

CAT3636

6-Channel Quad-Mode[®] Fractional LED Driver in TQFN 3x3

Description

The CAT3636 is a high efficiency Quad-Mode fractional charge pump that can drive up to six LEDs programmable by a one wire digital interface. The inclusion of a 1.33x fractional charge pump mode increases device efficiency by up to 10% over traditional 1.5x charge pumps with no added external capacitors.

Low noise input ripple is achieved by operating at a constant switching frequency which allows the use of small external ceramic capacitors. The multi-fractional charge pump supports a wide range of input voltages from 2.5 V to 5.5 V.

The EN/SET logic input functions as a chip enable and a “1-wire” addressable interface for control and current setting of all LEDs. Three groups of two LEDs can be configured with independent LED currents between 0.25 mA and 32 mA.

The device is available in a tiny 16-lead TQFN 3 mm x 3 mm package with a max height of 0.8 mm.

ON Semiconductor’s Quad-Mode[®] 1.33x charge pump switching architecture is patented.

Features

- High Efficiency 1.33x Charge Pump
- Quad-Mode Charge Pump: 1x, 1.33x, 1.5x, 2x
- Drives up to 6 LEDs at 32 mA Each
- 1-Wire EZDim™ LED Current Programming
- Power Efficiency up to 92%
- Low Noise Input Ripple in All Modes
- “Zero” Current Shutdown Mode
- Soft Start and Current Limiting
- Short Circuit Protection
- Thermal Shutdown Protection
- Tiny 3 mm x 3 mm, 16-lead TQFN Package
- These Devices are Pb-Free, Halogen Free/BFR Free and are RoHS Compliant

Applications

- LCD Display Backlight
- Color RGB LEDs
- Cellular Phones
- Digital Still Cameras
- Handheld Devices

Pin #	Name	Function
1	LEDC2	LEDC2 cathode terminal
2	LEDC1	LEDC1 cathode terminal
3	LEDB2	LEDB2 cathode terminal
4	LEDB1	LEDB1 cathode terminal
5	LEDA2	LEDA2 cathode terminal
6	LEDA1	LEDA1 cathode terminal
7	VOUT	Charge pump output, connect to LED anodes
8	VIN	Charge pump input, connect to battery or supply
9	C1+	Bucket capacitor 1, positive terminal
10	C1-	Bucket capacitor 1, negative terminal
11	C2+	Bucket capacitor 2, positive terminal
12	C2-	Bucket capacitor 2, negative terminal
13/14	NC	No connect
15	GND	Ground reference
16	EN/SET	Device enable (active high) and 1 wire control input
TAB	TAB	Connect to GND on the PCB

Pin Function

VIN is the supply pin for the charge pump. A small 1 μ F ceramic bypass capacitor is required between the VIN pin and ground near the device. The operating input voltage range is from 2.5 V to 5.5 V. Whenever the input supply falls below the under-voltage threshold (2 V) all the LED channels will be automatically disabled and the device register are reset to default values.

EN/SET is the enable and one wire addressable control logic input for all LED channels. Guaranteed levels of logic high and logic low are set at 1.3 V and 0.4 V respectively. When EN/SET is initially taken high, the device becomes enabled and all LED currents remain at 0 mA. To place the device into zero current mode, the EN/SET pin must be held low for more than 1.5 ms.

VOUT is the charge pump output that is connected to the LED anodes. A small 1 μ F ceramic bypass capacitor is required between the VOUT pin and ground near the device.

GND is the ground reference for the charge pump. The pin must be connected to the ground plane on the PCB.

C1+, C1- are connected to each side of the ceramic bucket capacitor C1.

C2+, C2- are connected to each side of the ceramic bucket capacitor C2.

LEDxx provide the internal regulated current for each of the LED cathodes. These pins enter high-impedance zero current state whenever the device is placed in shutdown mode.

TAB is the exposed pad underneath the package. For best thermal performance, the tab should be soldered to the PCB and connected to the ground plane.

CAT3636

Block Diagram

Figure 20. CAT3636 Functional Block Diagram

Basic Operation

At power-up, the CAT3636 starts operating in 1x mode where the output will be approximately equal to the input supply voltage (less any internal voltage losses). If the output voltage is sufficient to regulate all LED currents, the device remains in 1x operating mode.

If the input voltage is insufficient or falls to a level where the regulated currents cannot be maintained, the device automatically switches into 1.33x mode (after a fixed delay time of about 400 μ s). In 1.33x mode, the output voltage is approximately equal to 1.33 times the input supply voltage (less any internal voltage losses).

If the input voltage is insufficient again or falls to a level where the regulated currents cannot be maintained, the

device will automatically switch to the 1.5x boost mode (after a fixed delay time of about 400 μ s). In 1.5x mode, the output is approximately equal to 1.5 times the input supply voltage (less any internal voltage losses).

If the input voltage fails more or is still insufficient to drive the LEDs, it will automatically switch again into 2x mode where the output is approximately equal to 2 times the input supply voltage (less any internal voltage losses).

If the device detects a sufficient input voltage is present to drive all LED currents in 1x mode, it will change automatically back to 1x mode. This only applies for changing back to the 1x mode

LED Current Setting

The current in each of the six LED channels is programmed through the 1-wire EN/SET digital control input. By pulsing this signal according to a specific protocol, a set of internal registers can be addressed and written into allowing to configure each bank of LEDs with the desired current. There are six registers: the first five are 4 bits long and the sixth is 1 bit long. The registers are programmed by first selecting the register address and then programming data into that register.

An internal counter records the number of falling edges to identify the address and data. The address is serially programmed adhering to low and high duration time delays. One down pulse corresponds to register 1 being selected. Two down pulses correspond to register 2 being selected and so on up to register 6. T_{LO} and T_{HI} must be within 200 ns to 100 μ s. Anything below 200 ns may be ignored.

Once the final rising edge of the address pointer is programmed, the user must wait 500 μ s to 1000 μ s before programming the first data pulse falling edge. If the falling edge of the data is not received within 1000 μ s, the device will revert back to waiting for an address.

Data in a register is reset once it is selected by the address pointer. If a register is selected but no data is programmed, then the register value is reset back to its initial default value with all data bits to 0.

Once the final rising edge of the data pulses is programmed, the user must wait 1.5 ms before programming another address. If programming fails or is interrupted, the user must wait $T_{RESETDELAY}$ 2 ms from the last rising edge before reprogramming can commence.

Upon power-up, the device automatically starts looking for an address. The device requires a minimum 10 μ s delay (T_{SETUP}) to ensure the initialization of the internal logic at power-up. After this time delay, the device registers may be programmed adhering to the timing constraints shown in Figure 21. If no falling edge is detected within 100 μ s of power-up, then the user must wait 2 ms before trying to program the device again.

To power-down the device and turn-off all current sources, the EN/SET input should be kept low for a duration T_{OFF} of 1.5 ms or more. The driver typically powers-down with a delay of about 1 ms. All register data are lost.

Figure 21. EN/SET One Wire Addressable Timing Diagram

Register Configuration and Programming

Table 6. REGISTER ADDRESS AND DATA

Register	Address Pulses	Description	Bits	DATA Pattern			
				Bit 3	Bit 2	Bit 1	Bit 0
REG1	1	Bank Enable and IMODE	4	IMODE	ENA	ENB	ENC
REG2	2	Global Current Setting	4	See Table 8 for values			
REG3	3	Bank A Current Setting	4				
REG4	4	Bank B Current Setting	4				
REG5	5	Bank C Current Setting	4				
REG6	6	Return Lockout	1				RTLKO

Register REG1 allows to set the mode and select the pairs of LEDs to be turned on. A low LED current mode exists to allow for very low current operation under 4 mA per channel. If IMODE equals 1, the high current range is selected up to 32 mA. If IMODE is set to 0, all currents are divided by 8. Each bank of LEDs (A, B or C) can be turned on independently by setting the respective bit ENA, ENB, ENC to 1, as shown in Table 7. For example, to enable all 6 LEDs in low current mode, REG1 is programmed to 0111 binary (9 data pulses).

Table 7. REG1 REGISTER SETTING

Data Pulses	REG1 Value (binary)	IMODE	Bank Enable		
			ENA	ENB	ENC
0	0000	0	-	-	-
1	1111	1	On	On	On
2	1110	1	On	On	-
3	1101	1	On	-	On
4	1100	1	On	-	-
5	1011	1	-	On	On
6	1010	1	-	On	-
7	1001	1	-	-	On
8	1000	1	-	-	-
9	0111	0	On	On	On
10	0110	0	On	On	-
11	0101	0	On	-	On
12	0100	0	On	-	-
13	0011	0	-	On	On
14	0010	0	-	On	-
15	0001	0	-	-	On
16	0000	0	-	-	-

Register REG2 allows to set the same current for all 6 channels. REG3, REG4, REG5 allow to set the current respectively in banks A, B and C. The three banks can be programmed with independent current values.

Table 8. REG2-5 CURRENT SETTING REGISTERS

Data Pulses	REGx Value (binary)	LED Current IMODE = 0	LED Current IMODE = 1
0	0000	0.0 mA	2 mA
1	1111	3.75 mA	32 mA
2	1110	3.5 mA	30 mA
3	1101	3.25 mA	28 mA
4	1100	3 mA	26 mA
5	1011	2.75 mA	24 mA
6	1010	2.5 mA	22 mA
7	1001	2.25 mA	20 mA
8	1000	2 mA	18 mA
9	0111	1.75 mA	16 mA
10	0110	1.5 mA	14 mA
11	0101	1.25 mA	12 mA
12	0100	1 mA	10 mA
13	0011	0.75 mA	8 mA
14	0010	0.5 mA	6 mA
15	0001	0.25 mA	4 mA
16	0000	0.0 mA	2 mA

REG6 contains the return lockout (RTLKO) bit. This stops the charge pump returning to 1x mode. One pulse sets it to 1. Two pulses or no pulses set RTLKO to 0. When RTLKO is set to 1, the charge pump cannot automatically return to 1x mode when in one of the charge pump modes. The device can however move from 1x to 1.33x to 1.5x to 2x if the input voltage is not sufficient to drive the programmed LED currents.

REG6 also triggers a charge pump reset as soon as it is addressed. This forces the charge pump to start from 1x mode and reassess the correct mode it should be in to drive the LEDs most efficiently. If the input voltage has risen or the device has been reprogrammed to other LED values, it is recommended to trigger this reset allowing the charge pump to run in the most efficient mode.

The CAT3636 enters a “zero current” shutdown mode if EN/SET is held low for 1.5 ms or more. All registers are reset back to zero when the device is placed in shutdown.

Programming Examples

Programming 6 LEDs to 32 mA

Programming 6 LEDs to 20 mA

Programming 6 LEDs to 1 mA

CAT3636

Unused LED Channels

For applications with only four or two LEDs, unused LED banks can be disabled via the enable register internally and left to float.

For applications with 5 LEDs or less, unused LEDs can also be disabled by connecting the LED pin directly to V_{OUT}, as shown on Figure 22. If LED pin voltage is within 1 V of V_{OUT}, then the channel is switched off and a 200 μ A test current is placed in the channel to sense when the channel moves below V_{OUT} – 1 V.

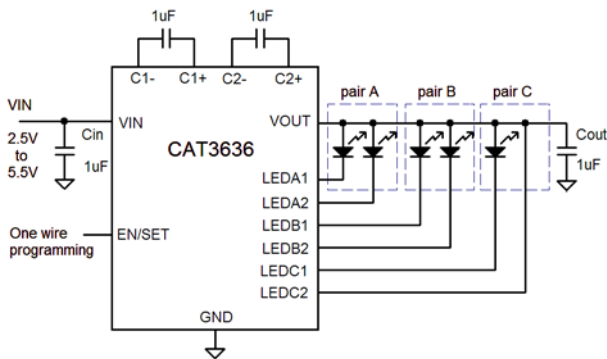

Figure 22. Five LED Application

Protection Mode

If an LED is disconnected, the output voltage V_{OUT} automatically limits at about 5.5 V. This is to prevent the output pin from exceeding its absolute maximum rating.

If the die temperature exceeds +150°C the driver will enter a thermal protection shutdown mode. When the device temperature drops by about 20°C the device will resume normal operation.

LED Selection

LEDs with forward voltages (V_F) ranging from 1.3 V to 5.0 V may be used with the CAT3636. Selecting LEDs with lower V_F is recommended in order to improve the efficiency by keeping the driver in 1x mode longer as the battery voltage decreases.

For example, if a white LED with a V_F of 3.3 V is selected over one with V_F of 3.5 V, the CAT3636 will stay in 1x mode for lower supply voltage of 0.2 V. This helps improve the efficiency and extends battery life.

External Components

The driver requires two external 1 μ F ceramic capacitors for decoupling input, output, and for the charge pump. Both capacitors type X5R and X7R are recommended for the LED driver application. In all charge pump modes, the input current ripple is kept very low by design and an input bypass capacitor of 1 μ F is sufficient.

In 1x mode, the device operates in linear mode and does not introduce switching noise back onto the supply.

Recommended Layout

In charge pump mode, the driver switches internally at a high frequency. It is recommended to minimize trace length to all four capacitors. A ground plane should cover the area under the driver IC as well as the bypass capacitors. Short connection to ground on capacitors C_{IN} and C_{OUT} can be implemented with the use of multiple via. A copper area matching the TQFN exposed pad (TAB) must be connected to the ground plane underneath. The use of multiple via improves the package heat dissipation.
