## 8-BIT MCU WITH 4 TO 8K ROM/OTP/EPROM, 256 BYTES RAM, ADC, WDG, SPI AND 1 OR 2 TIMERS

- User Program Memory (ROM/OTP/EPROM): 4 to 8 K bytes
- Data RAM: 256 bytes, including 64 bytes of stack
- Master Reset and Power-On Reset
- Run, Wait, Slow, Halt and RAM Retention modes
- 22 multifunctional bidirectional I/O lines:
- 22 programmable interrupt inputs
- 8 high sink outputs
- 6 analog alternate inputs
- 10 to 14 alternate functions
- EMI filtering
- Programmable watchdog (WDG)
- One or two 16-bit Timers, each featuring:
- 2 Input Captures
- 2 Output Compares
- External Clock input (on Timer A only)
- PWM and Pulse Generator modes
- Synchronous Serial Peripheral Interface (SPI)
- 8-bit Analog-to-Digital converter (6 channels) (ST72212 and ST72213 only)
- 8-bit Data Manipulation
- 63 Basic Instructions
- 17 main Addressing Modes
- $8 \times 8$ Unsigned Multiply Instruction
- True Bit Manipulation
- Complete Development Support on PC/DOSWINDOWS ${ }^{\text {TM }}$ Real-Time Emulator
- Full Software Package on DOS/WINDOWS ${ }^{\text {M }}$ (C-Compiler, Cross-Assembler, Debugger)

## Device Summary

| Features | ST72101G1 | ST72101G2 | ST72213G1 | ST72212G2 |
| :---: | :---: | :---: | :---: | :---: |
| Program Memory- bytes | 4K | 8K | 4K | 8K |
| RAM (stack) - bytes | 256 (64) |  |  |  |
| 16-bit Timers | one | one | one | two |
| ADC | no | no | yes | yes |
| Other Peripherals | Watchdog, SPI |  |  |  |
| Operating Supply | 3 to 5.5 V |  |  |  |
| CPU Frequency | 8 MHz max (16MHz oscillator) - 4 MHz max over $85^{\circ} \mathrm{C}$ |  |  |  |
| Temperature Range | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |  |  |  |
| Package | SO28-SDIP32 |  |  |  |

## 1 GENERAL DESCRIPTION

### 1.1 INTRODUCTION

The ST72101, ST72213 and ST72212 HCMOS Microcontroller Units are members of the ST7 family. These devices are based on an industrystandard 8-bit core and feature an enhanced instruction set. They normally operate at a 16 MHz oscillator frequency. Under software control, the ST72101, ST72213 and ST72212 may be placed in either WAIT, SLOW or HALT modes, thus reducing power consumption. The enhanced instruction set and addressing modes afford real programming potential. In addition to standard 8 -bit data management, the ST72101, ST72213 and ST72212 feature true bit manipulation, $8 \times 8$
unsigned multiplication and indirect addressing modes on the whole memory. The devices include an on-chip oscillator, CPU, program memory (ROM/OTP/EPROM versions), RAM, 22 I/O lines and the following on-chip peripherals: Analog-toDigital Converter (ADC) with 6 multiplexed analog inputs (ST72212 and ST72213 only), industry standard synchronous SPI serial interface, digital Watchdog, one or two independent 16-bit Timers, one featuring an External Clock Input, and both featuring Pulse Generator capabilities, 2 Input Captures and 2 Output Compares.

| 31 | 27 | $\mathrm{V}_{\text {SS }}$ | S | Ground |  |
| 32 | 28 | $\mathrm{V}_{\mathrm{DD}}$ | S | Main power supply |  |

Note 1: $\mathrm{V}_{\mathrm{PP}}$ on EPROM/OTP only.

### 1.3 EXTERNAL CONNECTIONS

The following figure shows the recommended external connections for the device.
The $\mathrm{V}_{\mathrm{PP}}$ pin is only used for programming OTP and EPROM devices and must be tied to ground in user mode.
The 10 nF and $0.1 \mu \mathrm{~F}$ decoupling capacitors on the power supply lines are a suggested EMC performance/cost tradeoff.

The external reset network is intended to protect the device against parasitic resets, especially in noisy environments.
Unused I/Os should be tied high to avoid any unnecessary power consumption on floating lines. An alternative solution is to program the unused ports as inputs with pull-up.

Figure 8. Recommended External Connections

### 1.4 MEMORY MAP

## 2 CENTRAL PROCESSING UNIT

### 2.1 INTRODUCTION

This CPU has a full 8-bit architecture and contains six internal registers allowing efficient 8-bit data manipulation.

### 2.2 MAIN FEATURES

- 63 basic instructions
- Fast 8-bit by 8-bit multiply
- 17 main addressing modes
- Two 8-bit index registers
- 16-bit stack pointer
- Low power modes
- Maskable hardware interrupts
- Non-maskable software interrupt

### 2.3 CPU REGISTERS

The 6 CPU registers shown in Figure 1 are not present in the memory mapping and are accessed by specific instructions.

## Accumulator (A)

The Accumulator is an 8-bit general purpose register used to hold operands and the results of the arithmetic and logic calculations and to manipulate data.

## Index Registers (X and Y)

In indexed addressing modes, these 8 -bit registers are used to create either effective addresses or temporary storage areas for data manipulation. (The Cross-Assembler generates a precede instruction (PRE) to indicate that the following instruction refers to the Y register.)
The Y register is not affected by the interrupt automatic procedures (not pushed to and popped from the stack).

## Program Counter (PC)

The program counter is a 16-bit register containing the address of the next instruction to be executed by the CPU. It is made of two 8-bit registers PCL (Program Counter Low which is the LSB) and PCH (Program Counter High which is the MSB).

Figure 10. CPU Registers

## CPU REGISTERS (Cont'd) <br> CONDITION CODE REGISTER (CC)

## Read/Write

Reset Value: 111x1xxx
7

| 1 | 1 | 1 | $H$ | I | N | Z | C |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

The 8-bit Condition Code register contains the interrupt mask and four flags representative of the result of the instruction just executed. This register can also be handled by the PUSH and POP instructions.

These bits can be individually tested and/or controlled by specific instructions.

## Bit $4=\mathbf{H}$ Half carry.

This bit is set by hardware when a carry occurs between bits 3 and 4 of the ALU during an ADD or ADC instruction. It is reset by hardware during the same instructions.
0: No half carry has occurred.
1: A half carry has occurred.
This bit is tested using the JRH or JRNH instruction. The H bit is useful in BCD arithmetic subroutines.

## Bit 3 = I Interrupt mask.

This bit is set by hardware when entering in interrupt or by software to disable all interrupts except the TRAP software interrupt. This bit is cleared by software.
0 : Interrupts are enabled.
1: Interrupts are disabled.
This bit is controlled by the RIM, SIM and IRET instructions and is tested by the JRM and JRNM instructions.

Note: Interrupts requested while I is set are latched and can be processed when I is cleared. By default an interrupt routine is not interruptable
because the I bit is set by hardware at the start of the routine and reset by the IRET instruction at the end of the routine. If the I bit is cleared by software in the interrupt routine, pending interrupts are serviced regardless of the priority level of the current interrupt routine.

Bit $2=\mathbf{N}$ Negative.
This bit is set and cleared by hardware. It is representative of the result sign of the last arithmetic, logical or data manipulation. It is a copy of the $7^{\text {th }}$ bit of the result.
0 : The result of the last operation is positive or null.
1: The result of the last operation is negative (i.e. the most significant bit is a logic 1).

This bit is accessed by the JRMI and JRPL instructions.

## Bit $1=\mathbf{Z}$ Zero.

This bit is set and cleared by hardware. This bit indicates that the result of the last arithmetic, logical or data manipulation is zero.
0 : The result of the last operation is different from zero.
1: The result of the last operation is zero.
This bit is accessed by the JREQ and JRNE test instructions.

## Bit $0=\mathbf{C}$ Carry/borrow.

This bit is set and cleared by hardware and software. It indicates an overflow or an underflow has occurred during the last arithmetic operation.
0: No overflow or underflow has occurred.
1: An overflow or underflow has occurred.
This bit is driven by the SCF and RCF instructions and tested by the JRC and JRNC instructions. It is also affected by the "bit test and branch", shift and rotate instructions.

## CENTRAL PROCESSING UNIT (Cont'd)

Stack Pointer (SP)
Read/Write
Reset Value: 01 7Fh

The Stack Pointer is a 16 -bit register which is always pointing to the next free location in the stack. It is then decremented after data has been pushed onto the stack and incremented before data is popped from the stack (see Figure 11).
Since the stack is 64 bytes deep, the 10 most significant bits are forced by hardware. Following an MCU Reset, or after a Reset Stack Pointer instruction (RSP), the Stack Pointer contains its reset value (the SP5 to SP0 bits are set) which is the stack higher address.

The least significant byte of the Stack Pointer (called S) can be directly accessed by a LD instruction.
Note: When the lower limit is exceeded, the Stack Pointer wraps around to the stack upper limit, without indicating the stack overflow. The previously stored information is then overwritten and therefore lost. The stack also wraps in case of an underflow.
The stack is used to save the return address during a subroutine call and the CPU context during an interrupt. The user may also directly manipulate the stack by means of the PUSH and POP instructions. In the case of an interrupt, the PCL is stored at the first location pointed to by the SP. Then the other registers are stored in the next locations as shown in Figure 11.

- When an interrupt is received, the SP is decremented and the context is pushed on the stack.
- On return from interrupt, the SP is incremented and the context is popped from the stack.
A subroutine call occupies two locations and an interrupt five locations in the stack area.

Figure 11. Stack Manipulation Example

Stack Lower Address $=0140 \mathrm{~h}$
Stack Higher Address $=017 \mathrm{Fh}$

## 3 CLOCKS, RESET, INTERRUPTS \& POWER SAVING MODES

### 3.1 CLOCK SYSTEM

### 3.1.1 General Description

The MCU accepts either a Crystal or Ceramic resonator, or an external clock signal to drive the internal oscillator. The internal clock ( $\mathrm{f}_{\mathrm{CPU}}$ ) is derived from the external oscillator frequency (fosc).
The external Oscillator clock is first divided by 2 , and division factor of 32 can be applied if Slow Mode is selected by setting the SMS bit in the Miscellaneous Register. This reduces the frequency of the ficpu; the clock signal is also routed to the on-chip peripherals.
The internal oscillator is designed to operate with an AT-cut parallel resonant quartz crystal resonator in the frequency range specified for $f_{\text {osc }}$. The circuit shown in Figure 13 is recommended when using a crystal, and Table 6 lists the recommended capacitance and feedback resistance values. The crystal and associated components should be mounted as close as possible to the input pins in order to minimize output distortion and start-up stabilisation time.
Use of an external CMOS oscillator is recommended when crystals outside the specified frequency ranges are to be used.

Table 6. Recommended Values for 16 MHz Crystal Resonator ( $\mathrm{C}_{0}<7 \mathrm{pF}$ )

| $\mathbf{R}_{\text {SMAX }}$ | $\mathbf{4 0} \Omega$ | $\mathbf{6 0} \Omega$ | $\mathbf{1 5 0} \Omega$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{C}_{\text {OSCIN }}$ | 56 pF | 47 pF | 22 pF |
| $\mathrm{C}_{\text {OSCOUT }}$ | 56 pF | 47 pF | 22 pF |

$\mathrm{C}_{0}$ : parasitic shunt capacitance of the quartz crystal.
$\mathbf{R}_{\text {SMAX }}$ : equivalent serial resistor of the crystal (uper limit, see crystal specification).
Coscout, Coscin: maximum total capacitance on OSCIN and OSCOUT, including the external capacitance plus the parasitic capacitance of the board and the device.

Figure 12. External Clock Source Connections

Figure 13. Crystal/Ceramic Resonator

Figure 14. Clock Prescaler Block Diagram

### 3.2 RESET

### 3.2.1 Introduction

There are three sources of Reset:

- RESET pin (external source)
- Power-On Reset (Internal source)
- WATCHDOG (Internal Source)

The Reset Service Routine vector is located at address FFFEh-FFFFh.

### 3.2.2 External Reset

The RESET pin is both an input and an open-drain output with integrated pull-up resistor. When one of the internal Reset sources is active, the Reset pin is driven low, for a duration of $t_{\text {RESET, }}$ to reset the whole application.

### 3.2.3 Reset Operation

The duration of the Reset state is a minimum of 4096 internal CPU Clock cycles. During the Reset state, all I/Os take their reset value.
A Reset signal originating from an external source must have a duration of at least tPULSE in order to be recognised. This detection is asynchronous and therefore the MCU can enter Reset state even in Halt mode.
At the end of the Reset cycle, the MCU may be held in the Reset state by an External Reset signal. The RESET pin may thus be used to ensure $V_{D D}$ has risen to a point where the MCU can operate correctly before the user program is run. Fol-
lowing a Reset event, or after exiting Halt mode, a 4096 CPU Clock cycle delay period is initiated in order to allow the oscillator to stabilise and to ensure that recovery has taken place from the Reset state.
In the high state, the RESET pin is connected internally to a pull-up resistor ( $\mathrm{R}_{\mathrm{ON}}$ ). This resistor can be pulled low by external circuitry to reset the device.
The RESET pin is an asynchronous signal which plays a major role in EMS performance. In a noisy environment, it is recommended to use the external connections shown in Figure 8.

### 3.2.4 Power-on Reset

This circuit detects the ramping up of $V_{D D}$, and generates a pulse that is used to reset the application (at approximately $\mathrm{V}_{\mathrm{DD}}=2 \mathrm{~V}$ ).
Power-On Reset is designed exclusively to cope with power-up conditions, and should not be used in order to attempt to detect a drop in the power supply voltage.
Caution: to re-initialize the Power-On Reset, the power supply must fall below approximately 0.8 V (Vtn), prior to rising above 2 V . If this condition is not respected, on subsequent power-up the Reset pulse may not be generated. An external Reset pulse may be required to correctly reactivate the circuit.

Figure 15. Reset Block Diagram

## 4 INTERRUPTS

The ST7 core may be interrupted by one of two different methods: maskable hardware interrupts as listed in the Interrupt Mapping Table and a nonmaskable software interrupt (TRAP). The Interrupt processing flowchart is shown in Figure 1.
The maskable interrupts must be enabled by clearing the I bit in order to be serviced. However, disabled interrupts may be latched and processed when they are enabled (see external interrupts subsection).
Note: After reset, all interrupts are disabled.
When an interrupt has to be serviced:

- Normal processing is suspended at the end of the current instruction execution.
- The PC, X, A and CC registers are saved onto the stack.
- The I bit of the CC register is set to prevent additional interrupts.
- The PC is then loaded with the interrupt vector of the interrupt to service and the first instruction of the interrupt service routine is fetched (refer to the Interrupt Mapping Table for vector addresses).
The interrupt service routine should finish with the IRET instruction which causes the contents of the saved registers to be recovered from the stack.
Note: As a consequence of the IRET instruction, the I bit will be cleared and the main program will resume.

## Priority Management

By default, a servicing interrupt cannot be interrupted because the I bit is set by hardware entering in interrupt routine.
In the case when several interrupts are simultaneously pending, an hardware priority defines which one will be serviced first (see the Interrupt Mapping Table).

## Interrupts and Low Power Mode

All interrupts allow the processor to leave the WAIT low power mode. Only external and specifically mentioned interrupts allow the processor to leave the HALT low power mode (refer to the "Exit from HALT" column in the Interrupt Mapping Table).

### 4.1 NON MASKABLE SOFTWARE INTERRUPT

This interrupt is entered when the TRAP instruction is executed regardless of the state of the I bit.

It will be serviced according to the flowchart on Figure 1.

### 4.2 EXTERNAL INTERRUPTS

External interrupt vectors can be loaded into the PC register if the corresponding external interrupt occurred and if the I bit is cleared. These interrupts allow the processor to leave the Halt low power mode.
The external interrupt polarity is selected through the miscellaneous register or interrupt register (if available).
An external interrupt triggered on edge will be latched and the interrupt request automatically cleared upon entering the interrupt service routine.
If several input pins, connected to the same interrupt vector, are configured as interrupts, their signals are logically ANDed and inverted before entering the edge/level detection block.
Caution: The type of sensitivity defined in the Miscellaneous or Interrupt register (if available) applies to the ei source. In case of an ANDed source (as described on the I/O ports section), a low level on an I/O pin configured as input with interrupt, masks the interrupt request even in case of risingedge sensitivity.

### 4.3 PERIPHERAL INTERRUPTS

Different peripheral interrupt flags in the status register are able to cause an interrupt when they are active if both:

- The I bit of the CC register is cleared.
- The corresponding enable bit is set in the control register.
If any of these two conditions is false, the interrupt is latched and thus remains pending.
Clearing an interrupt request is done by:
- Writing " 0 " to the corresponding bit in the status register or
- Access to the status register while the flag is set followed by a read or write of an associated register.
Note: the clearing sequence resets the internal latch. A pending interrupt (i.e. waiting for being enabled) will therefore be lost if the clear sequence is executed.

## INTERRUPTS (Cont'd)

Figure 16. Interrupt Processing Flowchart

Table 7. Interrupt Mapping

Note 1: Timer B is available on ST72212 only.

### 4.4 POWER SAVING MODES

### 4.4.1 Introduction

There are three Power Saving modes. Slow Mode is selected by setting the relevant bits in the Miscellaneous register. Wait and Halt modes may be entered using the WFI and HALT instructions.

### 4.4.2 Slow Mode

In Slow mode, the oscillator frequency can be divided by a value defined in the Miscellaneous Register. The CPU and peripherals are clocked at this lower frequency. Slow mode is used to reduce power consumption, and enables the user to adapt clock frequency to available supply voltage.

### 4.4.3 Wait Mode

Wait mode places the MCU in a low power consumption mode by stopping the CPU. All peripherals remain active. During Wait mode, the I bit (CC Register) is cleared, so as to enable all interrupts. All other registers and memory remain unchanged. The MCU will remain in Wait mode until an Interrupt or Reset occurs, whereupon the Program Counter branches to the starting address of the Interrupt or Reset Service Routine.
The MCU will remain in Wait mode until a Reset or an Interrupt occurs, causing it to wake up.
Refer to Figure 17 below.

Figure 17. WAIT Flow Chart

Note: Before servicing an interrupt, the CC register is pushed on the stack. The l-Bit is set during the interrupt routine and cleared when the CC register is popped.

## POWER SAVING MODES (Cont'd)

### 4.4.4 Halt Mode

The Halt mode is the MCU lowest power consumption mode. The Halt mode is entered by executing the HALT instruction. The internal oscillator is then turned off, causing all internal processing to be stopped, including the operation of the on-chip peripherals. The Halt mode cannot be used when the watchdog is enabled, if the HALT instruction is executed while the watchdog system is enabled, a watchdog reset is generated thus resetting the entire MCU.
When entering Halt mode, the I bit in the CC Register is cleared so as to enable External Interrupts. If an interrupt occurs, the CPU becomes active.
The MCU can exit the Halt mode upon reception of an interrupt or a reset. Refer to the Interrupt Mapping Table. The oscillator is then turned on and a stabilization time is provided before releasing CPU operation. The stabilization time is 4096 CPU clock cycles.
After the start up delay, the CPU continues operation by servicing the interrupt which wakes it up or by fetching the reset vector if a reset wakes it up.

Figure 18. HALT Flow Chart

1) or some specific interrupts
2) if reset PERIPH. CLOCK = ON ; if interrupt PERIPH. CLOCK = OFF
Note: Before servicing an interrupt, the CC register is pushed on the stack. The I-Bit is set during the interrupt routine and cleared when the CC register is popped.

### 4.5 MISCELLANEOUS REGISTER

The Miscellaneous register allows to select the SLOW operating mode, the polarity of external interrupt requests and to output the internal clock.
Register Address: 0020h — Read/Write
Reset Value: 00000000 (00h)

$$
\begin{array}{ll}
7 & 0
\end{array}
$$

Bit 7:6 = PEI[3:2] External Interrupt El1 Polarity Option.
These bits are set and cleared by software. They determine which event on El1 causes the external interrupt according to Table 8.
Table 8. El1 External Interrupt Polarity Options

| MODE | PEI3 | PEI2 |
| :---: | :---: | :---: |
| Falling edge and low level <br> (Reset state) | 0 | 0 |
| Falling edge only | 1 | 0 |
| Rising edge only | 0 | 1 |
| Rising and falling edge | 1 | 1 |

Note: Any modification of one of these two bits resets the interrupt request related to this interrupt vector.

Bit $5=\mathbf{M C O}$ Main Clock Out
This bit is set and cleared by software. When set, it enables the output of the Internal Clock on the PC2 I/O port.
0 - PC2 is a general purpose I/O port.
1 - MCO alternate function ( $\mathrm{f}_{\mathrm{CPU}}$ is output on PC2 pin).

Bit 4:3 = PEI[1:0] External Interrupt EIO Polarity Option.
These bits are set and cleared by software. They determine which event on EIO causes the external interrupt according to Table 9.

Table 9. EIO External Interrupt Polarity Options

| MODE | PEI1 | PEI0 |
| :---: | :---: | :---: |
| Falling edge and low level <br> (Reset state) | 0 | 0 |
| Falling edge only | 1 | 0 |
| Rising edge only | 0 | 1 |
| Rising and falling edge | 1 | 1 |

Note: Any modification of one of these two bits resets the interrupt request related to this interrupt vector.

Bit 1:2 = Unused, always read at 0 .
Warning: Software must write 1 to these bits for compatibility with future products.

Bit $0=$ SMS Slow Mode Select
This bit is set and cleared by software.
0 - Normal mode - $\mathrm{f}_{\mathrm{CPU}}=$ Oscillator frequency $/ 2$ (Reset state)
1- Slow mode - $\mathrm{f}_{\mathrm{CPU}}=$ Oscillator frequency $/ 32$

## 5 ON-CHIP PERIPHERALS

### 5.1 I/O PORTS

### 5.1.1 Introduction

The I/O ports offer different functional modes:

- transfer of data through digital inputs and outputs and for specific pins:
- analog signal input (ADC)
- alternate signal input/output for the on-chip peripherals.
- external interrupt generation

An I/O port is composed of up to 8 pins. Each pin can be programmed independently as digital input (with or without interrupt generation) or digital output.

### 5.1.2 Functional Description

Each port is associated to 2 main registers:

- Data Register (DR)
- Data Direction Register (DDR)
and some of them to an optional register:
- Option Register (OR)

Each I/O pin may be programmed using the corresponding register bits in DDR and OR registers: bit $X$ corresponding to pin $X$ of the port. The same correspondence is used for the DR register.
The following description takes into account the OR register, for specific ports which do not provide this register refer to the I/O Port Implementation Section 5.1.3. The generic I/O block diagram is shown on Figure 20.

### 5.1.2.1 Input Modes

The input configuration is selected by clearing the corresponding DDR register bit.
In this case, reading the DR register returns the digital value applied to the external I/O pin.
Different input modes can be selected by software through the OR register.

## Notes:

1. All the inputs are triggered by a Schmitt trigger.
2. When switching from input mode to output mode, the DR register should be written first to output the correct value as soon as the port is configured as an output.

## Interrupt function

When an I/O is configured in Input with Interrupt, an event on this I/O can generate an external Interrupt request to the CPU. The interrupt polarity is given independently according to the description mentioned in the Miscellaneous register or in the interrupt register (where available).

Each pin can independently generate an Interrupt request
Each external interrupt vector is linked to a dedicated group of I/O port pins (see Interrupts section). If several input pins are configured as inputs to the same interrupt vector, their signals are logically ANDed before entering the edge/level detection block. For this reason if one of the interrupt pins is tied low, it masks the other ones.

### 5.1.2.2 Output Mode

The pin is configured in output mode by setting the corresponding DDR register bit.
In this mode, writing " 0 " or " 1 " to the DR register applies this digital value to the I/O pin through the latch. Then reading the DR register returns the previously stored value.
Note: In this mode, the interrupt function is disabled.

### 5.1.2.3 Digital Alternate Function

When an on-chip peripheral is configured to use a pin, the alternate function is automatically selected. This alternate function takes priority over standard I/O programming. When the signal is coming from an on-chip peripheral, the I/O pin is automatically configured in output mode (push-pull or open drain according to the peripheral).
When the signal is going to an on-chip peripheral, the I/O pin has to be configured in input mode. In this case, the pin's state is also digitally readable by addressing the DR register.

## Notes:

1. Input pull-up configuration can cause an unexpected value at the input of the alternate peripheral input.
2. When the on-chip peripheral uses a pin as input and output, this pin must be configured as an input (DDR = 0).
Warning: The alternate function must not be activated as long as the pin is configured as input with interrupt, in order to avoid generating spurious interrupts.

## I/O PORTS (Cont'd)

### 5.1.2.4 Analog Alternate Function

When the pin is used as an ADC input the I/O must be configured as input, floating. The analog multiplexer (controlled by the ADC registers) switches the analog voltage present on the selected pin to the common analog rail which is connected to the ADC input.
It is recommended not to change the voltage level or loading on any port pin while conversion is in progress. Furthermore it is recommended not to have clocking pins located close to a selected analog pin.
Warning: The analog input voltage level must be within the limits stated in the Absolute Maximum Ratings.

### 5.1.3 I/O Port Implementation

The hardware implementation on each I/O port depends on the settings in the DDR and OR registers and specific feature of the I/O port such as ADC Input (see Figure 20) or true open drain. Switching these I/O ports from one state to another should be done in a sequence that prevents unwanted side effects. Recommended safe transitions are illustrated in Figure 19. Other transitions are potentially risky and should be avoided, since they are likely to present unwanted side-effects such as spurious interrupt generation.

Figure 19. Recommended I/O State Transition Diagram

I/O PORTS (Cont'd)
Figure 20. I/O Block Diagram

Table 10. Port Mode Configuration

| Configuration Mode | Pull-up | P-buffer | $\mathbf{V}_{\text {DD }}$ Diode |
| :--- | :---: | :---: | :---: |
| Floating | 0 | 0 | 1 |
| Pull-up | 1 | 0 | 1 |
| Push-pull | 0 | 1 | 1 |
| True Open Drain | not present | not present | not present in OTP <br> and EPROM devices |
| Open Drain (logic level) | 0 | 0 | 1 |

## Legend:

0 - present, not activated
1- present and activated

## Notes:

- No OR Register on some ports (see register map).
- ADC Switch on ports with analog alternate functions.

Table 11. Port Configuration

| Port | Pin Name | Input (DDR = 0) |  | Output (DDR = 1) |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | OR = 0 | OR =1 | OR = 0 | OR = 1 |
| Port A | PA0:PA7 | Floating $^{*}$ | Floating with Interrupt | True Open Drain, <br> High Sink Capability | Reserved |
| Port B | PB0:PB7 | Floating $^{*}$ | Pull-up with Interrupt | Open Drain (Logic level) | Push-pull |

[^0]I/O PORTS (Cont'd)

### 5.1.4 Register Description

### 5.1.4.1 Data registers

Port A Data Register (PADR)
Port B Data Register (PBDR)
Port C Data Register (PCDR)
Read/Write
Reset Value: 00000000 (00h)
7
0

| D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

Bit 7:0 = D7-D0 Data Register 8 bits.
The DR register has a specific behaviour according to the selected input/output configuration. Writing the DR register is always taken in account even if the pin is configured as an input. Reading the DR register returns either the DR register latch content (pin configured as output) or the digital value applied to the I/O pin (pin configured as input).

### 5.1.4.2 Data direction registers

Port A Data Direction Register (PADDR)
Port B Data Direction Register (PBDDR)
Port C Data Direction Register (PCDDR)
Read/Write
Reset Value: 00000000 (00h) (input mode)
7
0

| DD7 | DD6 | DD5 | DD4 | DD3 | DD2 | DD1 | DD0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

Bit 7:0 = DD7-DD0 Data Direction Register 8 bits.
The DDR register gives the input/output direction configuration of the pins. Each bit is set and cleared by software.
0 : Input mode
1: Output mode

### 5.1.4.3 Option registers

Port A Option Register (PAOR)
Port B Option Register (PBOR)
Port C Option Register (PCOR)
Read/Write
Reset Value: 00000000 (00h) (no interrupt)
7
0

| 07 | 06 | 05 | 04 | 03 | 02 | 01 | 00 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## Bit 7:0 = 07-00 Option Register 8 bits.

For specific I/O pins, this register is not implemented. In this case the DDR register is enough to select the I/O pin configuration.
The OR register allow to distinguish: in input mode if the interrupt capability or the floating configuration is selected, in output mode if the push-pull or open drain configuration is selected.
Each bit is set and cleared by software.
Input mode:
0 : floating input
1: input interrupt with or without pull-up
Output mode (only for PB0:PB7, PC0:PC5):
0 : output open drain (with P-Buffer inactivated)
1: output push-pull
Output mode (only for PA0:PA7):
0 : output open drain
1: reserved

### 5.2 WATCHDOG TIMER (WDG)

### 5.2.1 Introduction

The Watchdog timer is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The Watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the counter's contents before the T6 bit becomes cleared.

### 5.2.2 Main Features

- Programmable timer (64 increments of 12288 CPU cycles)
- Programmable reset
- Reset (if watchdog activated) after a HALT instruction or when the T6 bit reaches zero

Figure 21. Watchdog Block Diagram

## WATCHDOG TIMER (Cont'd)

### 5.2.3 Functional Description

The counter value stored in the CR register (bits T6:T0), is decremented every 12,288 machine cycles, and the length of the timeout period can be programmed by the user in 64 increments.
If the watchdog is activated (the WDGA bit is set) and when the 7-bit timer (bits T6:T0) rolls over from 40h to 3Fh (T6 becomes cleared), it initiates a reset cycle pulling low the reset pin for typically 500ns.
The application program must write in the CR register at regular intervals during normal operation to prevent an MCU reset. The value to be stored in the CR register must be between FFh and COh (see Table 1):

- The WDGA bit is set (watchdog enabled)
- The T6 bit is set to prevent generating an immediate reset
- The T5:T0 bits contain the number of increments which represents the time delay before the watchdog produces a reset.
Table 13. Watchdog Timing ( $\mathrm{f}_{\mathrm{CPU}}=8 \mathrm{MHz}$ )

|  | CR Register <br> initial value | WDG timeout period <br> $(\mathbf{m s})$ |
| :---: | :---: | :---: |
| Max | FFh | 98.304 |
| Min | COh | 1.536 |

Notes: Following a reset, the watchdog is disabled. Once activated it cannot be disabled, except by a reset.
The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared). If the watchdog is activated, the HALT instruction will generate a Reset.

### 5.2.4 Low Power Modes

| Mode | Description |
| :--- | :--- |
| WAIT | No effect on Watchdog. |
| HALT | Immediate reset generation as soon as <br> the HALT instruction is executed if the <br> Watchdog is activated (WDGA bit is <br> set). |

### 5.2.5 Interrupts

None.

### 5.2.6 Register Description <br> CONTROL REGISTER (CR)

Read/Write
Reset Value: 01111111 (7Fh)

### 5.3 16-BIT TIMER

### 5.3.1 Introduction

The timer consists of a 16-bit free-running counter driven by a programmable prescaler.
It may be used for a variety of purposes, including measuring the pulse lengths of up to two input signals (input capture) or generating up to two output waveforms (output compare and PWM).
Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the CPU clock prescaler.
Some ST7 devices have two on-chip 16-bit timers. They are completely independent, and do not share any resources. They are synchronized after a MCU reset as long as the timer clock frequencies are not modified.
This description covers one or two 16-bit timers. In ST7 devices with two timers, register names are prefixed with TA (Timer A) or TB (Timer B).

### 5.3.2 Main Features

- Programmable prescaler: $\mathrm{f}_{\mathrm{CP}}$ divided by 2,4 or 8 .
- Overflow status flag and maskable interrupt
- External clock input (must be at least 4 times slower than the CPU clock speed) with the choice of active edge
- Output compare functions with:
- 2 dedicated 16-bit registers
- 2 dedicated programmable signals
- 2 dedicated status flags
- 1 dedicated maskable interrupt
- Input capture functions with:
- 2 dedicated 16-bit registers
- 2 dedicated active edge selection signals
-2 dedicated status flags
- 1 dedicated maskable interrupt
- Pulse Width Modulation mode (PWM)
- One Pulse mode
- 5 alternate functions on I/O ports (ICAP1, ICAP2, OCMP1, OCMP2, EXTCLK)*

The Block Diagram is shown in Figure 1.
*Note: Some timer pins may not be available (not bonded) in some ST7 devices. Refer to the device pin out description.
When reading an input signal on a non-bonded pin , the value will always be ' 1 '.

### 5.3.3 Functional Description

### 5.3.3.1 Counter

The main block of the Programmable Timer is a 16 -bit free running upcounter and its associated 16 -bit registers. The 16 -bit registers are made up of two 8-bit registers called high \& low.

## Counter Register (CR):

- Counter High Register (CHR) is the most significant byte (MS Byte).
- Counter Low Register (CLR) is the least significant byte (LS Byte).

## Alternate Counter Register (ACR)

- Alternate Counter High Register (ACHR) is the most significant byte (MS Byte).
- Alternate Counter Low Register (ACLR) is the least significant byte (LS Byte).
These two read-only 16-bit registers contain the same value but with the difference that reading the ACLR register does not clear the TOF bit (Timer overflow flag), located in the Status register (SR). (See note at the end of paragraph titled 16-bit read sequence).
Writing in the CLR register or ACLR register resets the free running counter to the FFFCh value.
Both counters have a reset value of FFFCh (this is the only value which is reloaded in the 16-bit timer). The reset value of both counters is also FFFCh in One Pulse mode and PWM mode.

The timer clock depends on the clock control bits of the CR2 register, as illustrated in Table 1. The value in the counter register repeats every 131072, 262144 or 524288 CPU clock cycles depending on the CC[1:0] bits.
The timer frequency can be $\mathrm{f}_{\mathrm{CPU}} / 2, \mathrm{f}_{\mathrm{CPU}} / 4, \mathrm{f}_{\mathrm{CPU}} / 8$ or an external frequency.

## 16-BIT TIMER (Cont'd)

Figure 22. Timer Block Diagram

## 16-BIT TIMER (Cont'd)

16-bit Read Sequence: (from either the Counter Register or the Alternate Counter Register).

Beginning of the sequence

Sequence completed
The user must read the MS Byte first, then the LS Byte value is buffered automatically.
This buffered value remains unchanged until the 16 -bit read sequence is completed, even if the user reads the MS Byte several times.
After a complete reading sequence, if only the CLR register or ACLR register are read, they return the LS Byte of the count value at the time of the read.
Whatever the timer mode used (input capture, output compare, One Pulse mode or PWM mode) an overflow occurs when the counter rolls over from FFFFh to 0000h then:

- The TOF bit of the SR register is set.
- A timer interrupt is generated if:
- TOIE bit of the CR1 register is set and
- I bit of the CC register is cleared.

If one of these conditions is false, the interrupt remains pending to be issued as soon as they are both true.

Clearing the overflow interrupt request is done in two steps:

1. Reading the $S R$ register while the TOF bit is set. 2. An access (read or write) to the CLR register.

Note: The TOF bit is not cleared by accessing the ACLR register. The advantage of accessing the ACLR register rather than the CLR register is that it allows simultaneous use of the overflow function and reading the free running counter at random times (for example, to measure elapsed time) without the risk of clearing the TOF bit erroneously.
The timer is not affected by WAIT mode.
In HALT mode, the counter stops counting until the mode is exited. Counting then resumes from the previous count (MCU awakened by an interrupt) or from the reset count (MCU awakened by a Reset).

### 5.3.3.2 External Clock

The external clock (where available) is selected if $C C 0=1$ and $C C 1=1$ in the CR2 register.
The status of the EXEDG bit in the CR2 register determines the type of level transition on the external clock pin EXTCLK that will trigger the free running counter.
The counter is synchronised with the falling edge of the internal CPU clock.
A minimum of four falling edges of the CPU clock must occur between two consecutive active edges of the external clock; thus the external clock frequency must be less than a quarter of the CPU clock frequency.

## 16-BIT TIMER (Cont'd)

Figure 23. Counter Timing Diagram, internal clock divided by 2

Figure 24. Counter Timing Diagram, internal clock divided by 4

Figure 25. Counter Timing Diagram, internal clock divided by 8

Note: The MCU is in reset state when the internal reset signal is high. When it is low, the MCU is running.

## 16-BIT TIMER (Cont'd)

### 5.3.3.3 Input Capture

In this section, the index, $i$, may be 1 or 2 because there are 2 input capture functions in the 16-bit timer.
The two input capture 16 -bit registers (IC1R and IC2R) are used to latch the value of the free running counter after a transition is detected by the ICAPi pin (see figure 5).

The ICiR register is a read-only register.
The active transition is software programmable through the IEDGi bit of Control Registers (CRi).
Timing resolution is one count of the free running counter: ( $\mathrm{f}_{\mathrm{CPU}} / \mathrm{CC}[1: 0]$ ).

## Procedure:

To use the input capture function, select the following in the CR2 register:

- Select the timer clock (CC[1:0]) (see Table 1).
- Select the edge of the active transition on the ICAP2 pin with the IEDG2 bit (the ICAP2 pin must be configured as a floating input).
And select the following in the CR1 register:
- Set the ICIE bit to generate an interrupt after an input capture coming from either the ICAP1 pin or the ICAP2 pin
- Select the edge of the active transition on the ICAP1 pin with the IEDG1 bit (the ICAP1pin must be configured as a floating input).

When an input capture occurs:

- The ICFi bit is set.
- The ICIR register contains the value of the free running counter on the active transition on the ICAPi in (see Figure 6).
- A timer interrupt is generated if the ICIE bit is set and the I bit is cleared in the CC register. Otherwise, the interrupt remains pending until both conditions become true.
Clearing the Input Capture interrupt request (i.e. clearing the ICFi bit) is done in two steps:

1. Reading the SR register while the ICFibit is set.
2. An access (read or write) to the ICiLR register.

## Notes:

1. After reading the ICIHR register, the transfer of input capture data is inhibited and ICFi will never be set until the ICiLR register is also read.
2. The ICIR register contains the free running counter value which corresponds to the most recent input capture.
3. The 2 input capture functions can be used together even if the timer also uses the 2 output compare functions.
4. In One Pulse mode and PWM mode only the input capture 2 function can be used.
5. The alternate inputs (ICAP1 \& ICAP2) are always directly connected to the timer. So any transitions on these pins activate the input capture function.
Moreover if one of the ICAPi pin is configured as an input and the second one as an output, an interrupt can be generated if the user toggles the output pin and if the ICIE bit is set.
This can be avoided if the input capture function $i$ is disabled by reading the ICHR (see note 1).
6. The TOF bit can be used with an interrupt in order to measure events that exceed the timer range (FFFFh).

## 16-BIT TIMER (Cont'd)

Figure 26. Input Capture Block Diagram

Figure 27. Input Capture Timing Diagram

## 16-BIT TIMER (Cont'd)

### 5.3.3.4 Output Compare

In this section, the index, $i$, may be 1 or 2 because there are 2 output compare functions in the 16-bit timer.
This function can be used to control an output waveform or indicate when a period of time has elapsed.
When a match is found between the Output Compare register and the free running counter, the output compare function:

- Assigns pins with a programmable value if the OCIE bit is set
- Sets a flag in the status register
- Generates an interrupt if enabled

Two 16-bit registers Output Compare Register 1 (OC1R) and Output Compare Register 2 (OC2R) contain the value to be compared to the counter register each timer clock cycle.

|  | MS Byte |  |
| :---: | :---: | :---: |
| LS Byte |  |  |
| OCRR OCHR | OCiLR |  |
|  |  |  |

These registers are readable and writable and are not affected by the timer hardware. A reset event changes the OCiR value to 8000 h .
Timing resolution is one count of the free running counter: ( $\mathrm{f}_{\mathrm{CPU} / \mathrm{CC}[1: 0]}$ ).

## Procedure:

To use the output compare function, select the following in the CR2 register:

- Set the OCIE bit if an output is needed then the OCMPi pin is dedicated to the output compare $i$ signal.
- Select the timer clock (CC[1:0]) (see Table 1).

And select the following in the CR1 register:

- Select the OLVLibit to applied to the OCMP ipins after the match occurs.
- Set the OCIE bit to generate an interrupt if it is needed.
When a match is found between OCRi register and CR register:
- OCFi bit is set.
- The OCMP i pin takes OLVLibit value (OCMPi pin latch is forced low during reset).
- A timer interrupt is generated if the OCIE bit is set in the CR2 register and the I bit is cleared in the CC register (CC).

The OCiR register value required for a specific timing application can be calculated using the following formula:

$$
\Delta \mathrm{OCR}=\frac{\Delta \mathrm{t} * \mathrm{f}_{\mathrm{CPU}}}{\mathrm{PRESC}}
$$

Where:
$\Delta \mathrm{t} \quad=$ Output compare period (in seconds)
$\mathrm{f}_{\mathrm{CPU}}=$ CPU clock frequency (in hertz)
PRESC $=$ Timer prescaler factor (2, 4 or 8 depending on CC[1:0] bits, see Table 1)

If the timer clock is an external clock, the formula is:

$$
\Delta \mathrm{OCiR}=\Delta \mathrm{t} * \mathrm{f}_{\mathrm{EXT}}
$$

Where:
$\Delta \mathrm{t} \quad=$ Output compare period (in seconds)
$\mathrm{f}_{\mathrm{EXT}}=$ External timer clock frequency (in hertz)

Clearing the output compare interrupt request (i.e. clearing the OCFi bit) is done by:

1. Reading the SR register while the OCFi bit is set.
2. An access (read or write) to the OCiLR register.

The following procedure is recommended to prevent the OCFi bit from being set between the time it is read and the write to the OCiR register:

- Write to the OCiHR register (further compares are inhibited).
- Read the SR register (first step of the clearance of the OCFi bit, which may be already set).
- Write to the OCiLR register (enables the output compare function and clears the OCFi bit).

## 16-BIT TIMER (Cont'd)

## Notes:

1. After a processor write cycle to the OCiHR register, the output compare function is inhibited until the OCiLR register is also written.
2. If the OCiE bit is not set, the OCMPi pin is a general I/O port and the OLVLi bit will not appear when a match is found but an interrupt could be generated if the OCIE bit is set.
3. When the timer clock is $\mathrm{f}_{\mathrm{CPJ}} / 2$, OCFi and OCMPi are set while the counter value equals the OCiR register value (see Figure 8). This behaviour is the same in OPM or PWM mode. When the timer clock is $\mathrm{f}_{\mathrm{CPU}} / 4, \mathrm{f}_{\mathrm{CPU}} / 8$ or in external clock mode, OCFi and OCMP $i$ are set while the counter value equals the OC/R register value plus 1 (see Figure 9).
4. The output compare functions can be used both for generating external events on the OCMP $i$ pins even if the input capture mode is also used.
5. The value in the 16 -bit OCiR register and the OLVi bit should be changed after each successful comparison in order to control an output waveform or establish a new elapsed timeout.

## Forced Compare Output capability

When the FOLVi bit is set by software, the OLVLi bit is copied to the OCMP $i$ pin. The OLVi bit has to be toggled in order to toggle the OCMP i pin when it is enabled (OCiE bit=1). The OCFi bit is then not set by hardware, and thus no interrupt request is generated.
FOLVLi bits have no effect in either One-Pulse mode or PWM mode.

Figure 28. Output Compare Block Diagram

## 16-BIT TIMER (Cont'd)

Figure 29. Output Compare Timing Diagram, $\mathrm{f}_{\text {TIMER }}=\mathrm{f}_{\mathrm{CPU}} / \mathbf{2}$

Figure 30. Output Compare Timing Diagram, $\mathrm{f}_{\text {TIMER }}=\mathbf{f}_{\mathrm{CPU}} / 4$

## 16-BIT TIMER (Cont'd)

### 5.3.3.5 One Pulse Mode

One Pulse mode enables the generation of a pulse when an external event occurs. This mode is selected via the OPM bit in the CR2 register.
The One Pulse mode uses the Input Capture1 function and the Output Compare1 function.

## Procedure:

To use One Pulse mode:

1. Load the OC1R register with the value corresponding to the length of the pulse (see the formula in the opposite column).
2. Select the following in the CR1 register:

- Using the OLVL1 bit, select the level to be applied to the OCMP1 pin after the pulse.
- Using the OLVL2 bit, select the level to be applied to the OCMP1 pin during the pulse.
- Select the edge of the active transition on the ICAP1 pin with the IEDG1 bit (the ICAP1 pin must be configured as floating input).

3. Select the following in the CR2 register:

- Set the OC1E bit, the OCMP1 pin is then dedicated to the Output Compare 1 function.
- Set the OPM bit.
- Select the timer clock CC[1:0] (see Table 1).

Then, on a valid event on the ICAP1 pin, the counter is initialized to FFFCh and the OLVL2 bit is loaded on the OCMP1 pin, the ICF1 bit is set and the value FFFDh is loaded in the IC1R register.
Because the ICF1 bit is set when an active edge occurs, an interrupt can be generated if the ICIE bit is set.

Clearing the Input Capture interrupt request (i.e. clearing the ICFi bit) is done in two steps:

1. Reading the SR register while the ICFi ibit is set.
2. An access (read or write) to the ICiLR register.

The OC1R register value required for a specific timing application can be calculated using the following formula:

$$
\text { OCiR Value }=\frac{t * f_{\mathrm{CPU}}}{\mathrm{PRESC}}-5
$$

Where:
$\mathrm{t} \quad=$ Pulse period (in seconds)
$\mathrm{f}_{\mathrm{CPU}}=$ CPU clock frequency (in hertz)
PRESC $=$ Timer prescaler factor ( 2,4 or 8 depending on the CC[1:0] bits, see Table 1)
If the timer clock is an external clock the formula is:

$$
O C i R=t * f_{E X T}-5
$$

Where:
$\mathrm{t} \quad=$ Pulse period (in seconds)
$\mathrm{f}_{\mathrm{EXT}}=$ External timer clock frequency (in hertz)

When the value of the counter is equal to the value of the contents of the OC1R register, the OLVL1 bit is output on the OCMP1 pin (see Figure 10).

## Notes:

1. The OCF1 bit cannot be set by hardware in One Pulse mode but the OCF2 bit can generate an Output Compare interrupt.
2. When the Pulse Width Modulation (PWM) and One Pulse mode (OPM) bits are both set, the PWM mode is the only active one.
3. If OLVL1=OLVL2 a continuous signal will be seen on the OCMP1 pin.
4. The ICAP1 pin can not be used to perform input capture. The ICAP2 pin can be used to perform input capture (ICF2 can be set and IC2R can be loaded) but the user must take care that the counter is reset each time a valid edge occurs on the ICAP1 pin and ICF1 can also generates interrupt if ICIE is set.
5. When One Pulse mode is used OC1R is dedicated to this mode. Nevertheless OC2R and OCF2 can be used to indicate that a period of time has elapsed but cannot generate an output waveform because the OLVL2 level is dedicated to One Pulse mode.

## 16-BIT TIMER (Cont'd)

### 5.3.3.6 Pulse Width Modulation Mode

Pulse Width Modulation (PWM) mode enables the generation of a signal with a frequency and pulse length determined by the value of the OC1R and OC2R registers.
The Pulse Width Modulation mode uses the complete Output Compare 1 function plus the OC2R register, and so these functions cannot be used when the PWM mode is activated.

## Procedure

To use Pulse Width Modulation mode:

1. Load the OC2R register with the value corresponding to the period of the signal using the formula in the opposite column.
2. Load the OC1R register with the value corresponding to the period of the pulse if OLVL1=0 and OLVL2=1, using the formula in the opposite column.
3. Select the following in the CR1 register:

- Using the OLVL1 bit, select the level to be applied to the OCMP1 pin after a successful comparison with OC1R register.
- Using the OLVL2 bit, select the level to be applied to the OCMP1 pin after a successful comparison with OC2R register.

4. Select the following in the CR2 register:

- Set OC1E bit: the OCMP1 pin is then dedicated to the output compare 1 function.
- Set the PWM bit.
- Select the timer clock (CC[1:0]) (see Table 1). If OLVL1 $=1$ and OLVL2=0, the length of the positive pulse is the difference between the OC2R and OC1R registers.
If OLVL1=OLVL2 a continuous signal will be seen on the OCMP1 pin.

The OCiR register value required for a specific timing application can be calculated using the following formula:

$$
\mathrm{OCiR} \text { Value }=\frac{\mathrm{t} * \mathrm{f}_{\mathrm{CPU}}}{\mathrm{PRESC}}-5
$$

Where:
$\mathrm{t} \quad=$ Signal or pulse period (in seconds)
$\mathrm{f}_{\mathrm{CPU}}=$ CPU clock frequency (in hertz)
PRESC $=$ Timer prescaler factor (2, 4 or 8 depending on CC[1:0] bits, see Table 1)
If the timer clock is an external clock the formula is:

$$
O C i R=t * f_{E X T}-5
$$

Where:
$\mathrm{t} \quad=$ Signal or pulse period (in seconds)
$\mathrm{f}_{\mathrm{EXT}}=$ External timer clock frequency (in hertz)

The Output Compare 2 event causes the counter to be initialized to FFFCh (See Figure 11)

## Notes:

1. After a write instruction to the OCiHR register, the output compare function is inhibited until the OCiLR register is also written.
2. The OCF1 and OCF2 bits cannot be set by hardware in PWM mode, therefore the Output Compare interrupt is inhibited.
3. The ICF1 bit is set by hardware when the counter reaches the OC2R value and can produce a timer interrupt if the ICIE bit is set and the I bit is cleared.
4. In PWM mode the ICAP1 pin can not be used to perform input capture because it is disconnected from the timer. The ICAP2 pin can be used to perform input capture (ICF2 can be set and IC2R can be loaded) but the user must take care that the counter is reset after each period and ICF1 can also generate an interrupt if ICIE is set.
5. When the Pulse Width Modulation (PWM) and One Pulse mode (OPM) bits are both set, the PWM mode is the only active one.

## 16-BIT TIMER (Cont'd)

### 5.3.4 Low Power Modes

| Mode | Description |
| :--- | :--- |
| WAIT | No effect on 16-bit Timer. <br> Timer interrupts cause the device to exit from WAIT mode. |
| HALT | 16-bit Timer registers are frozen. <br> In HALT mode, the counter stops counting until Halt mode is exited. Counting resumes from the previous <br> count when the MCU is woken up by an interrupt with "exit from HALT mode" capability or from the counter <br> reset value when the MCU is woken up by a RESET. <br> If an input capture event occurs on the ICAPi in, the input capture detection circuitry is armed. Consequent- <br> ly, when the MCU is woken up by an interrupt with "exit from HALT mode" capability, the ICF $i$ bit is set, and <br> the counter value present when exiting from HALT mode is captured into the ICiR register. |

### 5.3.5 Interrupts

| Interrupt Event | Event Flag | Enable Control Bit | Exit from Wait | $\begin{aligned} & \text { Exit } \\ & \text { from } \\ & \text { Halt } \end{aligned}$ |
| :---: | :---: | :---: | :---: | :---: |
| Input Capture 1 event/Counter reset in PWM mode | ICF1 | ICIE | Yes | No |
| Input Capture 2 event | ICF2 |  | Yes | No |
| Output Compare 1 event (not available in PWM mode) | OCF1 | OCIE | Yes | No |
| Output Compare 2 event (not available in PWM mode) | OCF2 |  | Yes | No |
| Timer Overflow event | TOF | TOIE | Yes | No |

Note: The 16-bit Timer interrupt events are connected to the same interrupt vector (see Interrupts chapter). These events generate an interrupt if the corresponding Enable Control Bit is set and the interrupt mask in the CC register is reset (RIM instruction).

### 5.3.6 Summary of Timer modes

| MODES |  | AVAILABLE RESOURCES |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: |
|  |  | Input Capture 2 | Output Compare 1 | Output Compare 2 |  |
| Input Capture (1 and/or 2) | Yes | Yes | Yes | Yes |  |
| Output Compare (1 and/or 2) | Yes | Yes | Yes | Yes |  |
| One Pulse mode | No | Not Recommended $^{\text {1 }}$ | No | Partially ${ }^{2)}$ |  |
| PWM Mode | No | Not Recommended $^{3)}$ | No | No |  |

1) See note 4 in Section 0.1.3.5 One Pulse Mode
${ }^{2)}$ See note 5 in Section 0.1.3.5 One Pulse Mode
${ }^{3}$ ) See note 4 in Section 0.1.3.6 Pulse Width Modulation Mode

## 16-BIT TIMER (Cont'd)

### 5.3.7 Register Description

Each Timer is associated with three control and status registers, and with six pairs of data registers (16-bit values) relating to the two input captures, the two output compares, the counter and the alternate counter.

## CONTROL REGISTER 1 (CR1)

Read/Write
Reset Value: 00000000 (00h)

| 7 |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| ICIE | OCIE | TOIE | FOLV2 | FOLV1 | OLVL2 | IEDG1 | OLVL1 |

Bit 7 = ICIE Input Capture Interrupt Enable.
0 : Interrupt is inhibited.
1: A timer interrupt is generated whenever the ICF1 or ICF2 bit of the SR register is set.

Bit $6=$ OCIE Output Compare Interrupt Enable. 0 : Interrupt is inhibited.
1: A timer interrupt is generated whenever the OCF1 or OCF2 bit of the SR register is set.

Bit $5=$ TOIE Timer Overflow Interrupt Enable.
0 : Interrupt is inhibited.
1: A timer interrupt is enabled whenever the TOF bit of the SR register is set.

Bit 4 = FOLV2 Forced Output Compare 2.
This bit is set and cleared by software.
0 : No effect on the OCMP2 pin.
1: Forces the OLVL2 bit to be copied to the OCMP2 pin, if the OC2E bit is set and even if there is no successful comparison.

## Bit 3 = FOLV1 Forced Output Compare 1.

This bit is set and cleared by software.
0 : No effect on the OCMP1 pin.
1: Forces OLVL1 to be copied to the OCMP1 pin, if the OC1E bit is set and even if there is no successful comparison.

## Bit 2 = OLVL2 Output Level 2.

This bit is copied to the OCMP2 pin whenever a successful comparison occurs with the OC2R register and OCxE is set in the CR2 register. This value is copied to the OCMP1 pin in One Pulse mode and Pulse Width Modulation mode.
Bit 1 = IEDG1 Input Edge 1.
This bit determines which type of level transition on the ICAP1 pin will trigger the capture.
0 : A falling edge triggers the capture.
1: A rising edge triggers the capture.

Bit $0=$ OLVL1 Output Level 1.
The OLVL1 bit is copied to the OCMP1 pin whenever a successful comparison occurs with the OC1R register and the OC1E bit is set in the CR2 register.

## 16-BIT TIMER (Cont'd) <br> CONTROL REGISTER 2 (CR2)

Read/Write
Reset Value: 00000000 (00h)

$$
\begin{array}{ll}
7 & 0
\end{array}
$$

Bit $7=$ OC1E Output Compare 1 Pin Enable.
This bit is used only to output the signal from the timer on the OCMP1 pin (OLV1 in Output Compare mode, both OLV1 and OLV2 in PWM and one-pulse mode). Whatever the value of the OC1E bit, the internal Output Compare 1 function of the timer remains active.
0: OCMP1 pin alternate function disabled (I/O pin free for general-purpose I/O).
1: OCMP1 pin alternate function enabled.
Bit $6=$ OC2E Output Compare 2 Pin Enable.
This bit is used only to output the signal from the timer on the OCMP2 pin (OLV2 in Output Compare mode). Whatever the value of the OC2E bit, the internal Output Compare 2 function of the timer remains active.
0: OCMP2 pin alternate function disabled (I/O pin free for general-purpose I/O).
1: OCMP2 pin alternate function enabled.
Bit 5 = OPM One Pulse mode.
0 : One Pulse mode is not active.
1: One Pulse mode is active, the ICAP1 pin can be used to trigger one pulse on the OCMP1 pin; the active transition is given by the IEDG1 bit. The length of the generated pulse depends on the contents of the OC1R register.

Bit 4 = PWM Pulse Width Modulation.
0 : PWM mode is not active.
1: PWM mode is active, the OCMP1 pin outputs a programmable cyclic signal; the length of the pulse depends on the value of OC1R register; the period depends on the value of OC2R register.

Bits 3:2 = CC[1:0] Clock Control.
The timer clock mode depends on these bits:
Table 15. Clock Control Bits

| Timer Clock | CC1 | CC0 |
| :---: | :---: | :---: |
| $\mathrm{f}_{\mathrm{CPU}} / 4$ | 0 | 0 |
| $\mathrm{f}_{\mathrm{CPU}} / 2$ | 0 | 1 |
| $\mathrm{f}_{\mathrm{CPU}} / 8$ | 1 | 0 |
| External Clock (where <br> available) | 1 | 1 |

Note: If the external clock pin is not available, programming the external clock configuration stops the counter.

Bit 1 = IEDG2 Input Edge 2.
This bit determines which type of level transition on the ICAP2 pin will trigger the capture.
0 : A falling edge triggers the capture.
1: A rising edge triggers the capture.
Bit $0=$ EXEDG External Clock Edge.
This bit determines which type of level transition on the external clock pin (EXTCLK) will trigger the counter register.
0 : A falling edge triggers the counter register.
1: A rising edge triggers the counter register.

## 16-BIT TIMER (Cont'd)

## STATUS REGISTER (SR)

Read Only
Reset Value: 00000000 (00h)
The three least significant bits are not used.

| 7 |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| ICF1 | OCF1 | TOF | ICF2 | OCF2 | 0 | 0 | 0 |

Bit 7 = ICF1 Input Capture Flag 1.
0 : No input capture (reset value).
1: An input capture has occurred on the ICAP1 pin or the counter has reached the OC2R value in PWM mode. To clear this bit, first read the SR register, then read or write the low byte of the IC1R (IC1LR) register.

Bit 6 = OCF1 Output Compare Flag 1.
0 : No match (reset value).
1: The content of the free running counter matches the content of the OC1R register. To clear this bit, first read the SR register, then read or write the low byte of the OC1R (OC1LR) register.

Bit $5=$ TOF Timer Overflow Flag.
0 : No timer overflow (reset value).
1: The free running counter has rolled over from FFFFh to 0000 h . To clear this bit, first read the SR register, then read or write the low byte of the CR (CLR) register.
Note: Reading or writing the ACLR register does not clear TOF.

Bit 4 = ICF2 Input Capture Flag 2.
0 : No input capture (reset value).
1: An input capture has occurred on the ICAP2 pin. To clear this bit, first read the SR register, then read or write the low byte of the IC2R (IC2LR) register.

Bit 3 = OCF2 Output Compare Flag 2.
0 : No match (reset value).
1: The content of the free running counter matches the content of the OC2R register. To clear this bit, first read the SR register, then read or write the low byte of the OC2R (OC2LR) register.

Bit 2-0 = Reserved, forced by hardware to 0 .

## INPUT CAPTURE 1 HIGH REGISTER (IC1HR)

Read Only
Reset Value: Undefined
This is an 8-bit read only register that contains the high part of the counter value (transferred by the input capture 1 event).

7 0

## INPUT CAPTURE 1 LOW REGISTER (IC1LR)

Read Only
Reset Value: Undefined
This is an 8-bit read only register that contains the low part of the counter value (transferred by the input capture 1 event).

7
0

## OUTPUT COMPARE 1 HIGH REGISTER (OC1HR)

Read/Write
Reset Value: 10000000 (80h)
This is an 8-bit register that contains the high part of the value to be compared to the CHR register.

7
0

## OUTPUT COMPARE 1 LOW REGISTER (OC1LR)

Read/Write
Reset Value: 00000000 (00h)
This is an 8-bit register that contains the low part of the value to be compared to the CLR register.

$$
\begin{array}{ll}
7 & 0
\end{array}
$$

## 16-BIT TIMER (Cont'd)

OUTPUT COMPARE 2 HIGH REGISTER (OC2HR)
Read/Write
Reset Value: 10000000 (80h)
This is an 8-bit register that contains the high part of the value to be compared to the CHR register.
$\qquad$

| MSB |  |  |  |  |  |  | LSB |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## OUTPUT COMPARE 2 LOW REGISTER (OC2LR)

Read/Write
Reset Value: 00000000 (00h)
This is an 8-bit register that contains the low part of the value to be compared to the CLR register.

## COUNTER HIGH REGISTER (CHR)

Read Only
Reset Value: 11111111 (FFh)
This is an 8-bit register that contains the high part of the counter value.

## COUNTER LOW REGISTER (CLR)

Read Only
Reset Value: 11111100 (FCh)
This is an 8-bit register that contains the low part of the counter value. A write to this register resets the counter. An access to this register after accessing the SR register clears the TOF bit.

7 0

| MSB |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| LSB |  |  |  |  |  |  |  |

## ALTERNATE COUNTER HIGH REGISTER (ACHR)

Read Only
Reset Value: 11111111 (FFh)
This is an 8-bit register that contains the high part of the counter value.

## 7 <br> 0

| MSB |  |  |  |  |  |  | LSB |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

## ALTERNATE COUNTER LOW REGISTER (ACLR)

Read Only
Reset Value: 11111100 (FCh)
This is an 8-bit register that contains the low part of the counter value. A write to this register resets the counter. An access to this register after an access to SR register does not clear the TOF bit in SR register.

## INPUT CAPTURE 2 HIGH REGISTER (IC2HR)

Read Only
Reset Value: Undefined
This is an 8-bit read only register that contains the high part of the counter value (transferred by the Input Capture 2 event).

$$
7 \quad 0
$$

## INPUT CAPTURE 2 LOW REGISTER (IC2LR)

Read Only
Reset Value: Undefined
This is an 8-bit read only register that contains the low part of the counter value (transferred by the Input Capture 2 event).

### 5.4 SERIAL PERIPHERAL INTERFACE (SPI)

### 5.4.1 Introduction

The Serial Peripheral Interface (SPI) allows fullduplex, synchronous, serial communication with external devices. An SPI system may consist of a master and one or more slaves or a system in which devices may be either masters or slaves.
The SPI is normally used for communication between the microcontroller and external peripherals or another microcontroller.
Refer to the Pin Description chapter for the devicespecific pin-out.

### 5.4.2 Main Features

- Full duplex, three-wire synchronous transfers
- Master or slave operation
- Four master mode frequencies
- Maximum slave mode frequency = fCPU/2.
- Four programmable master bit rates
- Programmable clock polarity and phase
- End of transfer interrupt flag
- Write collision flag protection
- Master mode fault protection capability.

### 5.4.3 General description

The SPI is connected to external devices through 4 alternate pins:

- MISO: Master In Slave Out pin
- MOSI: Master Out Slave In pin
- SCK: Serial Clock pin
- $\overline{\text { SS: }}$ Slave select pin

A basic example of interconnections between a single master and a single slave is illustrated on Figure 1.
The MOSI pins are connected together as are MISO pins. In this way data is transferred serially between master and slave (most significant bit first).
When the master device transmits data to a slave device via MOSI pin, the slave device responds by sending data to the master device via the MISO pin. This implies full duplex transmission with both data out and data in synchronized with the same clock signal (which is provided by the master device via the SCK pin).
Thus, the byte transmitted is replaced by the byte received and eliminates the need for separate transmit-empty and receiver-full bits. A status flag is used to indicate that the $\mathrm{I} / \mathrm{O}$ operation is complete.
Four possible data/clock timing relationships may be chosen (see Figure 4) but master and slave must be programmed with the same timing mode.

Figure 33. Serial Peripheral Interface Master/Slave

## SERIAL PERIPHERAL INTERFACE (Cont'd)

Figure 34. Serial Peripheral Interface Block Diagram

## SERIAL PERIPHERAL INTERFACE (Cont'd)

### 5.4.4 Functional Description

Figure 1 shows the serial peripheral interface (SPI) block diagram.
This interface contains 3 dedicated registers:

- A Control Register (CR)
- A Status Register (SR)
- A Data Register (DR)

Refer to the CR, SR and DR registers in Section 0.1.7 for the bit definitions.

### 5.4.4.1 Master Configuration

In a master configuration, the serial clock is generated on the SCK pin.

## Procedure

- Select the SPR0 \& SPR1 bits to define the serial clock baud rate (see CR register).
- Select the CPOL and CPHA bits to define one of the four relationships between the data transfer and the serial clock (see Figure 4).
- The $\overline{\mathrm{SS}}$ pin must be connected to a high level signal during the complete byte transmit sequence.
- The MSTR and SPE bits must be set (they remain set only if the $\overline{S S}$ pin is connected to a high level signal).

In this configuration the MOSI pin is a data output and to the MISO pin is a data input.

## Transmit sequence

The transmit sequence begins when a byte is written the DR register.
The data byte is parallel loaded into the 8-bit shift register (from the internal bus) during a write cycle and then shifted out serially to the MOSI pin most significant bit first.

When data transfer is complete:

- The SPIF bit is set by hardware
- An interrupt is generated if the SPIE bit is set and the I bit in the CCR register is cleared.
During the last clock cycle the SPIF bit is set, a copy of the data byte received in the shift register is moved to a buffer. When the DR register is read, the SPI peripheral returns this buffered value.
Clearing the SPIF bit is performed by the following software sequence:

1. An access to the SR register while the SPIF bit is set
2. A read to the DR register.

Note: While the SPIF bit is set, all writes to the DR register are inhibited until the SR register is read.

## SERIAL PERIPHERAL INTERFACE (Cont'd)

### 5.4.4.2 Slave Configuration

In slave configuration, the serial clock is received on the SCK pin from the master device.
The value of the SPR0 \& SPR1 bits is not used for the data transfer.

## Procedure

- For correct data transfer, the slave device must be in the same timing mode as the master device (CPOL and CPHA bits). See Figure 4.
- The $\overline{\mathrm{SS}}$ pin must be connected to a low level signal during the complete byte transmit sequence.
- Clear the MSTR bit and set the SPE bit to assign the pins to alternate function.
In this configuration the MOSI pin is a data input and the MISO pin is a data output.

## Transmit Sequence

The data byte is parallel loaded into the 8 -bit shift register (from the internal bus) during a write cycle and then shifted out serially to the MISO pin most significant bit first.
The transmit sequence begins when the slave device receives the clock signal and the most significant bit of the data on its MOSI pin.

When data transfer is complete:

- The SPIF bit is set by hardware
- An interrupt is generated if SPIE bit is set and I bit in CCR register is cleared.
During the last clock cycle the SPIF bit is set, a copy of the data byte received in the shift register is moved to a buffer. When the DR register is read, the SPI peripheral returns this buffered value.
Clearing the SPIF bit is performed by the following software sequence:

1. An access to the SR register while the SPIF bit is set.
2. A read to the DR register.

Notes: While the SPIF bit is set, all writes to the DR register are inhibited until the SR register is read.
The SPIF bit can be cleared during a second transmission; however, it must be cleared before the second SPIF bit in order to prevent an overrun condition (see Section 0.1.4.6).
Depending on the CPHA bit, the $\overline{\mathrm{SS}}$ pin has to be set to write to the DR register between each data byte transfer to avoid a write collision (see Section 0.1.4.4).

## SERIAL PERIPHERAL INTERFACE (Cont'd)

### 5.4.4.3 Data Transfer Format

During an SPI transfer, data is simultaneously transmitted (shifted out serially) and received (shifted in serially). The serial clock is used to synchronize the data transfer during a sequence of eight clock pulses.
The $\overline{\mathrm{SS}}$ pin allows individual selection of a slave device; the other slave devices that are not selected do not interfere with the SPI transfer.

## Clock Phase and Clock Polarity

Four possible timing relationships may be chosen by software, using the CPOL and CPHA bits.
The CPOL (clock polarity) bit controls the steady state value of the clock when no data is being transferred. This bit affects both master and slave modes.
The combination between the CPOL and CPHA (clock phase) bits selects the data capture clock edge.
Figure 4, shows an SPI transfer with the four combinations of the CPHA and CPOL bits. The diagram may be interpreted as a master or slave timing diagram where the SCK pin, the MISO pin, the MOSI pin are directly connected between the master and the slave device.
The $\overline{\mathrm{SS}}$ pin is the slave device select input and can be driven by the master device.

The master device applies data to its MOSI pinclock edge before the capture clock edge.

## CPHA bit is set

The second edge on the SCK pin (falling edge if the CPOL bit is reset, rising edge if the CPOL bit is set) is the MSBit capture strobe. Data is latched on the occurrence of the second clock transition.
No write collision should occur even if the $\overline{\mathrm{SS}}$ pin stays low during a transfer of several bytes (see Figure 3).

## CPHA bit is reset

The first edge on the SCK pin (falling edge if CPOL bit is set, rising edge if CPOL bit is reset) is the MSBit capture strobe. Data is latched on the occurrence of the first clock transition.
The $\overline{S S}$ pin must be toggled high and low between each byte transmitted (see Figure 3).
To protect the transmission from a write collision a low value on the $\overline{S S}$ pin of a slave device freezes the data in its DR register and does not allow it to be altered. Therefore the $\overline{S S}$ pin must be high to write a new data byte in the DR without producing a write collision.

Figure 35. CPHA / $\overline{\text { SS }}$ Timing Diagram

## SERIAL PERIPHERAL INTERFACE (Cont'd)

Figure 36. Data Clock Timing Diagram

## SERIAL PERIPHERAL INTERFACE (Cont'd)

### 5.4.4.4 Write Collision Error

A write collision occurs when the software tries to write to the DR register while a data transfer is taking place with an external device. When this happens, the transfer continues uninterrupted; and the software write will be unsuccessful.
Write collisions can occur both in master and slave mode.
Note: a "read collision" will never occur since the received data byte is placed in a buffer in which access is always synchronous with the MCU operation.

## In Slave mode

When the CPHA bit is set:
The slave device will receive a clock (SCK) edge prior to the latch of the first data transfer. This first clock edge will freeze the data in the slave device DR register and output the MSBit on to the external MISO pin of the slave device.
The SS pin low state enables the slave device but the output of the MSBit onto the MISO pin does not take place until the first data transfer clock edge.

When the CPHA bit is reset:
Data is latched on the occurrence of the first clock transition. The slave device does not have any way of knowing when that transition will occur; therefore, the slave device collision occurs when software attempts to write the DR register after its SS pin has been pulled low.
For this reason, the $\overline{\mathrm{SS}}$ pin must be high, between each data byte transfer, to allow the CPU to write in the DR register without generating a write collision.

## In Master mode

Collision in the master device is defined as a write of the DR register while the internal serial clock (SCK) is in the process of transfer.
The $\overline{\mathrm{SS}}$ pin signal must be always high on the master device.

## WCOL bit

The WCOL bit in the SR register is set if a write collision occurs.
No SPI interrupt is generated when the WCOL bit is set (the WCOL bit is a status flag only).
Clearing the WCOL bit is done through a software sequence (see Figure 5).

Figure 37. Clearing the WCOL bit (Write Collision Flag) Software Sequence

Clearing sequence before SPIF = 1 (during a data byte transfer)

Note: Writing in DR register instead of reading in it do not reset WCOL bit

## SERIAL PERIPHERAL INTERFACE (Cont'd)

### 5.4.4.5 Master Mode Fault

Master mode fault occurs when the master device has its $\overline{\mathrm{SS}}$ pin pulled low, then the MODF bit is set.
Master mode fault affects the SPI peripheral in the following ways:

- The MODF bit is set and an SPI interrupt is generated if the SPIE bit is set.
- The SPE bit is reset. This blocks all output from the device and disables the SPI peripheral.
- The MSTR bit is reset, thus forcing the device into slave mode.

Clearing the MODF bit is done through a software sequence:

1. A read or write access to the SR register while the MODF bit is set.
2. A write to the CR register.

Notes: To avoid any multiple slave conflicts in the case of a system comprising several MCUs, the SS pin must be pulled high during the clearing sequence of the MODF bit. The SPE and MSTR bits
may be restored to their original state during or after this clearing sequence.
Hardware does not allow the user to set the SPE and MSTR bits while the MODF bit is set except in the MODF bit clearing sequence.
In a slave device the MODF bit can not be set, but in a multi master configuration the device can be in slave mode with this MODF bit set.
The MODF bit indicates that there might have been a multi-master conflict for system control and allows a proper exit from system operation to a reset or default system state using an interrupt routine.

### 5.4.4.6 Overrun Condition

An overrun condition occurs when the master device has sent several data bytes and the slave device has not cleared the SPIF bit issuing from the previous data byte transmitted.
In this case, the receiver buffer contains the byte sent after the SPIF bit was last cleared. A read to the DR register returns this byte. All other bytes are lost.
This condition is not detected by the SPI peripheral.

## SERIAL PERIPHERAL INTERFACE (Cont'd)

### 5.4.4.7 Single Master and Multimaster Configurations

There are two types of SPI systems:

- Single Master System
- Multimaster System

## Single Master System

A typical single master system may be configured, using an MCU as the master and four MCUs as slaves (see Figure 6).
The master device selects the individual slave devices by using four pins of a parallel port to control the four SS pins of the slave devices.
The $\overline{S S}$ pins are pulled high during reset since the master device ports will be forced to be inputs at that time, thus disabling the slave devices.

Note: To prevent a bus conflict on the MISO line the master allows only one active slave device during a transmission.

For more security, the slave device may respond to the master with the received data byte. Then the master will receive the previous byte back from the slave device if all MISO and MOSI pins are connected and the slave has not written its DR register.
Other transmission security methods can use ports for handshake lines or data bytes with command fields.

## Multi-master System

A multi-master system may also be configured by the user. Transfer of master control could be implemented using a handshake method through the I/O ports or by an exchange of code messages through the serial peripheral interface system.
The multi-master system is principally handled by the MSTR bit in the CR register and the MODF bit in the SR register.

Figure 38. Single Master Configuration

## SERIAL PERIPHERAL INTERFACE (Cont'd)

### 5.4.5 Low Power Modes

| Mode | Description |
| :--- | :--- |
| WAIT | No effect on SPI. <br> SPI interrupt events cause the device to exit from WAIT mode. |
| HALT | SPI registers are frozen. <br> In HALT mode, the SPI is inactive. SPI operation resumes when the MCU is woken up by an interrupt with <br> "exit from HALT mode" capability. |

### 5.4.6 Interrupts

| Interrupt Event | Event Flag | Enable Control Bit | Exit from Wait | Exit from Halt |
| :---: | :---: | :---: | :---: | :---: |
| SPI End of Transfer Event | SPIF | SPIE | Yes | No |
| Master Mode Fault Event | MODF |  | Yes | No |

Note: The SPI interrupt events are connected to the same interrupt vector (see Interrupts chapter). They generate an interrupt if the corresponding Enable Control Bit is set and the interrupt mask in the CC register is reset (RIM instruction).

## SERIAL PERIPHERAL INTERFACE (Cont'd)

### 5.4.7 Register Description

CONTROL REGISTER (CR)

## Read/Write

Reset Value: 0000xxxx (0xh)

| 7 |  | 0 |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :---: |
| SPIE | SPE | SPR2 | MSTR | CPOL | CPHA | SPR1 | SPR0 |

Bit 7 = SPIE Serial peripheral interrupt enable. This bit is set and cleared by software.
0 : Interrupt is inhibited
1: An SPI interrupt is generated whenever SPIF=1 or $\mathrm{MODF}=1$ in the SR register

Bit 6 = SPE Serial peripheral output enable.
This bit is set and cleared by software. It is also cleared by hardware when, in master mode, $\overline{\mathrm{SS}}=0$ (see Section 0.1.4.5 Master Mode Fault).
0 : I/O port connected to pins
1: SPI alternate functions connected to pins
The SPE bit is cleared by reset, so the SPI peripheral is not initially connected to the external pins.

## Bit 5 = SPR2 Divider Enable.

this bit is set and cleared by software and it is cleared by reset. It is used with the $\operatorname{SPR}[1: 0]$ bits to set the baud rate. Refer to Table 1.
0 : Divider by 2 enabled
1: Divider by 2 disabled

## Bit 4 = MSTR Master.

This bit is set and cleared by software. It is also cleared by hardware when, in master mode, $\overline{\mathrm{SS}}=0$ (see Section 0.1.4.5 Master Mode Fault).
0 : Slave mode is selected
1: Master mode is selected, the function of the SCK pin changes from an input to an output and the functions of the MISO and MOSI pins are reversed.

Bit 3 = CPOL Clock polarity.
This bit is set and cleared by software. This bit determines the steady state of the serial Clock. The CPOL bit affects both the master and slave modes.
0 : The steady state is a low value at the SCK pin.
1: The steady state is a high value at the SCK pin.

Bit $2=$ CPHA Clock phase.
This bit is set and cleared by software.
0 : The first clock transition is the first data capture edge.
1: The second clock transition is the first capture edge.

Bit 1:0 = SPR[1:0] Serial peripheral rate.
These bits are set and cleared by software.Used with the SPR2 bit, they select one of six baud rates to be used as the serial clock when the device is a master.
These 2 bits have no effect in slave mode.
Table 17. Serial Peripheral Baud Rate

| Serial Clock | SPR2 | SPR1 | SPR0 |
| :---: | :---: | :---: | :---: |
| $\mathrm{f}_{\mathrm{CPU}} / 4$ | 1 | 0 | 0 |
| $\mathrm{f}_{\mathrm{CPU}} / 8$ | 0 | 0 | 0 |
| $\mathrm{f}_{\mathrm{CPU}} / 16$ | 0 | 0 | 1 |
| $\mathrm{f}_{\mathrm{CPU}} / 32$ | 1 | 1 | 0 |
| $\mathrm{f}_{\mathrm{CPU}} / 64$ | 0 | 1 | 0 |
| $\mathrm{f}_{\mathrm{CPU}} / 128$ | 0 | 1 | 1 |

## SERIAL PERIPHERAL INTERFACE (Cont'd) STATUS REGISTER (SR)

Read Only
Reset Value: 00000000 (00h)
7
0

| SPIF | WCOL | - | MODF | - | - | - | - |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

Bit 7 = SPIF Serial Peripheral data transfer flag.
This bit is set by hardware when a transfer has been completed. An interrupt is generated if SPIE=1 in the CR register. It is cleared by a software sequence (an access to the SR register followed by a read or write to the DR register).
0: Data transfer is in progress or has been approved by a clearing sequence.
1: Data transfer between the device and an external device has been completed.
Note: While the SPIF bit is set, all writes to the DR register are inhibited.

## Bit $6=$ WCOL Write Collision status.

This bit is set by hardware when a write to the DR register is done during a transmit sequence. It is cleared by a software sequence (see Figure 5).
0 : No write collision occurred
1: A write collision has been detected
Bit $5=$ Unused.

Bit 4 = MODF Mode Fault flag.
This bit is set by hardware when the $\overline{\mathrm{SS}}$ pin is pulled low in master mode (see Section 0.1.4.5 Master Mode Fault). An SPI interrupt can be generated if SPIE $=1$ in the CR register. This bit is cleared by a software sequence (An access to the SR register while MODF=1 followed by a write to the CR register).
0: No master mode fault detected
1: A fault in master mode has been detected

## DATA I/O REGISTER (DR)

## Read/Write

Reset Value: Undefined

$$
\begin{array}{ll}
7 & 0
\end{array}
$$

| D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

The DR register is used to transmit and receive data on the serial bus. In the master device only a write to this register will initiate transmission/reception of another byte.
Notes: During the last clock cycle the SPIF bit is set, a copy of the received data byte in the shift register is moved to a buffer. When the user reads the serial peripheral data I/O register, the buffer is actually being read.

## Warning:

A write to the DR register places data directly into the shift register for transmission.
A write to the the DR register returns the value located in the buffer and not the contents of the shift register (See Figure 2 ).

Bits 3-0 = Unused.

## SERIAL PERIPHERAL INTERFACE (Cont'd)

### 5.5 8-BIT A/D CONVERTER (ADC)

### 5.5.1 Introduction

The on-chip Analog to Digital Converter (ADC) peripheral is a 8 -bit, successive approximation converter with internal sample and hold circuitry. This peripheral has up to 8 multiplexed analog input channels (refer to device pin out description) that allow the peripheral to convert the analog voltage levels from up to 8 different sources.
The result of the conversion is stored in a 8 -bit Data Register. The A/D converter is controlled through a Control/Status Register.

### 5.5.2 Main Features

- 8 -bit conversion
- Up to 8 channels with multiplexed input
- Linear successive approximation
- Data register (DR) which contains the results
- Conversion complete status flag
- On/Off bit (to reduce consumption)

The block diagram is shown in Figure 1.

Figure 39. ADC Block Diagram

## 8-BIT A/D CONVERTER (ADC) (Cont'd)

### 5.5.3 Functional Description

The high level reference voltage $\mathrm{V}_{\text {DDA }}$ must be connected externally to the $\mathrm{V}_{\mathrm{DD}}$ pin. The low level reference voltage $\mathrm{V}_{\text {SSA }}$ must be connected externally to the $\mathrm{V}_{S S}$ pin. In some devices (refer to device pin out description) high and low level reference voltages are internally connected to the $\mathrm{V}_{\mathrm{DD}}$ and $V_{S S}$ pins.
Conversion accuracy may therefore be degraded by voltage drops and noise in the event of heavily loaded or badly decoupled power supply lines.

Figure 40. Recommended Ext. Connections

## Characteristics:

The conversion is monotonic, meaning the result never decreases if the analog input does not and never increases if the analog input does not.
If input voltage is greater than or equal to $\mathrm{V}_{\mathrm{DD}}$ (voltage reference high) then results $=$ FFh (full scale) without overflow indication.
If input voltage $\leq \mathrm{V}_{\mathrm{SS}}$ (voltage reference low) then the results $=00 \mathrm{~h}$.
The conversion time is 64 CPU clock cycles including a sampling time of 31.5 CPU clock cycles.
$R_{\text {AIN }}$ is the maximum recommended impedance for an analog input signal. If the impedance is too high, this will result in a loss of accuracy due to leakage and sampling not being completed in the alloted time.
The A/D converter is linear and the digital result of the conversion is given by the formula:

$$
\text { Digital result }=\frac{255 \times \text { Input Voltage }}{\text { Reference Voltage }}
$$

Where Reference Voltage is $\mathrm{V}_{\mathrm{DD}}-\mathrm{V}_{\mathrm{SS}}$.

The accuracy of the conversion is described in the Electrical Characteristics Section.

## Procedure:

Refer to the CSR and DR register description section for the bit definitions.
Each analog input pin must be configured as input, no pull-up, no interrupt. Refer to the "I/O Ports" chapter. Using these pins as analog inputs does not affect the ability of the port to be read as a logic input.
In the CSR register:

- Select the CH 2 to CH 0 bits to assign the analog channel to convert. Refer to Table 1.
- Set the ADON bit. Then the A/D converter is enabled after a stabilization time (typically 30 $\mu \mathrm{s})$. It then performs a continuous conversion of the selected channel.
When a conversion is complete
- The COCO bit is set by hardware.
- No interrupt is generated.
- The result is in the DR register.

A write to the CSR register aborts the current conversion, resets the COCO bit and starts a new conversion.

### 5.5.4 Low Power Modes

Note: The A/D converter may be disabled by resetting the ADON bit. This feature allows reduced power consumption when no conversion is needed.

| Mode | Description |
| :--- | :--- |
| WAIT | No effect on A/D Converter |
| HALT | A/D Converter disabled. <br> After wakeup from Halt mode, the A/D <br> Converter requires a stabilisation time <br> before accurate conversions can be <br> performed. |

### 5.5.5 Interrupts

None.

## 8-BIT A/D CONVERTER (ADC) (Cont'd)

### 5.5.6 Register Description CONTROL/STATUS REGISTER (CSR)

Read/Write
Reset Value: 00000000 (00h)

7

| COCO | - | ADON | 0 | - | CH 2 | CH 1 | CH 0 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Bit $7=\mathbf{C O C O}$ Conversion Complete
This bit is set by hardware. It is cleared by software reading the result in the DR register or writing to the CSR register.
0 : Conversion is not complete.
1: Conversion can be read from the DR register.

Bit $6=$ Reserved. Must always be cleared.

Bit $5=$ ADON $A / D$ converter On
This bit is set and cleared by software.
0 : A/D converter is switched off.
1: $A / D$ converter is switched on.
Note: A typical $30 \mu$ s delay time is necessary for the ADC to stabilize when the ADON bit is set.

Bit 4 = Reserved. Forced by hardware to 0.

Bit 3 = Reserved. Must always be cleared.

Bits 2:0: CH[2:0] Channel Selection

These bits are set and cleared by software. They select the analog input to convert.

Table 19. Channel Selection

| Pin $^{*}$ | CH2 | CH1 | CH0 |
| :---: | :---: | :---: | :---: |
| AIN0 | 0 | 0 | 0 |
| AIN1 | 0 | 0 | 1 |
| AIN2 | 0 | 1 | 0 |

## 6 INSTRUCTION SET

### 6.1 ST7 ADDRESSING MODES

The ST7 Core features 17 different addressing modes which can be classified in 7 main groups:

| Addressing Mode | Example |
| :--- | :--- |
| Inherent | nop |
| Immediate | Id A,\#\$55 |
| Direct | Id A,\$55 |
| Indexed | Id A, $(\$ 55, \mathrm{X})$ |
| Indirect | Id A,([\$55],X) |
| Relative | jrne loop |
| Bit operation | bset byte,\#5 |

The ST7 Instruction set is designed to minimize the number of bytes required per instruction: To do
so, most of the addressing modes may be subdivided in two sub-modes called long and short:

- Long addressing mode is more powerful because it can use the full 64 Kbyte address space, however it uses more bytes and more CPU cycles.
- Short addressing mode is less powerful because it can generally only access page zero (0000h 00FFh range), but the instruction size is more compact, and faster. All memory to memory instructions use short addressing modes only (CLR, CPL, NEG, BSET, BRES, BTJT, BTJF, INC, DEC, RLC, RRC, SLL, SRL, SRA, SWAP)
The ST7 Assembler optimizes the use of long and short addressing modes.

Table 21. ST7 Addressing Mode Overview

| Mode |  |  | Syntax | Destination/ Source | Pointer Address (Hex.) | $\begin{aligned} & \hline \text { Pointer } \\ & \text { Size } \\ & \text { (Hex.) } \end{aligned}$ | Length (Bytes) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Inherent |  |  | nop |  |  |  | + 0 |
| Immediate |  |  | Id A,\#\$55 |  |  |  | +1 |
| Short | Direct |  | Id A, \$10 | 00..FF |  |  | +1 |
| Long | Direct |  | Id A,\$1000 | 0000..FFFF |  |  | + 2 |
| No Offset | Direct | Indexed | Id A, (X) | 00..FF |  |  | +0 (with X register) <br> +1 (with Y register) |
| Short | Direct | Indexed | Id $\mathrm{A},(\$ 10, \mathrm{X})$ | 00..1FE |  |  | +1 |
| Long | Direct | Indexed | Id A,(\$1000, X) | 0000..FFFF |  |  | + 2 |
| Short | Indirect |  | Id A,[\$10] | 00..FF | 00..FF | byte | +2 |
| Long | Indirect |  | Id A,[\$10.w] | 0000..FFFF | 00..FF | word | + 2 |
| Short | Indirect | Indexed | Id A,([\$10],X) | 00..1FE | 00..FF | byte | + 2 |
| Long | Indirect | Indexed | Id A,([\$10.w],X) | 0000..FFFF | 00..FF | word | + 2 |
| Relative | Direct |  | jrne loop | PC-128/PC+127 ${ }^{11}$ |  |  | +1 |
| Relative | Indirect |  | jrne [\$10] | PC-128/PC+127 ${ }^{1)}$ | 00..FF | byte | + 2 |
| Bit | Direct |  | bset \$10,\#7 | 00..FF |  |  | +1 |
| Bit | Indirect |  | bset [\$10],\#7 | 00..FF | 00..FF | byte | + 2 |
| Bit | Direct | Relative | btjt \$10,\#7,skip | 00..FF |  |  | + 2 |
| Bit | Indirect | Relative | btjt [\$10],\#7,skip | 00..FF | 00..FF | byte | + 3 |

Note 1. At the time the instruction is executed, the Program Counter (PC) points to the instruction following JRxx.

## ST7 ADDRESSING MODES (Cont'd)

### 6.1.1 Inherent

All Inherent instructions consist of a single byte. The opcode fully specifies all the required information for the CPU to process the operation.

| Inherent Instruction | Function |
| :--- | :--- |
| NOP | No operation |
| TRAP | S/W Interrupt |
| WFI | Wait For Interrupt (Low Power <br> Mode) |
| HALT | Halt Oscillator (Lowest Power <br> Mode) |
| RET | Sub-routine Return |
| IRET | Interrupt Sub-routine Return |
| SIM | Set Interrupt Mask |
| RIM | Reset Interrupt Mask |
| SCF | Set Carry Flag |
| RCF | Reset Carry Flag |
| RSP | Load |
| LD | Clear |
| CLR | Push/Pop to/from the stack |
| PUSH/POP | Increment/Decrement |
| INC/DEC | Test Negative or Zero |
| TNZ | 1 or 2 Complement |
| CPL, NEG | Byte Multiplication |
| MUL | Shift and Rotate Operations |
| SLL, SRL, SRA, RLC, <br> RRC | Swap Nibbles |
| SWAP |  |

### 6.1.2 Immediate

Immediate instructions have two bytes, the first byte contains the opcode, the second byte contains the operand value.

| Immediate Instruction | Function |
| :--- | :--- |
| LD | Load |
| CP | Compare |
| BCP | Bit Compare |
| AND, OR, XOR | Logical Operations |
| ADC, ADD, SUB, SBC | Arithmetic Operations |

### 6.1.3 Direct

In Direct instructions, the operands are referenced by their memory address.
The direct addressing mode consists of two submodes:

## Direct (short)

The address is a byte, thus requires only one byte after the opcode, but only allows 00 - FF addressing space.

## Direct (long)

The address is a word, thus allowing 64 Kbyte addressing space, but requires 2 bytes after the opcode.

### 6.1.4 Indexed (No Offset, Short, Long)

In this mode, the operand is referenced by its memory address, which is defined by the unsigned addition of an index register ( X or Y ) with an offset. The indirect addressing mode consists of three sub-modes:

## Indexed (No Offset)

There is no offset, (no extra byte after the opcode), and allows $00-\mathrm{FF}$ addressing space.

## Indexed (Short)

The offset is a byte, thus requires only one byte after the opcode and allows $00-1$ FE addressing space.

## Indexed (long)

The offset is a word, thus allowing 64 Kbyte addressing space and requires 2 bytes after the opcode.

### 6.1.5 Indirect (Short, Long)

The required data byte to do the operation is found by its memory address, located in memory (pointer).
The pointer address follows the opcode. The indirect addressing mode consists of two sub-modes:

## Indirect (short)

The pointer address is a byte, the pointer size is a byte, thus allowing $00-\mathrm{FF}$ addressing space, and requires 1 byte after the opcode.

## Indirect (long)

The pointer address is a byte, the pointer size is a word, thus allowing 64 Kbyte addressing space, and requires 1 byte after the opcode.

## ST7 ADDRESSING MODES (Cont'd)

### 6.1.6 Indirect Indexed (Short, Long)

This is a combination of indirect and short indexed addressing modes. The operand is referenced by its memory address, which is defined by the unsigned addition of an index register value ( X or Y ) with a pointer value located in memory. The pointer address follows the opcode.
The indirect indexed addressing mode consists of two sub-modes:

## Indirect Indexed (Short)

The pointer address is a byte, the pointer size is a byte, thus allowing 00-1FE addressing space, and requires 1 byte after the opcode.

## Indirect Indexed (Long)

The pointer address is a byte, the pointer size is a word, thus allowing 64 Kbyte addressing space, and requires 1 byte after the opcode.

Table 22. Instructions Supporting Direct, Indexed, Indirect and Indirect Indexed Addressing Modes

| Long and Short <br> Instructions | Function |
| :--- | :--- |
| LD | Load |
| CP | Compare |
| AND, OR, XOR | Logical Operations |
| ADC, ADD, SUB, SBC | Arithmetic Addition/subtrac- <br> tion operations |
| BCP | Bit Compare |

| Short Instructions Only | Function |
| :--- | :--- |
| CLR | Clear |
| INC, DEC | Increment/Decrement |
| TNZ | Test Negative or Zero |
| CPL, NEG | 1 or 2 Complement |
| BSET, BRES | Bit Operations |
| BTJT, BTJF | Bit Test and Jump Opera- <br> tions |
| SLL, SRL, SRA, RLC, <br> RRC | Shift and Rotate Operations |

| SWAP | Swap Nibbles |
| :--- | :--- |
| CALL, JP | Call or Jump subroutine |

### 6.1.7 Relative Mode (Direct, Indirect)

This addressing mode is used to modify the PC register value by adding an 8-bit signed offset to it.

| Available Relative Direct/ <br> Indirect Instructions | Function |
| :--- | :--- |
| JRxx | Conditional Jump |
| CALLR | Call Relative |

The relative addressing mode consists of two submodes:

## Relative (Direct)

The offset follows the opcode.

## Relative (Indirect)

The offset is defined in memory, of which the address follows the opcode.

### 6.2 INSTRUCTION GROUPS

The ST7 family devices use an Instruction Set consisting of 63 instructions. The instructions may
be subdivided into 13 main groups as illustrated in the following table:

| Load and Transfer | LD | CLR |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Stack operation | PUSH | POP | RSP |  |  |  |  |  |
| Increment/Decrement | INC | DEC |  |  |  |  |  |  |
| Compare and Tests | CP | TNZ | BCP |  |  |  |  |  |
| Logical operations | AND | OR | XOR | CPL | NEG |  |  |  |
| Bit Operation | BSET | BRES |  |  |  |  |  |  |
| Conditional Bit Test and Branch | BTJT | BTJF |  |  |  |  |  |  |
| Arithmetic operations | ADC | ADD | SUB | SBC | MUL |  |  |  |
| Shift and Rotates | SLL | SRL | SRA | RLC | RRC | SWAP | SLA |  |
| Unconditional Jump or Call | JRA | JRT | JRF | JP | CALL | CALLR | NOP | RET |
| Conditional Branch | JRxx |  |  |  |  |  |  |  |
| Interruption management | TRAP | WFI | HALT | IRET |  |  |  |  |
| Code Condition Flag modification | SIM | RIM | SCF | RCF |  |  |  |  |

## Using a pre-byte

The instructions are described with one to four bytes.
In order to extend the number of available opcodes for an 8 -bit CPU (256 opcodes), three different prebyte opcodes are defined. These prebytes modify the meaning of the instruction they precede.
The whole instruction becomes:
PC-2 End of previous instruction
PC-1 Prebyte
PC Opcode
PC+1 Additional word (0 to 2) according to the number of bytes required to compute the effective address

These prebytes enable instruction in Y as well as indirect addressing modes to be implemented. They precede the opcode of the instruction in $X$ or the instruction using direct addressing mode. The prebytes are:
PDY 90 Replace an X based instruction using immediate, direct, indexed, or inherent addressing mode by a Y one.
PIX 92 Replace an instruction using direct, direct bit, or direct relative addressing mode to an instruction using the corresponding indirect addressing mode. It also changes an instruction using $X$ indexed addressing mode to an instruction using indirect $X$ indexed addressing mode.
PIY 91 Replace an instruction using X indirect indexed addressing mode by a $Y$ one.

## INSTRUCTION GROUPS (Cont'd)

| Mnemo | Description | Function/Example | Dst | Src | H | I | N | Z | C |

## 7 ELECTRICAL CHARACTERISTICS

### 7.1 ABSOLUTE MAXIMUM RATINGS

This product contains devices to protect the inputs against damage due to high static voltages, however it is advisable to take normal precaution to avoid application of any voltage higher than the specified maximum rated voltages.

For proper operation it is recommended that $\mathrm{V}_{\text {I }}$ and $V_{0}$ be higher than $V_{S S}$ and lower than $V_{D D}$. Reliability is enhanced if unused inputs are connected to an appropriate logic voltage level ( $\mathrm{V}_{\mathrm{DD}}$ or $\mathrm{V}_{\mathrm{SS}}$ ).

Power Considerations.The average chip-junction temperature, $\mathrm{T}_{\mathrm{J}}$, in Celsius can be obtained from:

$$
T_{J}=\quad T A+P D \times R t h J A
$$

Where: $T_{A}=$ Ambient Temperature.
RthJA = Package thermal resistance (junction-to ambient).
$P_{D}=P_{\text {INT }}+P_{\text {PORT }}$.
$P_{\text {INT }}=I_{D D} \times V_{D D}$ (chip internal power).
$\mathrm{P}_{\text {PORT }}=$ Port power dissipation determined by the user)

| Symbol | Parameter | Value | Unit |
| :---: | :--- | :---: | :---: |
| $\mathrm{V}_{\mathrm{DD}}$ | Supply Voltage | -0.3 to 6.0 | V |
| $\mathrm{~V}_{\mathrm{I}}$ | Input Voltage | $\mathrm{V}_{\mathrm{SS}}-0.3$ to $\mathrm{V}_{\mathrm{DD}}+0.3$ | V |
| $\mathrm{~V}_{\mathrm{Al}}$ | Analog Input Voltage (A/D Converter) | $\mathrm{V}_{\mathrm{SS}}-0.3$ to $\mathrm{V}_{\mathrm{DD}}+0.3$ | V |
| $\mathrm{~V}_{\mathrm{O}}$ | Output Voltage | $\mathrm{V}_{\mathrm{SS}}-0.3$ to $\mathrm{V}_{\mathrm{DD}}+0.3$ | V |
| $\mathrm{I}_{\mathrm{DD}}$ | Total Current into $\mathrm{V}_{\mathrm{DD}}$ (source) | 80 | mA |
| $\mathrm{~V}_{\mathrm{SS}}$ | Total Current out of $\mathrm{V}_{\mathrm{SS}}$ (sink) | 80 | mA |
| $\mathrm{~T}_{\mathrm{J}}$ | Junction Temperature | 150 | ${ }^{\circ} \mathrm{C}$ |
| $\mathrm{T}_{\mathrm{STG}}$ | Storage Temperature | -60 to 150 | ${ }^{\circ} \mathrm{C}$ |

Note: Stresses above those listed as "absolute maximum ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these conditions is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

### 7.2 RECOMMENDED OPERATING CONDITIONS

| Symbol | Parameter | Test Conditions | Value |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Typ. | Max. |  |
| $\mathrm{T}_{\text {A }}$ | Operating Temperature | 1 Suffix Version | 0 |  | 70 | ${ }^{\circ} \mathrm{C}$ |
|  |  | 6 Suffix Version | -40 |  | 85 | ${ }^{\circ} \mathrm{C}$ |
|  |  | 3 Suffix Version | -40 |  | 125 | ${ }^{\circ} \mathrm{C}$ |
| $V_{D D}$ | Operating Supply Voltage | $\begin{aligned} & \mathrm{f} \mathrm{OSC}=16 \mathrm{MHz}(1 \& 6 \text { Suffix }) \\ & \mathrm{f}_{\mathrm{OSC}}=8 \mathrm{MHz} \end{aligned}$ | $\begin{aligned} & 3.5 \\ & 3.0 \end{aligned}$ |  | $\begin{aligned} & 5.5 \\ & 5.5 \end{aligned}$ | V |
| ${ }_{\text {fosc }}$ | Oscillator Frequency | $\begin{aligned} & \mathrm{V}_{\mathrm{DD}}=3.0 \mathrm{~V} \\ & \mathrm{~V}_{\mathrm{DD}}=3.5 \mathrm{~V}(1 \& 6 \text { Suffix }) \end{aligned}$ | $\begin{aligned} & \hline 0^{19} \\ & 0^{1)} \end{aligned}$ |  | $\begin{gathered} \hline 8 \\ 16 \end{gathered}$ | MHz |

Note 1: A/D operation and Oscillator start-up are not guaranteed below 1 MHz .
Figure 41. Maximum Operating Frequency ( $\mathrm{f}_{\mathrm{osc}}$ ) Versus Supply Voltage ( $\mathrm{V}_{\mathrm{DD}}$ )

### 7.3 DC ELECTRICAL CHARACTERISTICS

( $\mathrm{T}_{\mathrm{A}}=-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ and $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V}$ unless otherwise specified)

| Symbol | Parameter | Test Conditions | Value |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Typ. | Max. |  |

## Notes:

1. Hysteresis voltage between switching levels. Based on characterisation results, not tested.
2. CPU running with memory access, no DC load or activity on I/O's; clock input (OSCIN) driven by external square wave.
3. No DC load or activity on I/O's; clock input (OSCIN) driven by external square wave.
4. Except OSCIN and OSCOUT
5. WAIT Mode with SLOW Mode selected. Based on characterisation results, not tested.

### 7.4 RESET CHARACTERISTICS

( $\mathrm{T}_{\mathrm{A}}=-40 \ldots+125^{\circ} \mathrm{C}$ and $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V} \pm 10 \%$ unless otherwise specified.

| Symbol | Parameter | Conditions | Min | Typ $^{1)}$ | Max | Unit |
| :---: | :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{R}_{\mathrm{ON}}$ | Reset Weak Pull-up $\mathrm{R}_{\mathrm{ON}}$ | $\mathrm{V}_{\mathrm{IN}}>\mathrm{V}_{\mathrm{IH}}$ <br> $\mathrm{V}_{\text {IN }}<\mathrm{V}_{\mathrm{IL}}$ | 60 | 40 <br> 120 | 80 <br> 240 | $\mathrm{k} \Omega$ |
| $\mathrm{t}_{\text {RESET }}$ | Pulse duration generated by watch- <br> dog and POR reset |  | $10^{1)}$ |  |  | $\mu \mathrm{s}$ |
| $\mathrm{t}_{\text {PULSE }}$ | Minimum pulse duration to be ap- <br> plied on external RESET pin |  | ns |  |  |  |

## Note:

1) These values given only as design guidelines and are not tested.

### 7.5 OSCILLATOR CHARACTERISTICS

( $\mathrm{T}_{\mathrm{A}}=-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ unless otherwise specified)

| Symbol | Parameter | Test Conditions | Value |  |  | Unit |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Min. | Typ. | Max. |  |
| $\mathrm{g}_{\mathrm{m}}$ | Oscillator transconductance |  | 2 |  | 9 | mA/V |
| $\mathrm{f}_{\text {OSC }}$ | Crystal frequency |  | 1 |  | 16 | MHz |
| $\mathrm{t}_{\text {START }}$ | Osc. start up time | $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V} \pm 10 \%$ |  |  | 50 | ms |

### 7.6 A/D CONVERTER CHARACTERISTICS (ST72212 and ST72213 only)

( $\mathrm{T}_{\mathrm{A}}=-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ and $\mathrm{V}_{\mathrm{DD}}=5 \mathrm{~V} \pm 10 \%$ unless otherwise specified)

| Symbol | Parameter | Conditions | Min | Typ | Max | Unit |
| :--- | :--- | :--- | :---: | :---: | :---: | :---: |
| $\mathrm{T}_{\text {SAMPLE }}$ | Sample Duration |  |  | 31.5 |  | $1 / \mathrm{f}_{\mathrm{CPU}}$ |
| Res | ADC Resolution | $\mathrm{f}_{\mathrm{CPU}}=8 \mathrm{MHz}$ <br> $\mathrm{V}_{\mathrm{DD}}=\mathrm{V}_{\mathrm{DDA}}=5 \mathrm{~V}$ |  | 8 |  | bit |
| DLE | Differential Linearity Error* |  |  | $\pm 0.6$ | $\pm 1$ |  |
| ILE | Integral Linearity Error |  |  |  |  |  |

*Note: ADC Accuracy vs. Negative Injection Current:
For $\mathrm{I}_{\text {inj }}=0.8 \mathrm{~mA}$, the typical leakage induced inside the die is $1.6 \mu \mathrm{~A}$ and the effect on the ADC accuracy is a loss of 1 LSB by $10 \mathrm{~K} \Omega$ increase of the external analog source impedance.
These measurement results and recommendations take worst case injection conditions into account:

- negative injection
- injection to an Input with analog capability, adjacent to the enabled Analog Input
- at 5V $\mathrm{V}_{\mathrm{DD}}$ supply, and worst case temperature.

## 8 GENERAL INFORMATION

### 8.1 EPROM ERASURE

EPROM version devices are erased by exposure to high intensity UV light admitted through the transparent window. This exposure discharges the floating gate to its initial state through induced photo current.
It is recommended that the EPROM devices be kept out of direct sunlight, since the UV content of sunlight can be sufficient to cause functional failure. Extended exposure to room level fluorescent lighting may also cause erasure.

An opaque coating (paint, tape, label, etc...) should be placed over the package window if the product is to be operated under these lighting conditions. Covering the window also reduces $I_{D D}$ in power-saving modes due to photo-diode leakage currents.
An Ultraviolet source of wave length 2537 Å yielding a total integrated dosage of $15 \mathrm{Watt}-\mathrm{sec} / \mathrm{cm}^{2}$ is required to erase the device. It will be erased in 15 to 20 minutes if such a UV lamp with a $12 \mathrm{~mW} / \mathrm{cm}^{2}$ power rating is placed 1 inch from the device window without any interposed filters.

### 8.3 ORDERING INFORMATION

Each device is available for production in user programmable version (OTP) as well as in factory coded version (ROM). OTP devices are shipped to customer with a default blank content FFh, while ROM factory coded parts contain the code sent by customer. There is one common EPROM version for debugging and prototyping which features the maximum memory size and peripherals of the family. Care must be taken to only use resources available on the target device.

### 8.3.1 Transfer Of Customer Code

Customer code is made up of the ROM contents and the list of the selected options (if any). The

ROM contents are to be sent on diskette, or by electronic means, with the hexadecimal file in .S19 format generated by the development tool. All unused bytes must be set to FFh.
The selected options are communicated to STMicroelectronics using the correctly completed OPTION LIST appended.
The STMicroelectronics Sales Organization will be pleased to provide detailed information on contractual points.

## 9 SUMMARY OF CHANGES

| Change Description (Rev. 1.5 to 1.6) | Page |
| :--- | :---: |
| Added new External Connections section | 9 |
| Removed RP external resistor | 16 |
| Changed ORed to ANDed in External interrupts paragraph, to read "If several input pins, con- <br> nected to the same interrupt vector, are configured as interrupts, their signals are logically AN- <br> Ded before entering the edge/level detection block". | 18 and 24 |
| Added note "Any modification of one of these two bits resets the interrupt request related to <br> this interrupt vector." | 23 |
| Added clamping diodes to I/O pin figure and table | 26 |
| Added sections on low power modes and interrupts to peripheral descriptions | $31,43,58,63$ |
| Changed 16-bit Timer Chapter | 32 to 48 |
| Added details to description of FOLV1 and FOLV2 bits | 44 |
| Added ADC recommended external connections | 63 |
| Added Reset characteristics section | 74 |
| Added figure to ADC electrical characteristics section | 75 |
|  | 49 to 61 |
| Change Description (Rev. 1.6 to 1.7) |  |
| SPR2 bit reinstated in SPI chapter | 60 |
| Change Description (Rev. 1.7 to 1.8) of 31 May 2001 |  |
