWRPT, are automatically advanced.

18.5.3.1 Receive Packet Layout

Figure 18-10 shows the layout of a received packet. The packets are preceded by a 6-byte header which contains a Next Packet Pointer in addition to a receive status vector which contains receive statistics, including the packet's size. The receive status vectors are shown in Table 18-5.

If the last byte in the packet ends on an odd value address, the hardware will automatically add a padding byte when advancing the Hardware Write Pointer. As such, all packets will start on an even boundary.

Address Memory Description Packet N - 1 End of the Previous Packet 101Fh 1020h 6Eh Low Byte Next Packet Pointer 1021h 10h High Byte 1022h rsv[7:0] status[7:0] 1023h rsv[15:8] status[15:8] **Receive Status Vector** rsv[23:16] status[23:16] 1024h rsv[30:24] 1025h status[31:24] 1026h data[1] 1027h data[2] Packet N Packet Data: Destination Address, Source Address, Type/Length, Data, Padding, CRC 1059h crc[31:24] data[m-3] 106Ah crc[23:16] data[m-2] 106Bh data[m-1] crc[15:8] 106Ch data[m] crc[7:0] Byte Skipped to Ensure 106Dh Even Buffer Address 106Eh Packet N + 1 Start of the Next Packet

FIGURE 18-10: SAMPLE RECEIVE PACKET LAYOUT

| Bit | Field | Description |
|------|-------------------------------|---|
| 31 | Zero | ·0' |
| 30 | Receive VLAN Type Detected | Current frame was recognized as a VLAN tagged frame. |
| 29 | Receive Unknown Opcode | Current frame was recognized as a control frame but it contained an unknown opcode. |
| 28 | Receive Pause Control Frame | Current frame was recognized as a control frame containing a valid pause frame opcode and a valid destination address. |
| 27 | Receive Control Frame | Current frame was recognized as a control frame for having a valid type/length designating it as a control frame. |
| 26 | Dribble Nibble | Indicates that after the end of this packet, an additional 1 to 7 bits were received. The extra bits were thrown away. |
| 25 | Receive Broadcast Packet | Indicates packet received had a valid Broadcast address. |
| 24 | Receive Multicast Packet | Indicates packet received had a valid Multicast address. |
| 23 | Received OK | Indicates that the packet had a valid CRC and no symbol errors. |
| 22 | Length Out of Range | Indicates that frame type/length field was larger than 1500 bytes (type field). |
| 21 | Length Check Error | Indicates that frame length field value in the packet does not match the actual data byte length. |
| 20 | CRC Error | Indicates that the frame CRC field value does not match the CRC calculated by the MAC. |
| 19 | Reserved | |
| 18 | Carrier Event Previously Seen | Indicates that at some time since the last receive, a carrier event was detected. The carrier event is not associated with this packet. A carrier event is activity on the receive channel that does not result in a packet receive attempt being made. |
| 17 | Reserved | |
| 16 | Long Event/Drop Event | Indicates a packet over 50,000 bit times occurred or that a packet was dropped since the last receive. |
| 15-0 | Received Byte Count | Indicates length of the received frame. This includes the destination address, source address, type/length, data, padding and CRC fields. This field is stored in little-endian format. |

TABLE 18-5:RECEIVE STATUS VECTORS

18.5.3.2 Reading Received Packets

To process the packet, an application will normally start reading from the beginning of the Next Packet Pointer. The application will save the Next Packet Pointer, any necessary bytes from the receive status vector, and then proceed to read the actual packet contents. If the AUTOINC bit is set, it will be able to sequentially read the entire packet without ever modifying the ERDPT registers. The Read Pointer would automatically wrap at the end of the circular receive buffer to the beginning. In the event that the application needed to randomly access the packet, it would be necessary to manually calculate the proper ERDPT registers, taking care to not exceed the end of the receive buffer, if the packet spans the ERXND to ERXST buffer boundary. In other words, given the packet start address and a desired offset, the application should follow the logic shown in Equation 18-1.

EQUATION 18-1: RANDOM ACCESS ADDRESS CALCULATION

| If Packet Star | t Address + Offset > ERXND, then |
|----------------|---|
| | ERDPT = Packet Start Address + Offset - (ERXND - ERXST + 1) |
| else | |
| | ERDPT = Packet Start Address + Offset |

18.5.3.3 Freeing Receive Buffer Space

After the user application has processed a packet (or part of the packet) and needs to free the occupied buffer space used by the processed data, it must advance the Receive Buffer Read Pointer pair, ERXRDPT. The module always writes up to, but not over, the memory pointed to by the ERXRDPT registers. If an attempt to overwrite the Receive Buffer Read Pointer location occurs, the packet in progress is aborted, the RXERIF flag is set and an interrupt is generated (if enabled). In this manner, the hardware will never overwrite unprocessed packets. Normally, the ERXRDPT pair is advanced close to a value pointed to by the Next Packet Pointer which precedes the receive status vector for the current packet.

The Receive Buffer Read Pointer Low Byte (ERXRDPTL register) is internally buffered to prevent the pointer from moving when only one byte is updated. To move the ERXRDPT pair, the application must write to ERXRDPTL first. The write will update the internal buffer but will not affect the register. When the application writes to ERXRDPTH, the internally buffered low byte will be loaded into the ERXRDPTL register at the same time. The ERXRDPT bytes can be read in any order. When they are read, the actual value of the registers will be returned. As a result, the buffered low byte is not readable.

In addition to advancing the Receive Buffer Read Pointer, after each packet is fully processed, the application must set the PKTDEC bit (ECON2<6>). This causes the EPKTCNT register to decrement by 1. After decrementing, if EPKTCNT is '0', the PKTIF flag bit is automatically cleared. Otherwise, it remains set, indicating that additional packets are in the receive buffer and are waiting to be processed. Attempting to decrement EPKTCNT below 0 does not cause an underflow to 255, but may cause an unintentional interrupt; the application should avoid decrementing EPKTCNT in this situation.

Additionally, if the EPKTCNT register ever maximizes at 255, all new packets which are received will be aborted, even if buffer space is available. To indicate the error, the RXERIF is set and an interrupt is generated (if enabled). To prevent this condition, the user application must properly decrement the counter whenever a packet is processed. Because only one pointer is available to control buffer area ownership, the application must process packets in the order they are received. If a packet is to be saved and processed later, the application should copy the packet to an unused location in memory. This can be done efficiently using the integrated DMA controller (see **Section 18.9 "Direct Memory Access Controller"**).

18.5.3.4 Receive Buffer Free Space

At any time the application needs to know how much receive buffer space is remaining, it should read the Hardware Write Pointers (ERXWRPT registers) and compare it with the ERXRDPT registers. Combined with the known size of the receive buffer, the free space can be derived.

| Note: | The ERXWRPT registers only update when a packet has been successfully |
|-------|---|
| | received. If the application reads it just |
| | before another packet is to be successfully |
| | completed, the value returned could be |
| | stale and off by the maximum frame length |
| | permitted (MAMXFLH:MAMXFLL) plus 8. |
| | Furthermore, as the application reads one |
| | byte of the ERXWRPT registers, a new |
| | packet may arrive and update the 13-bit |
| | pointer before the application has an |
| | opportunity to read the other byte of the |
| | ERXWRPT registers. |

When reading the ERXWRPT registers with the receive hardware enabled, special care must be taken to ensure the low and high bytes are read as a matching set.

To be assured that a matching set is obtained:

- 1. Read the EPKTCNT register and save its contents.
- 2. Read ERXWRPTL and ERXWRPTH.
- 3. Read the EPKTCNT register again.
- 4. Compare the two packet counts. If they are not the same, go back to step 2.

With the Hardware Write Pointers obtained, the free space can be calculated as shown in Example 18-2. The hardware prohibits moving the Write Pointer to the same value occupied by the ERXRDPT registers, so at least one byte will always go unused in the buffer. The Equation 18-2 calculation reflects the lost byte.

EQUATION 18-2: RECEIVE BUFFER FREE SPACE CALCULATION

```
If ERXWRPT > ERXRDPT, then

Free Space = (ERXND – ERXST) – (ERXWRPT – ERXRDPT)

else

if ERXWRPT = ERXRDPT, then

Free Space = (ERXND – ERXST)

else

Free Space = ERXRDPT – ERXWRPT – 1
```

18.6 Duplex Mode Configuration and Negotiation

The Ethernet module does not support Automatic Duplex mode negotiation. If it is connected to an automatic duplex negotiation enabled network switch or Ethernet controller, the module will be detected as a half-duplex device. To communicate in full duplex, the module and the remote node (switch, router or Ethernet controller) must be manually configured for full-duplex operation.

18.6.1 HALF-DUPLEX OPERATION

The Ethernet module operates in Half-Duplex mode when the FULDPX (MACON3<0>) and PDPXMD (PHCON1<8>) bits are cleared (= 0). If only one of these two bits is set, the module will be in an indeterminate state and not function correctly. Since switching between Full and Half-Duplex modes may result in this indeterminate state, it is recommended that the application not transmit any packets (maintain the TXRTS bit clear), and disable packet reception (maintain the RXEN bit clear) during this period.

In Half-Duplex mode, only one Ethernet controller may be transmitting on the physical medium at any time. If the application requests a packet to be transmitted by setting the TXRTS bit while another Ethernet controller is already transmitting, the Ethernet module will delay, waiting for the remote transmitter to stop. When it stops, the module will attempt to transmit its packet. Should another Ethernet controller start transmitting at approximately the same time, the data on the wire will become corrupt and a collision will occur.

The hardware will handle this condition in one of two ways. If the collision occurs before 64 bytes have been transmitted, the following events occur:

- 1. the TXRTS bit remains set;
- 2. the transmit error interrupt does not occur;
- 3. a random exponential backoff delay elapses, as defined by the IEEE 802.3 specification;
- 4. a new attempt to transmit the packet from the beginning occurs. The application does not need to intervene.

If the number of retransmission attempts reaches 15 and another collision occurs, the packet is aborted and the TXRTS bit is cleared. The application will then be responsible for taking appropriate action. The application will be able to determine that the packet was aborted instead of being successfully transmitted by reading the TXABRT flag. For more information, see **Section 18.5.2 "Transmitting Packets"**.

If the collision occurs after 64 bytes have already been transmitted, the packet is immediately aborted without any retransmission attempts. Ordinarily, in IEEE 802.3 compliant networks which are properly configured, this late collision will not occur. User intervention may be required to correct the issue. This problem may occur as a result of a full-duplex node attempting to transmit on the half-duplex medium. Alternately, the module may be attempting to operate in Half-Duplex mode while it may be connected to a full-duplex network. Excessively long cabling and network size may also be a possible cause of late collisions.

18.6.2 FULL-DUPLEX OPERATION

The Ethernet module operates in Full-Duplex mode when the FULDPX (MACON3<0>) and PDPXMD (PHCON1<8>) bits are both set (= 1). If only one of these two bits is clear, the module will be in an indeterminate state and not function correctly. Again, since switching between Full and Half-Duplex modes may result in this indeterminate state, it is recommended that the application not transmit any packets and should disable packet reception during this period.

In Full-Duplex mode, packets will be transmitted while simultaneously packets may be received. Given this, it is impossible to cause any collisions when transmitting packets.

18.7 Flow Control

The Ethernet module implements hardware flow control for both Full and Half-Duplex modes. The operation of this feature differs depending on which mode is being used.

18.7.1 HALF-DUPLEX MODE

In Half-Duplex mode, setting the FCEN0 bit (EFLOCON<0>) causes flow control to be enabled. When FCEN0 is set, a continuous preamble pattern of alternating '1's and '0's (55h) will automatically be transmitted on the Ethernet medium. Any connected nodes will see the transmission and either not transmit anything, waiting for the transmission to end, or will attempt to transmit and immediately cause a collision. Because a collision will always occur, no nodes on the network will be able to communicate with each other and no new packets will arrive.

When the application causes the module to transmit a packet by setting the TXRTS bit, the preamble pattern will stop being transmitted. An inter-packet delay will pass as configured by register MABBIPG, and then the module will attempt to transmit its packet. After the inter-packet delay, other nodes may begin to transmit. Because all traffic was jammed previously, several nodes may begin transmitting and a series of collisions may occur. When the module successfully finishes transmitting its packet or aborts it, the transmission of the preamble pattern will automatically restart. When the application wishes to no longer jam the network, it should clear the FCEN0 bit. The preamble transmission will resume.

Given the detrimental network effects that are possible and lack of effectiveness, it is not recommend that half-duplex flow control be used unless the application will be in a closed network environment with proper testing.

18.7.2 FULL-DUPLEX MODE

In Full-Duplex mode (MACON3<0> = 1), hardware flow control is implemented by means of transmitting pause control frames, as defined by the IEEE 802.3 specification. Pause control frames are 64-byte frames consisting of the reserved Multicast destination address of 01-80-C2-00-00-01, the source address of the sender, a special pause opcode, a 2-byte pause timer value and padding/CRC.

Normally, when a pause control frame is received by a MAC, the MAC will finish the packet it is transmitting and then stop transmitting any new frames. The pause timer value will be extracted from the control frame and used to initialize an internal timer. The timer will automatically decrement every 512 bit times, or 51.2 μ s. While the timer is counting down, reception of packets is still enabled. If new pause frames arrive, the timer will be re-initialized with the new pause timer value.

When the timer reaches zero, or was sent a frame with a zero pause timer value, the MAC that received the pause frame will resume transmitting any pending packets. To prevent a pause frame from stopping all traffic on the entire network, Ethernet switches and routers do not propagate pause control frames in Full-Duplex mode. The pause operation only applies to the direct recipient.

A sample network is shown in Figure 18-11. If Computer A were to be transmitting too much data to the microcontroller-based application in Full-Duplex mode, the Ethernet module could transmit a pause control frame to stop the data which is being sent to it. The Ethernet Switch would take the pause frame and stop sending data to the application. If Computer A continues to send data, the Ethernet Switch will buffer the data so it can be transmitted later when its pause timer expires. If the Ethernet Switch begins to run out of buffer space, it will likely transmit a pause control frame of its own to Computer A.

If, for some reason the Ethernet Switch does not generate a pause control frame of its own, or one of the nodes does not properly handle the pause frame it receives, then packets will inevitably be dropped. In any event, any communication between Computer A and Computer B will always be completely unaffected.

FIGURE 18-11: SAMPLE FULL-DUPLEX NETWORK

To enable flow control in Full-Duplex mode, set the TXPAUS and RXPAUS bits in the MACON1 register. Then, at any time that the receiver buffer is running out of space, set the Flow Control Enable bits, FCEN1:FCEN0 (EFLOCON<1:0>). The module will automatically finish transmitting anything that was in progress and then send a valid pause frame loaded with the selected pause timer value. Depending on the mode selected, the application may need to eventually clear Flow Control mode by again writing to the FCEN bits.

When the RXPAUS bit is set and a valid pause frame arrives with a non-zero pause timer value, the module will automatically inhibit transmissions. If the TXRTS bit becomes set to send a packet, the hardware will simply wait until the pause timer expires before attempting to send the packet and subsequently, clearing the TXRTS bit. Normally, this is transparent to the microcontroller, and it will never know that a pause frame had been received. Should it be desirable to know when the MAC is paused or not, the user should set the PASSALL bit (MACON1<1>), then manually interpret the pause control frames which may arrive.

18.8 Receive Filters

To minimize microcontroller processing overhead, the Ethernet module incorporates a range of different receive filters which can automatically reject packets which are not needed. Six different types of packet filters are implemented:

- Unicast
- Multicast
- Broadcast
- Pattern Match
- Magic Packet[™]
- Hash Table

The individual filters are all configured by the ERXFCON register (Register 18-20). More than one filter can be active at any given time. Additionally, the filters can be configured by the ANDOR bit to either logically AND or logically OR the tests of several filters. In other words, the filters may be set so that only packets accepted by all active filters are accepted, or a packet accepted by any one filter is accepted. The flowcharts in Figure 18-12 and Figure 18-13 show the effect that each of the filters will have, depending on the setting of ANDOR.

The device can enter Promiscuous mode and receive all legal packets by setting the ERXFCON register to 20h (enabling only the CRC filter for valid packets). The proper setting of the register will depend on the application requirements.

18.8.1 UNICAST FILTER

The Unicast receive filter checks the destination address of all incoming packets. If the destination address exactly matches the contents of the MAADR registers, the packet meets the Unicast filter criteria.

18.8.2 MULTICAST FILTER

The Multicast receive filter checks the destination address of all incoming packets. If the Least Significant bit of the first byte of the destination address is set, the packet meets the Multicast filter criteria.

18.8.3 BROADCAST FILTER

The Broadcast receive filter checks the destination address of all incoming packets. If the destination address is FF-FF-FF-FF-FF, the packet meets the Broadcast filter criteria.

18.8.4 HASH TABLE FILTER

The Hash Table receive filter is typically used to receive traffic sent to a specific Multicast group address. Because it checks the specific destination address of packets, it is capable of filtering out more unwanted packets than the Multicast filter.

The filter performs a 32-bit CRC over the six destination address bytes in the packet, using the polynomial 4C11DB7h. From the resulting 32-bit binary number, a 6-bit value is derived from bits 28:23. This value in turn points to location in a table formed by the Ethernet Hash Table registers, ETH0 through ETH7. If the bit in that location is set, the packet meets the Hash Table filter criteria and is accepted. The specific pointer values for each bit location in the table are shown in Table 18-9.

An example of the Hash Table operation is shown in Example 18-1. In this case, the destination address 01-00-00-00-01-2C produces a Table Pointer value of 34h, which points to bit 4 of ETH6. If this bit is '1', the packet will be accepted.

By extension, clearing every bit in the Hash Table registers means that the filter criteria will never be met. Similarly, if every bit in the Hash Table is set, the filter criteria will always be met.

FIGURE 18-13: RECEIVE FILTERING USING AND LOGIC

18.8.5 PATTERN MATCH FILTER

The Pattern Match filter selects up to 64 bytes from the incoming packet and calculates an IP checksum of the bytes. The checksum is then compared to the EPMCS registers. The packet meets the Pattern Match filter criteria if the calculated checksum matches the EPMCS registers. The Pattern Match filter may be useful for filtering packets which have expected data inside them.

To use the Pattern Match filter, the application must program the Pattern Match offset (EPMOH:EPMOL), all of the Pattern Match mask bytes (EPMM0:EPMM7) and the Pattern Match Checksum register pair (EPMCSH:EPMCSL). The Pattern Match offset should be loaded with the offset from the beginning of the destination address field to the 64-byte window which will be used for the checksum computation. Within the 64-byte window, each individual byte can be selectively included or excluded from the checksum computation by setting or clearing the respective bit in the Pattern Match mask. If a packet is received which would cause the 64 byte window to extend past the end of the CRC, the filter criteria will immediately not be met, even if the corresponding mask bits are all '0'.

| Note: | In all cases, the value of the Pattern Match | | | | | |
|-------|--|--|--|--|--|--|
| | offset must be even for proper operation. | | | | | |
| | Programming the EMPO register pair with | | | | | |
| | an odd value will cause unpredictable | | | | | |
| | results. | | | | | |

The Pattern Match Checksum registers should be programmed to the checksum which is expected for the selected bytes. The checksum is calculated in the same manner that the DMA module calculates checksums (see **Section 18.9.2 "Checksum Calculations**"). Data bytes which have corresponding mask bits programmed to '0' are completely removed for purposes of calculating the checksum, as opposed to treating the data bytes as zero.

As an example, if the application wished to filter all packets having a particular source MAC address of 00-04-A3-FF-FF-FF, it could program the Pattern Match offset to 0000h and then set bits 6 and 7 of EPMM0 and bits 0, 1, 2 and 3 of EPMM1 (assuming all other mask bits are '0'). The proper checksum to program into the EPMCS registers would be 5BFCh. As an alternative configuration, it could program the offset to 0006h and set bits 0, 1, 2, 3, 4 and 5 of EPMM0. The checksum would still be 5BFCh. However, the second case would be less desirable as packets less than 70 bytes long could never meet the Pattern Match criteria, even if they would generate the proper checksum given the mask configuration.

Another example of a Pattern Match filter is illustrated in Figure 18-14.

FIGURE 18-14: SAMPLE PATTERN MATCH FORMAT

18.8.6 MAGIC PACKET FILTER

The Magic Packet pattern consists of a sync pattern of six FFh bytes, followed by 16 repeats of the destination address (Figure 18-15). The Magic Packet filter checks the destination address and data fields of all incoming packets. If the destination address matches the MAADR registers and the data field holds a valid Magic Packet pattern someplace within it, then the packet will meet the Magic Packet filter criteria.

18.9 Direct Memory Access Controller

The Ethernet module incorporates a dual purpose DMA controller, which can be used to copy data between locations within the 8-Kbyte memory buffer. It can also be used to calculate a 16-bit checksum which is compatible with various industry standard communication protocols, including TCP, UDP, IP, ICMP, etc.

The DMA is controlled using three pointers and several status/control bits:

- EDMASTH:EDMASTL: Source Start Address
- EDMANDH:EDMANDL: Source End Address
- EDMADSTH:EDMADSTL: Destination Start Address
- DMAST and CSUMEN (ECON1<5,4>): DMA Start/Busy and Checksum Enable bits
- DMAIE and DMAIF (EIE<5> and EIR<5>): DMA Interrupt Enable and Flag bits

The Source and End Pointers define what data will be copied or checksumed. The Destination Pointer, used only when copying data, defines where copied data will be placed. All three pointers are with respect to the 8-Kbyte Ethernet memory and cannot be used to access memory in the PIC[®] microcontroller data memory space.

When a DMA operation begins, the EDMAST register pair is copied into an Internal Source Pointer. The DMA will execute on one byte at a time and then increment the Internal Source Pointer. However, if a byte is processed and the Internal Source Pointer is equal to the Receive Buffer End Pointer pair, ERXND, the Source Pointer will not be incremented. Instead, the Internal Source Pointer will be loaded with the Receive Buffer Start Pointer pair, ERXST. In this way, the DMA will follow the circular FIFO structure of the receive buffer and received packets can be processed using one operation. The DMA operation will end when the Internal Source Pointer matches the EDMAND Pointers.

While any DMA operation is in progress, the DMA Pointers and the CSUMEN bit (ECON1<4>) should not be modified. The DMA operation can be canceled at any time by clearing the DMAST bit (ECON1<5>). No registers will change; however, some memory bytes may already have been copied if a DMA copy was in progress.

Some operational requirements must always be kept in mind when using the DMA. Failure to observe these requirements may result in loss of Ethernet buffer data, or even complete failure of Ethernet operation:

- If the EDMAND Pointers cannot be reached because of the receive buffer wrapping behavior, the DMA operation will never end.
- By design, the DMA module cannot be used to copy or calculate a checksum over only one byte (EDMAST = EDMAND). An attempt to do so may overwrite all memory in the buffer and never end.

- After termination of a DMA operation (DMAST is cleared by hardware or firmware), the application must not set DMAST again within 4 instruction cycles.
- To ensure reliable operation, avoid having the application access EDATA during a DMA copy operation. EDATA may be safely accessed during DMA checksum operations.

18.9.1 COPYING MEMORY

To copy memory within the buffer:

- Program the EDMAST, EDMAND, 1. and EDMADST register pairs with the appropriate start, end and destination addresses. The EDMAST registers should point to the first byte to copy from, the EDMAND registers should point to the last byte to copy and the EDMADST registers should point to the first byte in the destination range. The destination range will always be linear, never wrapping at any values except from 8191 to 0 (the 8-Kbyte memory boundary). Extreme care should be taken when calculating the End Pointer to prevent a never ending DMA operation which would overwrite the entire 8-Kbyte buffer.
- If desired, set the DMAIE (EIE<5>) and ETHIE (PIE2<5>) bits, and clear the DMAIF (EIR<5>) flag bit to enable an interrupt at the end of the copy process.
- 3. Clear the CSUMEN (ECON1<4>) bit.
- Start the DMA copy by setting the DMAST (ECON1<5>) bit.

If a transmit operation is in progress (TXRTS bit is set) while the DMAST bit is set, the module will wait until the transmit operation is complete before attempting to do the DMA copy. This possible delay is required because the DMA and transmission engine are unable to access the buffer at the same time.

When the copy is complete, the DMA hardware will clear the DMAST bit, set the DMAIF bit and generate an interrupt (if enabled). The pointers and the EDMACS registers will not be modified.

After the DMA module has been initialized and has begun its copy, one instruction cycle (TCY) will be required for each byte copied. However, if the Ethernet receive hardware accumulates one byte of data, the DMA will stall that cycle, yielding to the higher priority operation. If a maximum size, 1518-byte packet was copied while no other memory bandwidth was being used, the DMA module would require slightly more than 145.7 μ s to complete at a core frequency of 41.667 MHz. The time required to copy a minimum size packet of 64 bytes would be approximately 6.2 μ s (at 41.667 MHz) plus register configuration time.

18.9.2 CHECKSUM CALCULATIONS

The checksum calculation logic treats the source data as a series of 16-bit big-endian integers. If the source range contains an odd number of bytes, a padding byte of 00h is effectively added to the end of the series for purposes of calculating the checksum.

The calculated checksum is the 16-bit, one's complement of the one's complement sum of all 16-bit integers. For example, if the bytes included in the checksum were {89h, ABh, CDh}, the checksum would begin by computing 89ABh + CD00h. A carry out of the 16th bit would occur in the example, so in 16-bit one's complement arithmetic, it would be added back to the first bit. The resulting value of 56ACh would finally be complemented to achieve a checksum of A953h.

To calculate a checksum:

- 1. Set the EDMAST and EDMAND register pairs to point to the first and last bytes of buffer data to be included in the checksum. Care should be taken when programming these pointers to prevent a never-ending checksum calculation due to receive buffer wrapping.
- To generate an optional interrupt when the checksum calculation is done, set the DMAIE (EIE<5>) and ETHIE (PIE2<5>) bits and clear the DMAIF (EIR<5>) bit.
- 3. Start the calculation by setting the CSUMEN (ECON1<4>) and DMAST (ECON1<5>) bits.

When the checksum is finished being calculated, the hardware will clear the DMAST bit, set the DMAIF bit and an interrupt will be generated if enabled. The DMA Pointers will not be modified, and no memory will be written to. The EDMACSH and EDMACSL registers will contain the calculated checksum. The application may write this value into a packet, compare this value with zero (to validate a received block of data containing a checksum field in it), or compare it with some other checksum, such as a pseudo header checksum used in various protocols (TCP, UDP, etc.).

When operating the DMA in Checksum mode, it takes one instruction cycle (TCY) for every byte included in the checksum. As a result, if a checksum over 1446 bytes was performed, the DMA module would require slightly more than 138.8 μ s to complete the operation at 41.667 MHz.

At the same frequency, a small 20-byte header field would take approximately $1.9 \,\mu s$ plus DMA setup time to calculate a sum. These estimated times assume that the Ethernet receive hardware does not need memory access bandwidth and the CPU does not issue any reads or writes to the EDATA register while the DMA is computing.

Like the DMA Copy mode, the checksum operation will not start until the TXRTS bit (ECON1<3>) is clear. This may considerably increase the checksum calculation time if the application transmits a large packet and immediately attempts to validate a checksum on a received packet.

TABLE 18-10: SUMMARY OF REGISTERS ASSOCIATED WITH THE DMA CONTROLLER

Legend: — = unimplemented. Shaded cells are not used.

18.10 Module Resets

The Ethernet module provides selective module Resets:

- Transmit Only Reset
- Receive Only Reset

18.10.1 MICROCONTROLLER RESETS

Following any standard Reset event, the Ethernet module returns to a known state. The contents of the Ethernet buffer memory are unknown. All SFR and PHY registers are loaded with their specified Reset values, depending on the type of Reset event. However, the PHY registers must not be accessed until the PHY start-up timer has expired and the PHYRDY bit (ESTAT<0>) becomes set, or at least 1 ms has passed since the ETHEN bit was set. For more details, see **Section 18.1.3.1 "Start-up Timer"**.

18.10.2 TRANSMIT ONLY RESET

The Transmit Only Reset is performed by writing a '1' to the TXRST bit (ECON1<7>). This resets the transmit logic only. Other register and control blocks, such as buffer management and host interface, are not affected by a Transmit Only Reset event. To return to normal operation, the TXRST bit is cleared in software.

18.10.3 RECEIVE ONLY RESET

The Receive Only Reset is performed by writing a '1' to the RXRST bit (ECON1<6>). This action resets receive logic only. Other register and control blocks, such as the buffer management and host interface blocks, are not affected by a Receive Only Reset event. To return to normal operation, the RXRST bit is cleared in software.

19.0 MASTER SYNCHRONOUS SERIAL PORT (MSSP) MODULE

19.1 Master SSP (MSSP) Module Overview

The Master Synchronous Serial Port (MSSP) module is a serial interface, useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be serial EEPROMs, shift registers, display drivers, A/D converters, etc. The MSSP module can operate in one of two modes:

- Serial Peripheral Interface (SPI)
- Inter-Integrated Circuit (I²C[™])
 - Full Master mode
 - Slave mode (with general address call)

The $\mathrm{I}^2\mathrm{C}$ interface supports the following modes in hardware:

- Master mode
- Multi-Master mode
- Slave mode

The 64-pin and 80-pin devices of the PIC18F97J60 family have one MSSP module, designated as MSSP1. The 100-pin devices have two MSSP modules, designated as MSSP1 and MSSP2. Each module operates independently of the other.

| Note: | Throughout this section, generic refer- |
|-------|--|
| | ences to an MSSP module in any of its |
| | operating modes may be interpreted as |
| | being equally applicable to MSSP1 or |
| | MSSP2. Register names and module I/O |
| | signals use the generic designator 'x' to |
| | indicate the use of a numeral to distinguish |
| | a particular module when required. |
| | Control bit names are not individuated. |

19.2 Control Registers

Each MSSP module has three associated control registers. These include a status register (SSPxSTAT) and two control registers (SSPxCON1 and SSPxCON2). The use of these registers and their individual configuration bits differ significantly depending on whether the MSSP module is operating in SPI or I^2C mode.

Additional details are provided under the individual sections.

| Note: | In devices with more than one MSSP |
|-------|---|
| | module, it is very important to pay close |
| | attention to the SSPxCON register names. |
| | SSP1CON1 and SSP1CON2 control |
| | different operational aspects of the same |
| | module, while SSP1CON1 and |
| | SSP2CON1 control the same features for |
| | two different modules. |

19.3 SPI Mode

The SPI mode allows 8 bits of data to be synchronously transmitted and received simultaneously. All four modes of SPI are supported. To accomplish communication, typically three pins are used:

- Serial Data Out (SDOx) RC5/SDO1 (or RD4/SDO2 for 100-pin devices)
- Serial Data In (SDIx) RC4/SDI1/SDA1 (or RD5/SDI2/SDA2 for 100-pin devices)
- Serial Clock (SCKx) RC3/SCK1/SCL1 (or RD6/SCK2/SCL2 for 100-pin devices)

Additionally, a fourth pin may be used when in a Slave mode of operation:

 Slave Select (SSx) – RF7/SS1 (or RD7/SS2 for 100-pin devices)

Figure 19-1 shows the block diagram of the MSSP module when operating in SPI mode.

FIGURE 19-1:

MSSP BLOCK DIAGRAM (SPI MODE)

19.3.1 REGISTERS

Each MSSP module has four registers for SPI mode operation. These are:

- MSSPx Control Register 1 (SSPxCON1)
- MSSPx Status Register (SSPxSTAT)
- Serial Receive/Transmit Buffer Register (SSPxBUF)
- MSSPx Shift Register (SSPxSR) Not directly accessible

SSPxCON1 and SSPxSTAT are the control and status registers in SPI mode operation. The SSPxCON1 register is readable and writable. The lower 6 bits of the SSPxSTAT are read-only. The upper two bits of the SSPxSTAT are read/write. SSPxSR is the shift register used for shifting data in or out. SSPxBUF is the buffer register to which data bytes are written to or read from.

In receive operations, SSPxSR and SSPxBUF together create a double-buffered receiver. When SSPxSR receives a complete byte, it is transferred to SSPxBUF and the SSPxIF interrupt is set.

During transmission, the SSPxBUF is not double-buffered. A write to SSPxBUF will write to both SSPxBUF and SSPxSR.

19.3.2 OPERATION

When initializing the SPI, several options need to be specified. This is done by programming the appropriate control bits (SSPxCON1<5:0> and SSPxSTAT<7:6>). These control bits allow the following to be specified:

- Master mode (SCKx is the clock output)
- Slave mode (SCKx is the clock input)
- Clock Polarity (Idle state of SCKx)
- Data Input Sample Phase (middle or end of data output time)
- Clock Edge (output data on rising/falling edge of SCKx)
- Clock Rate (Master mode only)
- · Slave Select mode (Slave mode only)

Each MSSP module consists of a transmit/receive shift register (SSPxSR) and a buffer register (SSPxBUF). The SSPxSR shifts the data in and out of the device, MSb first. The SSPxBUF holds the data that was written to the SSPxSR until the received data is ready. Once the 8 bits of data have been received, that byte is moved to the SSPxBUF register. Then, the Buffer Full detect bit, BF (SSPxSTAT<0>), and the interrupt flag bit, SSPxIF, are set. This double-buffering of the received data (SSPxBUF) allows the next byte to start reception before reading the data that was just received. Any write to the SSPxBUF register during transmission/reception of data will be ignored and the Write Collision detect bit, WCOL (SSPxCON1<7>), will be set. User software must clear the WCOL bit so that it can be determined if the following write(s) to the SSPxBUF register completed successfully.

When the application software is expecting to receive valid data, the SSPxBUF should be read before the next byte of data to transfer is written to the SSPxBUF. The Buffer Full bit, BF (SSPxSTAT<0>), indicates when SSPxBUF has been loaded with the received data (transmission is complete). When the SSPxBUF is read, the BF bit is cleared. This data may be irrelevant if the SPI is only a transmitter. Generally, the MSSP interrupt is used to determine when the transmission/reception has completed. The SSPxBUF must be read and/or written. If the interrupt method is not going to be used, then software polling can be done to ensure that a write collision does not occur. Example 19-1 shows the loading of the SSP1BUF (SSP1SR) for data transmission.

The SSPxSR is not directly readable or writable and can only be accessed by addressing the SSPxBUF register. Additionally, the SSPxSTAT register indicates the various status conditions.

EXAMPLE 19-1: LOADING THE SSP1BUF (SSP1SR) REGISTER

| LOOP | BTFSS | SSP1STAT, BF | ;Has data been received (transmit complete)? |
|------|-------|--------------|--|
| | BRA | LOOP | ;No |
| | MOVF | SSP1BUF, W | ;WREG reg = contents of SSP1BUF |
| | MOVWF | RXDATA | ;Save in user RAM, if data is meaningful |
| | MOVF | TXDATA, W | ;W reg = contents of TXDATA |
| | MOVWF | SSP1BUF | ;New data to xmit |

19.3.3 ENABLING SPI I/O

To enable the serial port, MSSP Enable bit, SSPEN (SSPxCON1<5>), must be set. To reset or reconfigure SPI mode, clear the SSPEN bit, reinitialize the SSPxCON registers and then set the SSPEN bit. This configures the SDIx, SDOx, SCKx and SSx pins as serial port pins. For the pins to behave as the serial port function, some must have their data direction bits (in the TRIS register) appropriately programmed as follows:

- SDIx is automatically controlled by the SPI module
- SDOx must have TRISC<5> (or TRISD<4>) bit cleared
- SCKx (Master mode) must have TRISC<3> (or TRISD<6>) bit cleared
- SCKx (Slave mode) must have TRISC<3> (or TRISD<6>) bit set
- SSx must have TRISF<7> (or TRISD<7>) bit set

Any serial port function that is not desired may be overridden by programming the corresponding data direction (TRIS) register to the opposite value.

19.3.4 TYPICAL CONNECTION

Figure 19-2 shows a typical connection between two microcontrollers. The master controller (Processor 1) initiates the data transfer by sending the SCKx signal. Data is shifted out of both shift registers on their programmed clock edge and latched on the opposite edge of the clock. Both processors should be programmed to the same Clock Polarity (CKP), then both controllers would send and receive data at the same time. Whether the data is meaningful (or dummy data) depends on the application software. This leads to three scenarios for data transmission:

- Master sends data Slave sends dummy data
- Master sends data Slave sends data
- Master sends dummy data Slave sends data

FIGURE 19-2: SPI MASTER/SLAVE CONNECTION

19.3.5 MASTER MODE

The master can initiate the data transfer at any time because it controls the SCKx. The master determines when the slave (Processor 2, Figure 19-2) will broadcast data by the software protocol.

In Master mode, the data is transmitted/received as soon as the SSPxBUF register is written to. If the SPI is only going to receive, the SDOx output could be disabled (programmed as an input). The SSPxSR register will continue to shift in the signal present on the SDIx pin at the programmed clock rate. As each byte is received, it will be loaded into the SSPxBUF register as if a normal received byte (interrupts and status bits appropriately set). This could be useful in receiver applications as a "Line Activity Monitor" mode. The clock polarity is selected by appropriately programming the CKP bit (SSPxCON1<4>). This then, would give waveforms for SPI communication as shown in Figure 19-3, Figure 19-5 and Figure 19-6, where the MSB is transmitted first. In Master mode, the SPI clock rate (bit rate) is user-programmable to be one of the following:

- Fosc/4 (or Tcy)
- Fosc/16 (or 4 Tcy)
- Fosc/64 (or 16 Tcy)
- Timer2 output/2

This allows a maximum data rate (at 40 MHz) of 10.00 Mbps.

Figure 19-3 shows the waveforms for Master mode. When the CKE bit is set, the SDOx data is valid before there is a clock edge on SCKx. The change of the input sample is shown based on the state of the SMP bit. The time when the SSPxBUF is loaded with the received data is shown.

FIGURE 19-3: SPI MODE WAVEFORM (MASTER MODE)

19.3.6 SLAVE MODE

In Slave mode, the data is transmitted and received as the external clock pulses appear on SCKx. When the last bit is latched, the SSPxIF interrupt flag bit is set.

Before enabling the module in SPI Slave mode, the clock line must match the proper Idle state. The clock line can be observed by reading the SCKx pin. The Idle state is determined by the CKP bit (SSPxCON1<4>).

While in Slave mode, the external clock is supplied by the external clock source on the SCKx pin. This external clock must meet the minimum high and low times as specified in the electrical specifications.

While in Sleep mode, the slave can transmit/receive data. When a byte is received, the device will wake-up from Sleep.

19.3.7 SLAVE SELECT SYNCHRONIZATION

The \overline{SSx} pin allows a Synchronous Slave mode. The SPI must be in Slave mode with \overline{SSx} pin control enabled (SSPxCON1<3:0> = 04h). When the \overline{SSx} pin is low, transmission and reception are enabled and the

SDOx pin is driven. When the SSx pin goes high, the SDOx pin is no longer driven, even if in the middle of a transmitted byte, and becomes a floating output. External pull-up/pull-down resistors may be desirable depending on the application.

- Note 1: When the SPI is in Slave mode with SSx pin control enabled (SSPxCON1<3:0> = 0100), the SPI module will reset if the SSx pin is set to VDD.
 - 2: If the SPI is used in Slave mode with CKE set, then the SSx pin control must be enabled.

When the SPI module resets, the bit counter is forced to '0'. This can be done by either forcing the SSx pin to a high level or clearing the SSPEN bit.

To emulate two-wire communication, the SDOx pin can be connected to the SDIx pin. When the SPI needs to operate as a receiver, the SDOx pin can be configured as an input. This disables transmissions from the SDOx. The SDIx can always be left as an input (SDIx function) since it cannot create a bus conflict.

FIGURE 19-4: SLAVE SYNCHRONIZATION WAVEFORM

FIGURE 19-5: SPI MODE WAVEFORM (SLAVE MODE WITH CKE = 0)

FIGURE 19-6: SPI MODE WAVEFORM (SLAVE MODE WITH CKE = 1)

19.3.8 OPERATION IN POWER-MANAGED MODES

In SPI Master mode, module clocks may be operating at a different speed than when in full power mode. In the case of Sleep mode, all clocks are halted.

In Idle modes, a clock is provided to the peripherals. That clock should be from the primary clock source, the secondary clock (Timer1 oscillator at 32.768 kHz) or the INTRC source. See **Section 2.7 "Clock Sources and Oscillator Switching**" for additional information.

In most cases, the speed that the master clocks SPI data is not important; however, this should be evaluated for each system.

If MSSP interrupts are enabled, they can wake the controller from Sleep mode, or one of the Idle modes, when the master completes sending data. If an exit from Sleep or Idle mode is not desired, MSSP interrupts should be disabled.

If the Sleep mode is selected, all module clocks are halted and the transmission/reception will remain in that state until the devices wakes. After the device returns to Run mode, the module will resume transmitting and receiving data.

In SPI Slave mode, the SPI Transmit/Receive Shift register operates asynchronously to the device. This allows the device to be placed in any power-managed mode and data to be shifted into the SPI Transmit/Receive Shift register. When all 8 bits have been received, the MSSP interrupt flag bit will be set, and if enabled, will wake the device.

19.3.9 EFFECTS OF A RESET

A Reset disables the MSSP module and terminates the current transfer.

19.3.10 BUS MODE COMPATIBILITY

Table 19-1 shows the compatibility between the standard SPI modes and the states of the CKP and CKE control bits.

TABLE 19-1:SPI BUS MODES

| Standard SPI Mode | Control Bits State | | | |
|-------------------|--------------------|-----|--|--|
| Terminology | СКР | CKE | | |
| 0, 0 | 0 | 1 | | |
| 0, 1 | 0 | 0 | | |
| 1, 0 | 1 | 1 | | |
| 1, 1 | 1 | 0 | | |

There is also an SMP bit which controls when the data is sampled.

19.3.11 SPI CLOCK SPEED AND MODULE INTERACTIONS

Because MSSP1 and MSSP2 are independent modules, they can operate simultaneously at different data rates. Setting the SSPM3:SSPM0 bits of the SSPxCON1 register determines the rate for the corresponding module.

An exception is when both modules use Timer2 as a time base in Master mode. In this instance, any changes to the Timer2 operation will affect both MSSP modules equally. If different bit rates are required for each module, the user should select one of the other three time base options for one of the modules.

TABLE 19-2: REGISTERS ASSOCIATED WITH SPI OPERATION

Legend: Shaded cells are not used by the MSSP module in SPI mode.

Note 1: These bits are only available in 100-pin devices; otherwise, they are unimplemented and read as '0'.

19.4 I²C Mode

The MSSP module in I²C mode fully implements all master and slave functions (including general call support) and provides interrupts on Start and Stop bits in hardware to determine a free bus (multi-master function). The MSSP module implements the standard mode specifications, as well as 7-bit and 10-bit addressing.

Two pins are used for data transfer:

- Serial clock (SCLx) RC3/SCK1/SCL1 (or RD6/SCK2/SCL2 for 100-pin devices)
- Serial data (SDAx) RC4/SDI1/SDA1 (or RD5/SDI2/SDA2 for 100-pin devices)

The user must configure these pins as inputs by setting the TRISC<4:3> or TRISD<5:4> bits.

FIGURE 19-7: MSSP BLOCK DIAGRAM (I²C[™] MODE)

19.4.1 REGISTERS

The MSSP module has six registers for $\mathsf{I}^2\mathsf{C}$ operation. These are:

- MSSPx Control Register 1 (SSPxCON1)
- MSSPx Control Register 2 (SSPxCON2)
- MSSPx Status Register (SSPxSTAT)
- MSSPx Receive Buffer/Transmit Register (SSPxBUF)
- MSSPx Shift Register (SSPxSR) Not directly accessible
- MSSPx Address Register (SSPxADD)

SSPxCON1, SSPxCON2 and SSPxSTAT are the control and status registers in I^2C mode operation. The SSPxCON1 and SSPxCON2 registers are readable and writable. The lower 6 bits of the SSPxSTAT are read-only. The upper two bits of the SSPxSTAT are read/write.

Many of the bits in SSPxCON2 assume different functions, depending on whether the module is operating in Master or Slave mode. SSPxCON2<5:1> also assume different names in Slave mode. The different aspects of SSPxCON2 are shown in Register 19-5 (for Master mode) and Register 19-6 (Slave mode).

SSPxSR is the shift register used for shifting data in or out. SSPxBUF is the buffer register to which data bytes are written to or read from.

SSPxADD register holds the slave device address when the MSSP is configured in I^2C Slave mode. When the MSSP is configured in Master mode, the lower seven bits of SSPxADD act as the Baud Rate Generator reload value.

In receive operations, SSPxSR and SSPxBUF together create a double-buffered receiver. When SSPxSR receives a complete byte, it is transferred to SSPxBUF and the SSPxIF interrupt is set.

During transmission, the SSPxBUF is not double-buffered. A write to SSPxBUF will write to both SSPxBUF and SSPxSR.

REGISTER 19-6: SSPxCON2: MSSPx CONTROL REGISTER 2 (I²C[™] SLAVE MODE)

Note 1: If the I²C module is active, this bit may not be set (no spooling) and the SSPxBUF may not be written (or writes to the SSPxBUF are disabled).

19.4.2 OPERATION

The MSSP module functions are enabled by setting the MSSP Enable bit, SSPEN (SSPxCON1<5>).

The SSPxCON1 register allows control of the I^2C operation. Four mode selection bits (SSPxCON1<3:0>) allow one of the following I^2C modes to be selected:

- I²C Master mode, clock = (FOSC/4) x (SSPxADD + 1)
- I²C Slave mode (7-bit addressing)
- I²C Slave mode (10-bit addressing)
- I²C Slave mode (7-bit addressing) with Start and Stop bit interrupts enabled
- I²C Slave mode (10-bit addressing) with Start and Stop bit interrupts enabled
- I²C Firmware Controlled Master mode, slave is Idle

Selection of any I²C mode, with the SSPEN bit set, forces the SCLx and SDAx pins to be open-drain, provided these pins are programmed to inputs by setting the appropriate TRISC or TRISD bits. To ensure proper operation of the module, pull-up resistors must be provided externally to the SCLx and SDAx pins.

19.4.3 SLAVE MODE

In Slave mode, the SCLx and SDAx pins must be configured as inputs (TRISC<4:3> or TRISD<5:4> are set). The MSSP module will override the input state with the output data when required (slave-transmitter).

The I^2C Slave mode hardware will always generate an interrupt on an exact address match. In addition, address masking will also allow the hardware to generate an interrupt for more than one address (up to 31 in 7-bit addressing, and up to 63 in 10-bit addressing). Through the mode select bits, the user can also choose to interrupt on Start and Stop bits.

When an address is matched, or the data transfer after an address match is received, the hardware automatically will generate the Acknowledge (\overline{ACK}) pulse and load the SSPxBUF register with the received value currently in the SSPxSR register.

Any combination of the following conditions will cause the MSSP module not to give this ACK pulse:

- The Buffer Full bit, BF (SSPxSTAT<0>), was set before the transfer was received.
- The MSSP Overflow bit, SSPOV (SSPxCON1<6>), was set before the transfer was received.

In this case, the SSPxSR register value is not loaded into the SSPxBUF, but bit SSPxIF is set. The BF bit is cleared by reading the SSPxBUF register, while bit SSPOV is cleared through software. The SCLx clock input must have a minimum high and low for proper operation. The high and low times of the I^2C specification, as well as the requirement of the MSSP module, are shown in timing parameter 100 and parameter 101.

19.4.3.1 Addressing

Once the MSSP module has been enabled, it waits for a Start condition to occur. Following the Start condition, the 8 bits are shifted into the SSPxSR register. All incoming bits are sampled with the rising edge of the clock (SCLx) line. The value of register SSPxSR<7:1> is compared to the value of the SSPxADD register. The address is compared on the falling edge of the eighth clock (SCLx) pulse. If the addresses match and the BF and SSPOV bits are clear, the following events occur:

- 1. The SSPxSR register value is loaded into the SSPxBUF register.
- 2. The Buffer Full bit, BF, is set.
- 3. An ACK pulse is generated.
- 4. The MSSP Interrupt Flag bit, SSPxIF, is set (and the interrupt is generated, if enabled) on the falling edge of the ninth SCLx pulse.

In 10-Bit Addressing mode, two address bytes need to be received by the slave. The five Most Significant bits (MSbs) of the first address byte specify if this is a 10-bit address. Bit R/\overline{W} (SSPxSTAT<2>) must specify a write so the slave device will receive the second address byte. For a 10-bit address, the first byte would equal '11110 A9 A8 0', where 'A9' and 'A8' are the two MSbs of the address. The sequence of events for 10-bit addressing is as follows, with steps 7 through 9 for the slave-transmitter:

- 1. Receive first (high) byte of address (bits SSPxIF, BF and UA are set).
- 2. Update the SSPxADD register with second (low) byte of address (clears bit UA and releases the SCLx line).
- 3. Read the SSPxBUF register (clears bit BF) and clear flag bit, SSPxIF.
- 4. Receive second (low) byte of address (bits SSPxIF, BF and UA are set).
- 5. Update the SSPxADD register with the first (high) byte of address. If match releases SCLx line, this will clear bit UA.
- 6. Read the SSPxBUF register (clears bit BF) and clear flag bit, SSPxIF.
- 7. Receive Repeated Start condition.
- 8. Receive first (high) byte of address (bits SSPxIF and BF are set).
- 9. Read the SSPxBUF register (clears bit BF) and clear flag bit SSPxIF.

19.4.3.2 Address Masking

Masking an address bit causes that bit to become a "don't care". When one address bit is masked, two addresses will be Acknowledged and cause an interrupt. It is possible to mask more than one address bit at a time, which makes it possible to Acknowledge up to 31 addresses in 7-bit mode, and up to 63 addresses in 10-bit mode (see Example 19-2).

The l^2C Slave behaves the same way whether address masking is used or not. However, when address masking is used, the l^2C slave can Acknowledge multiple addresses and cause interrupts. When this occurs, it is necessary to determine which address caused the interrupt by checking SSPxBUF.

In 7-Bit Addressing mode, address mask bits, ADMSK<5:1> (SSPxCON2<5:1>), mask the corresponding address bits in the SSPxADD register. For any ADMSK bits that are set (ADMSK<n> = 1), the corresponding address bit is ignored (SSPxADD<n> = x). For the module to issue an address Acknowledge, it is sufficient to match only on addresses that do not have an active address mask.

In 10-Bit Addressing mode, bits ADMSK<5:2> mask the corresponding address bits in the SSPxADD register. In addition, ADMSK1 simultaneously masks the two LSbs of the address (SSPxADD<1:0>). For any ADMSK bits that are active (ADMSK<n> = 1), the corresponding address bit is ignored (SSPxADD<n> = x). Also note, that although in 10-Bit Addressing mode, the upper address bits reuse part of the SSPxADD register bits. The address mask bits do not interact with those bits; they only affect the lower address bits.

- Note 1: ADMSK1 masks the two Least Significant bits of the address.
 - The two Most Significant bits of the address are not affected by address masking.

EXAMPLE 19-2: ADDRESS MASKING EXAMPLES

7-Bit Addressing:

SSPxADD<7:1> = A0h (1010000) (SSPxADD<0> is assumed to be '0') ADMSK<5:1> = 00111

Addresses Acknowledged: A0h, A2h, A4h, A6h, A8h, AAh, ACh, AEh

10-Bit Addressing:

SSPxADD<7:0> = A0h (10100000) (the two MSb of the address are ignored in this example since they are not affected by masking) ADMSK<5:1> = 00111

Addresses Acknowledged: A0h, A1h, A2h, A3h, A4h, A5h, A6h, A7h, A8h, A9h, AAh, ABh, ACh, ADh, AEh, AFh

19.4.3.3 Reception

When the R/W bit of the address byte is clear and an address match occurs, the R/W bit of the SSPxSTAT register is cleared. The received address is loaded into the SSPxBUF register and the SDAx line is held low (ACK).

When the address byte overflow condition exists, then the no Acknowledge (ACK) pulse is given. An overflow condition is defined as either bit BF (SSPxSTAT<0>) is set, or bit SSPOV (SSPxCON1<6>) is set.

An MSSP interrupt is generated for each data transfer byte. The interrupt flag bit, SSPxIF, must be cleared in software. The SSPxSTAT register is used to determine the status of the byte.

If SEN is enabled (SSPxCON2<0> = 1), SCKx/SCLx (RC3 or RD6) will be held low (clock stretch) following each data transfer. The clock must be released by setting bit, CKP (SSPxCON1<4>). See **Section 19.4.4** "**Clock Stretching**" for more details.

19.4.3.4 Transmission

When the R/W bit of the incoming address byte is set and an address match occurs, the R/W bit of the SSPxSTAT register is set. The received address is loaded into the SSPxBUF register. The ACK pulse will be sent on the ninth bit and pin RC3 or RD6 is held low, regardless of SEN (see **Section 19.4.4** "**Clock Stretching**" for more details). By stretching the clock, the master will be unable to assert another clock pulse until the slave is done preparing the transmit data. The transmit data must be loaded into the SSPxBUF register which also loads the SSPxSR register. Then, pin RC3 or RD6 should be enabled by setting bit, CKP (SSPxCON1<4>). The eight data bits are shifted out on the falling edge of the SCLx input. This ensures that the SDAx signal is valid during the SCLx high time (Figure 19-10).

The ACK pulse from the master-receiver is latched on the rising edge of the ninth SCLx input pulse. If the SDAx line is high (not ACK), then the data transfer is complete. In this case, when the ACK is latched by the slave, the slave logic is reset (resets SSPxSTAT register) and the slave monitors for another occurrence of the Start bit. If the SDAx line was low (ACK), the next transmit data must be loaded into the SSPxBUF register. Again, pin RC3 or RD6 must be enabled by setting bit CKP.

An MSSP interrupt is generated for each data transfer byte. The SSPxIF bit must be cleared in software and the SSPxSTAT register is used to determine the status of the byte. The SSPxIF bit is set on the falling edge of the ninth clock pulse.

FIGURE 19-9: I²C[™] SLAVE MODE TIMING WITH SEN = 0 AND ADMSK<5:1> = 01011 (RECEPTION, 7-BIT ADDRESS)

FIGURE 19-12: I²C[™] SLAVE MODE TIMING WITH SEN = 0 AND ADMSK<5:1> = 01001 (RECEPTION, 10-BIT ADDRESS)

19.4.4 CLOCK STRETCHING

Both 7-Bit and 10-Bit Slave modes implement automatic clock stretching during a transmit sequence.

The SEN bit (SSPxCON2<0>) allows clock stretching to be enabled during receives. Setting SEN will cause the SCLx pin to be held low at the end of each data receive sequence.

19.4.4.1 Clock Stretching for 7-Bit Slave Receive Mode (SEN = 1)

In 7-Bit Slave Receive mode, on the falling edge of the ninth clock at the end of the ACK sequence, if the BF bit is set, the CKP bit in the SSPxCON1 register is automatically cleared, forcing the SCLx output to be held low. The CKP being cleared to '0' will assert the SCLx line low. The CKP bit must be set in the user's ISR before reception is allowed to continue. By holding the SCLx line low, the user has time to service the ISR and read the contents of the SSPxBUF before the master device can initiate another receive sequence. This will prevent buffer overruns from occurring (see Figure 19-15).

- Note 1: If the user reads the contents of the SSPxBUF before the falling edge of the ninth clock, thus clearing the BF bit, the CKP bit will not be cleared and clock stretching will not occur.
 - 2: The CKP bit can be set in software regardless of the state of the BF bit. The user should be careful to clear the BF bit in the ISR before the next receive sequence in order to prevent an overflow condition.

19.4.4.2 Clock Stretching for 10-Bit Slave Receive Mode (SEN = 1)

In 10-Bit Slave Receive mode during the address sequence, clock stretching automatically takes place but CKP is not cleared. During this time, if the UA bit is set after the ninth clock, clock stretching is initiated. The UA bit is set after receiving the upper byte of the 10-bit address and following the receive of the second byte of the 10-bit address with the R/W bit cleared to '0'. The release of the clock line occurs upon updating SSPxADD. Clock stretching will occur on each data receive sequence as described in 7-bit mode.

Note: If the user polls the UA bit and clears it by updating the SSPxADD register before the falling edge of the ninth clock occurs and if the user hasn't cleared the BF bit by reading the SSPxBUF register before that time, then the CKP bit will still NOT be asserted low. Clock stretching on the basis of the state of the BF bit only occurs during a data sequence, not an address sequence.

19.4.4.3 Clock Stretching for 7-Bit Slave Transmit Mode

The 7-Bit Slave Transmit mode implements clock stretching by clearing the CKP bit after the falling edge of the ninth clock, if the BF bit is clear. This occurs regardless of the state of the SEN bit.

The user's ISR must set the CKP bit before transmission is allowed to continue. By holding the SCLx line low, the user has time to service the ISR and load the contents of the SSPxBUF before the master device can initiate another transmit sequence (see Figure 19-10).

- Note 1: If the user loads the contents of SSPxBUF, setting the BF bit before the falling edge of the ninth clock, the CKP bit will not be cleared and clock stretching will not occur.
 - 2: The CKP bit can be set in software regardless of the state of the BF bit.

19.4.4.4 Clock Stretching for 10-Bit Slave Transmit Mode

In 10-Bit Slave Transmit mode, clock stretching is controlled during the first two address sequences by the state of the UA bit, just as it is in 10-Bit Slave Receive mode. The first two addresses are followed by a third address sequence which contains the high-order bits of the 10-bit address and the R/W bit set to '1'. After the third address sequence is performed, the UA bit is not set, the module is now configured in Transmit mode and clock stretching is controlled by the BF flag as in 7-Bit Slave Transmit mode (see Figure 19-13).

19.4.4.5 Clock Synchronization and the CKP bit

When the CKP bit is cleared, the SCLx output is forced to '0'. However, clearing the CKP bit will not assert the SCLx output low until the SCLx output is already sampled low. Therefore, the CKP bit will not assert the SCLx line until an external I^2C master device has

already asserted the SCLx line. The SCLx output will remain low until the CKP bit is set and all other devices on the I^2 C bus have deasserted SCLx. This ensures that a write to the CKP bit will not violate the minimum high time requirement for SCLx (see Figure 19-14).

DS39762B-page 280

19.4.5 GENERAL CALL ADDRESS SUPPORT

The addressing procedure for the I^2C bus is such that the first byte after the Start condition usually determines which device will be the slave addressed by the master. The exception is the general call address, which can address all devices. When this address is used, all devices should, in theory, respond with an Acknowledge.

The general call address is one of eight addresses reserved for specific purposes by the I^2C protocol. It consists of all '0's with R/W = 0.

The general call address is recognized when the General Call Enable bit, GCEN, is enabled (SSPxCON2<7> set). Following a Start bit detect, 8 bits are shifted into the SSPxSR and the address is compared against the SSPxADD. It is also compared to the general call address and fixed in hardware.

If the general call address matches, the SSPxSR is transferred to the SSPxBUF, the BF flag bit is set (eighth bit) and on the falling edge of the ninth bit (ACK bit), the SSPxIF interrupt flag bit is set.

When the interrupt is serviced, the source for the interrupt can be checked by reading the contents of the SSPxBUF. The value can be used to determine if the address was device specific or a general call address.

In 10-Bit Addressing mode, the SSPxADD is required to be updated for the second half of the address to match and the UA bit is set (SSPxSTAT<1>). If the general call address is sampled when the GCEN bit is set, while the slave is configured in 10-Bit Addressing mode, then the second half of the address is not necessary, the UA bit will not be set and the slave will begin receiving data after the Acknowledge (Figure 19-17).

19.4.6 MASTER MODE

Master mode is enabled by setting and clearing the appropriate SSPM bits in SSPxCON1 and by setting the SSPEN bit. In Master mode, the SCLx and SDAx lines are manipulated by the MSSP hardware.

Master mode of operation is supported by interrupt generation on the detection of the Start and Stop conditions. The Stop (P) and Start (S) bits are cleared from a Reset or when the MSSP module is disabled. Control of the I^2C bus may be taken when the P bit is set, or the bus is Idle, with both the S and P bits clear.

In Firmware Controlled Master mode, user code conducts all I^2C bus operations based on Start and Stop bit conditions.

Once Master mode is enabled, the user has six options.

- 1. Assert a Start condition on SDAx and SCLx.
- 2. Assert a Repeated Start condition on SDAx and SCLx.
- 3. Write to the SSPxBUF register initiating transmission of data/address.
- 4. Configure the I²C port to receive data.
- 5. Generate an Acknowledge condition at the end of a received byte of data.
- 6. Generate a Stop condition on SDAx and SCLx.

Note: The MSSP module, when configured in I²C Master mode, does not allow queueing of events. For instance, the user is not allowed to initiate a Start condition and immediately write the SSPxBUF register to initiate transmission before the Start condition is complete. In this case, the SSPxBUF will not be written to and the WCOL bit will be set, indicating that a write to the SSPxBUF did not occur.

The following events will cause the MSSP Interrupt Flag bit, SSPxIF, to be set (and MSSP interrupt, if enabled):

- Start Condition
- Stop Condition
- Data Transfer Byte Transmitted/Received
- Acknowledge Transmit
- Repeated Start

FIGURE 19-18: MSSP BLOCK DIAGRAM (I²C™ MASTER MODE)

19.4.6.1 I²C Master Mode Operation

The master device generates all of the serial clock pulses and the Start and Stop conditions. A transfer is ended with a Stop condition or with a Repeated Start condition. Since the Repeated Start condition is also the beginning of the next serial transfer, the I²C bus will not be released.

In Master Transmitter mode, serial data is output through SDAx, while SCLx outputs the serial clock. The first byte transmitted contains the slave address of the receiving device (7 bits) and the Read/Write (R/W) bit. In this case, the R/W bit will be logic '0'. Serial data is transmitted 8 bits at a time. After each byte is transmitted, an Acknowledge bit is received. Start and Stop conditions are output to indicate the beginning and the end of a serial transfer.

In Master Receive mode, the first byte transmitted contains the slave address of the transmitting device (7 bits) and the R/W bit. In this case, the R/W bit will be logic '1'. Thus, the first byte transmitted is a 7-bit slave address followed by a '1' to indicate the receive bit. Serial data is received via SDAx, while SCLx outputs the serial clock. Serial data is received 8 bits at a time. After each byte is received, an Acknowledge bit is transmitted. Start and Stop conditions indicate the beginning and end of transmission.

The Baud Rate Generator used for the SPI mode operation is used to set the SCLx clock frequency for either 100 kHz, 400 kHz or 1 MHz I²C operation. See **Section 19.4.7** "**Baud Rate**" for more detail.

A typical transmit sequence would go as follows:

- 1. The user generates a Start condition by setting the Start Enable bit, SEN (SSPxCON2<0>).
- SSPxIF is set. The MSSP module will wait the required start time before any other operation takes place.
- 3. The user loads the SSPxBUF with the slave address to transmit.
- 4. Address is shifted out on the SDAx pin until all 8 bits are transmitted.
- 5. The MSSP module shifts in the ACK bit from the slave device and writes its value into the SSPxCON2 register (SSPxCON2<6>).
- 6. The MSSP module generates an interrupt at the end of the ninth clock cycle by setting the SSPxIF bit.
- 7. The user loads the SSPxBUF with eight bits of data.
- 8. Data is shifted out on the SDAx pin until all 8 bits are transmitted.
- The MSSP module shifts in the ACK bit from the slave device and writes its value into the SSPxCON2 register (SSPxCON2<6>).
- 10. The MSSP module generates an interrupt at the end of the ninth clock cycle by setting the SSPxIF bit.
- 11. The user generates a Stop condition by setting the Stop Enable bit, PEN (SSPxCON2<2>).
- 12. Interrupt is generated once the Stop condition is complete.

19.4.7 BAUD RATE

In I²C Master mode, the Baud Rate Generator (BRG) reload value is placed in the lower 7 bits of the SSPxADD register (Figure 19-19). When a write occurs to SSPxBUF, the Baud Rate Generator will automatically begin counting. The BRG counts down to 0 and stops until another reload has taken place. The BRG count is decremented twice per instruction cycle (TcY) on the Q2 and Q4 clocks. In I²C Master mode, the BRG is reloaded automatically.

Once the given operation is complete (i.e., transmission of the last data bit is followed by \overline{ACK}), the internal clock will automatically stop counting and the SCLx pin will remain in its last state.

Table 19-3 demonstrates clock rates based on instruction cycles and the BRG value loaded into SSPxADD.

19.4.7.1 Baud Rate and Module Interdependence

Because MSSP1 and MSSP2 are independent, they can operate simultaneously in I²C Master mode at different baud rates. This is done by using different BRG reload values for each module.

Because this mode derives its basic clock source from the system clock, any changes to the clock will affect both modules in the same proportion. It may be possible to change one or both baud rates back to a previous value by changing the BRG reload value.

FIGURE 19-19: BAUD RATE GENERATOR BLOCK DIAGRAM

TABLE 19-3: I²C[™] CLOCK RATE w/BRG

| Fosc | BRG Value | FscL (2 Rollovers of BRG) |
|------------|-----------|------------------------------|
| 41.667 MHz | 19h | 400 kHz ⁽¹⁾ |
| 41.667 MHz | 67h | 100 kHz |
| 31.25 MHz | 13h | 400 kHz ⁽¹⁾ |
| 31.25 MHz | 4Dh | 100 kHz |
| 20.833 MHz | 09h | 400 kHz ⁽¹⁾ |
| 20.833 MHz | 33h | 100 kHz |

Note 1: The I²C[™] interface does not conform to the 400 kHz I²C specification (which applies to rates greater than 100 kHz) in all details, but may be used with care where higher rates are required by the application.

19.4.7.2 Clock Arbitration

Clock arbitration occurs when the master, during any receive, transmit or Repeated Start/Stop condition, deasserts the SCLx pin (SCLx allowed to float high). When the SCLx pin is allowed to float high, the Baud Rate Generator (BRG) is suspended from counting until the SCLx pin is actually sampled high. When the SCLx pin is sampled high, the Baud Rate Generator is reloaded with the contents of SSPxADD<6:0> and begins counting. This ensures that the SCLx high time will always be at least one BRG rollover count in the event that the clock is held low by an external device (Figure 19-20).

19.4.8 I²C MASTER MODE START CONDITION TIMING

To initiate a Start condition, the user sets the Start Enable bit, SEN (SSPxCON2<0>). If the SDAx and SCLx pins are sampled high, the Baud Rate Generator is reloaded with the contents of SSPxADD<6:0> and starts its count. If SCLx and SDAx are both sampled high when the Baud Rate Generator times out (TBRG), the SDAx pin is driven low. The action of the SDAx being driven low while SCLx is high is the Start condition and causes the S bit (SSPxSTAT<3>) to be set. Following this, the Baud Rate Generator is reloaded with the contents of SSPxADD<6:0> and resumes its count. When the Baud Rate Generator times out (TBRG), the SEN bit (SSPxCON2<0>) will be automatically cleared by hardware. The Baud Rate Generator is suspended, leaving the SDAx line held low and the Start condition is complete.

Note: If, at the beginning of the Start condition, the SDAx and SCLx pins are already sampled low, or if during the Start condition, the SCLx line is sampled low before the SDAx line is driven low, a bus collision occurs. The Bus Collision Interrupt Flag, BCLxIF, is set, the Start condition is aborted and the I²C module is reset into its Idle state.

19.4.8.1 WCOL Status Flag

If the user writes the SSPxBUF when a Start sequence is in progress, the WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

Note: Because queueing of events is not allowed, writing to the lower 5 bits of SSPxCON2 is disabled until the Start condition is complete.

FIGURE 19-21: FIRST START BIT TIMING

19.4.9 I²C MASTER MODE REPEATED START CONDITION TIMING

A Repeated Start condition occurs when the RSEN bit (SSPxCON2 < 1>) is programmed high and the I²C logic module is in the Idle state. When the RSEN bit is set, the SCLx pin is asserted low. When the SCLx pin is sampled low, the Baud Rate Generator is loaded with the contents of SSPxADD<6:0> and begins counting. The SDAx pin is released (brought high) for one Baud Rate Generator count (TBRG). When the Baud Rate Generator times out, if SDAx is sampled high, the SCLx pin will be deasserted (brought high). When SCLx is sampled high, the Baud Rate Generator is reloaded with the contents of SSPxADD<6:0> and begins counting. SDAx and SCLx must be sampled high for one TBRG. This action is then followed by assertion of the SDAx pin (SDAx = 0) for one TBRG while SCLx is high. Following this, the RSEN bit (SSPxCON2<1>) will be automatically cleared and the Baud Rate Generator will not be reloaded, leaving the SDAx pin held low. As soon as a Start condition is detected on the SDAx and SCLx pins, the S bit (SSPxSTAT<3>) will be set. The SSPxIF bit will not be set until the Baud Rate Generator has timed out.

- Note 1: If RSEN is programmed while any other event is in progress, it will not take effect.
 - **2:** A bus collision during the Repeated Start condition occurs if:
 - SDAx is sampled low when SCLx goes from low-to-high.
 - SCLx goes low before SDAx is asserted low. This may indicate that another master is attempting to transmit a data '1'.

Immediately following the SSPxIF bit getting set, the user may write the SSPxBUF with the 7-bit address in 7-bit mode or the default first address in 10-bit mode. After the first eight bits are transmitted and an ACK is received, the user may then transmit an additional eight bits of address (10-bit mode) or eight bits of data (7-bit mode).

19.4.9.1 WCOL Status Flag

If the user writes the SSPxBUF when a Repeated Start sequence is in progress, the WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

Note: Because queueing of events is not allowed, writing of the lower 5 bits of SSPxCON2 is disabled until the Repeated Start condition is complete.

FIGURE 19-22: REPEATED START CONDITION WAVEFORM

19.4.10 I²C MASTER MODE TRANSMISSION

Transmission of a data byte, a 7-bit address or the other half of a 10-bit address is accomplished by simply writing a value to the SSPxBUF register. This action will set the Buffer Full flag bit, BF, and allow the Baud Rate Generator to begin counting and start the next transmission. Each bit of address/data will be shifted out onto the SDAx pin after the falling edge of SCLx is asserted (see data hold time specification parameter 106). SCLx is held low for one Baud Rate Generator rollover count (TBRG). Data should be valid before SCLx is released high (see data setup time specification parameter 107). When the SCLx pin is released high, it is held that way for TBRG. The data on the SDAx pin must remain stable for that duration and some hold time after the next falling edge of SCLx. After the eighth bit is shifted out (the falling edge of the eighth clock), the BF flag is cleared and the master releases SDAx. This allows the slave device being addressed to respond with an ACK bit during the ninth bit time if an address match occurred, or if data was received properly. The status of ACK is written into the ACKDT bit on the falling edge of the ninth clock. If the master receives an Acknowledge, the Acknowledge Status bit, ACKSTAT, is cleared; if not, the bit is set. After the ninth clock, the SSPxIF bit is set and the master clock (Baud Rate Generator) is suspended until the next data byte is loaded into the SSPxBUF, leaving SCLx low and SDAx unchanged (Figure 19-23).

After the write to the SSPxBUF, each bit of the address will be shifted out on the falling edge of SCLx until all seven address bits and the R/W bit are completed. On the falling edge of the eighth clock, the master will deassert the SDAx pin, allowing the slave to respond with an Acknowledge. On the falling edge of the ninth clock, the master will sample the SDAx pin to see if the address was recognized by a slave. The status of the ACK bit is loaded into the ACKSTAT status bit (SSPxCON2<6>). Following the falling edge of the ninth clock transmission of the address, the SSPxIF is set, the BF flag is cleared and the Baud Rate Generator is turned off until another write to the SSPxBUF takes place, holding SCLx low and allowing SDAx to float.

19.4.10.1 BF Status Flag

In Transmit mode, the BF bit (SSPxSTAT<0>) is set when the CPU writes to SSPxBUF, and is cleared when all 8 bits are shifted out.

19.4.10.2 WCOL Status Flag

If the user writes to the SSPxBUF when a transmit is already in progress (i.e., SSPxSR is still shifting out a data byte), the WCOL is set and the contents of the buffer are unchanged (the write doesn't occur) after 2 TcY after the SSPxBUF write. If SSPxBUF is rewritten within 2 TcY, the WCOL bit is set and SSPxBUF is updated. This may result in a corrupted transfer. The user should verify that the WCOL is clear after each write to SSPxBUF to ensure the transfer is correct. In all cases, WCOL must be cleared in software.

19.4.10.3 ACKSTAT Status Flag

In Transmit mode, the ACKSTAT bit (SSPxCON2<6>) is cleared when the slave has sent an Acknowledge $(\overline{ACK} = 0)$ and is set when the slave does not Acknowledge ($\overline{ACK} = 1$). A slave sends an Acknowledge when it has recognized its address (including a general call), or when the slave has properly received its data.

19.4.11 I²C MASTER MODE RECEPTION

Master mode reception is enabled by programming the Receive Enable bit, RCEN (SSPxCON2<3>).

| Note: | The MSSP module must be in an Idle state |
|-------|--|
| | before the RCEN bit is set or the RCEN bit |
| | will be disregarded. |

The Baud Rate Generator begins counting and on each rollover. The state of the SCLx pin changes (high-to-low/low-to-high) and data is shifted into the SSPxSR. After the falling edge of the eighth clock, the receive enable flag is automatically cleared, the contents of the SSPxSR are loaded into the SSPxBUF, the BF flag bit is set, the SSPxIF flag bit is set and the Baud Rate Generator is suspended from counting, holding SCLx low. The MSSP is now in Idle state awaiting the next command. When the buffer is read by the CPU, the BF flag bit is automatically cleared. The user can then send an Acknowledge bit at the end of reception by setting the Acknowledge Sequence Enable bit, ACKEN (SSPxCON2<4>).

19.4.11.1 BF Status Flag

In receive operation, the BF bit is set when an address or data byte is loaded into SSPxBUF from SSPxSR. It is cleared when the SSPxBUF register is read.

19.4.11.2 SSPOV Status Flag

In receive operation, the SSPOV bit is set when 8 bits are received into the SSPxSR and the BF flag bit is already set from a previous reception.

19.4.11.3 WCOL Status Flag

If the user writes the SSPxBUF when a receive is already in progress (i.e., SSPxSR is still shifting in a data byte), the WCOL bit is set and the contents of the buffer are unchanged (the write doesn't occur).

PIC18F97J60 FAMILY

19.4.12 ACKNOWLEDGE SEQUENCE TIMING

An Acknowledge sequence is enabled by setting the Acknowledge Sequence Enable bit. ACKEN (SSPxCON2<4>). When this bit is set, the SCLx pin is pulled low and the contents of the Acknowledge data bit are presented on the SDAx pin. If the user wishes to generate an Acknowledge, then the ACKDT bit should be cleared. If not, the user should set the ACKDT bit before starting an Acknowledge sequence. The Baud Rate Generator then counts for one rollover period (TBRG) and the SCLx pin is deasserted (pulled high). When the SCLx pin is sampled high (clock arbitration), the Baud Rate Generator counts for TBRG. The SCLx pin is then pulled low. Following this, the ACKEN bit is automatically cleared, the Baud Rate Generator is turned off and the MSSP module then goes into Idle mode (Figure 19-25).

19.4.12.1 WCOL Status Flag

If the user writes the SSPxBUF when an Acknowledge sequence is in progress, then WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

19.4.13 STOP CONDITION TIMING

A Stop bit is asserted on the SDAx pin at the end of a receive/transmit by setting the Stop Sequence Enable bit, PEN (SSPxCON2<2>). At the end of a receive/transmit, the SCLx line is held low after the falling edge of the ninth clock. When the PEN bit is set, the master will assert the SDAx line low. When the SDAx line is sampled low, the Baud Rate Generator is reloaded and counts down to '0'. When the Baud Rate Generator times out, the SCLx pin will be brought high and one TBRG (Baud Rate Generator rollover count) later, the SDAx pin will be deasserted. When the SDAx pin is sampled high while SCLx is high, the P bit (SSPxSTAT<4>) is set. A TBRG later, the PEN bit is cleared and the SSPxIF bit is set (Figure 19-26).

19.4.13.1 WCOL Status Flag

If the user writes the SSPxBUF when a Stop sequence is in progress, then the WCOL bit is set and the contents of the buffer are unchanged (the write doesn't occur).

FIGURE 19-25: ACKNOWLEDGE SEQUENCE WAVEFORM

FIGURE 19-26: STOP CONDITION RECEIVE OR TRANSMIT MODE

19.4.14 SLEEP OPERATION

While in Sleep mode, the I^2C module can receive addresses or data and when an address match or complete byte transfer occurs, wake the processor from Sleep (if the MSSP interrupt is enabled).

19.4.15 EFFECTS OF A RESET

A Reset disables the MSSP module and terminates the current transfer.

19.4.16 MULTI-MASTER MODE

In Multi-Master mode, the interrupt generation on the detection of the Start and Stop conditions allows the determination of when the bus is free. The Stop (P) and Start (S) bits are cleared from a Reset or when the MSSP module is disabled. Control of the I^2C bus may be taken when the P bit (SSPxSTAT<4>) is set, or the bus is Idle, with both the S and P bits clear. When the bus is busy, enabling the MSSP interrupt will generate the interrupt when the Stop condition occurs.

In multi-master operation, the SDAx line must be monitored for arbitration to see if the signal level is the expected output level. This check is performed in hardware with the result placed in the BCLxIF bit.

The states where arbitration can be lost are:

- Address Transfer
- Data Transfer
- · A Start Condition
- A Repeated Start Condition
- An Acknowledge Condition

19.4.17 MULTI -MASTER COMMUNICATION, BUS COLLISION AND BUS ARBITRATION

Multi-Master mode support is achieved by bus arbitration. When the master outputs address/data bits onto the SDAx pin, arbitration takes place when the master outputs a '1' on SDAx, by letting SDAx float high and another master asserts a '0'. When the SCLx pin floats high, data should be stable. If the expected data on SDAx is a '1' and the data sampled on the SDAx pin = 0, then a bus collision has taken place. The master will set the Bus Collision Interrupt Flag, BCLxIF and reset the I²C port to its Idle state (Figure 19-27).

If a transmit was in progress when the bus collision occurred, the transmission is halted, the BF flag is cleared, the SDAx and SCLx lines are deasserted and the SSPxBUF can be written to. When the user services the bus collision Interrupt Service Routine and if the l^2C bus is free, the user can resume communication by asserting a Start condition.

If a Start, Repeated Start, Stop or Acknowledge condition was in progress when the bus collision occurred, the condition is aborted, the SDAx and SCLx lines are deasserted and the respective control bits in the SSPxCON2 register are cleared. When the user services the bus collision Interrupt Service Routine and if the l^2C bus is free, the user can resume communication by asserting a Start condition.

The master will continue to monitor the SDAx and SCLx pins. If a Stop condition occurs, the SSPxIF bit will be set.

A write to the SSPxBUF will start the transmission of data at the first data bit regardless of where the transmitter left off when the bus collision occurred.

In Multi-Master mode, the interrupt generation on the detection of Start and Stop conditions allows the determination of when the bus is free. Control of the l^2C bus can be taken when the P bit is set in the SSPxSTAT register, or the bus is Idle and the S and P bits are cleared.

FIGURE 19-27: BUS COLLISION TIMING FOR TRANSMIT AND ACKNOWLEDGE

PIC18F97J60 FAMILY

19.4.17.1 Bus Collision During a Start Condition

During a Start condition, a bus collision occurs if:

- a) SDAx or SCLx are sampled low at the beginning of the Start condition (Figure 19-28).
- b) SCLx is sampled low before SDAx is asserted low (Figure 19-29).

During a Start condition, both the SDAx and the SCLx pins are monitored.

If the SDAx pin is already low, or the SCLx pin is already low, then all of the following occur:

- the Start condition is aborted;
- · the BCLxIF flag is set; and
- the MSSP module is reset to its Idle state (Figure 19-28).

The Start condition begins with the SDAx and SCLx pins deasserted. When the SDAx pin is sampled high, the Baud Rate Generator is loaded from SSPxADD<6:0> and counts down to 0. If the SCLx pin is sampled low while SDAx is high, a bus collision occurs, because it is assumed that another master is attempting to drive a data '1' during the Start condition.

If the SDAx pin is sampled low during this count, the BRG is reset and the SDAx line is asserted early (Figure 19-30). If, however, a '1' is sampled on the SDAx pin, the SDAx pin is asserted low at the end of the BRG count. The Baud Rate Generator is then reloaded and counts down to 0. If the SCLx pin is sampled as '0' during this time, a bus collision does not occur. At the end of the BRG count, the SCLx pin is asserted low.

Note: The reason that bus collision is not a factor during a Start condition is that no two bus masters can assert a Start condition at the exact same time. Therefore, one master will always assert SDAx before the other. This condition does not cause a bus collision because the two masters must be allowed to arbitrate the first address following the Start condition. If the address is the same, arbitration must be allowed to continue into the data portion, Repeated Start or Stop conditions.

19.4.17.2 Bus Collision During a Repeated Start Condition

During a Repeated Start condition, a bus collision occurs if:

- a) A low level is sampled on SDAx when SCLx goes from low level to high level.
- SCLx goes low before SDAx is asserted low, indicating that another master is attempting to transmit a data '1'.

When the user deasserts SDAx and the pin is allowed to float high, the BRG is loaded with SSPxADD<6:0> and counts down to 0. The SCLx pin is then deasserted and when sampled high, the SDAx pin is sampled.

If SDAx is low, a bus collision has occurred (i.e., another master is attempting to transmit a data '0', see Figure 19-31). If SDAx is sampled high, the BRG is

reloaded and begins counting. If SDAx goes from high-to-low before the BRG times out, no bus collision occurs because no two masters can assert SDAx at exactly the same time.

If SCLx goes from high-to-low before the BRG times out and SDAx has not already been asserted, a bus collision occurs. In this case, another master is attempting to transmit a data '1' during the Repeated Start condition (see Figure 19-32).

If, at the end of the BRG time-out, both SCLx and SDAx are still high, the SDAx pin is driven low and the BRG is reloaded and begins counting. At the end of the count, regardless of the status of the SCLx pin, the SCLx pin is driven low and the Repeated Start condition is complete.

FIGURE 19-32: BUS COLLISION DURING REPEATED START CONDITION (CASE 2)

19.4.17.3 Bus Collision During a Stop Condition

Bus collision occurs during a Stop condition if:

- a) After the SDAx pin has been deasserted and allowed to float high, SDAx is sampled low after the BRG has timed out.
- b) After the SCLx pin is deasserted, SCLx is sampled low before SDAx goes high.

The Stop condition begins with SDAx asserted low. When SDAx is sampled low, the SCLx pin is allowed to float. When the pin is sampled high (clock arbitration), the Baud Rate Generator is loaded with SSPxADD<6:0> and counts down to 0. After the BRG times out, SDAx is sampled. If SDAx is sampled low, a bus collision has occurred. This is due to another master attempting to drive a data '0' (Figure 19-33). If the SCLx pin is sampled low before SDAx is allowed to float high, a bus collision occurs. This is another case of another master attempting to drive a data '0' (Figure 19-34).

Legend: — = unimplemented, read as '0', r = reserved. Shaded cells are not used by the MSSP module in l^2C^{TM} mode.

Note 1: These bits are only available in 100-pin devices; otherwise, they are unimplemented and read as '0'.

2: Alternate bit definitions in I^2C^{TM} Slave mode.

NOTES:

20.0 ENHANCED UNIVERSAL SYNCHRONOUS ASYNCHRONOUS RECEIVER TRANSMITTER (EUSART)

The Enhanced Universal Synchronous Asynchronous Receiver Transmitter (EUSART) module is one of two serial I/O modules. (Generically, the EUSART is also known as a Serial Communications Interface or SCI.) The EUSART can be configured as a full-duplex asynchronous system that can communicate with peripheral devices, such as CRT terminals and personal computers. It can also be configured as a half-duplex synchronous system that can communicate with peripheral devices, such as A/D or D/A integrated circuits, serial EEPROMs, etc.

The Enhanced USART module implements additional features, including automatic baud rate detection and calibration, automatic wake-up on Sync Break reception and 12-bit Break character transmit. These features make it ideally suited for use in Local Interconnect Network bus (LIN bus) systems.

The 64-pin devices of the PIC18F97J60 family are equipped with one EUSART module, referred to as EUSART1. The 80-pin and 100-pin devices each have two independent EUSART modules, referred to as EUSART1 and EUSART2. They can be configured in the following modes:

- Asynchronous (full-duplex) with:
 - Auto-Wake-up on Character Reception
 - Auto-Baud Calibration
- 12-Bit Break Character Transmission
- Synchronous Master (half-duplex) with Selectable Clock Polarity
- Synchronous Slave (half-duplex) with Selectable Clock Polarity

The pins of EUSART1 and EUSART2 are multiplexed with the functions of PORTC (RC6/TX1/CK1 and RC7/RX1/DT1) and PORTG (RG1/TX2/CK2 and RG2/RX2/DT2), respectively. In order to configure these pins as an EUSART:

- For EUSART1:
 - bit SPEN (RCSTA1<7>) must be set (= 1)
 - bit TRISC<7> must be set (= 1)
 - bit TRISC<6> must be cleared (= 0) for Asynchronous and Synchronous Master modes
 - bit TRISC<6> must be set (= 1) for Synchronous Slave mode
- For EUSART2:
 - bit SPEN (RCSTA2<7>) must be set (= 1)
 - bit TRISG<2> must be set (= 1)
 - bit TRISG<1> must be cleared (= 0) for Asynchronous and Synchronous Master modes
 - bit TRISG<1> must be set (= 1) for Synchronous Slave mode

Note: The EUSARTx control will automatically reconfigure the pin from input to output as needed.

The operation of each Enhanced USART module is controlled through three registers:

- Transmit Status and Control (TXSTAx)
- Receive Status and Control (RCSTAx)
- Baud Rate Control (BAUDCONx)

These are detailed on the following pages in Register 20-1, Register 20-2 and Register 20-3, respectively.

| Note: | Throughout this section, references to | | | | | | | | | | |

REGISTER 20-3: BAUDCONX: BAUD RATE CONTROL REGISTER x

20.1 Baud Rate Generator (BRG)

The BRG is a dedicated 8-bit or 16-bit generator that supports both the Asynchronous and Synchronous modes of the EUSARTx. By default, the BRG operates in 8-bit mode; setting the BRG16 bit (BAUDCONx<3>) selects 16-bit mode.

The SPBRGHx:SPBRGx register pair controls the period of a free-running timer. In Asynchronous mode, bits BRGH (TXSTAx<2>) and BRG16 (BAUDCONx<3>) also control the baud rate. In Synchronous mode, BRGH is ignored. Table 20-1 shows the formula for computation of the baud rate for different EUSARTx modes which only apply in Master mode (internally generated clock).

Given the desired baud rate and FOSC, the nearest integer value for the SPBRGHx:SPBRGx registers can be calculated using the formulas in Table 20-1. From this, the error in baud rate can be determined. An example calculation is shown in Example 20-1. Typical baud rates and error values for the various Asynchronous modes are shown in Table 20-2. It may be advantageous to use the high baud rate (BRGH = 1), or the 16-bit BRG to reduce the baud rate error, or achieve a slow baud rate for a fast oscillator frequency.

Writing a new value to the SPBRGHx:SPBRGx registers causes the BRG timer to be reset (or cleared). This ensures that the BRG does not wait for a timer overflow before outputting the new baud rate.

20.1.1 OPERATION IN POWER-MANAGED MODES

The device clock is used to generate the desired baud rate. When one of the power-managed modes is entered, the new clock source may be operating at a different frequency. This may require an adjustment to the value in the SPBRGx register pair.

20.1.2 SAMPLING

The data on the RXx pin (either RC7/RX1/DT1 or RG2/RX2/DT2) is sampled three times by a majority detect circuit to determine if a high or a low level is present at the RXx pin.

20.1.3 AUTO-BAUD RATE DETECT

The Enhanced USARTx module supports the automatic detection and calibration of baud rate. This feature is active only in Asynchronous mode and while the WUE bit is clear.

The automatic baud rate measurement sequence (Figure 20-1) begins whenever a Start bit is received and the ABDEN bit is set. The calculation is self-averaging.

In the Auto-Baud Rate Detect (ABD) mode, the clock to the BRG is reversed. Rather than the BRG clocking the incoming RXx signal, the RXx signal is timing the BRG. In ABD mode, the internal Baud Rate Generator is used as a counter to time the bit period of the incoming serial byte stream.

Once the ABDEN bit is set, the state machine will clear the BRG and look for a Start bit. The Auto-Baud Rate Detect must receive a byte with the value 55h (ASCII "U", which is also the LIN bus Sync character) in order to calculate the proper bit rate. The measurement is taken over both a low and high bit time in order to minimize any effects caused by asymmetry of the incoming signal. After a Start bit, the SPBRGx begins counting up, using the preselected clock source on the first rising edge of RXx. After eight bits on the RXx pin or the fifth rising edge, an accumulated value totalling the proper BRG period is left in the SPBRGHx:SPBRGx register pair. Once the 5th edge is seen (this should correspond to the Stop bit), the ABDEN bit is automatically cleared.

If a rollover of the BRG occurs (an overflow from FFFFh to 0000h), the event is trapped by the ABDOVF status bit (BAUDCONx<7>). It is set in hardware by BRG rollovers and can be set or cleared by the user in software. ABD mode remains active after rollover events and the ABDEN bit remains set (Figure 20-2).

While calibrating the baud rate period, the BRG registers are clocked at 1/8th the preconfigured clock rate. Note that the BRG clock will be configured by the BRG16 and BRGH bits. Independent of the BRG16 bit setting, both the SPBRGx and SPBRGHx will be used as a 16-bit counter. This allows the user to verify that no carry occurred for 8-bit modes by checking for 00h in the SPBRGHx register. Refer to Table 20-4 for counter clock rates to the BRG. While the ABD sequence takes place, the EUSARTx state machine is held in Idle. The RCxIF interrupt is set once the fifth rising edge on RXx is detected. The value in the RCREGx needs to be read to clear the RCxIF interrupt. The contents of RCREGx should be discarded.

- Note 1: If the WUE bit is set with the ABDEN bit, Auto-Baud Rate Detection will occur on the byte *following* the Break character.
 - 2: It is up to the user to determine that the incoming character baud rate is within the range of the selected BRG clock source. Some combinations of oscillator frequency and EUSARTx baud rates are not possible due to bit error rates. Overall system timing and communication baud rates must be taken into consideration when using the Auto-Baud Rate Detection feature.

TABLE 20-4: BRG COUNTER CLOCK RATES

| BRG16 | BRGH | BRG Counter Clock |
|-------|------|-------------------|
| 0 | 0 | Fosc/512 |
| 0 | 1 | Fosc/128 |
| 1 | 0 | Fosc/128 |
| 1 | 1 | Fosc/32 |

Note: During the ABD sequence, SPBRGx and SPBRGHx are both used as a 16-bit counter, independent of the BRG16 setting.

20.1.3.1 ABD and EUSARTx Transmission

Since the BRG clock is reversed during ABD acquisition, the EUSARTx transmitter cannot be used during ABD. This means that whenever the ABDEN bit is set, TXREGx cannot be written to. Users should also ensure that ABDEN does not become set during a transmit sequence. Failing to do this may result in unpredictable EUSARTx operation.

20.2 EUSARTx Asynchronous Mode

The Asynchronous mode of operation is selected by clearing the SYNC bit (TXSTAx<4>). In this mode, the EUSARTx uses standard Non-Return-to-Zero (NRZ) format (one Start bit, eight or nine data bits and one Stop bit). The most common data format is 8 bits. An on-chip, dedicated 8-bit/16-bit Baud Rate Generator can be used to derive standard baud rate frequencies from the oscillator.

The EUSARTx transmits and receives the LSb first. The EUSARTx module's transmitter and receiver are functionally independent but use the same data format and baud rate. The Baud Rate Generator produces a clock, either x16 or x64 of the bit shift rate, depending on the BRGH and BRG16 bits (TXSTAx<2> and BAUDCONx<3>). Parity is not supported by the hardware but can be implemented in software and stored as the 9th data bit.

The TXCKP (BAUDCONx<4>) and RXDTP (BAUDCONx<5>) bits allow the TXx and RXx signals to be inverted (polarity reversed). Devices that buffer signals between TTL and RS-232 levels also invert the signal. Setting the TXCKP and RXDTP bits allows for the use of circuits that provide buffering without inverting the signal.

When operating in Asynchronous mode, the EUSARTx module consists of the following important elements:

- Baud Rate Generator
- Sampling Circuit
- Asynchronous Transmitter
- Asynchronous Receiver
- Auto-Wake-up on Sync Break Character
- 12-Bit Break Character Transmit
- Auto-Baud Rate Detection

20.2.1 EUSARTx ASYNCHRONOUS TRANSMITTER

The EUSARTx transmitter block diagram is shown in Figure 20-3. The heart of the transmitter is the Transmit (Serial) Shift Register (TSR). The Shift register obtains its data from the Read/Write Transmit Buffer register, TXREGx. The TXREGx register is loaded with data in software. The TSR register is not loaded until the Stop bit has been transmitted from the previous load. As soon as the Stop bit is transmitted, the TSR is loaded with new data from the TXREGx register (if available). Once the TXREGx register transfers the data to the TSR register (occurs in one TcY), the TXREGx register is empty and the TXxIF flag bit is set. This interrupt can be enabled or disabled by setting or clearing the interrupt enable bit, TXxIE. TXxIF will be set regardless of the state of TXxIE; it cannot be cleared in software. TXxIF is also not cleared immediately upon loading TXREGx, but becomes valid in the second instruction cycle following the load instruction. Polling TXxIF immediately following a load of TXREGx will return invalid results.

While TXxIF indicates the status of the TXREGx register, another bit, TRMT (TXSTAx<1>), shows the status of the TSR register. TRMT is a read-only bit which is set when the TSR register is empty. No interrupt logic is tied to this bit so the user has to poll this bit in order to determine if the TSR register is empty.

| Note 1: | The TSR register is not mapped in data |
|---------|---|
| | memory, so it is not available to the user. |
| 2: | Flag bit TXxIE is set when enable bit |

TXEN is set.

To set up an Asynchronous Transmission:

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the asynchronous serial port by clearing the SYNC bit and setting bit, SPEN.
- 3. If the signal from the TXx pin is to be inverted, set the TXCKP bit.
- 4. If interrupts are desired, set enable bit, TXxIE.
- 5. If 9-bit transmission is desired, set transmit bit, TX9. Can be used as address/data bit.
- 6. Enable the transmission by setting the TXEN bit which will also set bit, TXxIF.
- 7. If 9-bit transmission is selected, the ninth bit should be loaded in bit, TX9D.
- 8. Load data to the TXREGx register (starts transmission).
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

TABLE 20-5: REGISTERS ASSOCIATED WITH ASYNCHRONOUS TRANSMISSION

Legend: — = unimplemented locations read as '0'. Shaded cells are not used for asynchronous transmission.

Note 1: These bits are only available in 80-pin and 100-pin devices; otherwise, they are unimplemented and read as '0'.

20.2.2 EUSARTx ASYNCHRONOUS RECEIVER

The receiver block diagram is shown in Figure 20-6. The data is received on the RXx pin and drives the data recovery block. The data recovery block is actually a high-speed shifter operating at x16 times the baud rate, whereas the main receive serial shifter operates at the bit rate or at Fosc. This mode would typically be used in RS-232 systems.

The RXDTP bit (BAUDCON<5>) allows the RXx signal to be inverted (polarity reversed). Devices that buffer signals from RS-232 to TTL levels also perform an inversion of the signal (when RS-232 = positive, TTL = 0). Inverting the polarity of the RXx pin data by setting the RXDTP bit allows for the use of circuits that provide buffering without inverting the signal.

To set up an Asynchronous Reception:

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the asynchronous serial port by clearing the SYNC bit and setting bit, SPEN.
- 3. If the signal at the RXx pin is to be inverted, set the RXDTP bit.
- 4. If interrupts are desired, set enable bit, RCxIE.
- 5. If 9-bit reception is desired, set bit, RX9.
- 6. Enable the reception by setting bit, CREN.
- 7. Flag bit, RCxIF, will be set when reception is complete and an interrupt will be generated if enable bit, RCxIE, was set.
- 8. Read the RCSTAx register to get the 9th bit (if enabled) and determine if any error occurred during reception.
- 9. Read the 8-bit received data by reading the RCREGx register.
- 10. If any error occurred, clear the error by clearing enable bit, CREN.
- 11. If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

20.2.3 SETTING UP 9-BIT MODE WITH ADDRESS DETECT

This mode would typically be used in RS-485 systems. To set up an Asynchronous Reception with Address Detect Enable:

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the asynchronous serial port by clearing the SYNC bit and setting the SPEN bit.
- 3. If the signal at the RXx pin is to be inverted, set the RXDTP bit. If the signal from the TXx pin is to be inverted, set the TXCKP bit.
- 4. If interrupts are required, set the RCEN bit and select the desired priority level with the RCxIP bit.
- 5. Set the RX9 bit to enable 9-bit reception.
- 6. Set the ADDEN bit to enable address detect.
- 7. Enable reception by setting the CREN bit.
- 8. The RCxIF bit will be set when reception is complete. The interrupt will be Acknowledged if the RCxIE and GIE bits are set.
- 9. Read the RCSTAx register to determine if any error occurred during reception, as well as read bit 9 of data (if applicable).
- 10. Read RCREGx to determine if the device is being addressed.
- 11. If any error occurred, clear the CREN bit.
- 12. If the device has been addressed, clear the ADDEN bit to allow all received data into the receive buffer and interrupt the CPU.

TABLE 20-6: REGISTERS ASSOCIATED WITH ASYNCHRONOUS RECEPTION

Legend: — = unimplemented locations read as '0'. Shaded cells are not used for asynchronous reception.

Note 1: These bits are only available in 80-pin and 100-pin devices; otherwise, they are unimplemented and read as '0'.

20.2.4 AUTO-WAKE-UP ON SYNC BREAK CHARACTER

During Sleep mode, all clocks to the EUSARTx are suspended. Because of this, the Baud Rate Generator is inactive and a proper byte reception cannot be performed. The auto-wake-up feature allows the controller to wake-up due to activity on the RXx/DTx line while the EUSARTx is operating in Asynchronous mode.

The auto-wake-up feature is enabled by setting the WUE bit (BAUDCONx<1>). Once set, the typical receive sequence on RXx/DTx is disabled and the EUSARTx remains in an Idle state, monitoring for a wake-up event independent of the CPU mode. A wake-up event consists of a high-to-low transition on the RXx/DTx line. (This coincides with the start of a Sync Break or a Wake-up Signal character for the LIN protocol.)

Following a wake-up event, the module generates an RCxIF interrupt. The interrupt is generated synchronously to the Q clocks in normal operating modes (Figure 20-8) and asynchronously if the device is in Sleep mode (Figure 20-9). The interrupt condition is cleared by reading the RCREGx register.

The WUE bit is automatically cleared once a low-to-high transition is observed on the RXx line following the wake-up event. At this point, the EUSARTx module is in Idle mode and returns to normal operation. This signals to the user that the Sync Break event is over.

20.2.4.1 Special Considerations Using Auto-Wake-up

Since auto-wake-up functions by sensing rising edge transitions on RXx/DTx, information with any state changes before the Stop bit may signal a false End-of-Character (EOC) and cause data or framing errors. To work properly, therefore, the initial character in

the transmission must be all '0's. This can be 00h (8 bytes) for standard RS-232 devices or 000h (12 bits) for LIN bus.

Oscillator start-up time must also be considered, especially in applications using oscillators with longer start-up intervals (i.e., HS or HSPLL mode). The Sync Break (or Wake-up Signal) character must be of sufficient length and be followed by a sufficient interval to allow enough time for the selected oscillator to start and provide proper initialization of the EUSARTx.

20.2.4.2 Special Considerations Using the WUE Bit

The timing of WUE and RCxIF events may cause some confusion when it comes to determining the validity of received data. As noted, setting the WUE bit places the EUSARTx in an Idle mode. The wake-up event causes a receive interrupt by setting the RCxIF bit. The WUE bit is cleared after this when a rising edge is seen on RXx/DTx. The interrupt condition is then cleared by reading the RCREGx register. Ordinarily, the data in RCREGx will be dummy data and should be discarded.

The fact that the WUE bit has been cleared (or is still set), and the RCxIF flag is set, should not be used as an indicator of the integrity of the data in RCREGx. Users should consider implementing a parallel method in firmware to verify received data integrity.

To assure that no actual data is lost, check the RCIDL bit to verify that a receive operation is not in process. If a receive operation is not occurring, the WUE bit may then be set just prior to entering the Sleep mode.

20.2.5 BREAK CHARACTER SEQUENCE

The EUSARTx module has the capability of sending the special Break character sequences that are required by the LIN bus standard. The Break character transmit consists of a Start bit, followed by twelve '0' bits and a Stop bit. The Frame Break character is sent whenever the SENDB and TXEN bits (TXSTAx<3> and TXSTAx<5>) are set while the Transmit Shift Register (TSR) is loaded with data. Note that the value of data written to TXREGx will be ignored and all '0's will be transmitted.

The SENDB bit is automatically reset by hardware after the corresponding Stop bit is sent. This allows the user to preload the transmit FIFO with the next transmit byte following the Break character (typically, the Sync character in the LIN specification).

Note that the data value written to the TXREGx for the Break character is ignored. The write simply serves the purpose of initiating the proper sequence.

The TRMT bit indicates when the transmit operation is active or Idle, just as it does during normal transmission. See Figure 20-10 for the timing of the Break character sequence.

20.2.5.1 Break and Sync Transmit Sequence

The following sequence will send a message frame header made up of a Break, followed by an Auto-Baud Sync byte. This sequence is typical of a LIN bus master.

- 1. Configure the EUSARTx for the desired mode.
- 2. Set the TXEN and SENDB bits to set up the Break character.
- 3. Load the TXREGx with a dummy character to initiate transmission (the value is ignored).
- 4. Write '55h' to TXREGx to load the Sync character into the transmit FIFO buffer.
- 5. After the Break has been sent, the SENDB bit is reset by hardware. The Sync character now transmits in the preconfigured mode.

When the TXREGx becomes empty, as indicated by the TXxIF, the next data byte can be written to TXREGx.

20.2.6 RECEIVING A BREAK CHARACTER

The Enhanced USARTx module can receive a Break character in two ways.

The first method forces configuration of the baud rate at a frequency of 9/13 the typical speed. This allows for the Stop bit transition to be at the correct sampling location (13 bits for Break versus Start bit and 8 data bits for typical data).

The second method uses the auto-wake-up feature described in **Section 20.2.4 "Auto-Wake-up on Sync Break Character**". By enabling this feature, the EUSARTx will sample the next two transitions on RXx/DTx, cause an RCxIF interrupt and receive the next data byte followed by another interrupt.

Note that following a Break character, the user will typically want to enable the Auto-Baud Rate Detect feature. For both methods, the user can set the ABDEN bit once the TXxIF interrupt is observed.

FIGURE 20-10: SEND BREAK CHARACTER SEQUENCE

20.3 EUSARTx Synchronous Master Mode

The Synchronous Master mode is entered by setting the CSRC bit (TXSTAx<7>). In this mode, the data is transmitted in a half-duplex manner (i.e., transmission and reception do not occur at the same time). When transmitting data, the reception is inhibited and vice versa. Synchronous mode is entered by setting bit, SYNC (TXSTAx<4>). In addition, enable bit, SPEN (RCSTAx<7>), is set in order to configure the TXx and RXx pins to CKx (clock) and DTx (data) lines, respectively.

Clock polarity (CKx) is selected with the TXCKP bit (BAUDCON<4>). Setting TXCKP sets the Idle state on CKx as high, while clearing the bit sets the Idle state as low. Data polarity (DTx) is selected with the RXDTP bit (BAUDCONx<5>). Setting RXDTP sets the Idle state on DTx as high, while clearing the bit sets the Idle state as low. DTx is sampled when CKx returns to its Idle state. This option is provided to support Microwire devices with this module.

20.3.1 EUSARTx SYNCHRONOUS MASTER TRANSMISSION

The EUSARTx transmitter block diagram is shown in Figure 20-3. The heart of the transmitter is the Transmit (Serial) Shift Register (TSR). The Shift register obtains its data from the Read/Write Transmit Buffer register, TXREGx. The TXREGx register is loaded with data in software. The TSR register is not loaded until the last bit has been transmitted from the previous load. As soon as the last bit is transmitted, the TSR is loaded with new data from the TXREGx (if available).

Once the TXREGx register transfers the data to the TSR register (occurs in one TCY), the TXREGx is empty and the TXxIF flag bit is set. The interrupt can be enabled or disabled by setting or clearing the interrupt enable bit, TXxIE. TXxIF is set regardless of the state of enable bit, TXxIE; it cannot be cleared in software. It will reset only when new data is loaded into the TXREGx register.

While flag bit, TXxIF, indicates the status of the TXREGx register, another bit, TRMT (TXSTAx<1>), shows the status of the TSR register. TRMT is a read-only bit which is set when the TSR is empty. No interrupt logic is tied to this bit, so the user must poll this bit in order to determine if the TSR register is empty. The TSR is not mapped in data memory so it is not available to the user.

To set up a Synchronous Master Transmission:

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRG16 bit, as required, to achieve the desired baud rate.
- 2. Enable the synchronous master serial port by setting bits, SYNC, SPEN and CSRC.
- 3. If the signal from the CKx pin is to be inverted, set the TXCKP bit. If the signal from the DTx pin is to be inverted, set the RXDTP bit.
- 4. If interrupts are desired, set enable bit, TXxIE.
- 5. If 9-bit transmission is desired, set bit, TX9.
- 6. Enable the transmission by setting bit, TXEN.
- 7. If 9-bit transmission is selected, the ninth bit should be loaded in bit, TX9D.
- 8. Start transmission by loading data to the TXREGx register.
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

Legend: — = unimplemented, read as '0'. Shaded cells are not used for synchronous master transmission.

Note 1: These bits are only available in 80-pin and 100-pin devices; otherwise, they are unimplemented and read as '0'.

20.3.2 EUSARTx SYNCHRONOUS MASTER RECEPTION

Once Synchronous mode is selected, reception is enabled by setting either the Single Receive Enable bit, SREN (RCSTAx<5>), or the Continuous Receive Enable bit, CREN (RCSTAx<4>). Data is sampled on the RXx pin on the falling edge of the clock.

If enable bit, SREN, is set, only a single word is received. If enable bit, CREN, is set, the reception is continuous until CREN is cleared. If both bits are set, then CREN takes precedence.

To set up a Synchronous Master Reception:

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRG16 bit, as required, to achieve the desired baud rate.
- 2. Enable the synchronous master serial port by setting bits, SYNC, SPEN and CSRC.
- 3. Ensure bits, CREN and SREN, are clear.

- 4. If the signal from the CKx pin is to be inverted, set the TXCKP bit. If the signal from the DTx pin is to be inverted, set the RXDTP bit.
- 5. If interrupts are desired, set enable bit, RCxIE.
- 6. If 9-bit reception is desired, set bit, RX9.
- 7. If a single reception is required, set bit, SREN. For continuous reception, set bit, CREN.
- 8. Interrupt flag bit, RCxIF, will be set when reception is complete and an interrupt will be generated if the enable bit, RCxIE, was set.
- 9. Read the RCSTAx register to get the 9th bit (if enabled) and determine if any error occurred during reception.
- 10. Read the 8-bit received data by reading the RCREGx register.
- 11. If any error occurred, clear the error by clearing bit, CREN.
- 12. If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

TABLE 20-8: REGISTERS ASSOCIATED WITH SYNCHRONOUS MASTER RECEPTION

Legend: — = unimplemented, read as '0'. Shaded cells are not used for synchronous master reception.

Note 1: These bits are only available in 80-pin and 100-pin devices; otherwise, they are unimplemented and read as '0'.

20.4 EUSARTx Synchronous Slave Mode

Synchronous Slave mode is entered by clearing bit, CSRC (TXSTAx<7>). This mode differs from the Synchronous Master mode in that the shift clock is supplied externally at the CKx pin (instead of being supplied internally in Master mode). This allows the device to transfer or receive data while in any low-power mode.

20.4.1 EUSARTx SYNCHRONOUS SLAVE TRANSMISSION

The operation of the Synchronous Master and Slave modes is identical, except in the case of Sleep mode.

If two words are written to the TXREGx and then the SLEEP instruction is executed, the following will occur:

- a) The first word will immediately transfer to the TSR register and transmit.
- b) The second word will remain in the TXREGx register.
- c) Flag bit, TXxIF, will not be set.
- d) When the first word has been shifted out of TSR, the TXREGx register will transfer the second word to the TSR and flag bit, TXxIF, will now be set.
- e) If enable bit, TXxIE, is set, the interrupt will wake the chip from Sleep. If the global interrupt is enabled, the program will branch to the interrupt vector.

To set up a Synchronous Slave Transmission:

- Enable the synchronous slave serial port by setting bits, SYNC and SPEN, and clearing bit, CSRC.
- 2. Clear bits, CREN and SREN.
- 3. If the signal from the CKx pin is to be inverted, set the TXCKP bit. If the signal from the DTx pin is to be inverted, set the RXDTP bit.
- 4. If interrupts are desired, set enable bit, TXxIE.
- 5. If 9-bit transmission is desired, set bit, TX9.
- 6. Enable the transmission by setting enable bit, TXEN.
- 7. If 9-bit transmission is selected, the ninth bit should be loaded in bit TX9D.
- 8. Start transmission by loading data to the TXREGx register.
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

TABLE 20-9: REGISTERS ASSOCIATED WITH SYNCHRONOUS SLAVE TRANSMISSION

Legend: — = unimplemented, read as '0'. Shaded cells are not used for synchronous slave transmission.

Note 1: These bits are only available in 80-pin and 100-pin devices; otherwise, they are unimplemented and read as '0'.

20.4.2 EUSARTx SYNCHRONOUS SLAVE RECEPTION

The operation of the Synchronous Master and Slave modes is identical, except in the case of Sleep or any Idle mode, and bit SREN, which is a "don't care" in Slave mode.

If receive is enabled by setting the CREN bit prior to entering Sleep or any Idle mode, then a word may be received while in this low-power mode. Once the word is received, the RSR register will transfer the data to the RCREGx register. If the RCxIE enable bit is set, the interrupt generated will wake the chip from the low-power mode. If the global interrupt is enabled, the program will branch to the interrupt vector. To set up a Synchronous Slave Reception:

- 1. Enable the synchronous master serial port by setting bits, SYNC and SPEN, and clearing bit, CSRC.
- 2. If interrupts are desired, set enable bit, RCxIE.
- 3. If the signal from the CKx pin is to be inverted, set the TXCKP bit. If the signal from the DTx pin is to be inverted, set the RXDTP bit.
- 4. If 9-bit reception is desired, set bit, RX9.
- 5. To enable reception, set enable bit, CREN.
- Flag bit, RCxIF, will be set when reception is complete. An interrupt will be generated if enable bit, RCxIE, was set.
- 7. Read the RCSTAx register to get the 9th bit (if enabled) and determine if any error occurred during reception.
- 8. Read the 8-bit received data by reading the RCREGx register.
- 9. If any error occurred, clear the error by clearing bit, CREN.
- 10. If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

TABLE 20-10: REGISTERS ASSOCIATED WITH SYNCHRONOUS SLAVE RECEPTION

Legend: — = unimplemented, read as '0'. Shaded cells are not used for synchronous slave reception.

Note 1: These bits are only available in 80-pin and 100-pin devices; otherwise, they are unimplemented and read as '0'.

21.0 10-BIT ANALOG-TO-DIGITAL CONVERTER (A/D) MODULE

The Analog-to-Digital (A/D) converter module has 11 inputs for the 64-pin devices, 15 inputs for the 80-pin devices and 16 inputs for the 100-pin devices. This module allows conversion of an analog input signal to a corresponding 10-bit digital number.

The module has five registers:

- A/D Result Register High Byte (ADRESH)
- A/D Result Register Low Byte (ADRESL)
- A/D Control Register 0 (ADCON0)
- A/D Control Register 1 (ADCON1)
- A/D Control Register 2 (ADCON2)

The ADCON0 register, shown in Register 21-1, controls the operation of the A/D module. The ADCON1 register, shown in Register 21-2, configures the functions of the port pins. The ADCON2 register, shown in Register 21-3, configures the A/D clock source, programmed acquisition time and justification.

REGISTER 21-3: ADCON2: A/D CONTROL REGISTER 2

Note 1: If the A/D FRC clock source is selected, a delay of one TCY (instruction cycle) is added before the A/D clock starts. This allows the SLEEP instruction to be executed before starting a conversion.

The analog reference voltage is software selectable to either the device's positive and negative supply voltage (AVDD and AVSS), or the voltage level on the RA3/AN3/VREF+ and RA2/AN2/VREF- pins.

The A/D converter has a unique feature of being able to operate while the device is in Sleep mode. To operate in Sleep, the A/D conversion clock must be derived from the A/D converter's internal RC oscillator.

The output of the sample and hold is the input into the converter, which generates the result via successive approximation.

Each port pin associated with the A/D converter can be configured as an analog input or as a digital I/O. The ADRESH and ADRESL registers contain the result of

FIGURE 21-1: A/D BLOCK DIAGRAM

the A/D conversion. When the A/D conversion is complete, the result is loaded into the ADRESH:ADRESL register pair, the GO/DONE bit (ADCON0<1>) is cleared and A/D Interrupt Flag bit, ADIF, is set.

A device Reset forces all registers to their Reset state. This forces the A/D module to be turned off and any conversion in progress is aborted. The value in the ADRESH:ADRESL register pair is not modified for a Power-on Reset. These registers will contain unknown data after a Power-on Reset.

The block diagram of the A/D module is shown in Figure 21-1.

After the A/D module has been configured as desired, the selected channel must be acquired before the conversion is started. The analog input channels must have their corresponding TRIS bits selected as inputs. To determine acquisition time, see Section 21.1 "A/D Acquisition Requirements". After this acquisition time has elapsed, the A/D conversion can be started. An acquisition time can be programmed to occur between setting the GO/DONE bit and the actual start of the conversion.

The following steps should be followed to do an A/D conversion:

- 1. Configure the A/D module:
 - · Configure analog pins, voltage reference and digital I/O (ADCON1)
 - Select A/D input channel (ADCON0)
 - Select A/D acquisition time (ADCON2)
 - Select A/D conversion clock (ADCON2)
 - Turn on A/D module (ADCON0)

FIGURE 21-2: ANALOG INPUT MODEL

- 2. Configure A/D interrupt (if desired):
 - Clear ADIF bit
 - · Set ADIE bit
 - · Set GIE bit
- 3. Wait the required acquisition time (if required).
- 4. Start conversion:
 - Set GO/DONE bit (ADCON0<1>)
- 5. Wait for A/D conversion to complete, by either: • Polling for the GO/DONE bit to be cleared

OR

- Waiting for the A/D interrupt
- Read A/D Result registers (ADRESH:ADRESL); 6. clear bit, ADIF, if required.
- For next conversion, go to step 1 or step 2, as 7. required. The A/D conversion time per bit is defined as TAD. A minimum wait of 2 TAD is required before next acquisition starts.

21.1 **A/D Acquisition Requirements**

For the A/D converter to meet its specified accuracy, the charge holding capacitor (CHOLD) must be allowed to fully charge to the input channel voltage level. The Analog Input model is shown in Figure 21-2. The source impedance (Rs) and the internal sampling switch (Rss) impedance directly affect the time required to charge the capacitor, CHOLD. The sampling switch (Rss) impedance varies over the device voltage (VDD). The source impedance affects the offset voltage at the analog input (due to pin leakage current). The maximum recommended impedance for analog sources is 2.5 k Ω . After the analog input channel is selected (changed), the channel must be sampled for at least the minimum acquisition time before starting a conversion.

| Note: | When | the | conversion | is | started, | the |
|-------|---------|--------|-----------------|-----|------------|-----|
| | holding | , capa | acitor is disco | nne | ected from | the |
| | input p | in. | | | | |

EQUATION 21-1: ACQUISITION TIME

To calculate the minimum acquisition time, Equation 21-1 may be used. This equation assumes that 1/2 LSb error is used (1024 steps for the A/D). The 1/2 LSb error is the maximum error allowed for the A/D to meet its specified resolution.

Equation 21-3 shows the calculation of the minimum required acquisition time, TACQ. This calculation is based on the following application system assumptions:

| CHOLD | = | 25 pF |
|------------------|--------|------------------------------------|
| Rs | = | 2.5 kΩ |
| Conversion Error | \leq | 1/2 LSb |
| Vdd | = | $3V \rightarrow Rss = 2 \ k\Omega$ |
| Temperature | = | 85°C (system max.) |

| TACQ = | - | Amplifier Settling Time + Holding Capacitor Charging Time + Temperature Coefficient |
|--------|---|---|
| = | - | TAMP + TC + TCOFF |

EQUATION 21-2: A/D MINIMUM CHARGING TIME

| VHOLD | = | $(\text{VREF} - (\text{VREF}/2048)) \bullet (1 - e^{(-\text{TC/CHOLD}(\text{Ric} + \text{Rss} + \text{Rs}))})$ |
|-------|---|--|
| or | | |
| TC | = | -(Chold)(Ric + Rss + Rs) ln(1/2048) |

EQUATION 21-3: CALCULATING THE MINIMUM REQUIRED ACQUISITION TIME

| TACQ | = | TAMP + TC + TCOFF |
|---------|---------|---|
| TAMP | = | 0.2 μs |
| TCOFF | = | (Temp – 25°C)(0.02 μs/°C) (85°C – 25°C)(0.02 μs/°C) 1.2 μs |
| Tempera | ature c | oefficient is only required for temperatures $> 25^{\circ}$ C. Below 25° C, TCOFF = 0 ms. |
| ТС | = | -(Chold)(Ric + Rss + Rs) $\ln(1/2048) \mu s$ -(25 pF) (1 k Ω + 2 k Ω + 2.5 k Ω) $\ln(0.0004883) \mu s$ 1.05 μs |
| TACQ | = | $0.2 \ \mu s + 1 \ \mu s + 1.2 \ \mu s$ 2.4 \ \ \ \ \ s |

21.2 Selecting and Configuring Automatic Acquisition Time

The ADCON2 register allows the user to select an acquisition time that occurs each time the GO/\overline{DONE} bit is set.

When the GO/DONE bit is set, sampling is stopped and a conversion begins. The user is responsible for ensuring the required acquisition time has passed between selecting the desired input channel and setting the GO/DONE bit. This occurs when the ACQT2:ACQT0 bits (ADCON2<5:3>) remain in their Reset state ('000') and is compatible with devices that do not offer programmable acquisition times.

If desired, the ACQT bits can be set to select a programmable acquisition time for the A/D module. When the GO/DONE bit is set, the A/D module continues to sample the input for the selected acquisition time, then automatically begins a conversion. Since the acquisition time is programmed, there may be no need to wait for an acquisition time between selecting a channel and setting the GO/DONE bit.

In either case, when the conversion is completed, the GO/DONE bit is cleared, the ADIF flag is set and the A/D begins sampling the currently selected channel again. If an acquisition time is programmed, there is nothing to indicate if the acquisition time has ended or if the conversion has begun.

21.3 Selecting the A/D Conversion Clock

The A/D conversion time per bit is defined as TAD. The A/D conversion requires 11 TAD per 10-bit conversion. The source of the A/D conversion clock is software selectable.

There are seven possible options for TAD:

- 2 Tosc
- 4 Tosc
- 8 Tosc
- 16 Tosc
- 32 Tosc
- 64 Tosc
- Internal RC Oscillator

For correct A/D conversions, the A/D conversion clock (TAD) must be as short as possible but greater than the minimum TAD. See **Section 27.0** "**Electrical Characteristics**", A/D parameter 130 in Table 27-27 for more information.

Table 21-1 shows the resultant TAD times derived from the device operating frequencies and the A/D clock source selected.

| TABLE 21-1: | TAD VS. DEVICE OPERATING |
|-------------|--------------------------|
| | FREQUENCIES |

| AD Clock | Maximum | | | |
|-------------------|-------------|-------------------------|--|--|
| Operation | ADCS2:ADCS0 | Device Frequency | | |
| 2 Tosc | 000 | 2.68 MHz | | |
| 4 Tosc | 100 | 5.71 MHz | | |
| 8 Tosc | 001 | 11.43 MHz | | |
| 16 Tosc | 101 | 22.86 MHz | | |
| 32 Tosc | 010 | 41.67 MHz | | |
| 64 Tosc | 110 | 41.67 MHz | | |
| RC ⁽²⁾ | x11 | 1.00 MHz ⁽¹⁾ | | |

| Note 1: | The RC source has a typical TAD time of |
|---------|---|
| | 4 ms. |

2: See parameter 130 in Table 27-27 for A/D RC clock specifications.

21.4 Configuring Analog Port Pins

The ADCON1, TRISA, TRISF and TRISH registers control the operation of the A/D port pins. The port pins needed as analog inputs must have their corresponding TRIS bits set (input). If the TRIS bit is cleared (output), the digital output level (VOH or VOL) will be converted.

The A/D operation is independent of the state of the CHS3:CHS0 bits and the TRIS bits.

- Note 1: When reading the PORT register, all pins configured as analog input channels will read as cleared (a low level). Pins configured as digital inputs will convert an analog input. Analog levels on a digitally configured input will be accurately converted.
 - 2: Analog levels on any pin defined as a digital input may cause the digital input buffer to consume current out of the device's specification limits.

21.5 A/D Conversions

Figure 21-3 shows the operation of the A/D converter after the GO/DONE bit has been set and the ACQT2:ACQT0 bits are cleared. A conversion is started after the following instruction to allow entry into Sleep mode before the conversion begins.

Figure 21-4 shows the operation of the A/D converter after the GO/DONE bit has been set, the ACQT2:ACQT0 bits are set to '010' and a 4 TAD acquisition time has been selected before the conversion starts.

Clearing the GO/DONE bit during a conversion will abort the current conversion. The A/D Result register pair will NOT be updated with the partially completed A/D conversion sample. This means the ADRESH:ADRESL registers will continue to contain the value of the last completed conversion (or the last value written to the ADRESH:ADRESL registers).

After the A/D conversion is completed or aborted, a 2 TAD wait is required before the next acquisition can be started. After this wait, acquisition on the selected channel is automatically started.

| Note: | The GO/DONE bit should NOT be set in |
|-------|---|
| | the same instruction that turns on the A/D. |

21.6 Use of the ECCP2 Trigger

An A/D conversion can be started by the "Special Event Trigger" of the ECCP2 module. This requires that the CCP2M3:CCP2M0 bits (CCP2CON<3:0>) be programmed as '1011' and that the A/D module is enabled (ADON bit is set). When the trigger occurs, the GO/DONE bit will be set, starting the A/D acquisition and conversion and the Timer1 (or Timer3) counter will be reset to zero. Timer1 (or Timer3) is reset to automatically repeat the A/D acquisition period with minimal software overhead (moving ADRESH/ADRESL to the desired location). The appropriate analog input channel must be selected and the minimum acquisition period is either timed by the user, or an appropriate TACQ time is selected before the Special Event Trigger sets the GO/DONE bit (starts a conversion).

If the A/D module is not enabled (ADON is cleared), the Special Event Trigger will be ignored by the A/D module but will still reset the Timer1 (or Timer3) counter.

FIGURE 21-3: A/D CONVERSION TAD CYCLES (ACQT2:ACQT0 = 000, TACQ = 0)

FIGURE 21-4: A/D CONVERSION TAD CYCLES (ACQT2:ACQT0 = 010, TACQ = 4 TAD)

21.7 A/D Converter Calibration

The A/D converter in the PIC18F97J60 family of devices includes a self-calibration feature which compensates for any offset generated within the module. The calibration process is automated and is initiated by setting the ADCAL bit (ADCON0<7>). The next time the GO/DONE bit is set, the module will perform a "dummy" conversion (that is, with reading none of the input channels) and store the resulting value internally to compensate for offset. Thus, subsequent offsets will be compensated.

The calibration process assumes that the device is in a relatively steady-state operating condition. If A/D calibration is used, it should be performed after each device Reset, or if there are other major changes in operating conditions.

21.8 Operation in Power-Managed Modes

The selection of the automatic acquisition time and A/D conversion clock is determined in part by the clock source and frequency while in a power-managed mode.

If the A/D is expected to operate while the device is in a power-managed mode, the ACQT2:ACQT0 and ADCS2:ADCS0 bits in ADCON2 should be updated in accordance with the power-managed mode clock that will be used. After the power-managed mode is entered (either of the power-managed Run modes), an A/D acquisition or conversion may be started. Once an acquisition or conversion is started, the device should continue to be clocked by the same power-managed mode clock source until the conversion has been completed. If desired, the device may be placed into the corresponding power-managed Idle mode during the conversion.

If the power-managed mode clock frequency is less than 1 MHz, the A/D RC clock source should be selected.

Operation in Sleep mode requires the A/D RC clock to be selected. If bits, ACQT2:ACQT0, are set to '000' and a conversion is started, the conversion will be delayed one instruction cycle to allow execution of the SLEEP instruction and entry to Sleep mode. The IDLEN and SCS bits in the OSCCON register must have already been cleared prior to starting the conversion.

TABLE 21-2: SUMMARY OF A/D REGISTERS

Legend: — = unimplemented, read as '0', r = reserved. Shaded cells are not used for A/D conversion.

Note 1: Implemented in 100-pin devices only.

2: This register is not implemented on 64-pin devices.

NOTES:

22.0 COMPARATOR MODULE

The analog comparator module contains two comparators that can be configured in a variety of ways. The inputs can be selected from the analog inputs multiplexed with pins, RF1 through RF6, as well as the on-chip voltage reference (see Section 23.0 "Comparator Voltage Reference Module"). The digital outputs (normal or inverted) are available at the pin level and can also be read through the control register.

The CMCON register (Register 22-1) selects the comparator input and output configuration. Block diagrams of the various comparator configurations are shown in Figure 22-1.

22.1 **Comparator Configuration**

FIGURE 22-1:

There are eight modes of operation for the comparators, shown in Figure 22-1. Bits CM2:CM0 of the CMCON register are used to select these modes. The TRISF register controls the data direction of the comparator pins for each mode. If the Comparator

COMPARATOR I/O OPERATING MODES

mode is changed, the comparator output level may not be valid for the specified mode change delay shown in Section 27.0 "Electrical Characteristics".

| Note: | Comparator interrupts should be disabled |

DS39762B-page 334

22.2 Comparator Operation

A single comparator is shown in Figure 22-2, along with the relationship between the analog input levels and the digital output. When the analog input at VIN+ is less than the analog input VIN-, the output of the comparator is a digital low level. When the analog input at VIN+ is greater than the analog input VIN-, the output of the comparator is a digital high level. The shaded areas of the output of the comparator in Figure 22-2 represent the uncertainty due to input offsets and response time.

22.3 Comparator Reference

Depending on the comparator operating mode, either an external or internal voltage reference may be used. The analog signal present at VIN- is compared to the signal at VIN+ and the digital output of the comparator is adjusted accordingly (Figure 22-2).

FIGURE 22-2: SINGLE COMPARATOR

22.3.1 EXTERNAL REFERENCE SIGNAL

When external voltage references are used, the comparator module can be configured to have the comparators operate from the same or different reference sources. However, threshold detector applications may require the same reference. The reference signal must be between VSS and VDD and can be applied to either pin of the comparator(s).

22.3.2 INTERNAL REFERENCE SIGNAL

The comparator module also allows the selection of an internally generated voltage reference from the comparator voltage reference module. This module is described in more detail in **Section 23.0 "Comparator Voltage Reference Module"**.

The internal reference is only available in the mode where four inputs are multiplexed to two comparators (CM2:CM0 = 110). In this mode, the internal voltage reference is applied to the VIN+ pin of both comparators.

22.4 Comparator Response Time

Response time is the minimum time, after selecting a new reference voltage or input source, before the comparator output has a valid level. If the internal reference is changed, the maximum delay of the internal voltage reference must be considered when using the comparator outputs. Otherwise, the maximum delay of the comparators should be used (see Section 27.0 "Electrical Characteristics").

22.5 Comparator Outputs

The comparator outputs are read through the CMCON register. These bits are read-only. The comparator outputs may also be directly output to the RF1 and RF2 I/O pins. When enabled, multiplexors in the output path of the RF1 and RF2 pins will switch and the output of each pin will be the unsynchronized output of the comparator. The uncertainty of each of the comparators is related to the input offset voltage and the response time given in the specifications. Figure 22-3 shows the comparator output block diagram.

The TRISF bits will still function as an output enable/ disable for the RF1 and RF2 pins while in this mode.

The polarity of the comparator outputs can be changed using the C2INV and C1INV bits (CMCON<5:4>).

| Note 1: | When reading the PORT register, all pins |
|---------|---|
| | configured as analog inputs will read as |
| | '0'. Pins configured as digital inputs will |
| | convert an analog input according to the |
| | Schmitt Trigger input specification. |

2: Analog levels on any pin defined as a digital input may cause the input buffer to consume more current than is specified.

22.6 Comparator Interrupts

The comparator interrupt flag is set whenever there is a change in the output value of either comparator. Software will need to maintain information about the status of the output bits, as read from CMCON<7:6>, to determine the actual change that occurred. The CMIF bit (PIR2<6>) is the Comparator Interrupt Flag. The CMIF bit must be reset by clearing it. Since it is also possible to write a '1' to this register, a simulated interrupt may be initiated.

Both the CMIE bit (PIE2<6>) and the PEIE bit (INTCON<6>) must be set to enable the interrupt. In addition, the GIE bit (INTCON<7>) must also be set. If any of these bits are clear, the interrupt is not enabled, though the CMIF bit will still be set if an interrupt condition occurs.

| Note: | If a change in the CMCON register |
|-------|--|
| | (C1OUT or C2OUT) should occur when a |
| | read operation is being executed (start of |
| | the Q2 cycle), then the CMIF (PIR2 |
| | register) interrupt flag may not get set. |

The user, in the Interrupt Service Routine, can clear the interrupt in the following manner:

- a) Any read or write of CMCON will end the mismatch condition.
- b) Clear flag bit, CMIF.

A mismatch condition will continue to set flag bit, CMIF. Reading CMCON will end the mismatch condition and allow flag bit, CMIF, to be cleared.

22.7 Comparator Operation During Sleep

When a comparator is active and the device is placed in Sleep mode, the comparator remains active and the interrupt is functional, if enabled. This interrupt will wake-up the device from Sleep mode, when enabled. Each operational comparator will consume additional current, as shown in the comparator specifications. To minimize power consumption while in Sleep mode, turn off the comparators (CM2:CM0 = 111) before entering Sleep. If the device wakes up from Sleep, the contents of the CMCON register are not affected.

22.8 Effects of a Reset

A device Reset forces the CMCON register to its Reset state, causing the comparator modules to be turned off (CM2:CM0 = 111). However, the input pins (RF3 through RF6) are configured as analog inputs by default on device Reset. The I/O configuration for these pins is determined by the setting of the PCFG3:PCFG0 bits (ADCON1<3:0>). Therefore, device current is minimized when analog inputs are present at Reset time.

22.9 Analog Input Connection Considerations

A simplified circuit for an analog input is shown in Figure 22-4. Since the analog pins are connected to a digital output, they have reverse biased diodes to VDD and Vss. The analog input, therefore, must be between Vss and VDD. If the input voltage deviates from this

range by more than 0.6V in either direction, one of the diodes is forward biased and a latch-up condition may occur. A maximum source impedance of 10 k Ω is recommended for the analog sources. Any external component connected to an analog input pin, such as a capacitor or a Zener diode, should have very little leakage current.

NOTES:

23.0 COMPARATOR VOLTAGE REFERENCE MODULE

The comparator voltage reference is a 16-tap resistor ladder network that provides a selectable reference voltage. Although its primary purpose is to provide a reference for the analog comparators, it may also be used independently of them.

A block diagram of the module is shown in Figure 23-1. The resistor ladder is segmented to provide two ranges of CVREF values and has a power-down function to conserve power when the reference is not being used. The module's supply reference can be provided from either device VDD/VSS or an external voltage reference.

23.1 Configuring the Comparator Voltage Reference

The voltage reference module is controlled through the CVRCON register (Register 23-1). The comparator voltage reference provides two ranges of output voltage, each with 16 distinct levels. The range to be used

is selected by the CVRR bit (CVRCON<5>). The primary difference between the ranges is the size of the steps selected by the CVREF selection bits (CVR3:CVR0), with one range offering finer resolution. The equations used to calculate the output of the comparator voltage reference are as follows:

<u>If CVRR = 1:</u> CVREF = ((CVR3:CVR0)/24) x (CVRSRC) <u>If CVRR = 0:</u> CVREF = (CVRSRC/4) + ((CVR3:CVR0)/32) x (CVRSRC)

The comparator reference supply voltage can come from either VDD and VSS, or the external VREF+ and VREF- that are multiplexed with RA2 and RA3. The voltage source is selected by the CVRSS bit (CVRCON<4>).

The settling time of the comparator voltage reference must be considered when changing the CVREF output (see Table 27-3 in Section 27.0 "Electrical Characteristics").

Note 1: CVROE overrides the TRISF<5> bit setting.

PIC18F97J60 FAMILY

23.2 Comparator Voltage Reference Accuracy/Error

The full range of voltage reference cannot be realized due to the construction of the module. The transistors on the top and bottom of the resistor ladder network (Figure 23-1) keep CVREF from approaching the reference source rails. The voltage reference is derived from the reference source; therefore, the CVREF output changes with fluctuations in that source. The tested absolute accuracy of the voltage reference can be found in **Section 27.0 "Electrical Characteristics"**.

23.3 Operation During Sleep

When the device wakes up from Sleep through an interrupt, or a Watchdog Timer time-out, the contents of the CVRCON register are not affected. To minimize current consumption in Sleep mode, the voltage reference should be disabled.

23.4 Effects of a Reset

A device Reset disables the voltage reference by clearing bit, CVREN (CVRCON<7>). This Reset also disconnects the reference from the RA2 pin by clearing bit, CVROE (CVRCON<6>), and selects the high-voltage range by clearing bit, CVRR (CVRCON<5>). The CVR value select bits are also cleared.

23.5 Connection Considerations

The voltage reference module operates independently of the comparator module. The output of the reference generator may be connected to the RF5 pin if the CVROE bit is set. Enabling the voltage reference output onto RA2 when it is configured as a digital input will increase current consumption. Connecting RF5 as a digital output with CVRSS enabled will also increase current consumption.

The RF5 pin can be used as a simple D/A output with limited drive capability. Due to the limited current drive capability, a buffer must be used on the voltage reference output for external connections to VREF. Figure 23-2 shows an example buffering technique.

NOTES:

24.0 SPECIAL FEATURES OF THE CPU

PIC18F97J60 family devices include several features intended to maximize reliability and minimize cost through elimination of external components. These are:

- Oscillator Selection
- Resets:
 - Power-on Reset (POR)
 - Power-up Timer (PWRT)
 - Oscillator Start-up Timer (OST)
- Brown-out Reset (BOR)
- Interrupts
- Watchdog Timer (WDT)
- Fail-Safe Clock Monitor
- Two-Speed Start-up
- Code Protection
- In-Circuit Serial Programming

The oscillator can be configured for the application depending on frequency, power, accuracy and cost. All of the options are discussed in detail in **Section 2.0 "Oscillator Configurations"**.

A complete discussion of device Resets and interrupts is available in previous sections of this data sheet.

In addition to their Power-up and Oscillator Start-up Timers provided for Resets, the PIC18F97J60 family of devices has a configurable Watchdog Timer which is controlled in software.

The inclusion of an internal RC oscillator also provides the additional benefits of a Fail-Safe Clock Monitor (FSCM) and Two-Speed Start-up. FSCM provides for background monitoring of the peripheral clock and automatic switchover in the event of its failure. Two-Speed Start-up enables code to be executed almost immediately on start-up while the primary clock source completes its start-up delays.

All of these features are enabled and configured by setting the appropriate Configuration register bits.

24.1 Configuration Bits

The Configuration bits can be programmed (read as '0') or left unprogrammed (read as '1') to select various device configurations. These bits are mapped starting at program memory location 300000h. A complete list is shown in Table 24-1. A detailed explanation of the various bit functions is provided in Register 24-1 through Register 24-8.

24.1.1 CONSIDERATIONS FOR CONFIGURING THE PIC18F97J60 FAMILY DEVICES

Devices of the PIC18F97J60 family do not use persistent memory registers to store configuration information. The configuration bytes are implemented as volatile memory which means that configuration data must be programmed each time the device is powered up.

Configuration data is stored in the four words at the top of the on-chip program memory space, known as the Flash Configuration Words, which are located in the program memory space as shown in Table 5-1. The Configuration Words are stored in the same order shown in Table 24-1, with CONFIG1L at the lowest address and CONFIG3H at the highest. The data is automatically loaded in the proper Configuration registers during device power-up.

When creating applications for these devices, users should always specifically allocate the location of the Flash Configuration Word for configuration data. This is to make certain that program code is not stored in this address when the code is compiled.

The volatile memory cells used for the Configuration bits always reset to '1' on Power-on Resets. For all other types of Reset events, the previously programmed values are maintained and used without reloading from program memory.

The four Most Significant bits of CONFIG1H, CONFIG2H and CONFIG3H in program memory should also be '1111'. This makes these Configuration Words appear to be NOP instructions in the remote event that their locations are ever executed by accident. Since Configuration bits are not implemented in the corresponding locations, writing '1's to these locations has no effect on device operation.

To prevent inadvertent configuration changes during code execution, all programmable Configuration bits are write-once. After a bit is initially programmed during a power cycle, it cannot be written to again. Changing a device configuration requires that power to the device be cycled.

TABLE 24-1: CONFIGURATION BITS AND DEVICE IDs

 $\label{eq:logend: Legend: Legend: x = unknown, u = unchanged, - = unimplemented. Shaded cells are unimplemented, read as '0'.$

Note 1: Values reflect the unprogrammed state as received from the factory and following Power-on Resets. In all other Reset states, the configuration bytes maintain their previously programmed states.

2: The value of these bits in program memory should always be '1'. This ensures that the location is executed as a NOP if it is accidentally executed.

3: This bit should always be maintained as '0'.

4: Implemented on 100-pin devices only.

5: Implemented on 80-pin and 100-pin devices only.

6: See Register 24-7 and Register 24-8 for DEVID values. These registers are read-only and cannot be programmed by the user.

24.2 Watchdog Timer (WDT)

For PIC18F97J60 family devices, the WDT is driven by the INTRC oscillator. When the WDT is enabled, the clock source is also enabled. The nominal WDT period is 4 ms and has the same stability as the INTRC oscillator.

The 4 ms period of the WDT is multiplied by a 16-bit postscaler. Any output of the WDT postscaler is selected by a multiplexor, controlled by the WDTPS bits in Configuration Register 2H. Available periods range from 4 ms to 131.072 seconds (2.18 minutes). The WDT and postscaler are cleared whenever a SLEEP or CLRWDT instruction is executed, or a clock failure (primary or Timer1 oscillator) has occurred.

- Note 1: The CLRWDT and SLEEP instructions clear the WDT and postscaler counts when executed.
 - 2: When a CLRWDT instruction is executed, the postscaler count will be cleared.

24.2.1 CONTROL REGISTER

The WDTCON register (Register 24-9) is a readable and writable register. The SWDTEN bit enables or disables WDT operation. This allows software to override the WDTEN Configuration bit and enable the WDT only if it has been disabled by the Configuration bit.

Legend: — = unimplemented, read as '0'. Shaded cells are not used by the Watchdog Timer.

24.3 On-Chip Voltage Regulator

All of the PIC18F97J60 family devices power their core digital logic at a nominal 2.5V. This may create an issue for designs that are required to operate at a higher typical voltage, such as 3.3V. To simplify system design, all devices in the PIC18F97J60 family incorporate an on-chip regulator that allows the device to run its core logic from VDD.

The regulator is controlled by the ENVREG pin. Tying VDD to the pin enables the regulator, which in turn, provides power to the core from the other VDD pins. When the regulator is enabled, a low-ESR filter capacitor must be connected to the VDDCORE/VCAP pin (Figure 24-2). This helps to maintain the stability of the regulator. The recommended value for the filter capacitor is provided in Section 27.3 "DC Characteristics: PIC18F97J60 Family (Industrial)".

If ENVREG is tied to Vss, the regulator is disabled. In this case, separate power for the core logic, at a nominal 2.5V, must be supplied to the device on the VDDCORE/VCAP pin to run the I/O pins at higher voltage levels, typically 3.3V. Alternatively, the VDDCORE/VCAP and VDD pins can be tied together to operate at a lower nominal voltage. Refer to Figure 24-2 for possible configurations.

24.3.1 ON-CHIP REGULATOR AND BOR

When the on-chip regulator is enabled, PIC18F97J60 family devices also have a simple brown-out capability. If the voltage supplied to the regulator is inadequate to maintain a regulated level, the regulator Reset circuitry will generate a Brown-out Reset. This event is captured by the BOR flag bit (RCON<0>).

The operation of the BOR is described in more detail in Section 4.4 "Brown-out Reset (BOR)" and Section 4.4.1 "Detecting BOR". The Brown-out Reset voltage levels are specific in Section 27.1 "DC Characteristics: Supply Voltage".

24.3.2 POWER-UP REQUIREMENTS

The on-chip regulator is designed to meet the power-up requirements for the device. If the application does not use the regulator, then strict power-up conditions must be adhered to. While powering up, VDDCORE must never exceed VDD by 0.3 volts.

FIGURE 24-2: CONNECTIONS FOR THE ON-CHIP REGULATOR

24.4 Two-Speed Start-up

The Two-Speed Start-up feature helps to minimize the latency period, from oscillator start-up to code execution, by allowing the microcontroller to use the INTRC oscillator as a clock source until the primary clock source is available. It is enabled by setting the IESO Configuration bit.

Two-Speed Start-up should be enabled only if the primary oscillator mode is HS or HSPLL (Crystal-Based) modes. Since the EC and ECPLL modes do not require an Oscillator Start-up Timer delay, Two-Speed Start-up should be disabled.

When enabled, Resets and wake-ups from Sleep mode cause the device to configure itself to run from the internal oscillator block as the clock source, following the time-out of the Power-up Timer after a Power-on Reset is enabled. This allows almost immediate code execution while the primary oscillator starts and the OST is running. Once the OST times out, the device automatically switches to PRI_RUN mode. In all other power-managed modes, Two-Speed Start-up is not used. The device will be clocked by the currently selected clock source until the primary clock source becomes available. The setting of the IESO bit is ignored.

24.4.1 SPECIAL CONSIDERATIONS FOR USING TWO-SPEED START-UP

While using the INTRC oscillator in Two-Speed Start-up, the device still obeys the normal command sequences for entering power-managed modes, including serial SLEEP instructions (refer to **Section 3.1.4 "Multiple Sleep Commands"**). In practice, this means that user code can change the SCS1:SCS0 bit settings, or issue SLEEP instructions, before the OST times out. This would allow an application to briefly wake-up, perform routine "housekeeping" tasks and return to Sleep before the device starts to operate from the primary oscillator.

User code can also check if the primary clock source is currently providing the device clocking by checking the status of the OSTS bit (OSCCON<3>). If the bit is set, the primary oscillator is providing the clock. Otherwise, the internal oscillator block is providing the clock during wake-up from Reset or Sleep mode.

FIGURE 24-3: TIMING TRANSITION FOR TWO-SPEED START-UP (INTRC TO HSPLL)

24.5 Fail-Safe Clock Monitor

The Fail-Safe Clock Monitor (FSCM) allows the microcontroller to continue operation in the event of an external oscillator failure by automatically switching the device clock to the internal oscillator block. The FSCM function is enabled by setting the FCMEN Configuration bit.

When FSCM is enabled, the INTRC oscillator runs at all times to monitor clocks to peripherals and provide a backup clock in the event of a clock failure. Clock monitoring (shown in Figure 24-4) is accomplished by creating a sample clock signal which is the INTRC output divided by 64. This allows ample time between FSCM sample clocks for a peripheral clock edge to occur. The peripheral device clock and the sample clock are presented as inputs to the Clock Monitor latch (CM). The CM is set on the falling edge of the device clock source but cleared on the rising edge of the sample clock.

Clock failure is tested for on the falling edge of the sample clock. If a sample clock falling edge occurs while CM is still set, a clock failure has been detected (Figure 24-5). This causes the following:

- the FSCM generates an oscillator fail interrupt by setting bit, OSCFIF (PIR2<7>);
- the device clock source is switched to the internal oscillator block (OSCCON is not updated to show the current clock source – this is the fail-safe condition); and
- the WDT is reset.

During switchover, the postscaler frequency from the internal oscillator block may not be sufficiently stable for timing sensitive applications. In these cases, it may be desirable to select another clock configuration and enter an alternate power-managed mode. This can be done to attempt a partial recovery or execute a controlled shutdown. See Section 3.1.4 "Multiple Sleep Commands" and Section 24.4.1 "Special Considerations for Using Two-Speed Start-up" for more details.

The FSCM will detect failures of the primary or secondary clock sources only. If the internal oscillator block fails, no failure would be detected, nor would any action be possible.

24.5.1 FSCM AND THE WATCHDOG TIMER

Both the FSCM and the WDT are clocked by the INTRC oscillator. Since the WDT operates with a separate divider and counter, disabling the WDT has no effect on the operation of the INTRC oscillator when the FSCM is enabled.

As already noted, the clock source is switched to the INTRC clock when a clock failure is detected. This may mean a substantial change in the speed of code execution. If the WDT is enabled with a small prescale value, a decrease in clock speed allows a WDT time-out to occur and a subsequent device Reset. For this reason, Fail-Safe Clock events also reset the WDT and postscaler, allowing it to start timing from when execution speed was changed and decreasing the likelihood of an erroneous time-out.

24.5.2 EXITING FAIL-SAFE OPERATION

The fail-safe condition is terminated by either a device Reset or by entering a power-managed mode. On Reset, the controller starts the primary clock source specified in Configuration Register 2H (with any required start-up delays that are required for the oscillator mode, such as OST or PLL timer). The INTRC oscillator provides the device clock until the primary clock source becomes ready (similar to a Two-Speed Start-up). The clock source is then switched to the primary clock (indicated by the OSTS bit in the OSCCON register becoming set). The Fail-Safe Clock Monitor then resumes monitoring the peripheral clock.

The primary clock source may never become ready during start-up. In this case, operation is clocked by the INTRC oscillator. The OSCCON register will remain in its Reset state until a power-managed mode is entered.

24.5.3 FSCM INTERRUPTS IN POWER-MANAGED MODES

By entering a power-managed mode, the clock multiplexor selects the clock source selected by the OSCCON register. Fail-Safe Monitoring of the power-managed clock source resumes in the power-managed mode.

If an oscillator failure occurs during power-managed operation, the subsequent events depend on whether or not the oscillator failure interrupt is enabled. If enabled (OSCFIF = 1), code execution will be clocked by the INTRC multiplexor. An automatic transition back to the failed clock source will not occur.

If the interrupt is disabled, subsequent interrupts while in Idle mode will cause the CPU to begin executing instructions while being clocked by the INTRC source.

24.5.4 POR OR WAKE-UP FROM SLEEP

The FSCM is designed to detect oscillator failure at any point after the device has exited Power-on Reset (POR) or low-power Sleep mode. When the primary device clock is either EC or INTRC, monitoring can begin immediately following these events. For HS or HSPLL modes, the situation is somewhat different. Since the oscillator may require a start-up time considerably longer than the FSCM sample clock time, a false clock failure may be detected. To prevent this, the internal oscillator block is automatically configured as the device clock and functions until the primary clock is stable (the OST and PLL timers have timed out). This is identical to Two-Speed Start-up mode. Once the primary clock is stable, the INTRC returns to its role as the FSCM source.

Note: The same logic that prevents false oscillator failure interrupts on POR, or wake from Sleep, will also prevent the detection of the oscillator's failure to start at all following these events. This can be avoided by monitoring the OSTS bit and using a timing routine to determine if the oscillator is taking too long to start. Even so, no oscillator failure interrupt will be flagged.

As noted in Section 24.4.1 "Special Considerations for Using Two-Speed Start-up", it is also possible to select another clock configuration and enter an alternate power-managed mode while waiting for the primary clock to become stable. When the new power-managed mode is selected, the primary clock is disabled.

24.6 Program Verification and Code Protection

For all devices in the PIC18F97J60 family, the on-chip program memory space is treated as a single block. Code protection for this block is controlled by one Configuration bit, CP0. This bit inhibits external reads and writes to the program memory space. It has no direct effect in normal execution mode.

24.6.1 CONFIGURATION REGISTER PROTECTION

The Configuration registers are protected against untoward changes or reads in two ways. The primary protection is the write-once feature of the Configuration bits which prevents reconfiguration once the bit has been programmed during a power cycle. To safeguard against unpredictable events, Configuration bit changes resulting from individual cell level disruptions (such as ESD events) will cause a parity error and trigger a device Reset.

The data for the Configuration registers is derived from the Flash Configuration Words in program memory. When the CP0 bit is programmed (cleared), the source data for device configuration is also protected as a consequence.

24.7 In-Circuit Serial Programming

PIC18F97J60 family microcontrollers can be serially programmed while in the end application circuit. This is simply done with two lines for clock and data and three other lines for power, ground and the programming voltage. This allows customers to manufacture boards with unprogrammed devices and then program the microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

24.8 In-Circuit Debugger

When the DEBUG Configuration bit is programmed to a '0', the In-Circuit Debugger functionality is enabled. This function allows simple debugging functions when used with MPLAB[®] IDE. When the microcontroller has this feature enabled, some resources are not available for general use. Table 24-3 shows which resources are required by the background debugger.

| TABLE 24-3: | DEBUGGER RESOURCES |
|-------------|--------------------|
|-------------|--------------------|

| - | |
|-----------------|-----------|
| I/O pins: | RB6, RB7 |
| Stack: | 2 levels |
| Program Memory: | 512 bytes |
| Data Memory: | 10 bytes |

25.0 INSTRUCTION SET SUMMARY

The PIC18F97J60 family of devices incorporates the standard set of 75 PIC18 core instructions, as well as an extended set of 8 new instructions for the optimization of code that is recursive or that utilizes a software stack. The extended set is discussed later in this section.

25.1 Standard Instruction Set

The standard PIC18 instruction set adds many enhancements to the previous PIC[®] MCU instruction sets, while maintaining an easy migration from these PIC MCU instruction sets. Most instructions are a single program memory word (16 bits), but there are four instructions that require two program memory locations.

Each single-word instruction is a 16-bit word divided into an opcode, which specifies the instruction type and one or more operands, which further specify the operation of the instruction.

The instruction set is highly orthogonal and is grouped into four basic categories:

- Byte-oriented operations
- Bit-oriented operations
- Literal operations
- Control operations

The PIC18 instruction set summary in Table 25-2 lists **byte-oriented**, **bit-oriented**, **literal** and **control** operations. Table 25-1 shows the opcode field descriptions.

Most byte-oriented instructions have three operands:

- 1. The file register (specified by 'f')
- 2. The destination of the result (specified by 'd')
- 3. The accessed memory (specified by 'a')

The file register designator 'f' specifies which file register is to be used by the instruction. The destination designator 'd' specifies where the result of the operation is to be placed. If 'd' is zero, the result is placed in the WREG register. If 'd' is one, the result is placed in the file register specified in the instruction.

All **bit-oriented** instructions have three operands:

- 1. The file register (specified by 'f')
- 2. The bit in the file register (specified by 'b')
- 3. The accessed memory (specified by 'a')

The bit field designator 'b' selects the number of the bit affected by the operation, while the file register designator 'f' represents the number of the file in which the bit is located. The **literal** instructions may use some of the following operands:

- A literal value to be loaded into a file register (specified by 'k')
- The desired FSR register to load the literal value into (specified by 'f')
- No operand required (specified by '—')

The **control** instructions may use some of the following operands:

- A program memory address (specified by 'n')
- The mode of the CALL or RETURN instructions (specified by 's')
- The mode of the table read and table write instructions (specified by 'm')
- No operand required (specified by '—')

All instructions are a single word, except for four double-word instructions. These instructions were made double-word to contain the required information in 32 bits. In the second word, the 4 MSbs are '1's. If this second word is executed as an instruction (by itself), it will execute as a NOP.

All single-word instructions are executed in a single instruction cycle, unless a conditional test is true or the program counter is changed as a result of the instruction. In these cases, the execution takes two instruction cycles with the additional instruction cycle(s) executed as a NOP.

The double-word instructions execute in two instruction cycles.

One instruction cycle consists of four oscillator periods. Thus, for an oscillator frequency of 4 MHz, the normal instruction execution time is 1 μ s. If a conditional test is true, or the program counter is changed as a result of an instruction, the instruction execution time is 2 μ s. Two-word branch instructions (if true) would take 3 μ s.

Figure 25-1 shows the general formats that the instructions can have. All examples use the convention 'nnh' to represent a hexadecimal number.

The Instruction Set Summary, shown in Table 25-2, lists the standard instructions recognized by the Microchip MPASM[™] Assembler.

Section 25.1.1 "Standard Instruction Set" provides a description of each instruction.

TABLE 25-1: OPCODE FIELD DESCRIPTIONS

| Field | Description | | | |
|-----------------|---|--|--|--|
| a | RAM access bit: | | | |
| | a = 0: RAM location in Access RAM (BSR register is ignored) | | | |
| | a = 1: RAM bank is specified by BSR register | | | |
| bbb | Bit address within an 8-bit file register (0 to 7). | | | |
| BSR | Bank Select Register. Used to select the current RAM bank. | | | |
| C, DC, Z, OV, N | ALU Status bits: Carry, Digit Carry, Zero, Overflow, Negative. | | | |
| d | Destination select bit: | | | |
| | d = 0: store result in WREG | | | |
| | d = 1: store result in file register f | | | |
| dest | Destination: either the WREG register or the specified register file location. | | | |
| f | 8-bit Register file address (00h to FFh), or 2-bit FSR designator (0h to 3h). | | | |
| fs | 12-bit Register file address (000h to FFFh). This is the source address. | | | |
| f _d | 12-bit Register file address (000h to FFFh). This is the destination address. | | | |
| GIE | Global Interrupt Enable bit. | | | |
| k | Literal field, constant data or label (may be either an 8-bit, 12-bit or a 20-bit value). | | | |
| label | Label name. | | | |
| mm | The mode of the TBLPTR register for the table read and table write instructions. Only used with table read and table write instructions: | | | |
| * | No Change to register (such as TBLPTR with table reads and writes) | | | |
| *+ | Post-Increment register (such as TBLPTR with table reads and writes) | | | |
| *_ | Post-Decrement register (such as TBLPTR with table reads and writes) | | | |
| +* | Pre-Increment register (such as TBLPTR with table reads and writes) | | | |
| n | The relative address (2's complement number) for relative branch instructions or the direct address for | | | |
| 11 | Call/Branch and Return instructions. | | | |
| PC | Program Counter. | | | |
| PCL | Program Counter Low Byte. | | | |
| PCH | Program Counter High Byte. | | | |
| PCLATH | Program Counter High Byte Latch. | | | |
| PCLATU | Program Counter Upper Byte Latch. | | | |
| PD | Power-Down bit. | | | |
| PRODH | Product of Multiply High Byte. | | | |
| PRODL | Product of Multiply Low Byte. | | | |
| s | Fast Call/Return mode select bit: | | | |
| 2 | s = 0: do not update into/from shadow registers | | | |
| | s = 1: certain registers loaded into/from shadow registers (Fast mode) | | | |
| TBLPTR | 21-bit Table Pointer (points to a program memory location). | | | |
| TABLAT | 8-bit Table Latch. | | | |
| TO | Time-out bit. | | | |
| TOS | Top-of-Stack. | | | |
| u | Unused or Unchanged. | | | |
| WDT | Watchdog Timer. | | | |
| WREG | Working register (accumulator). | | | |
| х | Don't care ('0' or '1'). The assembler will generate code with $x = 0$. It is the recommended form of use for compatibility with all Microchip software tools. | | | |
| Zs | 7-bit offset value for indirect addressing of register files (source). | | | |
| zd | 7-bit offset value for indirect addressing of register files (destination). | | | |
| { } | Optional argument. | | | |
| [text] | Indicates an indexed address. | | | |
| (text) | The contents of text. | | | |
| [expr] <n></n> | Specifies bit n of the register indicated by the pointer expr. | | | |
| \rightarrow | Assigned to. | | | |
| < > | Register bit field. | | | |
| E | In the set of. | | | |
| italics | User-defined term (font is Courier). | | | |

TABLE 25-2:PIC18F97J60 FAMILY INSTRUCTION SET

Note 1: When a PORT register is modified as a function of itself (e.g., MOVF PORTB, 1, 0), the value used will be that value present on the pins themselves. For example, if the data latch is '1' for a pin configured as input and is driven low by an external device, the data will be written back with a '0'.

2: If this instruction is executed on the TMR0 register (and, where applicable, d = 1), the prescaler will be cleared if assigned.

3: If Program Counter (PC) is modified or a conditional test is true, the instruction requires two cycles. The second cycle is executed as a NOP.

4: Some instructions are two-word instructions. The second word of these instructions will be executed as a NOP unless the first word of the instruction retrieves the information embedded in these 16 bits. This ensures that all program memory locations have a valid instruction.

| TABLE 25-2: | PIC18F97J60 FAMILY INSTRUCTION SET (| (CONTINUED) |) |
|--------------------|--------------------------------------|-------------|---|
|--------------------|--------------------------------------|-------------|---|

Note 1: When a PORT register is modified as a function of itself (e.g., MOVF PORTB, 1, 0), the value used will be that value present on the pins themselves. For example, if the data latch is '1' for a pin configured as input and is driven low by an external device, the data will be written back with a '0'.

2: If this instruction is executed on the TMR0 register (and, where applicable, d = 1), the prescaler will be cleared if assigned.

3: If Program Counter (PC) is modified or a conditional test is true, the instruction requires two cycles. The second cycle is executed as a NOP.

4: Some instructions are two-word instructions. The second word of these instructions will be executed as a NOP unless the first word of the instruction retrieves the information embedded in these 16 bits. This ensures that all program memory locations have a valid instruction.

25.2 Extended Instruction Set

In addition to the standard 75 instructions of the PIC18 instruction set, the PIC18F97J60 family of devices also provide an optional extension to the core CPU functionality. The added features include eight additional instructions that augment Indirect and Indexed Addressing operations and the implementation of Indexed Literal Offset Addressing for many of the standard PIC18 instructions.

The additional features of the extended instruction set are enabled by default on unprogrammed devices. Users must properly set or clear the XINST Configuration bit during programming to enable or disable these features.

The instructions in the extended set can all be classified as literal operations, which either manipulate the File Select Registers, or use them for Indexed Addressing. Two of the instructions, ADDFSR and SUBFSR, each have an additional special instantiation for using FSR2. These versions (ADDULNK and SUBULNK) allow for automatic return after execution.

The extended instructions are specifically implemented to optimize reentrant program code (that is, code that is recursive or that uses a software stack) written in high-level languages, particularly C. Among other things, they allow users working in high-level languages to perform certain operations on data structures more efficiently. These include:

- Dynamic allocation and deallocation of software stack space when entering and leaving subroutines
- Function Pointer invocation
- Software Stack Pointer manipulation
- Manipulation of variables located in a software stack

A summary of the instructions in the extended instruction set is provided in Table 25-3. Detailed descriptions are provided in **Section 25.2.2** "**Extended Instruction Set**". The opcode field descriptions in Table 25-1 (page 358) apply to both the standard and extended PIC18 instruction sets.

Note: The instruction set extension and the Indexed Literal Offset Addressing mode were designed for optimizing applications written in C; the user may likely never use these instructions directly in assembler. The syntax for these commands is provided as a reference for users who may be reviewing code that has been generated by a compiler.

25.2.1 EXTENDED INSTRUCTION SYNTAX

Most of the extended instructions use indexed arguments, using one of the File Select Registers and some offset to specify a source or destination register. When an argument for an instruction serves as part of Indexed Addressing, it is enclosed in square brackets ("[]"). This is done to indicate that the argument is used as an index or offset. The MPASM[™] Assembler will flag an error if it determines that an index or offset value is not bracketed.

When the extended instruction set is enabled, brackets are also used to indicate index arguments in byte-oriented and bit-oriented instructions. This is in addition to other changes in their syntax. For more details, see Section 25.2.3.1 "Extended Instruction Syntax with Standard PIC18 Commands".

Note: In the past, square brackets have been used to denote optional arguments in the PIC18 and earlier instruction sets. In this text and going forward, optional arguments are denoted by braces ("{ }").

25.2.3 BYTE-ORIENTED AND BIT-ORIENTED INSTRUCTIONS IN INDEXED LITERAL OFFSET MODE

| Note: | Enabling the PIC18 instruction set exten- | | | | |
|-------|---|--|--|--|--|
| | sion may cause legacy applications to | | | | |
| | behave erratically or fail entirely. | | | | |

In addition to eight new commands in the extended set, enabling the extended instruction set also enables Indexed Literal Offset Addressing (Section 5.6.1 "Indexed Addressing with Literal Offset"). This has a significant impact on the way that many commands of the standard PIC18 instruction set are interpreted.

When the extended set is disabled, addresses embedded in opcodes are treated as literal memory locations: either as a location in the Access Bank (a = 0) or in a GPR bank designated by the BSR (a = 1). When the extended instruction set is enabled and a = 0, however, a file register argument of 5Fh or less is interpreted as an offset from the pointer value in FSR2 and not as a literal address. For practical purposes, this means that all instructions that use the Access RAM bit as an argument – that is, all byte-oriented and bit-oriented instructions, or almost half of the core PIC18 instructions – may behave differently when the extended instruction set is enabled.

When the content of FSR2 is 00h, the boundaries of the Access RAM are essentially remapped to their original values. This may be useful in creating backward-compatible code. If this technique is used, it may be necessary to save the value of FSR2 and restore it when moving back and forth between C and assembly routines in order to preserve the Stack Pointer. Users must also keep in mind the syntax requirements of the extended instruction set (see Section 25.2.3.1 "Extended Instruction Syntax with Standard PIC18 Commands").

Although the Indexed Literal Offset mode can be very useful for dynamic stack and pointer manipulation, it can also be very annoying if a simple arithmetic operation is carried out on the wrong register. Users who are accustomed to the PIC18 programming must keep in mind that, when the extended instruction set is enabled, register addresses of 5Fh or less are used for Indexed Literal Offset Addressing.

Representative examples of typical byte-oriented and bit-oriented instructions in the Indexed Literal Offset mode are provided on the following page to show how execution is affected. The operand conditions shown in the examples are applicable to all instructions of these types.

25.2.3.1 Extended Instruction Syntax with Standard PIC18 Commands

When the extended instruction set is enabled, the file register argument 'f' in the standard byte-oriented and bit-oriented commands is replaced with the literal offset value 'k'. As already noted, this occurs only when 'f' is less than or equal to 5Fh. When an offset value is used, it must be indicated by square brackets ("[]"). As with the extended instructions, the use of brackets indicates to the compiler that the value is to be interpreted as an index or an offset. Omitting the brackets, or using a value greater than 5Fh within the brackets, will generate an error in the MPASM Assembler.

If the index argument is properly bracketed for Indexed Literal Offset Addressing, the Access RAM argument is never specified; it will automatically be assumed to be '0'. This is in contrast to standard operation (extended instruction set disabled), when 'a' is set on the basis of the target address. Declaring the Access RAM bit in this mode will also generate an error in the MPASM Assembler.

The destination argument 'd' functions as before.

In the latest versions of the MPASM Assembler, language support for the extended instruction set must be explicitly invoked. This is done with either the command line option, $/_{Y}$, or the PE directive in the source listing.

25.2.4 CONSIDERATIONS WHEN ENABLING THE EXTENDED INSTRUCTION SET

It is important to note that the extensions to the instruction set may not be beneficial to all users. In particular, users who are not writing code that uses a software stack may not benefit from using the extensions to the instruction set.

Additionally, the Indexed Literal Offset Addressing mode may create issues with legacy applications written to the PIC18 assembler. This is because instructions in the legacy code may attempt to address registers in the Access Bank below 5Fh. Since these addresses are interpreted as literal offsets to FSR2 when the instruction set extension is enabled, the application may read or write to the wrong data addresses.

When porting an application to the PIC18F97J60 family, it is very important to consider the type of code. A large, reentrant application that is written in C and would benefit from efficient compilation will do well when using the instruction set extensions. Legacy applications that heavily use the Access Bank will most likely not benefit from using the extended instruction set.

25.2.5 SPECIAL CONSIDERATIONS WITH MICROCHIP MPLAB[®] IDE TOOLS

The latest versions of Microchip's software tools have been designed to fully support the extended instruction set for the PIC18F97J60 family. This includes the MPLAB C18 C Compiler, MPASM assembly language and MPLAB Integrated Development Environment (IDE).

When selecting a target device for software development, MPLAB IDE will automatically set default Configuration bits for that device. The default setting for the XINST Configuration bit is '0', disabling the extended instruction set and Indexed Literal Offset Addressing. For proper execution of applications developed to take advantage of the extended instruction set, XINST must be set during programming.

To develop software for the extended instruction set, the user must enable support for the instructions and the Indexed Addressing mode in their language tool(s). Depending on the environment being used, this may be done in several ways:

- A menu option or dialog box within the environment that allows the user to configure the language tool and its settings for the project
- A command line option
- A directive in the source code

These options vary between different compilers, assemblers and development environments. Users are encouraged to review the documentation accompanying their development systems for the appropriate information.

26.0 DEVELOPMENT SUPPORT

The PIC[®] microcontrollers are supported with a full range of hardware and software development tools:

- Integrated Development Environment
 - MPLAB® IDE Software
- Assemblers/Compilers/Linkers
 - MPASM[™] Assembler
 - MPLAB C18 and MPLAB C30 C Compilers
 - MPLINK[™] Object Linker/
 - MPLIB[™] Object Librarian
 - MPLAB ASM30 Assembler/Linker/Library
- Simulators
 - MPLAB SIM Software Simulator
- Emulators
 - MPLAB ICE 2000 In-Circuit Emulator
 - MPLAB ICE 4000 In-Circuit Emulator
- In-Circuit Debugger
 - MPLAB ICD 2
- Device Programmers
 - PICSTART[®] Plus Development Programmer
 - MPLAB PM3 Device Programmer
 - PICkit[™] 2 Development Programmer
- Low-Cost Demonstration and Development Boards and Evaluation Kits

26.1 MPLAB Integrated Development Environment Software

The MPLAB IDE software brings an ease of software development previously unseen in the 8/16-bit microcontroller market. The MPLAB IDE is a Windows[®] operating system-based application that contains:

- A single graphical interface to all debugging tools
 - Simulator
 - Programmer (sold separately)
 - Emulator (sold separately)
 - In-Circuit Debugger (sold separately)
- · A full-featured editor with color-coded context
- A multiple project manager
- Customizable data windows with direct edit of contents
- High-level source code debugging
- Visual device initializer for easy register initialization
- · Mouse over variable inspection
- Drag and drop variables from source to watch windows
- · Extensive on-line help
- Integration of select third party tools, such as HI-TECH Software C Compilers and IAR C Compilers

The MPLAB IDE allows you to:

- Edit your source files (either assembly or C)
- One touch assemble (or compile) and download to PIC MCU emulator and simulator tools (automatically updates all project information)
- Debug using:
 - Source files (assembly or C)
 - Mixed assembly and C
 - · Machine code

MPLAB IDE supports multiple debugging tools in a single development paradigm, from the cost-effective simulators, through low-cost in-circuit debuggers, to full-featured emulators. This eliminates the learning curve when upgrading to tools with increased flexibility and power.

26.2 MPASM Assembler

The MPASM Assembler is a full-featured, universal macro assembler for all PIC MCUs.

The MPASM Assembler generates relocatable object files for the MPLINK Object Linker, Intel[®] standard HEX files, MAP files to detail memory usage and symbol reference, absolute LST files that contain source lines and generated machine code and COFF files for debugging.

The MPASM Assembler features include:

- Integration into MPLAB IDE projects
- User-defined macros to streamline
 assembly code
- Conditional assembly for multi-purpose source files
- Directives that allow complete control over the assembly process

26.3 MPLAB C18 and MPLAB C30 C Compilers

The MPLAB C18 and MPLAB C30 Code Development Systems are complete ANSI C compilers for Microchip's PIC18 family of microcontrollers and the dsPIC30, dsPIC33 and PIC24 family of digital signal controllers. These compilers provide powerful integration capabilities, superior code optimization and ease of use not found with other compilers.

For easy source level debugging, the compilers provide symbol information that is optimized to the MPLAB IDE debugger.

26.4 MPLINK Object Linker/ MPLIB Object Librarian

The MPLINK Object Linker combines relocatable objects created by the MPASM Assembler and the MPLAB C18 C Compiler. It can link relocatable objects from precompiled libraries, using directives from a linker script.

The MPLIB Object Librarian manages the creation and modification of library files of precompiled code. When a routine from a library is called from a source file, only the modules that contain that routine will be linked in with the application. This allows large libraries to be used efficiently in many different applications.

The object linker/library features include:

- Efficient linking of single libraries instead of many smaller files
- Enhanced code maintainability by grouping related modules together
- Flexible creation of libraries with easy module listing, replacement, deletion and extraction

26.5 MPLAB ASM30 Assembler, Linker and Librarian

MPLAB ASM30 Assembler produces relocatable machine code from symbolic assembly language for dsPIC30F devices. MPLAB C30 C Compiler uses the assembler to produce its object file. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. Notable features of the assembler include:

- Support for the entire dsPIC30F instruction set
- Support for fixed-point and floating-point data
- · Command line interface
- Rich directive set
- Flexible macro language
- MPLAB IDE compatibility

26.6 MPLAB SIM Software Simulator

The MPLAB SIM Software Simulator allows code development in a PC-hosted environment by simulating the PIC MCUs and dsPIC[®] DSCs on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a comprehensive stimulus controller. Registers can be logged to files for further run-time analysis. The trace buffer and logic analyzer display extend the power of the simulator to record and track program execution, actions on I/O, most peripherals and internal registers.

The MPLAB SIM Software Simulator fully supports symbolic debugging using the MPLAB C18 and MPLAB C30 C Compilers, and the MPASM and MPLAB ASM30 Assemblers. The software simulator offers the flexibility to develop and debug code outside of the hardware laboratory environment, making it an excellent, economical software development tool.

26.7 MPLAB ICE 2000 High-Performance In-Circuit Emulator

The MPLAB ICE 2000 In-Circuit Emulator is intended to provide the product development engineer with a complete microcontroller design tool set for PIC microcontrollers. Software control of the MPLAB ICE 2000 In-Circuit Emulator is advanced by the MPLAB Integrated Development Environment, which allows editing, building, downloading and source debugging from a single environment.

The MPLAB ICE 2000 is a full-featured emulator system with enhanced trace, trigger and data monitoring features. Interchangeable processor modules allow the system to be easily reconfigured for emulation of different processors. The architecture of the MPLAB ICE 2000 In-Circuit Emulator allows expansion to support new PIC microcontrollers.

The MPLAB ICE 2000 In-Circuit Emulator system has been designed as a real-time emulation system with advanced features that are typically found on more expensive development tools. The PC platform and Microsoft[®] Windows[®] 32-bit operating system were chosen to best make these features available in a simple, unified application.

26.8 MPLAB ICE 4000 High-Performance In-Circuit Emulator

The MPLAB ICE 4000 In-Circuit Emulator is intended to provide the product development engineer with a complete microcontroller design tool set for high-end PIC MCUs and dsPIC DSCs. Software control of the MPLAB ICE 4000 In-Circuit Emulator is provided by the MPLAB Integrated Development Environment, which allows editing, building, downloading and source debugging from a single environment.

The MPLAB ICE 4000 is a premium emulator system, providing the features of MPLAB ICE 2000, but with increased emulation memory and high-speed performance for dsPIC30F and PIC18XXXX devices. Its advanced emulator features include complex triggering and timing, and up to 2 Mb of emulation memory.

The MPLAB ICE 4000 In-Circuit Emulator system has been designed as a real-time emulation system with advanced features that are typically found on more expensive development tools. The PC platform and Microsoft Windows 32-bit operating system were chosen to best make these features available in a simple, unified application.

26.9 MPLAB ICD 2 In-Circuit Debugger

Microchip's In-Circuit Debugger, MPLAB ICD 2, is a powerful, low-cost, run-time development tool, connecting to the host PC via an RS-232 or high-speed USB interface. This tool is based on the Flash PIC MCUs and can be used to develop for these and other PIC MCUs and dsPIC DSCs. The MPLAB ICD 2 utilizes the in-circuit debugging capability built into the Flash devices. This feature, along with Microchip's In-Circuit Serial Programming[™] (ICSP[™]) protocol, offers costeffective, in-circuit Flash debugging from the graphical user interface of the MPLAB Integrated Development Environment. This enables a designer to develop and debug source code by setting breakpoints, single stepping and watching variables, and CPU status and peripheral registers. Running at full speed enables testing hardware and applications in real time. MPLAB ICD 2 also serves as a development programmer for selected PIC devices.

26.10 MPLAB PM3 Device Programmer

The MPLAB PM3 Device Programmer is a universal, CE compliant device programmer with programmable voltage verification at VDDMIN and VDDMAX for maximum reliability. It features a large LCD display (128 x 64) for menus and error messages and a modular, detachable socket assembly to support various package types. The ICSP™ cable assembly is included as a standard item. In Stand-Alone mode, the MPLAB PM3 Device Programmer can read, verify and program PIC devices without a PC connection. It can also set code protection in this mode. The MPLAB PM3 connects to the host PC via an RS-232 or USB cable. The MPLAB PM3 has high-speed communications and optimized algorithms for quick programming of large memory devices and incorporates an SD/MMC card for file storage and secure data applications.

26.11 PICSTART Plus Development Programmer

The PICSTART Plus Development Programmer is an easy-to-use, low-cost, prototype programmer. It connects to the PC via a COM (RS-232) port. MPLAB Integrated Development Environment software makes using the programmer simple and efficient. The PICSTART Plus Development Programmer supports most PIC devices in DIP packages up to 40 pins. Larger pin count devices, such as the PIC16C92X and PIC17C76X, may be supported with an adapter socket. The PICSTART Plus Development Programmer is CE compliant.

26.12 PICkit 2 Development Programmer

The PICkit[™] 2 Development Programmer is a low-cost programmer with an easy-to-use interface for programming many of Microchip's baseline, mid-range and PIC18F families of Flash memory microcontrollers. The PICkit 2 Starter Kit includes a prototyping development board, twelve sequential lessons, software and HI-TECH's PICC[™] Lite C compiler, and is designed to help get up to speed quickly using PIC[®] microcontrollers. The kit provides everything needed to program, evaluate and develop applications using Microchip's powerful, mid-range Flash memory family of microcontrollers.

26.13 Demonstration, Development and Evaluation Boards

A wide variety of demonstration, development and evaluation boards for various PIC MCUs and dsPIC DSCs allows quick application development on fully functional systems. Most boards include prototyping areas for adding custom circuitry and provide application firmware and source code for examination and modification.

The boards support a variety of features, including LEDs, temperature sensors, switches, speakers, RS-232 interfaces, LCD displays, potentiometers and additional EEPROM memory.

The demonstration and development boards can be used in teaching environments, for prototyping custom circuits and for learning about various microcontroller applications.

In addition to the PICDEM[™] and dsPICDEM[™] demonstration/development board series of circuits, Microchip has a line of evaluation kits and demonstration software for analog filter design, KEELOQ[®] security ICs, CAN, IrDA[®], PowerSmart[®] battery management, SEEVAL[®] evaluation system, Sigma-Delta ADC, flow rate sensing, plus many more.

Check the Microchip web page (www.microchip.com) and the latest *"Product Selector Guide"* (DS00148) for the complete list of demonstration, development and evaluation kits.

27.0 ELECTRICAL CHARACTERISTICS

Absolute Maximum Ratings^(†)

| Ambient temperature under bias | 40°C to +100°C |
|--|----------------|
| Storage temperature | |
| Voltage on any digital only input pin or MCLR with respect to Vss (except VDD) | |
| Voltage on any combined digital and analog pin with respect to Vss | |
| Voltage on VDDCORE with respect to Vss | |
| Voltage on VDD with respect to Vss | |
| Total power dissipation (Note 1) | |
| Maximum current out of Vss pin | |
| Maximum current into VDD pin | 250 mA |
| Input clamp current, Iк (VI < 0 or VI > VDD) (Note 2) | |
| Output clamp current, IOK (VO < 0 or VO > VDD) (Note 2) | |
| Maximum output current sunk by any PORTB and PORTC I/O pins | |
| Maximum output current sunk by any PORTD, PORTE and PORTJ I/O pins | 8 mA |
| Maximum output current sunk by any PORTA, PORTF, PORTG and PORTH I/O pins (Note 3) | 2 mA |
| Maximum output current sourced by any PORTB and PORTC I/O pins | 25 mA |
| Maximum output current sourced by any PORTD, PORTE and PORTJ I/O pins | 8 mA |
| Maximum output current sourced by any PORTA, PORTF, PORTG and PORTH I/O pins (Note | |
| Maximum current sunk by all ports combined | 200 mA |
| Maximum current sourced by all ports combined | 200 mA |
| | |

Note 1: Power dissipation is calculated as follows:

 $Pdis = Vdd x \{Idd - \sum Ioh\} + \sum \{(Vdd - Voh) x Ioh\} + \sum (Vol x Iol) + \sum (Vtpout x Itpout)$

- 2: No clamping diodes are present.
- **3:** Exceptions are RA<1> and RA<0>, which are capable of directly driving LEDs up to 8 mA.

† NOTICE: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

27.1 DC Characteristics: Supply Voltage, PIC18F97J60 Family (Industrial)

Note 1: This is the limit to which VDD can be lowered in Sleep mode, or during a device Reset, without losing RAM data.

| | 7J60 Family strial) | Standard Operating Conditions (unless otherwise stated)Operating temperature $-40^{\circ}C \le TA \le +85^{\circ}C$ for industrial | | | | | | | |
|--------------|---|--|-------|-------|------------|---|--|--|--|
| Param No. | Device | Тур | Max | Units | Conditions | | | | |
| | Power-Down Current (IPD) ⁽¹⁾ | | | | | | | | |
| | All devices | 19.0 | 69.0 | μA | -40°C | VDD = 2.0V, | | | |
| | | 21.0 | 69.0 | μA | +25°C | $VDDCORE = 2.0V^{(4)}$ | | | |
| | | 45.0 | 149.0 | μA | +85°C | (Sleep mode) | | | |
| | All devices | 26.0 | 104.0 | μA | -40°C | VDD = 2.5V, | | | |
| | | 29.0 | 104.0 | μA | +25°C | VDDCORE = $2.5V^{(4)}$ | | | |
| | | 60.0 | 184.0 | μA | +85°C | (Sleep mode) | | | |
| | All devices | 40.0 | 203.0 | μA | -40°C |) (==========) ((5) | | | |
| | | 44.0 | 203.0 | μA | +25°C | VDD = 3.3V ⁽⁵⁾ (Sleep mode) | | | |
| | | 105.0 | 209.0 | μA | +85°C | (Ciccp mode) | | | |

Note 1: The power-down current in Sleep mode does not depend on the oscillator type. Power-down current is measured with the part in Sleep mode, with all I/O pins in high-impedance state and tied to VDD or VSs and all features that add delta current disabled (such as WDT, Timer1 oscillator, etc.).

2: The supply current is mainly a function of operating voltage, frequency and mode. Other factors, such as I/O pin loading and switching rate, oscillator type and circuit, internal code execution pattern and temperature, also have an impact on the current consumption.

The test conditions for all IDD measurements in active operation mode are:

OSC1 = external square wave, from rail-to-rail; all I/O pins tri-stated, pulled to VDD;

MCLR = VDD; WDT enabled/disabled as specified.

- **3:** Standard, low-cost 32 kHz crystals have an operating temperature range of -10°C to +70°C. Extended temperature crystals are available at a much higher cost.
- 4: Voltage regulator disabled (ENVREG = 0, tied to Vss).
- 5: Voltage regulator enabled (ENVREG = 1, tied to VDD).
- 6: For ∆IETH, the specified current includes current sunk through TPOUT+ and TPOUT-. LEDA and LEDB are disabled for all testing.

| | | 14.5 | 21.6 | mA | +85°C | | | | |

Note 1: The power-down current in Sleep mode does not depend on the oscillator type. Power-down current is measured with the part in Sleep mode, with all I/O pins in high-impedance state and tied to VDD or VSs and all features that add delta current disabled (such as WDT, Timer1 oscillator, etc.).

2: The supply current is mainly a function of operating voltage, frequency and mode. Other factors, such as I/O pin loading and switching rate, oscillator type and circuit, internal code execution pattern and temperature, also have an impact on the current consumption.

The test conditions for all IDD measurements in active operation mode are:

- OSC1 = external square wave, from rail-to-rail; all I/O pins tri-stated, pulled to VDD;
- MCLR = VDD; WDT enabled/disabled as specified.
- **3:** Standard, low-cost 32 kHz crystals have an operating temperature range of -10°C to +70°C. Extended temperature crystals are available at a much higher cost.
- 4: Voltage regulator disabled (ENVREG = 0, tied to Vss).
- 5: Voltage regulator enabled (ENVREG = 1, tied to VDD).
- 6: For ∆IETH, the specified current includes current sunk through TPOUT+ and TPOUT-. LEDA and LEDB are disabled for all testing.

| D312 | VRur | Unit Resistor Value (R) | — | 2k | — | Ω | |
| 310 | TSET | Settling Time ⁽¹⁾ | | | 10 | μs | |

Note 1: Settling time measured while CVRR = 1 and CVR3:CVR0 transitions from '0000' to '1111'.

TABLE 27-4: INTERNAL VOLTAGE REGULATOR SPECIFICATIONS

| Operatin | Operating Conditions: $-40^{\circ}C \le TA \le +85^{\circ}C$ (unless otherwise stated) | | | | | | |
|--------------|---|--|---|-----|--|----|---|
| Param No. | Sym | Sym Characteristics Min Typ Max Units Comments | | | | | |
| | Vrgout | Regulator Output Voltage | | 2.5 | | V | |
| | Cf | External Filter Capacitor Value | 1 | 10 | | μF | Capacitor must be low series resistance |

27.4 AC (Timing) Characteristics

27.4.1 TIMING PARAMETER SYMBOLOGY

The timing parameter symbols have been created following one of the following formats:

| 1. TppS2ppS | | 3. TCC:ST | (I ² C specifications only) |
|----------------------------|---------------------------------|-----------|--|
| 2. TppS | | 4. Ts | (I ² C specifications only) |
| Т | | | |
| F | Frequency | Т | Time |
| Lowercase le | etters (pp) and their meanings: | | |
| рр | | | |
| сс | ECCP1 | osc | OSC1 |
| ck | CLKO | rd | RD |
| cs | CS | rw | RD or WR |
| di | SDIx | sc | SCKx |
| do | SDOx | SS | SSx |
| dt | Data in | tO | TOCKI |
| io | I/O port | t1 | T13CKI |
| mc | MCLR | wr | WR |
| Uppercase le | etters and their meanings: | | |
| S | | | |
| F | Fall | Р | Period |
| н | High | R | Rise |
| I | Invalid (High-Impedance) | V | Valid |
| L | Low | Z | High-Impedance |
| I ² C only | | | |
| AA | Output access | High | High |
| BUF | Bus free | Low | Low |
| TCC:ST (I ² C s | specifications only) | | |
| CC | | | |
| HD | Hold | SU | Setup |
| ST | | | |
| DAT | DATA input hold | STO | Stop condition |
| STA | Start condition | | |

27.4.2 TIMING CONDITIONS

The temperature and voltages specified in Table 27-5 apply to all timing specifications unless otherwise noted. Figure 27-3 specifies the load conditions for the timing specifications.

TABLE 27-5: TEMPERATURE AND VOLTAGE SPECIFICATIONS – AC

| | Standard Operating Conditions (unless otherwise stated) |
|--------------------|--|
| AC CHARACTERISTICS | Operating temperature $-40^{\circ}C \le TA \le +85^{\circ}C$ for industrial Operating voltage VDD range as described in DC spec Section 27.1 and Section 27.3. |
| | |

FIGURE 27-3: LOAD CONDITIONS FOR DEVICE TIMING SPECIFICATIONS

27.4.3 TIMING DIAGRAMS AND SPECIFICATIONS

TABLE 27-6: EXTERNAL CLOCK TIMING REQUIREMENTS

| Param. No. | Symbol | Characteristic | Min | Мах | Units | Conditions |
|---------------|---------------|---|-----|---------|-------|--------------------------|
| 1A | Fosc | External CLKI Frequency ⁽¹⁾ | DC | 41.6667 | MHz | EC Oscillator mode |
| | | Oscillator Frequency ⁽¹⁾ | 6 | 25 | MHz | HS Oscillator mode |
| 1 | Tosc | External CLKI Period ⁽¹⁾ | 24 | _ | ns | EC Oscillator mode |
| | | Oscillator Period ⁽¹⁾ | 40 | 167 | ns | HS Oscillator mode |
| 2 | Тсү | Instruction Cycle Time ⁽¹⁾ | 96 | _ | ns | TCY = 4/FOSC, Industrial |
| 3 | TosL, TosH | External Clock in (OSC1) High or Low Time | 10 | — | ns | EC Oscillator mode |
| 4 | TosR, TosF | External Clock in (OSC1) Rise or Fall Time | — | 7.5 | ns | EC Oscillator mode |
| 5 | | Clock Frequency Tolerance | _ | ±50 | ppm | Ethernet module enabled |

Note 1: Instruction cycle period (TcY) equals four times the input oscillator time base period for all configurations except PLL. All specified values are based on characterization data for that particular oscillator type under standard operating conditions with the device executing code. Exceeding these specified limits may result in an unstable oscillator operation and/or higher than expected current consumption. All devices are tested to operate at "min." values with an external clock applied to the OSC1/CLKI pin. When an external clock input is used, the "max." cycle time limit is "DC" (no clock) for all devices.

| Param No. | Sym | Characteristic | Min | Тур† | Max | Units | Conditions |
|--------------|-----------------|-------------------------------|-----|------|------|-------|------------|
| F10 | Fosc | Oscillator Frequency Range | 8 | — | 25 | MHz | HSPLL mode |
| | | | 8 | _ | 37.5 | MHz | ECPLL mode |
| F11 | Fsys | On-Chip VCO System Frequency | 20 | _ | 62.5 | MHz | |
| F12 | t _{rc} | PLL Start-up Time (Lock Time) | — | _ | 2 | ms | |
| F13 | ΔCLK | CLKO Stability (Jitter) | -2 | _ | +2 | % | |

TABLE 27-7: PLL CLOCK TIMING SPECIFICATIONS (VDD = 2.6V TO 3.6V)

† Data in "Typ" column is at 3.3V, 25°C, unless otherwise stated. These parameters are for design guidance only and are not tested.

TABLE 27-8: AC CHARACTERISTICS: INTERNAL RC ACCURACY PIC18F97J60 FAMILY (INDUSTRIAL)

| Param No. | Characteristic | Min | Тур | Max | Units | Conditions |
|--------------|---|------|-----|------|-------|------------|

| D102 | Св | Bus Capacitive Loading | | | 400 | pF | |

TABLE 27-21: I²C[™] BUS DATA REQUIREMENTS (SLAVE MODE)

Note 1: As a transmitter, the device must provide this internal minimum delay time to bridge the undefined region (min. 300 ns) of the falling edge of SCLx to avoid unintended generation of Start or Stop conditions.

2: A Fast mode I²C[™] bus device can be used in a Standard mode I²C bus system, but the requirement, TSU:DAT ≥ 250 ns, must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCLx signal. If such a device does stretch the LOW period of the SCLx signal, it must output the next data bit to the SDAx line,

TR max. + TSU:DAT = 1000 + 250 = 1250 ns (according to the Standard mode I²C bus specification), before the SCLx line is released.

28.0 DC AND AC CHARACTERISTICS GRAPHS AND TABLES

Graphs and tables are not available at this time.

NOTES:

APPENDIX A: REVISION HISTORY

Revision A (March 2006)

Original data sheet for the PIC18F97J60 family of devices.

Revision B (October 2006)

First revision. Includes preliminary electrical specifications; revised and updated material on the Ethernet module; updated material on Reset integration; and updates to the device memory map.

APPENDIX B: DEVICE DIFFERENCES

The differences between the devices listed in this data sheet are shown in Table B-1.

| Features | PIC18F66J60 | PIC18F66J65 | PIC18F67J60 | PIC18F86J60 | PIC18F86J65 | PIC18F87J60 | PIC18F96J60 | PIC18F96J65 | PIC18F97J60 |

THE MICROCHIP WEB SITE

Microchip provides online support via our WWW site at www.microchip.com. This web site is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the web site contains the following information:

- **Product Support** Data sheets and errata, application notes and sample programs, design resources, user's guides and hardware support documents, latest software releases and archived software
- General Technical Support Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
- Business of Microchip Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Microchip sales offices, distributors and factory representatives

CUSTOMER CHANGE NOTIFICATION SERVICE

Microchip's customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip web site at www.microchip.com, click on Customer Change Notification and follow the registration instructions.

CUSTOMER SUPPORT

Users of Microchip products can receive assistance through several channels:

- Distributor or Representative
- Local Sales Office
- Field Application Engineer (FAE)
- Technical Support
- Development Systems Information Line

Customers should contact their distributor, representative or field application engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

Technical support is available through the web site at: http://support.microchip.com

READER RESPONSE

It is our intention to provide you with the best documentation possible to ensure successful use of your Microchip product. If you wish to provide your comments on organization, clarity, subject matter, and ways in which our documentation can better serve you, please FAX your comments to the Technical Publications Manager at (480) 792-4150.

Please list the following information, and use this outline to provide us with your comments about this document.
