

FEATURES

- 10 MHz–300 MHz Input Frequency
- Baseband (I/Q) Digital Output
- 10 kHz–150 kHz Output Signal Bandwidth
- 12 dB SSB NF
- > -1 dBm IIP3 (High IIP3 Mode)
- 25 dB Continuous AGC Range + 16 dB Gain Step
- Support for LO and Sampling Clock Synthesis
- Programmable Decimation Rate, Output Format, AAF Cutoff, AGC and Synthesizer Settings
- 360 Ω Input Impedance
- 2.7 V–3.6 V Supply Voltage
- Low Current: 42 mA Typ (High IIP3 Mode), 30 mA Typ (Low IIP3, Fixed Gain Mode)
- 48-Lead LQFP Package (1.4 mm Thick)

APPLICATIONS

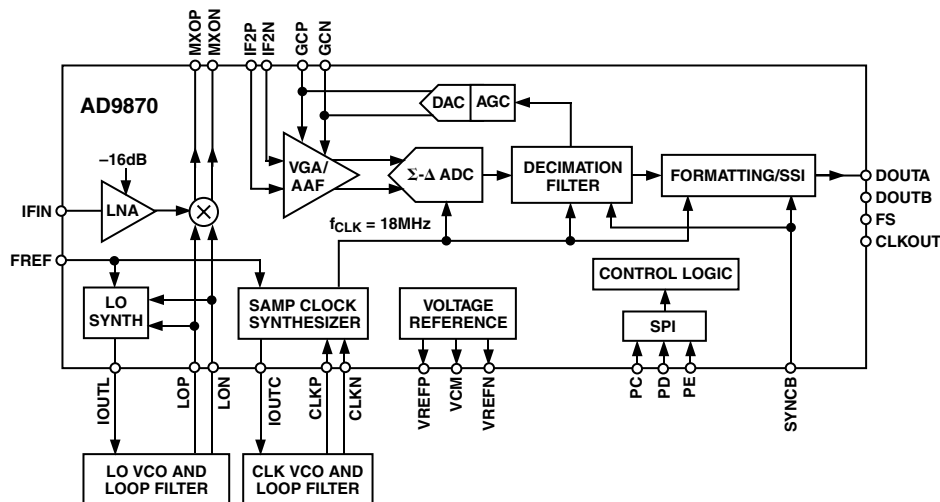

- Portable and Mobile Radio Products
- Digital UHF/VHF FDMA Products
- TETRA

PRODUCT DESCRIPTION

The AD9870 is a general-purpose IF subsystem that digitizes a low-level 10 MHz–300 MHz IF input with a bandwidth of up to 150 kHz. The signal chain of the AD9870 consists of a low-noise amplifier, a mixer, a variable gain amplifier with integral antialias filter, a bandpass sigma-delta analog-to-digital converter, and a decimation filter with programmable decimation factor. An automatic gain control (AGC) circuit provides the AD9870 with 25 dB of continuous gain adjustment. The high dynamic range of the bandpass sigma-delta converter allows the AD9870 to cope with blocking signals that are as much as 70 dB stronger than the desired signal. Auxiliary blocks include clock and LO synthesizers as well as a serial peripheral interface (SPI) port.

The SPI port programs numerous parameters of the AD9870, including the synthesizer divide ratios, the AGC attack and decay times, the AGC target signal level, the decimation factor, the output data format, the 16 dB attenuator, and the bias currents of several blocks. Reducing bias currents allows the user to reduce power consumption at the expense of reduced performance.

*Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum ratings for extended periods may affect device reliability.

Model	Temperature Range	Package Description	Package Option
AD9870	-40°C to +85°C	48-Lead Thin Plastic Quad Flatpack (LQFP)	ST-48
AD9870EB		Evaluation Board	

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD9870 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high-energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PIN CONFIGURATION

PIN FUNCTION DESCRIPTIONS

Pin	Mnemonic	Description	Pin	Mnemonic	Description
1	MXOP	Mixer Output, Positive	25	PE	Enable Input for SPI Port
2	MXON	Mixer Output, Negative	26	VDDD	Positive Power Supply for Internal Digital Functions
3	GNDF	Ground for VGA	27	VDDH	Positive Power Supply for Digital Interface
4	IF2N	Second IF Input (to VGA), Negative	28	CLKOUT	Clock Output for SSI Port
5	IF2P	Second IF Input (to VGA), Positive	29	DOUTA	Data Output for SSI Port
6	VDDF	Positive Power Supply for Antialias Filter/VGA	30	DOUTB	Data Output for SSI Port, Unused
7	GCP	Filter Capacitor for VGA Gain Control, Positive	31	FS	Frame Sync for SSI Port
8	GCN	Filter Capacitor for VGA Gain Control, Negative	32	GNDH	Ground for Digital Interface
9	VDDA	Positive Power Supply for ADC	33	SYNCB	Resets the SSI and Decimator Counters
10	GNDA	Ground for ADC	34	GNDS	Substrate Ground
11	VREFP	Voltage Reference, Positive	35	FREF	Reference Frequency Input for Both Synthesizers
12	VREFN	Voltage Reference, Negative	36	GNDL	Ground for LO Synthesizer
13	VCM	Common-Mode Voltage (Requires 20 kΩ to GNDA)	37	GNDP	Ground for LO Synthesizer Charge Pump
14	VDDQ	Pos. Power Supply for Clock Synth. Charge Pump	38	IOUTL	LO Synthesizer Charge Pump Output Current
15	IOUTC	Clock Synthesizer Charge Pump Output Current	39	VDDP	Positive Power Supply for LO Synth. Charge Pump
16	GNDQ	Ground for Clock Synthesizer Charge Pump	40	VDDL	Positive Power Supply for LO Synthesizer
17	VDDC	Positive Power Supply for Clock Synthesizer	41	CXVM	External Capacitor for Mixer Bias
18	GNDC	Ground for Clock Synthesizer	42	LON	LO Input to Mixer and LO Synthesizer, Negative
19	CLKP	Sampling Clock Input/Clock VCO Tank, Positive	43	LOP	LO Input to Mixer and LO Synthesizer, Positive
20	CLKN	Sampling Clock Input/Clock VCO Tank, Negative	44	CXVL	External Capacitor for Preamp Power Supply
21	GNDS	Substrate Ground	45	GNDI	Ground for Mixer and Preamp
22	GNDD	Ground for Digital Functions	46	CXIF	External Capacitor for Preamp Bias
23	PC	Clock Input for SPI Port	47	IFIN	First IF Input (to Preamp)
24	PD	Data I/O for SPI Port	48	VDDI	Positive Power Supply for Mixer and Preamp

SERIAL PERIPHERAL INTERFACE (SPI)

The Serial Peripheral Interface (SPI) is a bidirectional serial port. It is used to load configuration information into the registers listed below as well as to read back their contents. Table I provides a list of the registers that may be programmed through the SPI port. Addresses and default values are given in hexadecimal form.

Table I. SPI Address Map

Address (Hex)	Bit Breakdown	Width	Default Value	Name	Description
POWER CONTROL REGISTERS					
0x00	(7:0)	8	0xFF	STBY	Standby Control Bits (REF, LO, CKO, CK, GC, LNAMX, VGA, ADC).
0x01	(7:6)	2	0	LNAB	LNA Bias Current (0 = 0.5 mA, 1 = 1 mA, 2 = 2 mA, 3 = 3 mA).
	(5:4)	2	0	MIXB	Mixer Bias Current (0 = 1 mA, 1 = 2 mA, 2 = 3 mA, 3 = 4 mA).
	(3:2)	2	0	CKOB	CK Oscillator Bias (0 = 0.25 mA, 1 = 0.35 mA, 2 = 0.53 mA, 3 = 0.85 mA).
	(1:0)	2	1	ADCB	ADC Amplifier Bias (0 = 2.4 mA, 1 = 3.2 mA, 2 = 4.0 mA, 3 = 4.8 mA).
0x02	(7:0)	8	0x00	TEST	Factory Test Mode.
AGC					
0x03	(7)	1	0	ATTEN	Apply 16 dB attenuation in the front end.
	(6:0)	7	0x3F	AGCG(14:8)	AGC Gain Setting (7 MSBs of a 15-bit two's-complement word).
0x04	(7:0)	8	0xFF	AGCG(7:0)	AGC Gain Setting (8 LSBs of a 15-bit two's-complement word). Default corresponds to maximum gain.
0x05	(7:4)	4	0	AGCA	AGC Attack Time Setting. Default yields 50 Hz raw loop bandwidth.
	(3:0)	4	0	AGCD	AGC Decay Time Setting. Default is decay time = attack time.
0x06	(7:4)	4	0	AGCO	AGC Overload Update Setting. Default is slowest update.
	(3:0)	4	0	AGCD	Fast AGC (Minimizes resistance seen between GCN and GCP).
	(2:0)	3	0	AGCR	AGC Enable/Reference Level (disabled, 3 dB, 6 dB, 9 dB, 12 dB, 15 dB below clip).
DECIMATION FACTOR					
0x07	(3:0)	4	4	M	Decimation Factor = $60 \times (M + 1)$. Default is decimate-by-300.
LO SYNTHESIZER					
0x08	(5:0)	6	0x00	LOR(13:8)	Reference Frequency Divisor (6 MSBs of a 14-Bit Word).
0x09	(7:0)	8	0x38	LOR(7:0)	Reference Frequency Divisor (8 LSBs of a 14-Bit Word). Default (56) Yields 300 kHz from $f_{REF} = 16.8$ MHz.
0x0A	(7:5)	3	0x5	LOA	"A" Counter (Prescaler Control Counter).
	(4:0)	5	0x00	LOB(12:8)	"B" Counter MSBs (5 MSBs of a 13-Bit Word). Default LOA and LOB Values Yield 300 kHz from 73.35 MHz–2.25 MHz.
0x0B	(7:0)	8	0x1D	LOB(7:0)	"B" Counter LSBs (8 LSBs of a 13-Bit Word).
0x0C	(6)	1	0	LOF	Enable Fast Acquire.
	(5)	1	0	LOINV	Invert Charge Pump (0 = Pump_Up \Rightarrow IOUTL Sources Current).
	(4:2)	3	0	LOI	Charge Pump Current in Normal Operation. $I_{PUMP} = (LOI + 1) \times 0.625$ mA.
	(1:0)	2	0	LOTM	Manual Control of LO Charge Pump (3 = Off, 2 = Down, 1 = Up, 0 = Normal).
0x0D	(3:0)	4	0x0	LOFA(13:8)	LO Fast Acquire Time Unit (4 MSBs of a 14-Bit Word).
0x0E	(7:0)	8	0x04	LOFA(7:0)	LO Fast Acquire Time Unit (8 LSBs of a 14-Bit Word).
CLOCK SYNTHESIZER					
0x10	(5:0)	6	00	CKR(13:8)	Reference Frequency Divisor (6 MSBs of a 14-Bit Word).
0x11	(7:0)	8	0x38	CKR(7:0)	Reference Frequency Divisor (8 LSBs of a 14-Bit Word). Default Yields 300 kHz from $f_{REF} = 16.8$ MHz. Min = 3, Max = 16383.
0x12	(4:0)	5	0x00	CKN(12:8)	Synthesized Frequency Divisor (5 MSBs of a 13-Bit Word).

AD9870

Address (Hex)	Bit Breakdown	Width	Default Value	Name	Description
CLOCK SYNTHESIZER (Continued)					
0x13	(7:0)	8	0x3C	CKN(7:0)	Synthesized Frequency Divisor (8 LSBs of a 13-Bit Word). Default Yields 300 kHz from $f_{CLK} = 18$ MHz. Min = 3, Max = 8191.
0x14	(6)	1	0	CKF	Enable Fast Acquire.
	(5)	1	0	CKINV	Invert Charge Pump (0 = Pump_Up \Rightarrow IOUTC Sources Current).
	(4:2)	3	0	CKI	Charge Pump Current in Normal Operation. $I_{PUMP} = (CKI + 1) \times 0.625$ mA.
	(1:0)	2	0	CKTM	Manual Control of CLK Charge Pump (0 = Off, 1 = Down, 2 = Up, 3 = Normal).
0x15	(3:0)	4	0x0	CKFA(13:8)	CK Fast Acquire Time Unit (4 MSBs of a 14-Bit Word).
0x16	(7:0)	8	0x04	CKFA(7:0)	CK Fast Acquire Time Unit (8 LSBs of a 14-Bit Word).
SSI CONTROL					
0x18	(7:0)	8	0x12	SSICRA	SSI Control Register A. See Table III. (Default is FS and CLKOUT Three-Stated.)
0x19	(1:0)	2	0x0	SSICRB	SSI Control Register B. See Table III.
0x1A	(3:0)	4	1	SSIORD	Output Rate Divisor. $f_{CLKOUT} = f_{CLK}/SSIORD$.
AAF CAPACITOR SETTING/CALIBRATION					
0x1C	(7:0)	8	0x00	AAR	Antialias Response Selector. 0x60 Is Recommended.
0x1D	5	1	0	ERRN	Error Flag.
	(4:0)	5	0x0	CAPN	AAF N-Well Capacitor Setting.
0x1E	5	1	0	ERRP	Error Flag.
	(4:0)	15	0x0	CAPP	AAF Poly-Poly Capacitor Setting.
TEST REGISTERS AND SPI PORT READ ENABLE					
0x38	(7:0)	8	0x00	TEST	Factory Test Mode.
0x39	0	1	0	TEST	Factory Test Mode.
0x3A	(7:4, 2:0)	7	0x0	TEST	Factory Test Mode.
	(3)	1	0	SPIREN	Enable Read from SPI Port.
0x3B–0x3F	(7:0)	1	0x00	TEST	Factory Test Mode.

Figure 1. SPI Timing

Figure 1 illustrates the timing for the SPI port. After the peripheral enable (PE) signal goes low, data (PD) is read on the rising edges of the clock (PC). The first bit is a read/not-write indicator; the next six bits are address bits; the eighth bit is ignored; the last eight bits are data. Address and data are given MSB first. If the read/not-write indicator is a zero, a write operation occurs and the data bits are shifted in. If the read/not-write indicator is a one and if the read-back enable bit (Reg. 3A, Bit 3) has been set, a read operation occurs and data is shifted out the data pin on the falling edges of the clock. PE stays low during the operation and goes high at the end of the transfer. If PE rises before an additional eight clock cycles have passed, the operation is aborted.

If PE stays low for an additional eight clock cycles, the destination address is incremented and another eight bits of data are shifted in. Again, should PE rise early, the current byte is ignored. By using this implicit addressing mode, the entire chip can be configured with a single write operation. Registers identified as being subject to frequent updates, namely those associated with power control and AGC operation, have been assigned adjacent addresses to minimize the time required to update them. The auto-increment mode is not supported for read operations.

Multibyte registers are “big-endian” (the most significant byte has the lower address) and are updated when a write to the least significant byte occurs.

SYNCHRONOUS SERIAL INTERFACE (SSI)

The primary output of the AD9870 is the converted signal, which is available from the SSI port as a serial bit stream. The bit stream consists of a 16-bit I word followed by a 16-bit Q word, where each word is given MSB first and is in two’s-complement form. AGC, signal strength, and synchronization information may also be embedded in the data stream. The output bit rate (f_{CLKOUT}) is equal to the modulator clock frequency (f_{CLK}) divided by the contents of the SSIORD register. Users must verify that the output bit rate is sufficient to accommodate the required number of bits per frame (see Table II) and that the chosen output rate does not introduce harmful spurs. Idle (high) bits are used to fill out each frame; the frame lengths listed in Table II assume that with embedded frame sync (EFS = 1), at least 10 idle bits are desired.

Table II. Max Legal SSIORD Values for 16-Bit I/O Data and Decimation by 60 n

Bits per Sample (Min No. of Bits per Frame)			
EAGC = 0		EAGC = 1	
EFS = 1	EFS = 0	EFS = 0	EFS = 1
32	49	48/40*	69/59*

M	Dec'n Factor	Output Sample Rate (kSPS, for $f_{CLK} = 18 \text{ MHz}$)	Max SSIORD Setting (Decimal)			
			EAGC = 0		EAGC = 1	
			EFS = 0	EFS = 1	EFS = 0	EFS = 1
0	60	300	1	1	1	1
1	120	150	3	2	2	1
2	180	100	5	3	3	2
3	240	75	7	4	5	3
4	300	60	9	5	6	4
5	360	50	11	7	7	5
6	420	42.857	13	8	8	5

14	900	20	15	15	15	12
15	960	18.75	15	15	15	13

*If the AAGC Bit of SSICRA is set.

Figure 2 illustrates the output timing of the SSI port for several SSI control register settings. In the default mode of operation, data is shifted out on rising edges of CLKOUT after a pulse is output from the frame sync (FS) pin. As described above, the output data consists of a 16-bit I sample followed by a 16-bit Q sample plus two optional bytes containing AGC and status information.

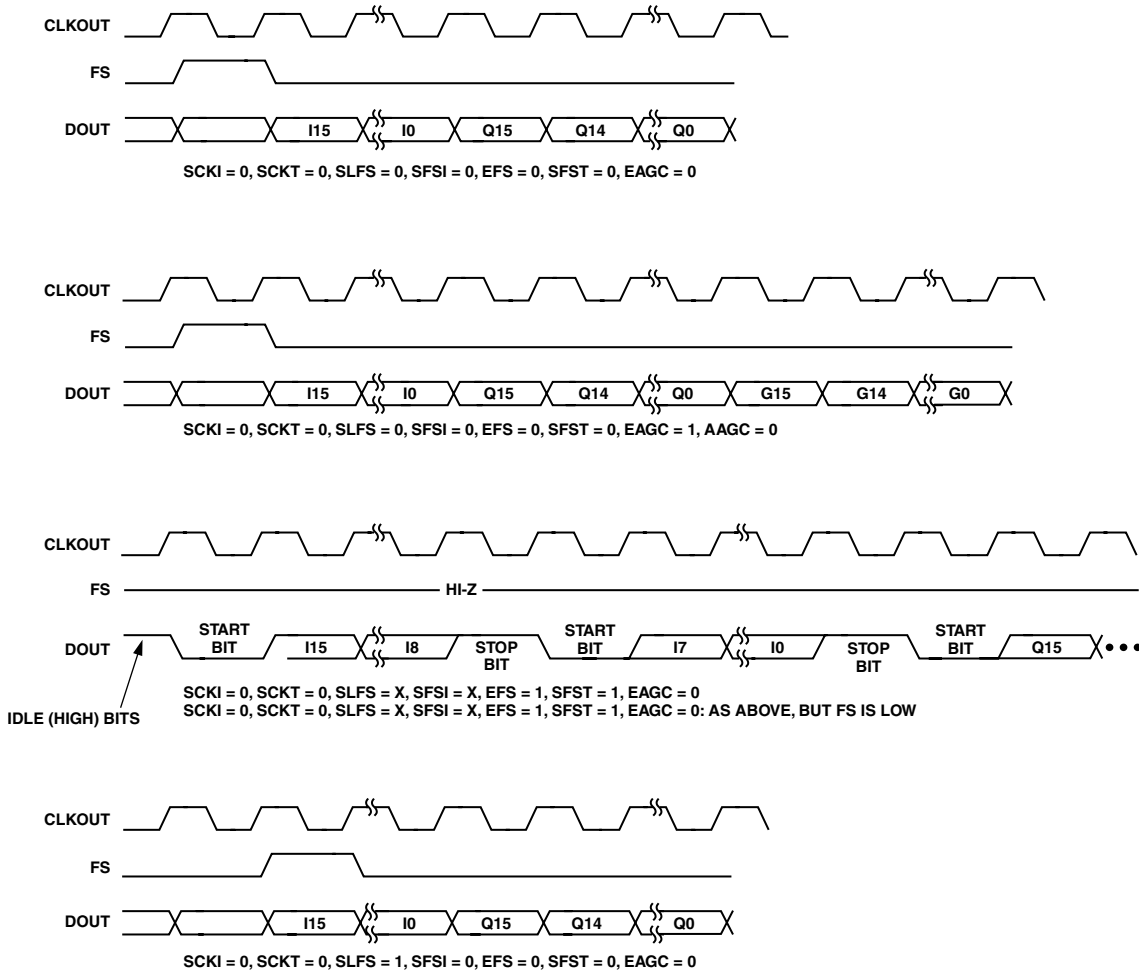

Figure 2. SSI Timing for Several SSICR Settings

The two optional bytes are output if the EAGC bit of SSICRA is set. The first byte contains the eight most significant bits of the AGC DAC setting while the second byte contains a 2-bit overload field, a 2-bit reset field, a 2-bit large-signal field, a zero bit, and a trailing high bit. The overload, reset, and large-signal fields contain the number of overload, reset, and large-signal events since the last report, respectively, saturating at three should the number of events equal or exceed this amount. The two optional bytes follow the I and Q data as a 16-bit word provided the AAGC bit of SSICRA is not set. If the AAGC bit is set, the two bytes follow the I and Q data in an alternating fashion. In this “alternate AGC data” mode, the LSB of the byte containing the AGC DAC setting is zero; the LSB of the byte containing reset/overload information is always a one. Figure 3 illustrates the fields of the SSI data frames.

Figure 3. SSI Frame Structure

When the embedded frame sync bit (EFS) is set, FS is either low or in a high Z state (as determined by the SFST bit), and framing information is embedded in the data stream. In this mode, each eight bits of data are surrounded by a start bit (low) and a stop bit (high), and each frame ends with at least 10 high bits. Other control bits can be used to invert the frame sync (SFSI), to delay the frame sync pulse by one clock period (SLFS), to invert the clock (SCKI), or to set the clock (SCKT) to a high Z state. Note that if EFS is set, SLFS is a don't care.

The AD9870 also provides the means for controlling the switching characteristics of the digital output signals. With a 25 pF load, the rise and fall times of these signals are no more than 120 ns, 45 ns, 16 ns, or 10 ns if the DS (drive strength) setting is 0, 1, 2, or 3, respectively.

Table III. SSI Control Registers

Name	Width	Description
SSICRA (ADDR = 0x18)		
AAGC	1	Alternate AGC Data Bytes
EAGC	1	Embed AGC Data
EFS	1	Embed Frame Sync
SFST	1	Three-State Frame Sync
SFSI	1	Invert Frame Sync
SLFS	1	Late Frame Sync (1 = Late, 0 = Early)
SCKT	1	Three-State CLKOUT
SCKI	1	Invert CLKOUT
SSICRB (ADDR = 0x19)		
DS	2	FS, CLKOUT, and DOUT Drive Strength

POWER CONTROL

To allow power consumption to be minimized, the AD9870 possesses numerous SPI-programmable power-down and bias control bits.

Each major block may be powered down through the appropriate bit of the STBY register. This scheme provides the greatest flexibility for configuring the IC to a specific application as well as for tailoring the IC's power-down and wake-up characteristics. Table IV summarizes the function of each of the STBY bits.

Note, when all the blocks are in standby, the master reference circuit is also put into standby and thus the current is reduced by a further 0.4 mA.

The AD9870 also allows control over the bias current in several key blocks. The effects on current consumption and system performance are described in the section dealing with the affected block.

Table IV. Standby Control Bits

STBY Bit	Effect	Current Reduction (mA) ¹	Wake-Up Time (ms)
REF	Voltage Reference Off, VREFP, VREFN in High Z State.	1.5	1.0 (C _{REF} = 4.7 μF) Note 2
LO	LO Synthesizer Off, IOU _{TL} in High Z State.	4.8	
CKO	Clock Oscillator Off.	0.25	Note 2
CK	Clock Synthesizer Off, IOU _{TC} in High Z State.	1.4	Note 2
	Clock Buffer Off if ADC Is Off.		
GC	Gain Control DAC Off. GCP, GCN in High Z State.	3	Depends on C _{GC}
LNAMX	LNA and Mixer Off. I(VDDI) = 0, CXVM, CXVL, CXIF in High Z.	10	
VGA	VGA/AAF Off. IF2P, IF2N in High Z State.	6	0.1
ADC	ADC Off; Clock Buffer Off if CK Synth. Off; VCM in High Z State; Clock-to-Digital Filter Suspended; Digital Outputs Static.	13.8	0.1

NOTES

¹When all blocks are in standby, the master reference circuit is also put into standby and thus the current is reduced by a further 0.4 mA.

²Wake-up time is application-dependent.

LO SYNTHESIZER

The LO synthesizer shown in Figure 4 is a fully programmable PLL capable of 6.25 kHz resolution at input frequencies up to 300 MHz and reference clocks of up to 25 MHz. It consists of a low-noise digital Phase-Frequency Detector (PFD), a variable output current charge pump (CP), a 14-bit reference divider, programmable A and B counters and a dual-modulus 8/9 prescaler. The A (3-bit) and B (13-bit) counters, in conjunction with the dual 8/9 modulus prescaler, implement an N divider with $N = 8 \times B + A$. In addition, the 14-bit reference counter (R Counter) allows selectable input reference frequencies, f_{REF} , at the PFD input. A complete PLL (Phase-Locked Loop) can be implemented if the synthesizer is used with an external loop filter and VCO (Voltage Controlled Oscillator).

AD9870

The A, B, and R counters can be programmed via the following registers: LOA, LOB, and LOR. The charge pump output current is programmable via the LOI register from 0.625 mA to 5.0 mA using the following equation: $I_{PUMP} = (LOI + 1) \times 0.625 \text{ mA}$. An on-chip lock detect function (enabled by the LOF bit) automatically increases the output current for faster settling during channel changes. The synthesizer may also be disabled using the LO standby bit located in the STBY register.

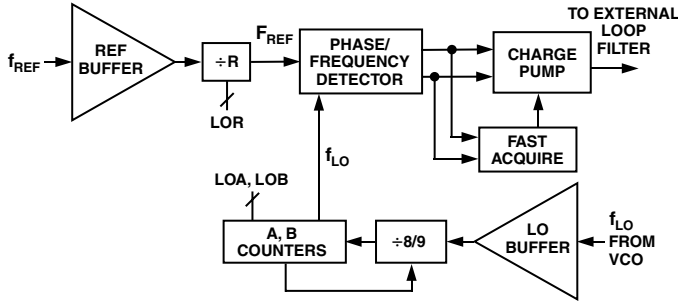

Figure 4. LO Synthesizer

The LO (and CLK) Synthesizer works in the following manner. The reference frequency, f_{REF} , is buffered and divided by the value held in the R counter. The internal F_{REF} is then compared to a divided version of the VCO frequency, f_{LO} . The phase/frequency detector provides UP and DOWN pulses whose width vary depending upon the difference in phase and frequency of its two input signals. The UP/DOWN pulses control the charge pump, making current available to charge the external low-pass loop filter when there is a discrepancy between the inputs of the PFD. The output of the low-pass filter feeds an external VCO whose output frequency, F_{LO} , is driven such that its divided down version, F_{LO} , matches that of F_{REF} thus closing the feedback loop.

The synthesized frequency is related to the reference frequency and the LO register contents as follows:

$$f_{LO} = (8 \times LOB + LOA) / LOR \times f_{REF}$$

Note, the minimum allowable value in the LOB register is 3 and its value must always be greater than that loaded into LOA. The stability, phase noise, spur performance, and transient response of the AD9870's LO (and CLK) synthesizers are determined by the external loop filter, the VCO, the N-divide factor, and the reference frequency, f_{REF} . An excellent reference book on PLL synthesizers titled *PLL Performance, Simulation and Design* by Deen Banerjee is available for free at www.national.com.

An example may help illustrate how the values of LOA, LOB, and LOR can be selected. Consider an application employing a 13 MHz crystal oscillator (i.e., $f_{REF} = 13 \text{ MHz}$) with the requirement that $F_{REF} = 100 \text{ kHz}$ and $f_{LO} = 143 \text{ MHz}$ (i.e., high-side injection with $IF = 140.75 \text{ MHz}$ and $f_{SAMPLE} = 18 \text{ MSPS}$). LOR is selected to be 130 such that $f_{REF} = 100 \text{ kHz}$. The N-divider factor is 1430, which can be realized by selecting $LOB = 178$ and $LOA = 6$.

Figure 5 shows the equivalent input structures of the synthesizers' LO and REF buffers (excluding the ESD structures). The LO input is fed to the LO synthesizers buffer as well as the AD9870's mixer's LO port. Both inputs are self-biasing and thus tolerate ac-coupled inputs. The LO input can be driven with a single-ended or differential signal. Single-ended dc-coupled inputs should ensure sufficient signal swing above and below the common-mode bias of the LO and REF buffers (i.e., 1.38 V and $V_{DDL}/2$).

Figure 5. Equivalent Input of LO and REF Buffers

Fast Acquire Mode

The fast acquire circuit attempts to boost the output current when the phase difference between the divided-down LO (i.e., f_{LO}) and the divided-down reference frequency (i.e., f_{REF}) exceeds the threshold determined by the LOFA register. The LOFA register specifies a divisor for the f_{REF} signal, and it is the period (T) of this divided-down clock that specifies the time interval which controls the fast acquire algorithm.

Assume for the moment that the nominal charge pump current is at its lowest setting (i.e., $LOI = 0$) and denote this minimum current by I_0 . When the output pulse from the phase comparator exceeds T, the output current for the next pulse is $2I_0$; when the pulse is wider than $2T$, the output current for the next pulse is $3I_0$, and so forth, up to eight times the minimum output current. If the nominal charge pump current is more than the minimum value (i.e., $LOI > 0$), the preceding rule is only applied if it results in an increase in the instantaneous charge pump current. If the charge pump current is set to its lowest value ($LOI = 0$) and the fast acquire circuit is enabled, the instantaneous charge pump current will never fall below $2I_0$, even when the pulsewidth is less than T. Thus the charge pump current when fast acquire is enabled is given by

$$I_{PUMP-FA} = I_0 \times (1 + \max(1, LOI, \text{Pulsewidth}/T)).$$

The recommended setting for LOFA is LOR/16. Choosing a larger value for LOFA will increase T. Thus, for a given phase difference between the LO input and the f_{REF} input, the instantaneous charge pump current will be less than that available for a LOFA value of LOR/16. Similarly, a smaller value for LOFA will decrease T, making more current available for the same phase difference. In other words, a smaller value of LOFA will enable the synthesizer to settle faster in response to a frequency hop than will a large LOFA value. Care must be taken to choose a value of LOFA which is large enough (values greater than four recommended) to prevent the loop from oscillating back and forth in response to a frequency hop.

Table V. SPI Registers Associated with LO Synthesizer

Address (Hex)	Bit Breakdown	Width	Default Value	Name

CLOCK SYNTHESIZER

The clock synthesizer is a fully programmable integer-N PLL capable of 2.2 kHz resolution at clock input frequencies up to 18 MHz and reference frequencies up to 25 MHz. It is similar to the LO synthesizer described previously in Figure 4 with the following exceptions:

- It does not include an 8/9 prescaler nor an A Counter.
- It includes a negative-resistance core which when used in conjunction with an external varactor serves as the VCO.

The 14-bit reference counter and 13-bit N-divider counter can be programmed via the following registers: CKR and CKN. The charge pump current is programmable via the CKI register from 0.625 mA to 5.0 mA using the following equation:

$$I_{PUMP} = (CKI + 1) \times 0.625 \text{ mA.}$$

The fast acquire subcircuit of the charge pump is controlled by the CKFA register in the same manner as the LO synthesizer is controlled by the LOFA register. An on-chip lock detect function (enabled by the CKF bit) automatically increases the output current for faster settling during channel changes. The synthesizer may also be disabled using the CKOB standby bit located in the STBY register.

Figure 6. External Loop Filter, Varactor and L-C Tank Are Required to Realize a Complete Clock Synthesizer

The AD9870 clock synthesizer circuitry includes a negative-resistance core so that only an external L-C tank circuit with a varactor is needed to realize a voltage controlled oscillator (VCO). Figure 6 shows the external components required to complete the clock synthesizer along with the equivalent input of the CLK input. The resonant frequency of the VCO is approximately determined by L_{OSC} and the series equivalent capacitance of C_{OSC} and C_{VAR} . As a result, L_{OSC} , C_{OSC} , and C_{VAR} should be selected to provide sufficient tuning range to ensure proper locking of the clock synthesizer. The bias, I_{BIAS} , of the negative-resistance core has four programmable settings. Lower equivalent Q of the L-C tank circuit may require a higher bias setting of the negative-resistance core to ensure proper oscillation. R_{BIAS} should be selected such that the common-mode voltage at CLKP and CLKN is approximately 1.6 V. The synthesizer may be disabled via the CK standby bit to allow the user to employ an external synthesizer and/or VCO in place of those resident on the IC.

AD9870

IF1 LNA/MIXER

The AD9870 contains a single-ended LNA followed by “Gilbert-type” active mixer as shown in Figure 7a. The mixer’s differential LO port is driven by an LO buffer stage which can be driven single-ended or differential. The LO signal level can range from 0.3 V p-p to 1.0 V p-p with negligible effect on performance. The input impedance at the IFIN pin is $360\ \Omega \parallel 2\ \text{pF}$ ($\pm 20\%$) and has no significant variation with respect to the programmable bias settings. Figure 7b. shows the S11 parameters of the AD9870 with the following LNA/Mixer bias setting: LNAB = 3, MIXB = 3.

Figure 7a. Simplified Schematic of AD9870's LNA/Mixer

Figure 7b. Input Impedance (i.e. S11) of the AD9870's IF1 Input

Both the LNA and mixer have four programmable bias settings so that current consumption can be minimized for a given application. Figures 7c, 7d, and 7e show how the LNA and mixer's noise figure (NF), linearity (IIP3), conversion gain, current consumption and frequency response are all affected for a given LNA/Mixer bias setting. The measurements were taken at an IF = 73.35 MHz, an LO = 71.1 MHz, and supplies set to 3.0 V. Note, since the current consumption of the LNA/Mixer portion of the IC can be reduced by only 5 mA at most relative to the nominal current consumption of the entire IC in the high IIP3 mode (i.e., 42 mA), most applications will benefit with the AD9870's LNA/Mixer configured for the high bias mode (i.e., LNAB = 3, MIXB = 3 for SPI Port Register 1).

0x03	(7)	1	0	ATTEN

ANTI_ALIAS FILTER

The AD9870 includes a programmable continuous-time third order antialias filter (AAF) as shown in Figure 8. Its purpose is to suppress any noise or spectral components occurring at $N \times f_{CLK} \pm (f_{CLK}/8)$ from aliasing back into the sigma-delta ADC's passband centered at $f_{CLK}/8$. It consists of a programmable capacitor at the mixer output providing a real pole plus a second order programmable filter built into the VGA providing a complex pole pair.

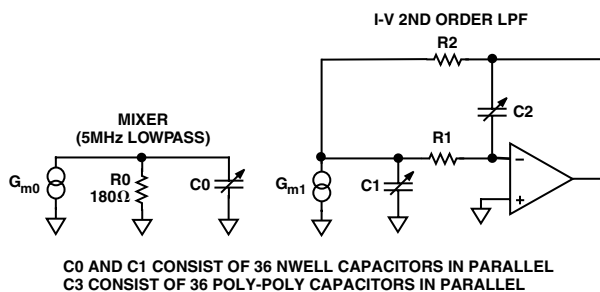

Figure 8. Equivalent Circuit of Antialias Filter

The AAF is typically tuned during the start-up phase of the AD9870. The user initiates tuning of the AAF by writing a value to the AAR (antialias response) register. The following two considerations should be noted when tuning the AAF response. First, the accuracy of the tuning algorithm is sensitive to on-chip digital noise. Thus, *placing the ADC in standby (i.e., register STBY) prior to tuning the AAF is recommended*. Second, although the default setting of the AAR register is 0x00, *writing 0x00 is not recommended* since all subsequent writes to this register will be ignored until power to the AD9870 is reapplied to reset this register.

The AAF tuning algorithm works in the following manner. The AD9870 measures the oscillation frequency of an on-chip RC oscillator relative to the frequency applied to the CLKP, CLKN pins. It then uses this measurement in conjunction with the AAR setting to program the capacitors of the AAF which sets the filters poles. The on-chip circuitry sets the capacitor-programming registers (CAPN and CAPP) to the required values based on the clock frequency and the AAR setting.

The recommended -3 dB cutoff frequency is $f_{CLK}/3.2$ (selected by setting AAR = 0x60) since it provides minimal signal attenuation in the passband region of $f_{CLK}/8$ and sufficient attenuation of the potential alias components in the transition band region. For this setting the frequency-scaling resolution is sufficient to yield less than 10% tuning error with clock frequencies between 13 MHz and 18 MHz. Figure 9a shows the measured response of the antialias filter when it has been tuned with AAR = 0x60 at an ADC clock frequency of 18 MHz. The multiple curves show the possible tuning error due to the finite resolution of the tuning capacitors. In this example, the capacitor across the mixer load resistors yields a pole at 5 MHz, which degrades the mixer gain at 2.25 MHz by approximately 0.8 dB. The nominal -3 dB cutoff frequency of the antialias filter is 5.6 MHz. The nominal attenuation at the first alias (15.75 MHz) is 28 dB and falls at 60 dB/decade so that the nominal attenuation at 50 MHz is 60 dB.

Figure 9a. Antialias filter response with AAR = 0x60 and $f_{CLK} = 18$ MHz. Note, the curves have been normalized individually to 0 dB at $f_0 = 2.25$ MHz.

Since the frequency measurements are performed relative to the clock frequency, the AAF's normalized frequency response remains relatively independent of the ADC clock frequency. There is guaranteed to be sufficient range in the programmable capacitor arrays to support the response of Figure 9a for clock frequencies between 13 MHz and 18 MHz with the resolution indicated. Also, the normalized frequency response of the AAF remains relatively independent of the programmed -3 dB cutoff frequency over a 13 MHz to 18 MHz frequency range as shown in Figure 9b. If the user specifies an unattainable response, the on-chip circuitry sets CAPN and/or CAPP to the limit of their ranges and also sets the ERRN and/or ERRP bit to indicate that the specified response cannot be supported.

Figure 9b. Measured Normalized AAF Frequency Response for $AAR = 0 \times 60$ Setting with $f_{CLK} = 13, 15,$ and 18 MHz

Figure 9c. Measured AAF Frequency Response for Different AAR Settings with $f_{CLK} = 18$ MHz

Changing the AAR setting from the recommended value of 0×60 scales the frequency axis in an inverse way as shown in Figure 9c. For example, to scale the frequency response down by a factor of 1.5 set the AAR register to 1.5 times 0×60 (i.e., 0×90). This AAR setting will not cause an error flag to be set for $f_{CLK} = 18$ MHz since the 3.7 MHz cutoff is within the guaranteed range. For $f_{CLK} = 18$ MHz, this AAR setting would increase the attenuation at the first alias by 10 dB, lower the -3 dB cutoff from 5.6 MHz to 3.7 MHz, and reduce the mixer gain by 0.8 dB due to the reduced mixer pole frequency. However, reducing f_{CLK} to 13 MHz while using the same AAR setting in many parts may cause a deviation in the normalized frequency response since the -3 dB cutoff of 2.7 MHz is well below the 3.5 MHz lower limit. In general, -3 dB cutoff frequencies can be approximated by the following equation:

$$f_{-3 \text{ dB}} = (f_{CLK}/3.2) \times (0 \times 60/AAR)$$

where AAR is the hexadecimal contents of the AAR register and 0×60 is its hexadecimal default setting.

Table VIII. SPI Registers Associated with AAF

Address (Hex)	Bit Breakdown	Width	Default Value	Name
0x1C	(7:0)	8	0x00	AAR

	(4:0)	5	0x0	CAPN
0x1E	5	1	0	ERRP
	(4:0)	15	0x0	CAPP

VARIABLE GAIN AMPLIFIER OPERATION WITH AUTOMATIC GAIN CONTROL

The AD9870 contains a variable gain amplifier (VGA) as well as all of the necessary signal estimation and control circuitry to implement automatic gain control (AGC) as shown in Figure 10. The AGC control circuitry provides a high degree of programmability to allow the user to optimize the AGC response as well as the AD9870's dynamic range for a given application. The VGA is programmable over a 25 dB (typ) range and implemented in the same circuitry as the AAF circuitry previously discussed. Since its input is self-biasing and presents a high impedance to the mixer output load, the differential output signal appearing at the mixer output (MXOP, MXON) must be ac coupled to the VGA input (IF2P, IF2N) with $0.1 \mu\text{F}$ ceramic chip capacitors. Note, an external $20 \text{ k}\Omega$ resistor in parallel with a $0.1 \mu\text{F}$ capacitor from VCM (Pin 13) to GNDA is required to ensure common-mode compatibility between the ADC input and VGA output.

The purpose of the VGA is to extend the usable dynamic range of the AD9870 by allowing the sigma-delta ADC to digitize low level signals in the presence of larger unfiltered interferer signals without saturation or "clipping" the ADC. The VGA can operate in either a user controlled variable gain control mode or automatic gain control (AGC) mode. The VGA may also be disabled using the VGA standby bit located in the STBY register.

Note, ideally the quiescent current of the VGA circuitry should be reduced from 6 mA to 0 mA when the standby is invoked. However, it has been found that the standby current increases to 1.3 mA a few seconds (temperature dependent) after placing the VGA in standby. Hence, the user is recommended to write to the STBY register periodically (0.1 kSPS) and toggle the VGA bit (i.e., write 0 followed by 1) to ensure that the standby current remains at approximately 0 mA.

Figure 10. Functional Block Diagram of VGA and AGC

Variable Gain Control

When in variable gain mode, the gain of the VGA can be adjusted by writing to the 16-bit AGCR register. Note, proper loading of the AGCR register requires that address 0x03 always be written prior to 0x04. The maximum update rate of the AGCG register is $f_{CLK}/100$. The MSB of this register is the bit which enables 16 dB of attenuation in the preamp. This feature allows the AD9870 to cope with large level signals beyond the VGA's range to prevent overloading of the ADC.

The gain of the VGA is set by an 8-bit control DAC which provides a differential control signal to the VGA appearing at pins GCP and GCN. Two external 0.1 μ F capacitors, C_{DAC} , from GCP and GCN to analog ground, are required to "smooth" or filter the DAC's output each time it updates. Note, the differential equivalent value of these two capacitors (i.e., $C_{DAC/2}$) in combination with the DAC's programmable output resistance sets the -3 dB bandwidth and time constant associated with this RC network.

Automatic Gain Control (AGC)

The gain of the VGA is automatically adjusted when the AGC is enabled via the AGCR register. In this mode, the gain of the VGA is continuously updated in an attempt to ensure that the maximum signal level into the ADC does not exceed a fixed analog ADC clip level and that the rms output level of the ADC is equal to a programmable reference level. This programmable level can be set at 3 dB, 6 dB, 9 dB, 12 dB, and 15 dB below the ADC saturation (clip level) by writing values from 1 to 5 to the 3-bit AGCR field. Note, the ADC clip level is defined to be -2 dBFS of its full-scale (i.e., 0.28 V rms). If AGCR is 0, automatic gain control is disabled.

The AGC control loop and estimation circuitry are implemented both in the analog and digital domain to cope with out-of-band interferers and in-band signals which could otherwise overload the ADC. If the largest signal into the ADC falls outside the passband of the first stage digital filter and exceeds the ADC clip level of -2 dBFS, a control loop based on an analog comparator is used to reduce the VGA gain and prevent ADC clipping. If the largest signal into the ADC is the target signal (and/or interferer) falling within the passband defined by the first decimation filter (but below the ADC clip level), a control loop based on a digital estimation of the signal power is used to control the VGA gain.

Referring to Figure 10, an analog comparator is used to compare the VGA output (or ADC input) to a reference threshold which is close to that of the ADC clip level. The output of the comparator will be a digital signal named "OLW" which drives the digital integrator within the AGC control loop when an overload condition is detected. Note, the detection of an overload condition via this analog signal estimation path takes precedence over the digital signal estimation path in the AGC control loop until the analog overload condition is removed. For signals falling within the passband of the first stage decimate-by-20 digital filter, the rms power of the I and Q signal is estimated digitally by the following equation:

$$X_{EST}[N] = A_{BS}(I[N]) + A_{BS}(Q[N]) \quad (1)$$

As a result, the VGA and other registers involved in the AGC algorithm are updated at $f_{CLK}/20$. The number of overload and ADC reset occurrences within the final I/Q update rate of the AD9870 as well as the AGC value (8 MSBs) can be read from the SSI data upon proper configuration.

A description of the AGC control algorithm and the user adjustable parameters follows. First consider the situation in which the in-band signal is bigger than all out-of-band signals. In this case, the amplitude of the in-band signal will be tracked to the programmed reference level by the AGC using the output of the digital estimation block. If the difference is negative (i.e., the signal is too large), the gain is decreased with a proportionality constant determined by the AGCA setting. Large AGCA values result in large gain changes thus rapid tracking of changes in signal strength. If the difference between the target and estimated signal level is positive (i.e., the signal is too small), the gain is increased but now the proportionality constant is determined by both the AGCA and AGCD settings. AGCD is effectively subtracted from AGCA, so large AGCD results in smaller gain changes and thus slower tracking of fading signals.

The 4-bit code in the AGCA field sets the raw bandwidth of the AGC loop. With $AGCA = 0$, the AGC loop bandwidth is at its minimum of 50 Hz. Each increment of AGCA increases the loop bandwidth by a factor of $2^{1/2}$; thus the maximum bandwidth is 9 kHz. A general expression for the attack bandwidth is

$$BW_A = 50 \times (f_{CLK}/18 \text{ MHz}) \times 2^{(AGCA/2)} \text{ Hz} \quad (2)$$

The attack time may be estimated from the loop bandwidth if one assumes that the loop dynamics are essentially that of a single-pole system as described by the following equation.

$$t_{ATTACK} = 2.2/(100 \times \pi \times 2^{AGCA/2}) = 0.35/BW_A \quad (3)$$

This approximation is good if the extra pole caused by the RC filter on the DAC output is at a sufficiently high frequency. If the RC pole is placed at four times the raw AGC pole (i.e., $RC = 1/(8 \times \pi \times BW)$) then Equation 3 yields an attack time which is high by about 25%. A more accurate formula for this case is to replace the 2.2 in the numerator of Equation 3 by 1.7.

The 4-bit code in the AGCD field sets the ratio of the attack time to the decay time in the amplitude estimation circuitry. When AGCD is zero, this ratio is one. Incrementing AGCD multiplies the decay time-constant by $2^{1/2}$, allowing a 180:1 range in the decay time relative to the attack time. The decay time may be computed from

$$t_{DECAY} = t_{ATTACK} \times 2^{(AGCD/2)} \quad (4)$$

The 4-bit code in the AGCO field sets the weighting applied to gain updates when overload is detected. Each increment in AGCO doubles the weighting factor. At the highest AGCO setting, each reset event will cause a 6 dB reduction in the VGA gain.

Lastly, the AGCF bit reduces the DAC source resistance by a factor of 8. This facilitates fast acquisition by lowering the RC time constant which is formed with the external capacitors connected from the GCP and GCN pins to ground. For an overshoot-free step response in the AGC loop, the capacitors should be chosen such that the RC time constant is less than one quarter that of the raw loop. Specifically,

$$RC \leq 1/(8 \pi BW) \quad (5)$$

where R is the resistance between the GCN and GCP pins and ground ($30 \text{ k}\Omega \pm 30\%$ if $AGCF = 0$, $<3.8 \text{ k}\Omega$ if $AGCF = 1$) and BW is the raw loop bandwidth. Note that with C chosen at this upper limit, the loop bandwidth increases by approximately 30%.

	(2:0)	3	0	AGCR

System Noise Figure (NF) vs. VGA (or AGC) Control

The AD9870's system NF is a strong function of the gain setting of the VGA. The noise present at the output of the VGA and input of the ADC is relatively large and independent of the VGA setting. Under small signal conditions in which the VGA is set to its maximum gain, this noise referred back to the input of the LNA's input has less of an effect on raising the AD9870's system NF. However, under large signal conditions in which the gain of the VGA must be reduced to prevent ADC clipping, this noise quickly becomes a significant contributor in determining the AD9870's overall NF. Figure 11 shows how the NF of the AD9870 in AGC mode remains relatively constant as an interferer signal input power is increased until its power reaches a programmed reference level (i.e., -3 dB) at which point the NF degrades almost 1 dB per dB as the interferer signal is increased beyond this point, forcing the VGA gain to decrease. As a result, it is recommended that the AGC referenced level be set to 3 (i.e., AGCR = 1) to maintain the best possible NF over the widest input signal range.

Figure 11. Noise Figure vs. Interferer Signal Level with an IF = 73.35 MHz and CLK = 18 MSPS and AGCR = 1

DECIMATION FILTER

The decimation filter consists of a complex mix by $f_{CLK}/8$ and a cascade of three linear phase FIR filters: DEC1, DEC2, and DEC3 as shown in Figure 12. DEC1 downsamples by a factor of 20 using a fourth-order comb filter. DEC2 also uses a fourth-order comb filter, but its decimation factor is set by the M control register. DEC3 is a decimate-by-3 FIR filter.

Figure 12. Decimation Filter Architecture

Figure 13a shows the response of the complete decimation filter on a linear frequency axis for frequencies up to the third alias. As this figure shows, the alias with the least attenuation is located at the lower end of the third alias band and has an attenuation of 83 dB.

Figure 13a. Frequency Response for $f_{CLKOUT} = 20$ kHz, Showing the First Three Alias Bands

Figure 13b shows the full response of the decimation filter with the decimation factor set to 60 on a logarithmic frequency scale, while Figure 13c shows the folded frequency response on a linear frequency scale and Figure 13d shows a blowup of the passband. The location of the cutoff frequency shown in Figure 13b is inversely proportional to the decimation factor. However, since both DEC1 and DEC2 are fourth-order comb filters, their combination is also a fourth-order comb filter and thus the shapes of the frequency responses shown in Figures 13c and 13d are independent of the decimation factor.

Figure 13b. Decimator Frequency Response

Figure 13c. Folded Decimator Frequency Response

As Figure 13d shows, the gain variation across the passband is approximately 0.4 dB. Normalization of full-scale is accurate to within 0.4 dB across all decimation modes.

Figure 13d. Passband Frequency Response of the Decimator

Evaluation Board and Software

The evaluation board along with its accompanying software provide a simple means to evaluate the AD9870. The block diagram in Figure 14 shows the major blocks of the evaluation board. The evaluation board is designed to be flexible allowing the user to configure it for different potential applications. The power supply distribution block provides filtered, adjustable voltages to the various supply pins of the AD9870. In the IF Input signal path, component pads are available to implement different IF impedance matching networks. The LO and CLK signals can be externally applied or internally derived from a user-supplied VCO Module interface daughter board. The reference for the on-chip LO and CLK synthesizers can be applied via the external FREF input or an on-board crystal oscillator.

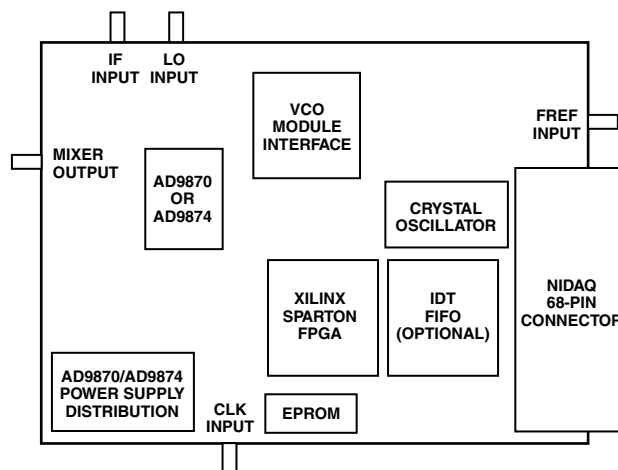

Figure 14. Evaluation Board Platform

The evaluation board is designed to interface to a PC via a National Instruments PCI-DIO-32HS digital IO card. A XILINX FPGA formats the data between the AD987x and digital I/O board. Software developed using National Instruments LabVIEW™ and provided as MS Windows™ executable programs is supplied for the configuration of the SPI port registers and evaluation of the AD9870 output data. These programs have a convenient graphical user interface allowing for easy access to the various SPI port configuration registers and real time frequency analysis of output data.
