

HD66724/HD66725

**(Graphics LCD Controller/Driver
with Key Scan Function)**

HITACHI

ADE-207-309(Z)
Rev 1.2
'99.8

Description

The HD66724/HD66725, dot-matrix graphics LCD controller and driver LSI incorporating a key scan function up to a 4-by-8 key matrix, display characters such as alphanumerics, katakana, hiragana and symbols as well as graphics such as kanji and pictograms. They can be configured to drive a dot-matrix liquid crystal display and control key scan functions under the control of the microprocessor connected via the clock-synchronized serial or 4/8-bit bus. The HD66724 is capable of displaying up to three 12-character lines, 72-by-24 dot graphics and 144 segments. The HD66725 is capable of displaying up to three 16-character lines, 96-by-24 dot graphics and 192 segments. Of the 144 (192) segments displayed, 48 (64) segments can be grayscaled. The HD66724/HD66725 have a smooth horizontal/vertical scroll display and double-height display so that the user can easily see a variety of information within a small LCM.

The HD66724/HD66725 have various functions to reduce the power consumption of an LCD system such as low-voltage operation of 1.8 V or less, a booster to generate maximum triple LCD drive voltage from the supplied voltage, and voltage-followers to decrease the direct current flow in the LCD drive bleeder-resistors. Combining these hardware functions with software functions such as standby and sleep modes allows fine power control. The HD66724/HD66725 are suitable for any portable battery-driven product requiring long-term driving capabilities and small physical dimensions such as cellular phones, pagers, portable audio devices, or electronic wallets.

Features

- Control and drive of a character and graphics LCD with built-in key scan functions
- Three 12- (16-) character lines, 72 (96) -by-24 dot graphics, and 144 (192) segments
- 48 (64) grayscale segments
- Control up to a 4×8 (32 key) matrix key scan.
- 3 general ports built-in
- Low-power operation support:

HITACHI

HD66724/HD66725

- V_{CC} = 1.8 to 5.5 V (low voltage)
- V_{LCD} = 3.0 to 6.5 V (liquid crystal drive voltage)
- Single, double or triple booster for liquid crystal drive voltage
- Contrast adjuster and voltage followers to decrease direct current flow in the LCD drive bleeder-resistors
- Wake-up feature using key scan interrupt
- Programmable drive duty ratios and bias values displayed on LCD
- Clock-synchronized serial interface
- 4-/8-bit bus interface capability (except when key scan circuit is used)
- 80 × 8-bit display data RAM (80 characters max)
- 20,736-bit (6 × 8 dots : 432 characters) character generator ROM
- 384 × 8-bit (64 characters) character generator RAM
- 96 × 2-bit (192 segment-icons and marks max) segment RAM
- 72- (96-) segment × 26-common-signal liquid crystal display driver
- Programmable display sizes and duty ratios
- Vertical and horizontal smooth scrolls
- Vertical double-height display
- Selectable CGROM memory bank (max. 432 fonts)
- Wide range of instruction functions:
 - Clear display, display on/off control, icon and mark control, character blink, black-white reversed blinking cursor, return home, cursor on/off, black-white reversed raster-row
- No wait time for instruction execution and RAM access (zero instruction)
- Internal oscillation (with external or built-in resistor) hardware reset
- Shift change of segment and common driver
- Slim chip with bumps for chip-on-glass (COG) mounting, and tape carrier package (TCP)

Table 1 Programmable Display Sizes and Duty Ratios

Duty Ratio	Optimum Drive Bias	Character Display		Graphics Display		Segment Display	Scanned Keys	General Ports
		HD66724	HD66725	HD66724	HD66725			
1/2	1/2	Unavailable	Unavailable	Unavailable	Unavailable		32 (4 × 8)	3
1/10	1/4	1 line x 12 characters	1 line x 16 characters	72 × 8 dots	96 × 8 dots	HD66724: 144		
1/18	1/5	2 lines x 12 characters	2 lines x 16 characters	72 × 16 dots	96 × 16 dots	HD66725: 192		
1/26	1/6	3 lines x 12 characters	3 lines x 16 characters	72 × 24 dots	96 × 24 dots			

Total Current Consumption Characteristics (V_{CC} = 3 V, f_{osc} = 32 kHz, TYP Conditions, LCD Drive Power Current Included)

Character Display Size	Duty Ratio	Optimum Drive Bias	Frame Frequency	Total Power Consumption				Sleep Mode	Standby Mode
				Internal Logic	LCD Power	Total*			
Segment only	1/2	1/2	80 Hz	(14 µA)	(12 µA)	(26 µA)	(11 µA)	0.1 µA	
1-line display	1/10	1/4	80 Hz	(20 µA)	(17 µA)	(54 µA)	(11 µA)		
2-line display	1/18	1/5	74 Hz	(20 µA)	(17 µA)	(54 µA)	(11 µA)		
3-line display	1/26	1/6	77 Hz	(20 µA)	(17 µA)	(54 µA)	(11 µA)		

Note : When duty ratio = 1/2 and a double booster is not used:

the total power consumption = Internal logic current + LCD power current

When duty ratio = 1/10 and a double booster is used:

the total power consumption = Internal logic current + LCD power current x 2

Type Name

Types	External Dimensions	Operation Voltages	Internal Fonts
HD66724RA03TA0L	TCP	1.8 V to 5.5 V	Katakana, alphanumericics, symbols and European fonts
HCD66724RA03BP	Au-bumped chip		
HD66725A03TA0L	TCP		
HCD66725A03BP	Au-bumped chip

Pin Functions

Table 2 Pin Functional Description

Signals	Number of Pins	I/O	Connected to	Functions
IM2, IM1	2	I	V _{cc} or GND	Selects the MPU interface mode: IM2 IM1 MPU interface “GND” “GND” Clock-synchronized serial interface “GND” “Vcc” 68-system parallel bus interface “Vcc” “GND” Setting inhibited “Vcc” “Vcc” 80-system parallel bus interface
IMO/ID	1	I	V _{cc} or GND	Inputs the ID of the device ID code for a serial bus interface. Selects the transfer bus width for a parallel bus interface. GND: 8-bit bus, Vcc: 4-bit bus
CS*	2	I	MPU	Selects the HD66724/HD66725: Low: HD66724/HD66725 are selected and can be accessed High: HD66724/HD66725 are not selected and cannot be accessed Must be fixed at GND level when not in use.
RS	2	I	MPU	Selects the register for a parallel bus interface. Low: Instruction High: RAM access Selects the key scan interrupt method in the standby period for a serial interface. Monitors a total of eight keys connected to KST0 at the GND level and monitors all keys at the Vcc level to generate an interrupt. Must be fixed at the Vcc or GND level.
E/WR*/SCL	2	I	MPU	Inputs the serial transfer clock for a serial interface. Fetches data at the rising edge of a clock. For a 68-system parallel bus interface, serves as an enable signal to activate data read/write operation. For an 80-system parallel bus interface, serves as a write strobe signal and writes data at the low level.
RW/RD*/ SDA	2	I/O or I	MPU	Serves as the bidirectional serial transfer data for a serial interface. Sends/Receives data. For a 68-system parallel bus interface, serves as a signal to select data read/write operation. For an 80-system parallel bus interface, serves as a write strobe signal and reads data at the low level.
IRQ*	2	O	MPU	Generates the key scan interrupt signal.
KST0– KST3	8	O	Key matrix	Generates strobe signals for latching scanned data from the key matrix at specific time intervals. Available for a serial interface only.
DB0/KIN0– DB7/KIN7	16	I or I/O	Key matrix or MPU	Samples key state from key matrix synchronously with strobe signals for a serial interface. Serves as a bidirectional data bus for a parallel bus interface. For a four-bit bus, data transfer uses KIN7/DB7–KIN4/DB4; leave KIN3/DB3–KIN0/DB0 disconnected.

Table 2 Pin Functional Description (cont)

Signals	Number of Pins	I/O	Connected to	Functions
PORT0–PORT2	6	O	General output	General output ports. These ports cannot drive current such as for LEDs or backlighting control. Boost the current using an external transistor.
COMS1/2, COMS2/1	2	O	LCD	Two common output signals for segment-icon display.
COM1/24– COM24/1	24	O	LCD	Common output signals for character/graphics display: COM1 to COM8 for the first line; COM9 to COM16 for the second line, and COM17 to COM24 for the third line. All the unused pins output deselection waveforms. In the sleep mode (SLP = 1) or standby mode (STB = 1), all pins output GND level. The CMS bit can change the shift direction of the common signal. For example, if CMS = 0, COM1/24 is COM1. If CMS = 1, COM1/24 is COM24.
SEG1/72– SEG72/1 (HD66724)	72	O	LCD	Segment output signals for segment-icon display and character/graphics display. In the sleep mode (SLP = 1) or standby mode (STB = 1), all pins output GND level.
SEG1/96– SEG96/1 (HD66725)	96			The SGS bit can change the shift direction of the segment signal. For example, if SGS = 0, SEG1/72 (96) is SEG1. If SGS = 1, SEG1/72 (96) is SEG72 (96).
V1OUT– V5OUT	10	O or I	Open or external bleeder-resistor	Used for output from the internal operational amplifiers when they are used (OPOFF = GND); attach a capacitor to stabilize the output. When the amplifiers are not used (OPOFF = V_{cc}), V1 to V5 voltages can be supplied to these pins externally.
V_{LCD}	4	—	Power supply	Power supply for LCD drive. V_{LCD} – GND = 6.5 V max.
V_{cc} , GND	14	—	Power supply	V_{cc} : +1.8 V to +5.5 V; GND (logic): 0 V
OSC1, OSC2	2	I or O	Oscillation resistor or clock	For R-C oscillation using an external resistor, connect an external resistor. For R-C oscillation using an internal resistor, connect R1–R3 to OSC2 and leave OSC1 disconnected. For external clock supply, input clock pulses to OSC1.
R1–R3	3	O	OSC2	For R-C oscillation using an internal resistor, adjust the internal resistor value. Fluctuation of the resistor value is $\pm 30\%$ of the reference value. Care must be taken to avoid fluctuation of the frame frequency in crystal display drive operation.
Vci	5	I	Power supply	Inputs a reference voltage and supplies power to the booster; generates the liquid crystal display drive voltage from the operating voltage. Vci = 0 V to 3.0 V $\leq V_{cc}$ Must be left disconnected when the booster is not used.

Table 2 Pin Functional Description (cont)

Signals	Number of Pins	I/O	Connected to	Functions
VOUT	4	O	V_{LCD} pin/booster capacitance	Potential difference between V_{ci} and GND is boosted twice or three times and then output. Magnitude of boost is selected by instruction.
C1+, C1-	10	—	Booster capacitance	External capacitance should be connected here when using the double or triple booster.
C2+, C2-	8	—	Booster capacitance	External capacitance should be connected here when using the triple booster. Must be left disconnected only when using the double booster.
RESET*	2	I	MPU or external R-C circuit	Reset pin. Initializes the LSI when low. Must reset after power-on.
OPOFF	1	I	V_{cc} or GND	Turns the internal operational amplifier off when OPOFF = V_{cc} , and turns it on when OPOFF = GND. If the amplifier is turned off (OPOFF = V_{cc}), V1 to V5 must be supplied to the V1OUT to V5OUT pins.
VccDUM	1	O	Input pins	Outputs the internal V_{cc} level; shorting this pin sets the adjacent input pin to the V_{cc} level.
GNDDUM	1	O	Input pins	Outputs the internal GND level; shorting this pin sets the adjacent input pin to the GND level.
TEST	1	I	GND	Test pin. Must be fixed at GND level.
VTEST1– VTEST3	3	—	—	Test pins. Must be left disconnected.

Block Function Description

System Interface

The HD66724/HD66725 have five types of system interfaces, and a clock-synchronized serial, a 68-system 4-bit/8-bit bus, and a 80-system 4-bit/8-bit bus. The interface mode is selected by the IM2-0 pins. The key scan of the HD66724/HD66725 are not available for the 4-bit/8-bit bus interface. Instead, use the clock-synchronized serial interface.

The HD66724/HD66725 have two 8-bit registers: an instruction register (IR) and a data register (DR).

The IR stores instruction codes, such as clear display, display control, and address information for the display data RAM (DDRAM), character generator RAM (CGRAM), and segment RAM (SEGRAM).

The DR temporarily stores the data to be written to and read from the DDRAM, CGRAM, or SEGRAM. The data written to the DR from the MPU is automatically written to the DDRAM, CGRAM, or SEGRAM by internal operation. Since the data is read from the RAM through the DR, the first read data is invalid and the second read data is valid. After reading, the data in DDRAM, CGRAM, or SEGRAM at the next address is sent to the DR for the next reading from the MPU.

Execution time for instruction excluding clear display is 0 clock cycle and instructions can be written in succession.

Table 3 Register Selection by RS and R/W Bits

R/W Bits	RS Bits	Operations
0	0	Writes an instruction to the IR
1	0	Reads key scan data (SCAN0-3)
0	1	Writes the data to the DR to DDRAM, CGRAM, or SEGRAM
1	1	Reads the data from the DDRAM, CGRAM, or SEGRAM to DR

Key Scan Registers (SCAN0 to SCAN3)

The key matrix scanner senses and holds the key states at each rising edge of key strobe signals KST0 to KST3 that are output by the HD66724/HD66725. After passing through the key matrix, these strobe signals are used to sample the key states on eight inputs from KIN0 to KIN7, enabling up to 32 keys to be scanned.

Key states KIN0 to KIN7 are sampled by key strobe signal KST0 and latched into register SCAN0. Similarly, the data sampled by strobe signals KST1 to KST3 is latched into registers SCAN1 to SCAN3, respectively. For details, see the Key Scan Control section.

General Output Ports (PORT0 to PORT 2)

The HD66724/HD66725 have three general output ports. These ports control drive current such as that for LEDs or backlighting by using the current boosted by an external transistor.

Address Counter (AC)

The address counter (AC) assigns addresses to DDRAM, CGRAM, or SEGRAM. When an address set instruction is written into the IR, the address information is sent from the IR to the AC. Selection of DDRAM, CGRAM, and SEGRAM is also determined concurrently by the RAM select bit (RM1/0).

After writing into (reading from) DDRAM, CGRAM, or SEGRAM, the AC is automatically incremented by 1 (or decremented by 1). The cursor display position is determined by the address counter value.

Display Data RAM (DDRAM)

The display data RAM (DDRAM) stores display data represented in 8-bit character codes in the character display mode. Its capacity is 80×8 bits, or 80 characters, which is equivalent to an area of 16 characters \times 5 lines. Any number of display lines (LCD drive duty ratio) from 1 to 3 can be selected by software. Here, assignment of DDRAM addresses is the same for all display modes (table 5). The line to be displayed at the top of the display (display-start line) can also be selected by register settings. The graphics display mode does not use the data in the DDRAM.

Character Generator ROM (CGROM)

The character generator ROM (CGROM) generates 6×8 -dot character patterns from 8-bit character codes. It is equipped with a memory bank to generate 240 character patterns or 192 character patterns, which can be switched according to applications. For details, see the CGROM Bank Switching Function section. Table 6 illustrates the relation between character codes and character patterns for the Hitachi standard CGROM. User-defined character patterns are also available using a mask-programmed ROM (see the Modifying Character Patterns section).

Character Generator RAM (CGRAM)

The character generator RAM (CGRAM) allows the user to redefine the character patterns in the character display mode. Up to 64 character patterns of 6×8 -dot characters can be simultaneously displayed. The DDRAM-specified character code can be selected to display one of these user font patterns.

The CGRAM serves as a RAM to store 72×24 -dot (96×24 -dot) bit pattern data in the graphics display mode. Here, display patterns are directly written to the CGRAM. Character codes set in the DDRAM are not used. For details, see the Graphics Display Function section.

Segment RAM (SEGRAM)

The segment RAM (SEGRAM) is used to enable control of segments such as icons and marks through the user program. Segments and characters are driven by a multiplexing drive method.

The SEGRAM has a capacity of 96×2 bits, to control the display of a maximum of 144 (192) icons and marks. While COMS1 and COMS2 outputs are being selected, the SEGRAM is read and segments (icons and marks) are displayed by a multiplexing drive method (72 (96) segments each during COMS1 and COMS2 selection).

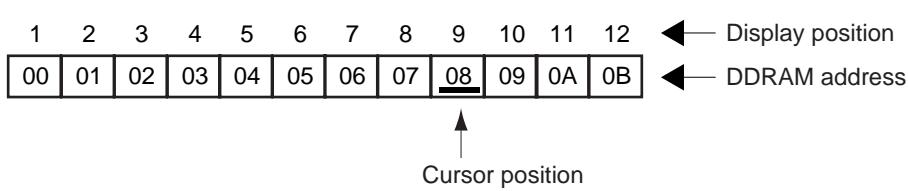

Bits in SEGRAM corresponding to segments to be displayed are directly set by the MPU, regardless of the contents of DDRAM and CGRAM.

Timing Generator

The timing generator generates timing signals for the operation of internal circuits such as DDRAM, CGROM, CGRAM, and SEGRAM. The RAM read timing for display and internal operation timing by MPU access are generated separately to avoid interference with one another. This prevents flickering in areas other than the display area when writing the data to the DDRAM, for example.

Cursor/Blink Control Circuit

The cursor/blink (or black-white reversed) control is used to create a cursor or a flashing area on the display in a position corresponding to the location stored in the address counter (AC).

Note: The cursor/blink or black-white reversed control is also active when the address counter indicates the CGRAM or SEGRAM. However, it has no effect on the display.

Figure 1 Cursor Position and DDRAM Address (When AC = 08H)

Oscillation Circuit (OSC)

The HD66724/HD66725 can provide R-C oscillation simply through the addition of an external oscillation-resistor between the OSC1 and OSC2 pins. The appropriate oscillation frequency for operating voltage, display size, and frame frequency can be obtained by adjusting the external-resistor value. Internal resistors can be used for R-C oscillation. If this is done, care must be taken due to variations in the oscillation frequency caused by fluctuations in internal-resistor values. Clock pulses can also be supplied externally. Since R-C oscillation stops during the standby mode, current consumption can be reduced. For details, see the Oscillation Circuit section.

Liquid Crystal Display Driver Circuit

The liquid crystal display driver circuit consists of 26 common signal drivers (COM1 to COM24, COMS1, COMS2) and 72 (96) segment signal drivers (SEG1 to SEG72 (96)). When the number of lines are selected by a program, the required common signal drivers automatically output drive waveforms, while the other common signal drivers continue to output deselection waveforms.

HD66724/HD66725

The character pattern data is sent serially through a 72-bit (96-bit) shift register and latched when all needed data has arrived. The latched data then enables the segment signal drivers to generate drive waveform outputs.

The shift direction of 72-bit (96-bit) data can be changed by the SGS bit. The shift direction for the common driver can also be changed by the CMS bit by selecting an appropriate direction for the device mounting configuration.

When multiplexing drive is not used, or during the standby or sleep mode, all the above common and segment signal drivers output the GND level, halting the display.

Booster (DC-DC Converter)

The booster doubles or triples a voltage input to the Vci pin. With this, both the internal logic units and LCD drivers can be controlled with a single power supply. Boost output level from single to triple boost can be software-selected. For details, see the Power Supply for Liquid Crystal Display Drive section.

V-Pin Voltage Follower

A voltage follower for each voltage level (V1 to V5) reduces current consumption by the LCD drive power supply circuit. No external resistors are required because of the internal bleeder-resistor, which generates different levels of LCD drive voltage. This internal bleeder-resistor can be software-specified from 1/2 bias to 1/6.5 bias, according to the liquid crystal display drive duty value. The voltage followers can be turned off while multiplexing drive is not being used. For details, see the Power Supply for Liquid Crystal Display Drive section.

Contrast Adjuster

The contrast adjuster can be used to adjust LCD contrast in 32 steps by varying the LCD drive voltage by software. This can be used to select an appropriate LCD brightness or to compensate for temperature.

Table 4 DDRAM Addresses and Display Positions

Display Line	1st Char.	2nd Char.	3rd Char.	4th Char.	5th Char.	6th Char.	7th Char.	8th Char.	9th Char.	10th Char.	11th Char.	12th Char.	13th Char.	14th Char.	15th Char.	16th Char.
1st	00	01	02	03	04	05	06	07	08	09	0A	0B	0C	0D	0E	0F
2nd	10	11	12	13	14	15	16	17	18	19	1A	1B	1C	1D	1E	1F
3rd	20	21	22	23	24	25	26	27	28	29	2A	2B	2C	2D	2E	2F
4th	30	31	32	33	34	35	36	37	38	39	3A	3B	3C	3D	3E	3F
5th	40	41	42	43	44	45	46	47	48	49	4A	4B	4C	4D	4E	4F

Note: When SGS = 0, SEG 1/72 (96) to SEG 6/67 (91) appear at the first character at the extreme left of the screen.

When SGS = 1, SEG 72 (96)/1 to SEG 67 (91)/6 appear at the first character at the extreme left of the screen.

Table 5 Display-Line Modes, Display-Start Line, and DDRAM Addresses

CGRAM Address (HEX)	200 to 205	206 to 20B	20C to 211	212 to 217	218 to 21D	21E to 223	224 to 229	22A to 22F	230 to 235	236 to 23B	23C to 241	242 to 247	248 to 24D	24E to 253	254 to 259	25A to 25F	
Font Bank		Memory Bank: ROM = 1															
Character Code	"90"H	"91"H	"92"H	"93"H	"94"H	"95"H	"96"H	"97"H	"98"H	"99"H	"9A"H	"9B"H	"9C"H	"9D"H	"9E"H	"9F"H	
CGRAM Address (HEX)	300 to 305	306 to 30B	30C to 311	312 to 317	318 to 31D	31E to 323	324 to 329	32A to 32F	330 to 335	336 to 33B	33C to 341	342 to 347	348 to 34D	34E to 353	354 to 359	35A to 35F	

- Notes:
1. In the character display mode (GR = 0), CGRAM font pattern is displayed using character codes set to DDRAM as per the above table. In the graphics display mode (GR = 1), CGRAM data is displayed irrespective of the DDRAM set data (character code).
 2. When the memory bank switching bit generates ROM = 0, CGRAM fonts for 16 character codes "00"H to "0F"H can be displayed. When ROM = 1, CGRAM fonts for 64 character codes "00"H to "1F"H and "80"H to "9F"H can be displayed.

Table 9 Relationship between CGRAM Address and Character Pattern (CGRAM Data)

Character Code	'00"H						'01"H						'8F"H							
CGRAM Address	000	001	002	003	004	005	006	007	008	009	00A	00B	00C	35A	35B	35C	35D	35E	35F
DB0	0	0	1	1	1	0	0	1	1	1	1	0	0	0	1	1	1	1	1
DB1	0	1	0	0	0	1	0	1	0	0	0	1	0	0	1	0	0	0	0
DB2	0	1	0	0	0	1	0	1	0	0	0	1	0	0	1	0	0	0	0
DB3	0	1	0	0	0	1	0	1	1	1	1	0	0	0	1	1	1	1	0
DB4	0	1	1	1	1	1	0	1	0	0	0	1	0	0	1	0	0	0	0
DB5	0	1	0	0	0	1	0	1	0	0	0	1	0	0	1	0	0	0	0
DB6	0	1	0	0	0	1	0	1	1	1	1	0	0	0	1	0	0	0	0
DB7	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Notes:

1. The least significant bit (LSB) of write data is displayed on the first line. The most significant bit (MSB) is displayed on the 8th raster-row.
2. The 8th raster-row is the cursor position and its display is formed by a logical OR with the cursor.
3. A set bit in the CGRAM data corresponds to display selection (lit) and 0 to non-selection (unlit).

Table 10 Relationship between Display Position and CGRAM Address in Graphics Display Mode (GR = 1)

Display Line	1st Char.	2nd Char.	3rd Char.	4th Char.	5th Char.	6th Char.	7th Char.	8th Char.	9th Char.	10th Char.	11th Char.	12th Char.	13th Char.	14th Char.	15th Char.	16th Char.
1st	000 to 005	006 to 00B	00C to 011	012 to 017	018 to 023	01E to 029	024 to 02F	02A to 035	030 to 03B	036 to 041	03C to 041	042 to 047	048 to 04D	04E to 053	054 to 059	05A to 05F
2nd	100 to 105	106 to 10B	10C to 111	112 to 117	118 to 11D	11E to 123	124 to 129	12A to 12F	130 to 135	136 to 13B	13C to 141	142 to 147	148 to 14D	14E to 153	154 to 159	15A to 15F
3rd	202 to 205	206 to 20B	20C to 211	212 to 217	218 to 21D	21E to 223	224 to 229	22A to 22F	230 to 235	236 to 23B	23C to 241	242 to 247	248 to 24D	24E to 253	254 to 259	25A to 25F
4th	303 to 305	306 to 30B	33C to 311	312 to 317	318 to 31D	31E to 323	324 to 329	32A to 32F	330 to 335	336 to 33B	33C to 341	342 to 347	348 to 34D	34E to 353	354 to 359	35A to 35F

Notes:

1. In the graphic display mode (GR = 1), graphics pattern is displayed using bitmap data set to CGRAM as per the above table.
2. Each display character and display line are converted to 6-dot width/character and 8 dots/line, respectively.
3. The 4th line is displayed by vertical smooth scroll operation.

Notes:

- In the graphics display mode (GR=1), the CGRAM data is displayed irrespective of the DDRAM set data.
- The HD66725 can display addresses from 000H to 35FH.
- A set bit in the CGRAM data corresponds to display selection (lit) and 0 to non-selection (unlit).

Notes: 1. 0 or 1.

2. Blinking is provided by repeatedly turning on the segment for 32 frames and turning it off for the next 32 frames.
3. Double-speed blinking is provided by repeatedly turning on the segment for 16 frames and turning it off for the next 16 frames.

Modifying Character Patterns

Character Pattern Development Procedure

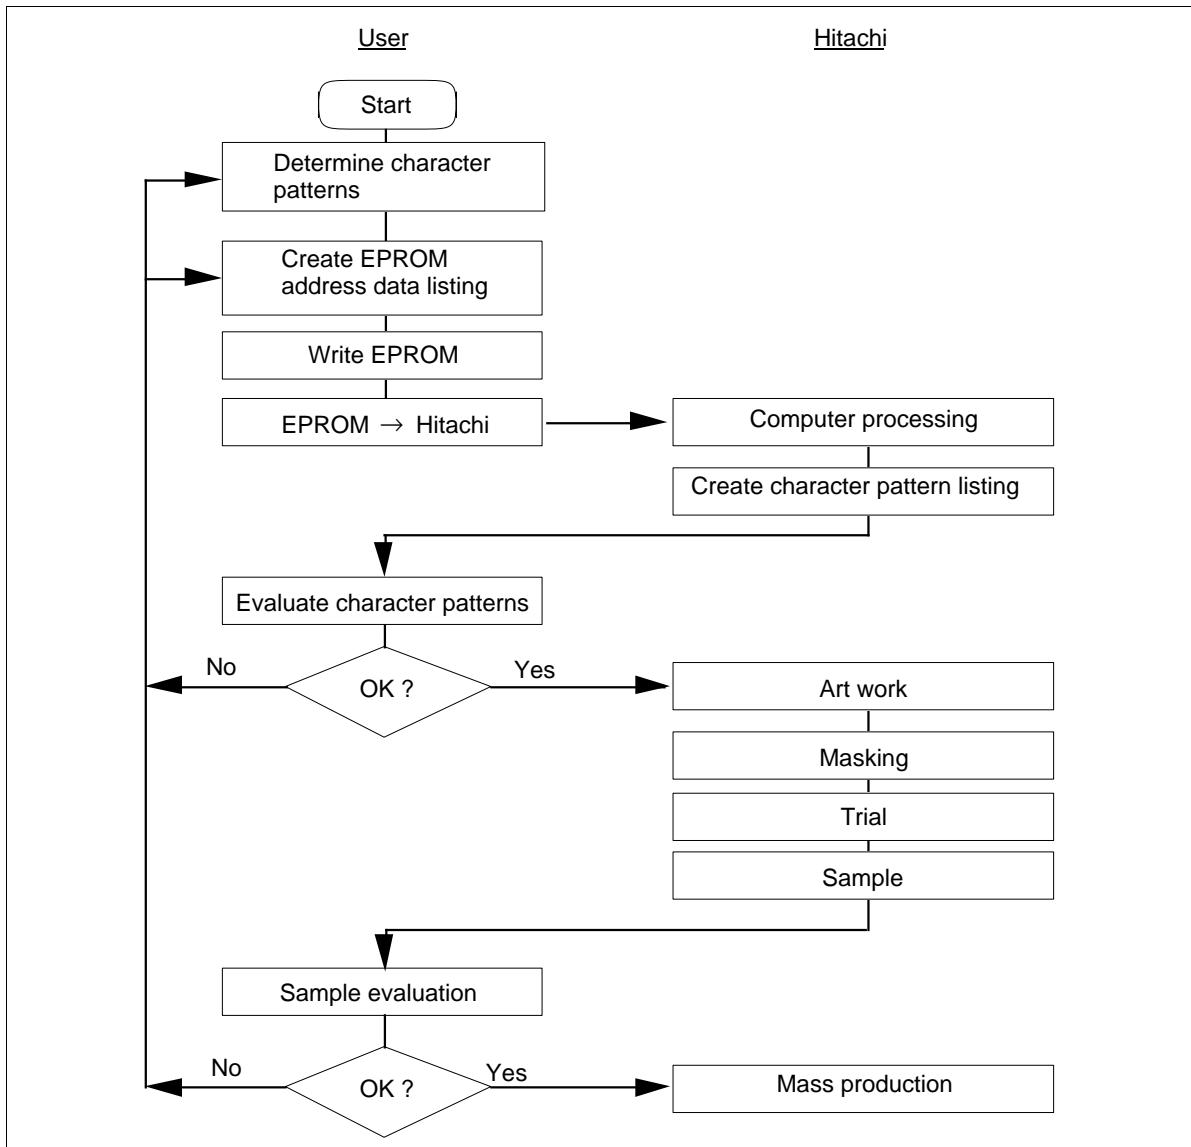

Figure 2 Character Pattern Development Procedure

The following operations correspond to the numbers listed in figure 2:

1. Determine the correspondence between character codes and character patterns.
2. Create a listing indicating the correspondence between EPROM addresses and data.
3. Program the character patterns into an EPROM.
4. Send the EPROM to Hitachi.
5. Computer processing of the EPROM is performed at Hitachi to create a character pattern listing, which is sent to the user.
6. If there are no problems within the character pattern listing, a trial LSI is created at Hitachi and samples are sent to the user for evaluation. When the user confirms that the character patterns are correctly written, Hitachi will commence LSI mass production.

Programming Character Patterns

This section explains the correspondence between addresses and data used to program character patterns in EPROM.

Programming to EPROM: The HD66724/HD66725 character generator ROM can generate 432 6 × 8-dot character patterns. Table 17 shows the correspondence between the EPROM address, data, and the character pattern.

Table 17 Examples of Correspondence between EPROM Address, Data, and Character Pattern (6 × 8 Dots)

A ₁₂	EPROM Address									MSB	Data						LSB		
	A ₁₁	A ₁₀	A ₉	A ₈	A ₇	A ₆	A ₅	A ₄	A ₃		A ₂	A ₁	A ₀	O ₅	O ₄	O ₃	O ₂	O ₁	O ₀
0	0	1	0	1	1	0	0	1	0	0	0	0	0	0	1	0	0	0	1
									0	0	0	1		0	1	0	0	0	1
									0	0	1	0		0	1	0	0	0	1
									0	0	1	1		0	0	1	0	1	0
									0	1	0	0		0	0	0	1	0	0
									0	1	0	1		0	0	0	1	0	0
									0	1	1	0		0	0	0	1	0	0
									0	1	1	1		0	0	0	1	0	0
									0	1	1	1		0	0	0	0	0	0

ROM bit Character code 0 Line position

- Notes:
1. EPROM address: Bit A₁₂ corresponds to the CGROM memory bank switch bit ("ROM").
 2. EPROM address: Bits A₁₁ to A₄ correspond to a character code.
 3. EPROM address: Bits A₂ to A₀ specify the line position of the character pattern. EPROM address bit A₃ must be set to 0.
 4. EPROM data: Bits O₅ to O₀ correspond to character pattern data.
 5. Areas which are lit (indicated by shading) are stored as 1, and unlit areas as 0.
 6. The eighth raster-row is also stored in the CGROM, and must also be programmed. If the eighth raster-row is used for a cursor, this data must all be set to zero.
 7. EPROM data: Bits O₇ to O₆ are invalid. 0 must be written in all bits.

Handling Unused Character Patterns:

1. EPROM data outside the character pattern area: This is ignored by character generator ROM for display operation so any data is acceptable.
2. EPROM data in CGRAM area: Always fill with zeros.
3. Treatment of unused user patterns in the HD66724/HD66725 EPROM: Depending on to the user application, these are handled in either of two ways:

- a. When unused character patterns are not programmed: If an unused character code is written into DDRAM, all its dots are lit, because the EPROM is filled with 1s after it is erased.
- b. When unused character patterns are programmed as 0s: Nothing is displayed even if unused character codes are written into DDRAM. (This is equivalent to a space.)

Instructions

Outline

Only the instruction register (IR) and the data register (DR) of the HD66724/HD66725 can be controlled by the MPU. Before starting internal operation of the HD66724/HD66725, control information is temporarily stored in these registers to allow interfacing with various peripheral control devices or MPUs which operate at different speeds. The internal operation of the HD66724/HD66725 is determined by signals sent from the MPU. These signals, which include the register selection signal (RS), the read/write signal (R/W), and the data bus signal (DB0 to DB7), make up the HD66724/HD66725 instructions. There are five categories of instructions that:

- Control the display
- Control power management
- Set internal RAM addresses
- Transfer data with the internal RAM
- Control key scan (when serial interface mode)

Normally, instructions that perform data transfer with the internal RAM are used the most. However, auto-incrementation by 1 (or auto-decrementation by 1) of internal HD66724/HD66725 RAM addresses after each data write can lighten the MPU program load.

Because instructions other than clear display instruction are executed in 0 cycle, instructions can be written in succession.

While the clear display instruction is being executed for internal operation, or during reset, no instruction other than the key scan read instruction can be executed.

Instruction Descriptions

Key Scan Data Read

In the serial interface mode, the key scan data read instruction reads scan data in scan registers SCAN0 to SCAN3. Following transfer of the start byte, scan data read operation starts from scan register SCAN0 and proceeds in the order of SCAN1, SCAN2, and SCAN3. When data read from SCAN 0 to SCAN3 is completed, the operation starts from SCAN0 again. For details, see the Key Scan Control section.

(SSE = 0)

(SSE = 1)

Figure 3 Key Scan Data Read Instruction

Clear Display

The clear display instruction writes space code 20H (the character pattern for character code 20H must be a blank pattern) into all DDRAM addresses. It then sets DDRAM address 0 into the address counter. It also sets I/D to 1 (increment mode) in the entry mode set instruction. Since the execution of this instruction needs 85 clock cycles, do not send the next instruction during the execution time.

R/W	RS	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
0	0	0	0	0	0	0	0	0	1

Figure 4 Clear Display Instruction

Return Home

The return home instruction sets DDRAM address 0 into the address counter. The DDRAM contents do not change. The cursor or blinking goes to the top left of the display.

R/W	RS	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
0	0	0	0	0	0	0	0	1	0

Figure 5 Return Home Instruction

Start Oscillation

The start oscillation instruction restarts the oscillator from the halt state in the standby mode. After issuing this instruction, wait at least 10 ms for oscillation to stabilize before issuing the next instruction. (Refer to the Standby Mode section.)

R/W	RS	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
0	0	0	0	0	0	0	0	1	1

Figure 6 Start Oscillation Instruction

Driver Output Control

CMS: Selects the output shift direction of a common driver. When CMS = "0", COM1/24 shifts to COM1, and COM24/1 to COM24. When CMS = "1", COM1/24 shifts to COM24, and COM24/1 to COM1. Output position of a common driver shifts depending on the CEN bit setting. For details, see the Display On/Off Control section.

SGS: Selects the output shift direction of a segment driver. When SGS = "0", SEG1/72 (96) shifts to SEG1, and SEG72 (96)/1 to SEG72 (96). When SGS = "1", SEG1/72 (96) shifts SEG72 (96), and SEG72 (96)/1 to SEG1.

0	0	0	0	0	0	0	1	CMS	SGS

Figure 7 Driver Output Control Instruction

Power Control

AMP: When AMP = 1, each voltage follower for the V1 to V5 pins and the booster are turned on. When AMP = 0, current consumption can be reduced when the display is not being used. In this case, set BT1/0 = 00 for single boosting output.

SLP: When SLP = 1, the HD66724/HD66725 enter the sleep mode, where the internal operations are halted except for the key scan function and the R-C oscillator, thus reducing current consumption. For details, refer to the Sleep Mode section. Only the following instructions can be executed during the sleep mode.

- a. Key scan data read
- b. Key scan control (IRE, KF1/0 bit)
- c. Power control (AMP, SLP, and STB bits)
- d. Port control (PT2-0 bits)

During the sleep mode, the other RAM data and instructions cannot be updated although they are retained.

STB: When STB = 1, the HD66724/HD66725 enter the standby mode, where display operation and key scan completely stop, halting all the internal operations including the internal R-C oscillator. Further, no external clock pulses are supplied. This setting can be used as the system wake-up, because an interrupt is generated when a specific key is pressed. For details, refer to the Standby Mode section. Only the following instructions can be executed during the standby mode.

- a. Standby mode cancel (STB = 0)
- b. Voltage follower circuit on/off (AMP = 1/0)
- c. Start oscillator
- d. Key scan interrupt generation enabled/disabled (IRE = 1/0)
- e. Port control (PT2-0 bits)

During the standby mode, the other RAM data and instructions may be lost. To prevent this, they must be set again after the standby mode is canceled.

BT1-0: When SW = 1, it switches the output of V5OUT between single, double, and triple boost. The liquid crystal display drive voltage level can be selected according to its drive duty ratio and bias. A lower amplification of the booster consumes less current.

BS2-0: When SW = 1, it sets the crystal display drive bias value within the range of 1/4 to 1/6.5 bias. The liquid crystal display drive bias value can be selected according to its drive duty ratio and voltage. For details, see the Liquid Crystal Display Drive Bias Selector Circuit section.

1	1	1	Inhibit

Entry Mode Set

ROM: Switches the CGROM memory bank in the character mode (GR = 0). Uses bank 0 for display when ROM = 0 and bank 1 for display when ROM = 1. For details, see the CGROM Bank Switching Function section.

I/D: Increments (I/D = 1) or decrements (I/D = 0) the DDRAM address by 1 when a character code is written into or read from DDRAM. The cursor or blinking moves to the right when incremented by 1 and to the left when decremented by 1. The same applies to the writing and reading of CGRAM and SEGRAM.

GR: Activates the character mode when GR = 0. Displays the font pattern on CGROM or CGRAM according to the character code written in DDRAM. Activates the graphics mode when GR = 1. Displays a given pattern according to the bitmap data written in CGRAM. In this case, data in DDRAM is not used for display. Segment pattern display set to SEGRAM is enabled both in the character mode and graphics mode. For details, see the Graphics Display Function section.

Figure 11 Entry Mode Set Instruction

Cursor Control

B/W: When B/W is 1, the character at the cursor position is cyclically (every 32 frames) blink-displayed with black-white inversion.

When B/W = 1 and LC = 1, all characters including the cursor on the display line appear with black-white inversion. The characters do not blink. For details, refer to the Line-Cursor Display section.

C: The cursor is displayed on the 8th raster-row when C is 1. The 6-dot cursor is ORed with the character pattern and displayed on the 8th raster-row.

HD66724/HD66725

B: The character indicated by the cursor blinks when B is 1. The blinking is displayed as switching between all black dots and displayed characters every 32 frames. The cursor and blinking can be set to display simultaneously. When LC and B = 1, the blinking is displayed as switching between all white dots and displayed characters.

Figure 13 Cursor Control Examples

Display On/Off Control

D: Display is on when D is 1 and off when D is 0. When off, the display data remains in DDRAM, and can be displayed instantly by setting D to 1. When D is 0, the display is off with the SEG1 to SEG72 (96) outputs, COM1 to COM24 outputs, and COMS1/2 output set to the GND level and off. Because of this, the HD66724/HD66725 can control charging current for the LCD with AC driving.

CEN: Switches the common driver position from COM1 to COM8. When CEN = 1, it outputs the first line of COM1 to COM8 in the center of the screen. For details, see the Partial-Display-On Function section.

LC: When LC = 1, a cursor attribute is assigned to the line that contains the address counter (AC) value. Cursor mode can be selected with the B/W, C, and B bits. Refer to the Line-Cursor Display section.

Display Line Control

NL2-0: Specifies the display lines. Display lines change the liquid crystal display drive duty ratio. DDRAM address mapping does not depend on the number of display lines.

R/W	RS	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
0	0	0	0	1	1	1	NL2	NL1	NL0

0	0	0	Segment display	1/2 Duty	COMS1, COMS2
0	0	1	One character line + segment display	1/10 Duty	COM1-8, COMS1, COMS2
0	1	0	Two character lines + segment display	1/18 Duty	COM1-16, COMS1, COMS2
0	1	1	Three character lines + segment display	1/26 Duty	COM1-24, COMS1, COMS2
1	*	*	Setting inhibited		

Double-Height Display Control

DL3-1: Specifies the double-height display for a given line. When DL1 = 1, the first line is displayed at double height. When DL2 = 1, the second line is displayed at double height. When DL3 = 1, the third line is displayed at double height. Double-height display of multiple lines is possible. For details, see the Double-Height Display section.

Figure 16 Double-Height Display Control Instruction

Vertical Scroll Control 1/2

SN2-0: Specifies the display start line output from COM1. Because DDRAM is assigned a 5-line display area, data is displayed sequentially from the first line to the fifth line then repeated from the first line again.

SL2-0: Selects the top raster-row to be displayed (display-start raster-row) in the display-start line specified by SN2 to SN0. Any raster-row from the first to eighth can be selected (Table 24). This function

is used to achieve vertical smooth scrolling together with SN2 to SN0. For details, refer to the Vertical Smooth Scroll section. During horizontal scrolling, the SN0 bit must be 0 (SN0 = 0).

1	1	1	8th raster-row

Horizontal Scroll Control

SSE: When SSE = 0, it selects SE2 and SE1 bits and when SSE = 1, it selects SE3 and SE4 bits.

SE3-1: Specifies the horizontal smooth scroll display for a given line. When SE = 1, the first line is displayed in a horizontal scroll. When SE = 1, the second line is displayed in a horizontal scroll. When SE = 1, the third line is displayed in a horizontal scroll. When SE = 4, the fourth line is displayed in a horizontal scroll. Horizontal scroll display of multiple lines is possible.

SQ2-0: Shifts the line to which horizontal smooth scroll is specified by units of 3 dots, up to 21 dots, to the left. For details, see the Horizontal Smooth Scroll section.

1	1	0	Displayed with 18 dots shifted to the left
1	1	1	Displayed with 21 dots shifted to the left

Key Scan Control

IRE: When IRE = 1, it permits interrupts when a key is pressed. This causes interrupts to occur in the standby period when the oscillator clock is halted, as well as key scan interrupts during normal operation, allowing system wake-up.

KF1-0: Sets the key scan cycle. The following table shows the key scan pulse width and key scan cycle used when the oscillation frequency (fosc) is 32 kHz, which depend on the oscillation frequency. For details, see the Key Scan Control section.

R/W	RS	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0
0	0	0	1	1	0	1	IRE	KF1	KF0

Figure 19 Key Scan Control Instruction

Table 26 KF Bits and Key Scan Cycle

KF1	KF0	Key Scan Pulse Width	Key Scan Cycle
0	0	0.25 ms	1.0 ms (32 clock cycles)
0	1	0.5 ms	2.0 ms (64 clock cycles)
1	0	1.0 ms	4.0 ms (128 clock cycles)
1	1	2.0 ms	8.0 ms (256 clock cycles)

Note: The data is a value obtained when the oscillation frequency (fosc) is 32 kHz. The value depends on the oscillation frequency.

Port Control

PT2-0: Controls the output level of a port output pin (PORT2-PORT0). When PT0 = 0, it specifies the POT0 output to GND and when PT0 = 1, to VCC. Similarly, PT1 and PT2 bits control PORT1 and PORT2 output levels respectively.

R/W	RS	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0

Figure 20 Port Control Instruction

RAM Address Set

RM1-0: Selects DDRAM, CGRAM, and SEGRAM. The selected RAM is accessed with this setting.

AD9-0: Initially sets RAM addresses to the address counter (AC). Once RAM data is accessed, the AC is automatically updated according to the I/D bit. This allows consecutive accesses without resetting addresses. RAM address setting is not allowed in the sleep mode or standby mode.

Write Data to RAM

WD7-0 : Writes 8-bit data to DDRAM and CGRAM lower 2-bit data to SEGRAM. DDRAM/ CGRAM/ SEGRAM is selected by the previous specification of the RM 1/0bit. After a write, the address is automatically incremented or decremented by 1 according to the I/D bit setting in the entry mode set instruction. During the sleep and standby modes, DDRAM, CGRAM, or SEGRAM cannot be accessed.

0	1	WD7	WD6	WD5	WD4	WD3	WD2	WD1	WD0

Figure 22 Write Data to RAM Instruction

Read Data from RAM

RD7-0 : Reads the 8-bit data from DDRAM, CGRAM or SEGRAM. DDRAM/CGRAM/SEGRAM is selected by the previous specification of the RM 1/0 bit. In the parallel bus interface mode, the first-byte data read will be invalid immediately after the RAM address is set, and the subsequent second-byte data will be read normally. In the serial interface mode, two bytes will be invalid immediately after the start byte, and the subsequent third-byte data will be read normally. For details, see the Serial Data Transfer section. After a DDRAM read, the address is automatically incremented or decremented by 1 according to the I/D bit setting in the entry mode set instruction.

SL2-0: Display-start raster-row specifications (000: 1st raster-row...111: 8th raster-row)
SSE: SE1-4 bit selection (SSE = 0: SE1/2 bit selection, SSE = 1: SE3/4 bit selection)
SE1-4: Horizontal smooth scroll display line specifications (SE1 = 1: 1st line, SE2 = 1: 2nd line, SE3 = 1: 3rd line, SE4 = 1: 4th line)
SQ2-0: Horizontal scroll dots specifications (000: 0-dot shift...111: 21-dot shift)
IRE = 1: Key scan interrupt generation enabled
KF1/0: Key scan cycle set
PT2-0: Port output control (PT2 = 1: PORT2 = Vcc, PT1 = 1: PORT1 = Vcc, PT0 = 1: PORT0 = Vcc)
RM1/0: RAM selection (00/01: DDRAM, 10: CGRAM, 11: SEGRAM)
ADD9-0: DDRAM/CGRAM/SEGRAM address set (DDRAM: 000H-04FH, CGRAM: 000H-35FH, SEGRAM: 000H-047H)

Reset Function

The HD66724/HD66725 are internally initialized by RESET input. During initialization, the system executes a clear display instruction after reset is canceled. The system executes the other instructions during the reset period. Because the busy flag (BF) indicates a busy state (BF = 1) during the reset period and execution of the clear display instruction following reset cancellation, no instruction or RAM data access from the MPU is accepted. Here, reset input must be held back for at least 1 ms, and an issuing instruction must wait for 1,000 clock cycles after reset is canceled because the display clearing continues after reset cancellation.

Instruction Set Initialization:

1. Clear display executed (Writes 20H to DDRAM)
2. Return home executed (Sets the address counter (AC) to 00H to select DDRAM)
3. Start oscillator executed
4. Driver output control (SGS = 0, CMS = 0)
5. Power control (AMP = 0: LCD power off, SLP = 0: Sleep mode off, STB = 0: Standby mode off)
6. Single boost (BT1/0 = 00), 1/6.5 bias drive (BS2/1/0 = 000), Weak contrast (CT4-0 = 00000)
7. Entry mode set (ROM = 0: CGROM bank 0, I/D = 1: Increment by 1, GR = 0: Character display mode)
8. Cursor display off (B/W = 0, C = 0, B = 0)
9. Display on/off control (D = 0: Display off, CEN = 0: Normal position, LC = 0: Line-cursor off)
10. Display control (NL2/1/0 = 100: 1/34 duty ratio)
11. Double-height display off (DL3/2/1 = 000)
12. Vertical scroll control (SN2/1/0 = 000: First line displayed at the top, SL2/1/0: First raster-row displayed at the top of the first line)
13. Horizontal scroll off (SEE = 0, SE2/1 = 00, SE4/3 = 00, SQ2/1/0 = 000)
14. Key scan control (IRE = 0: Key scan interrupt (IRQ) generation disabled, KF1/0 = 00: Key scan set to 32 cycles)
15. Port control (PT2/1/0 = 000: PORT2/1/0 output = GND level)

RAM Data Initialization:

1. DDRAM

All addresses are initialized to 20H by the clear display instruction after the reset is canceled.

2. CGRAM/SEGRAM

This is not automatically initialized by reset input but must be initialized by software while display is off (D = 0)

Output Pin Initialization:

1. LCD driver output pins (SEG/COM): Outputs GND level
2. Booster output pins (VLOUT): Outputs GND level
3. Oscillator output pin (OSC2): Outputs oscillation signal
4. Key strobe pins (KST0 to KST3): KST0 outputs GND level. KST1 to KST3 output V_{CC} level.
5. Key scan interrupt pin (IRQ*): Outputs V_{CC} level
6. General output port (PORT0–PORT2): Outputs GND level

Serial Data Transfer

Setting the IM1 and IM2 pins (interface mode pins) to the GND level allows standard clock-synchronized serial data transfer, using the chip select line (CS*), serial data line (SDA), and serial transfer clock line (SCL). For a serial interface, the IM0/ID pin function uses an ID pin.

The HD66724/HD66725 initiate serial data transfer by transferring the start byte at the falling edge of CS* input. They end serial data transfer at the rising edge of CS* input.

The HD66724/HD66725 are selected when the 6-bit chip address in the start byte transferred from the transmitting device matches the 6-bit device identification code assigned to the HD66724/HD66725. The HD66724/HD66725, when selected, receive the subsequent data string. The least significant bit of the identification code can be determined by the ID pin. The five upper bits must be 01110. Two different chip addresses must be assigned to a single HD66724/HD66725 because the seventh bit of the start byte is used as a register select bit (RS): that is, when RS = 0, an instruction can be issued or key scan data can be read, and when RS = 1, the data can be written to or read from RAM. Read or write is selected according to the eighth bit of the start byte (R/W bit) as shown in table 33.

After receiving the start byte, the HD66724/HD66725 receive or transmit the subsequent data byte-by-byte. The data is transferred with the MSB first. To transfer the data consecutively, note that only the display-clear instruction requires a longer execution time than the others (table 32).

Two bytes of the RAM read data after the start byte are invalid. The HD66724/HD66725 start to read the correct RAM data from the third byte. Write a dummy instruction ("00H") before reading the key scan data.

Table 33 Start Byte Format

Transfer Bit	S	1	2	3	4	5	6	7	8
Start byte format	Transfer start		Device ID code					RS	R/W

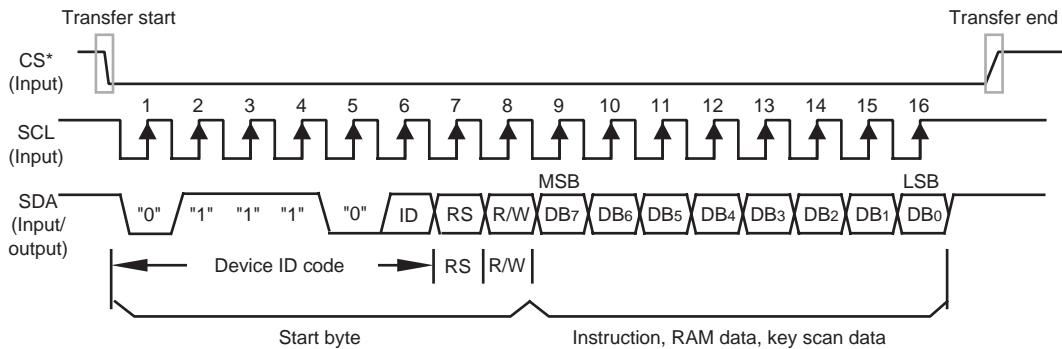

Note: ID bit is selected by the IM0/ID pin.

Table 34 RS and R/W Bit Function of Clock-Synchronized Serial Interface Data

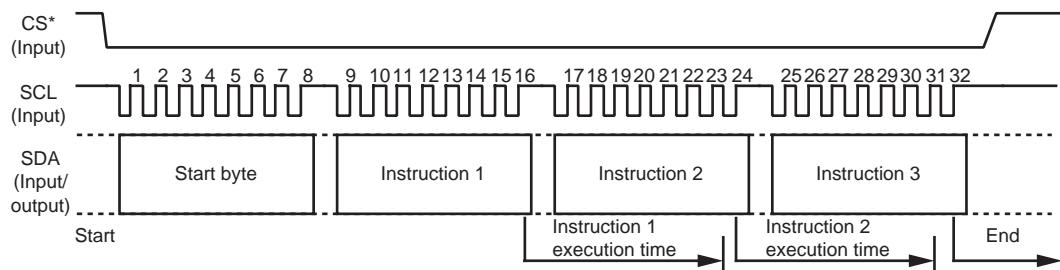

RS	R/W	Function
0	0	Writes instruction
0	1	Reads key scan data
1	0	Writes RAM data
1	1	Reads RAM data

HD66724/HD66725

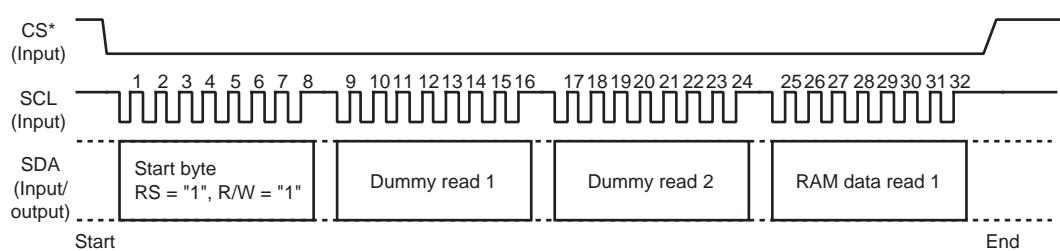

a) Basic Data-Transfer Timing through Clock-Synchronized Serial Bus Interface

b) Consecutive Data-Transfer Timing through Clock-Synchronized Serial Bus Interface

c) RAM Data Read-Transfer Timing

Note: Two bytes of RAM read data after the start byte are invalid. The HD66724/HD66725 start to read correct RAM data from the third byte.

Figure 25 Clock-Synchronized Serial Interface Timing Sequence

Key Scan Control

The key matrix scanner senses and holds the key states at each rising edge of key strobe signals (KST) that are output by the HD66724/HD66725. The key strobe signals are output as time-multiplexed signals from KST0 to KST3. After passing through the key matrix, these strobe signals are used to sample the key state of eight inputs KIN0 to KIN7, enabling up to 32 keys to be scanned.

The states of inputs KIN0 to KIN7 are sampled by key strobe signal KST0 and latched into the SCAN0 register. Similarly, the data sampled by strobe signals KST1 to KST3 is latched into the SCAN1 to SCAN3 registers, respectively. Key pressing is stored as 1 in these registers.

The generation cycle and pulse width of the key strobe signals depend on the operating frequency (oscillation frequency) of the HD66724/HD66725 and the key scan cycle determined by the KF0 and KF1 bits. For example, when the operating frequency is 32 kHz and KF0 and KF1 are both 10, the generation cycle is 4.0 ms and the pulse width is 1.0 ms. When the operating frequency (oscillation frequency) is changed, the above generation cycle and the pulse width are changed in inverse proportion.

In order to compensate for the mechanical features of the keys, such as chattering and noise and for the key-strobe generation cycle and the pulse width of the HD66724/HD66725, software should read the scanned data two to three times in succession to obtain valid data. Multiple keypress combinations should also be processed in the software.

Up to three keys can be pressed simultaneously. Note, however, that if the third key is pressed on the intersection between the rows and columns of the first two keys pressed, incorrect data will be sampled. For three-key input, the third key must be on a separate column or row.

The input pins KIN0 to KIN7 are pulled up to V_{CC} with internal MOS transistors (see the Electrical Characteristics section). External resistors may also be required to further pull the voltages up when the internal pull-ups are insufficient for the desired noise margins or for a large key matrix.

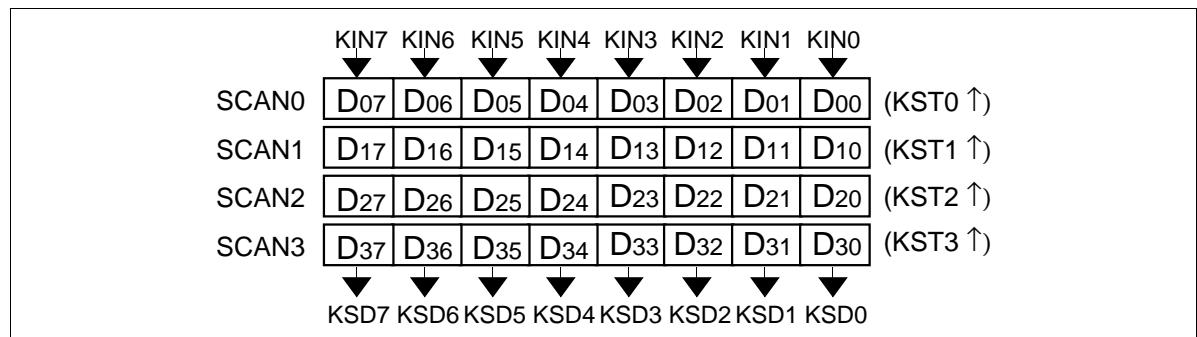

Figure 26 Key Scan Register Configuration

HD66724/HD66725

Table 35 Key Scan Cycles for Each Operating Frequency

KF1	KF0	Key Scan Pulse Width	Key Scan Cycle
0	0	0.25 ms	1.0 ms (32 clock cycles)
0	1	0.5 ms	2.0 ms (64 clock cycles)
1	0	1.0 ms	4.0 ms (128 clock cycles)
1	1	2.0 ms	8.0 ms (256 clock cycles)

Note: The data is a value obtained when the oscillation frequency (fosc) is 32 kHz. The value depends on the oscillation frequency.

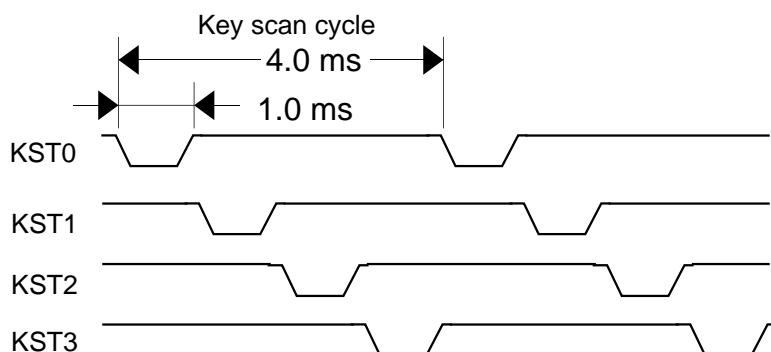

Figure 27 Key Strobe Output Timing (KF1/0 = 10, fcp/fosc = 32 kHz)

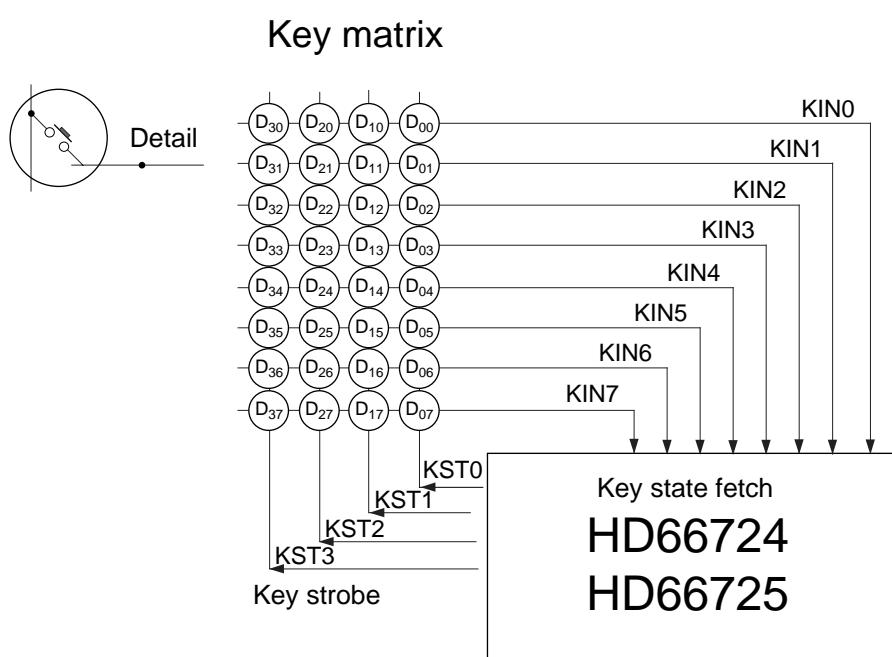

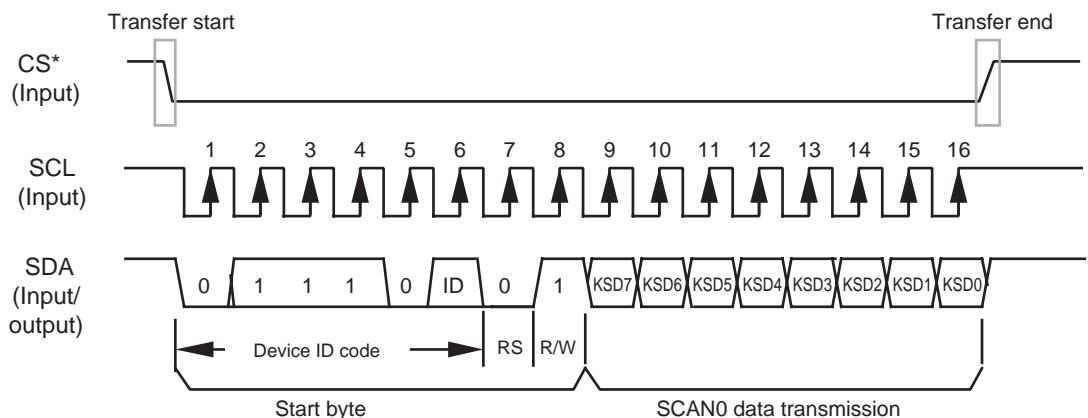

Figure 28 Key Scan Configuration

The key scan data can be read by an MPU via a serial interface. First, a start byte should be transferred. After the HD66724/HD66725 have received the start byte, the MPU reads scan data KSD7 to KSD0 from the SCAN0 register starting from the MSB. Similarly, the MPU reads the data from SCAN1, SCAN2 and SCAN3 in that order. After reading SCAN3, the MPU starts reading at SCAN0 again.

The HD66724/HD66725 may be read out while they are latching scan data and are thus unstable. Consequently, they should also be reconfirmed with software if required.

Write a dummy instruction ("00H") before reading the key scan data.

a) Scan Data Read Timing through Clock-synchronized Serial Bus Interface

b) Consecutive Scan Data Read Timing

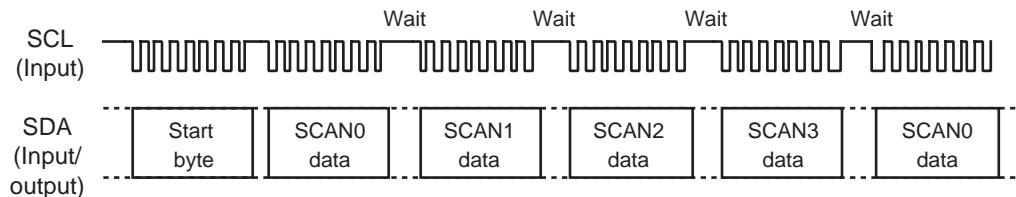

Figure 29 Scan Data Serial Transfer Timing

Key Scan Interrupt (Wake-Up Function)

If the interrupt enable bit (IRE) is set to 1, the HD66724/HD66725 send an interrupt signal to the MPU on detecting that a key has been pressed in the key scan circuit by setting the IRQ* output pin to a low level. An interrupt signal can be generated by pressing any key in a 32-key matrix. The interrupt level continues to be output during the key scan cycle during which the key is being pressed.

Normal key scanning is performed and interrupts can occur in the HD66724/HD66725 sleep mode (SLP = 1). Accordingly, power consumption can be minimized in the sleep mode, by triggering the MPU to read key states via the interrupt which is generated only when the HD66724/HD66725 detect a key input. For details, refer to the Sleep Mode section.

On the other hand, normal key scanning and the internal operating clock stop in the standby mode (STB = 1). During this period, the KST0 output is kept low, so the HD66724/HD66725 can always monitor eight key inputs (KIN0-KIN7) connected to KST0 when RS = GND. Therefore, if any of the eight keys is pressed, an interrupt occurs. When RS = Vcc, all outputs KST0 to KST3 are kept low, so the HD66724/HD66725 can always monitor 32 key inputs. If any of 32 keys is pressed, an interrupt occurs. Accordingly, power consumption can further be minimized in the standby mode, where the whole system is inactive, by triggering the MPU via the interrupt which is generated only when the HD66724/HD66725 detect a key input from the above keys. For details, refer to the Standby Mode section.

The IRQ* output pin is pulled up to the V_{CC} with an internal MOS resistor of approximately 50 kΩ. Additional external resistors may be required to obtain stronger pull-ups. Interrupts may occur if noise occurs in KIN0-KIN7 input during key scanning. Interrupts must be inhibited if not needed by setting the interrupt enable bit (IRE) to 0.

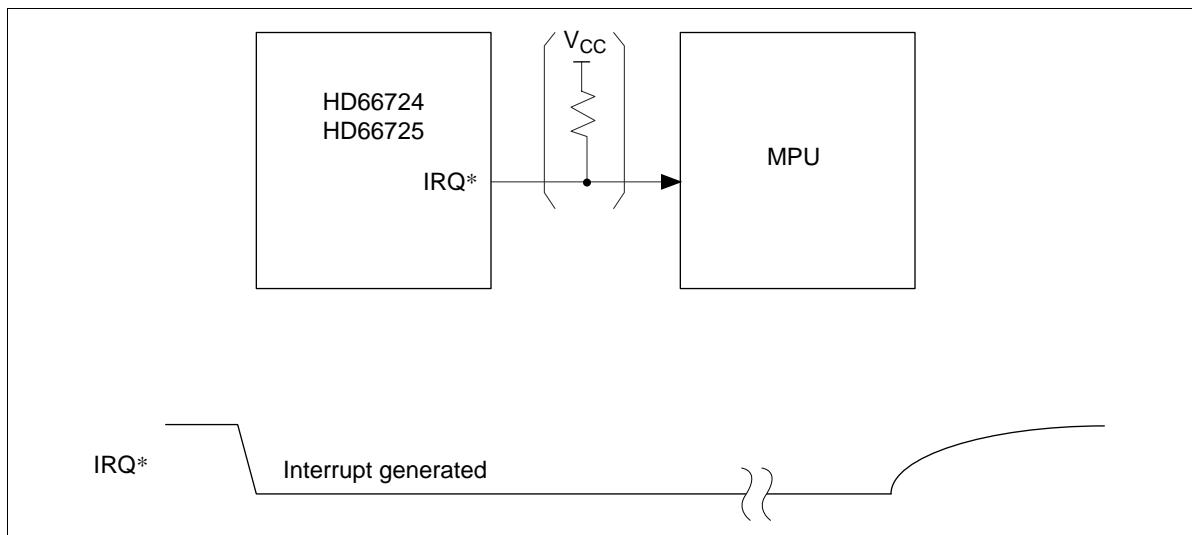

Figure 30 Interrupt Generation

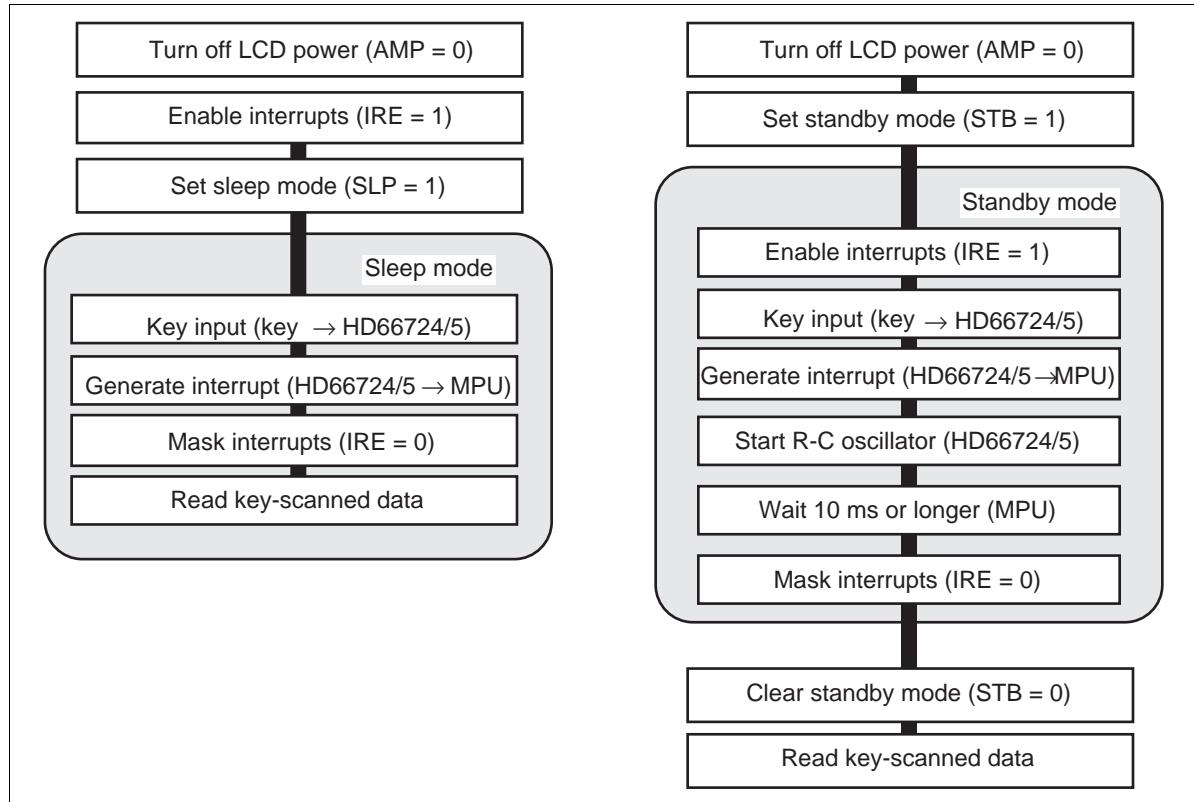

Figure 31 Key Scan Interrupt Processing Flow in Sleep and Standby Modes

Parallel Data Transfer

8-Bit Interface

Setting the IM2/1/0 (interface mode) to the GND/V_{CC}/GND level allows 68-system 8-bit parallel data transfer. A direct interface using the 8-bit E-clock-synchronized bus or an interface via the I/O bus can be established. Setting the IM2/1/0 to the V_{CC}/V_{CC}/GND level allows 80-system 8-bit parallel data transfer. When the number of buses or mounting area is limited, use a 4-bit bus interface or serial data transfer.

Using a parallel bus interface disables the key scan function. To prevent this, use a clock-synchronized serial interface.

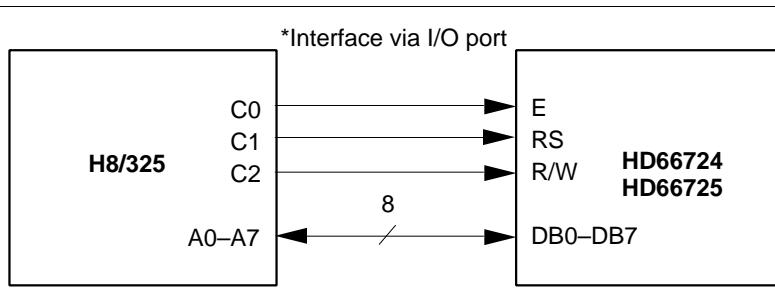

Figure 32 Interface to 8-Bit Microcomputer

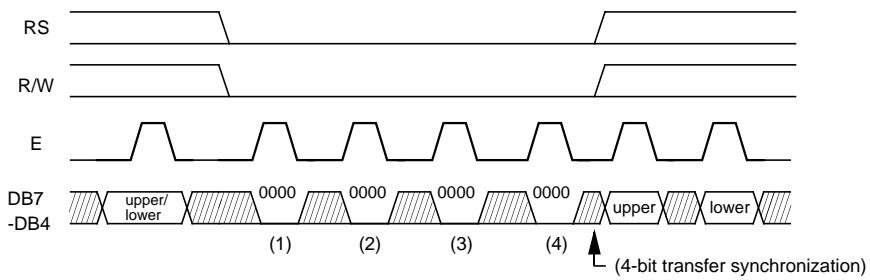

4-Bit Interface

Setting the IM2/1/0 (interface mode) to the GND/V_{CC}/V_{CC} level allows 68-system 4-bit parallel data transfer using pins DB7/KIN7-DB4/KIN4. Setting the IM2/1/0 to the V_{CC}/V_{CC}/V_{CC} level allows 80-system 4-bit parallel data transfer. 8-bit instructions and RAM data are divided into four upper/lower bits and transfer starts from the upper four bits.

Using a parallel bus interface disables the key scan function. To prevent this, use a clock-synchronized serial interface.

Note: Transfer synchronization function for a 4-bit bus interface

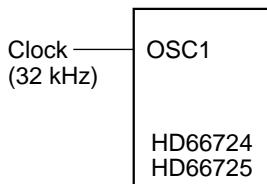

The HD66724/HD66725 support transfer synchronization function which resets the upper/lower counter to count upper/lower four-bit data transfer in the 4-bit bus interface. Noise causing transfer mismatch between the four upper and lower bits can be corrected by a reset triggered by consecutively writing a 0000 instruction four times. The next transfer starts from the upper four bits. Executing synchronization function periodically can recover any runaway in the display system.

**Figure 33 4-Bit Transfer Synchronization**

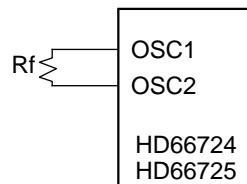

Oscillator Circuit

The HD66724/HD66725 can either be supplied with operating pulses externally (external clock mode), oscillate using an internal CR oscillator with an external oscillator-resistor (external resistor oscillation mode), or oscillate using an internal oscillator-resistor (internal resistor oscillation mode). Internal oscillator-resistors fluctuate by $\pm 30\%$ depending on products. Avoid frame frequency fluctuations as these affect video quality. To prevent these, use an external resistor.

1) External clock mode

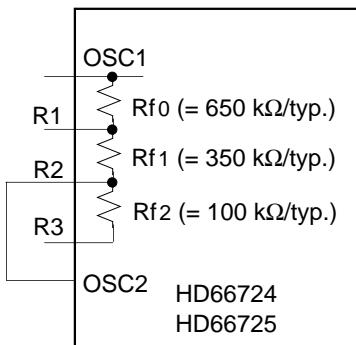

2) External resistor oscillation mode

The oscillator frequency can be adjusted by oscillator resistor (R_f). If R_f is increased or power supply voltage is decreased, the oscillator frequency decreases. For the relationship between R_f resistor value and oscillation frequency, see the Electric Characteristics Footnote section.

3) Internal resistor oscillation mode

Note that the internal resistors R_{f0} , R_{f1} , and R_{f2} fluctuate by $\pm 30\%$ depending on products.

- i) R1-OSC2 short-circuiting
 $R_f = R_{f0} = 650 \text{ k}\Omega$ (typ.)
- ii) R1-R2 short-circuiting, R3-OSC2 short-circuiting
 $R_f = R_{f0} + R_{f2} = 750 \text{ k}\Omega$ (typ.)
- iii) R2-OSC2 short-circuiting
 $R_f = R_{f0} + R_{f1} = 800 \text{ k}\Omega$ (typ.)
- iv) R3-OSC2 short-circuiting
 $R_f = R_{f0} + R_{f1} + R_{f2} = 900 \text{ k}\Omega$ (typ.)

Power Supply for Liquid Crystal Display Drive

When External Power Supply and Internal Operational Amplifiers are Used

To supply LCD drive voltage directly from the external power supply without using the internal booster, circuits should be connected as shown in figure 36. Here, contrast can be adjusted through the CT bits of the contrast control instruction.

The HD66724/HD66725 incorporate a voltage-follower operational amplifier for each V1 to V5 to reduce current flowing through the internal bleeder-resistors, which generate different levels of liquid-crystal drive voltages. Thus, potential differences between V_{LCD} and V1 and between V5 and GND must be 0.1 V or higher. Note that the OPOFF pin must be grounded when using the operational amplifiers. Place a capacitor of about 0.1 μ F to 0.5 μ F between each internal operational amplifier V1out to V5out output and GND and stabilize the output level of the operational amplifier.

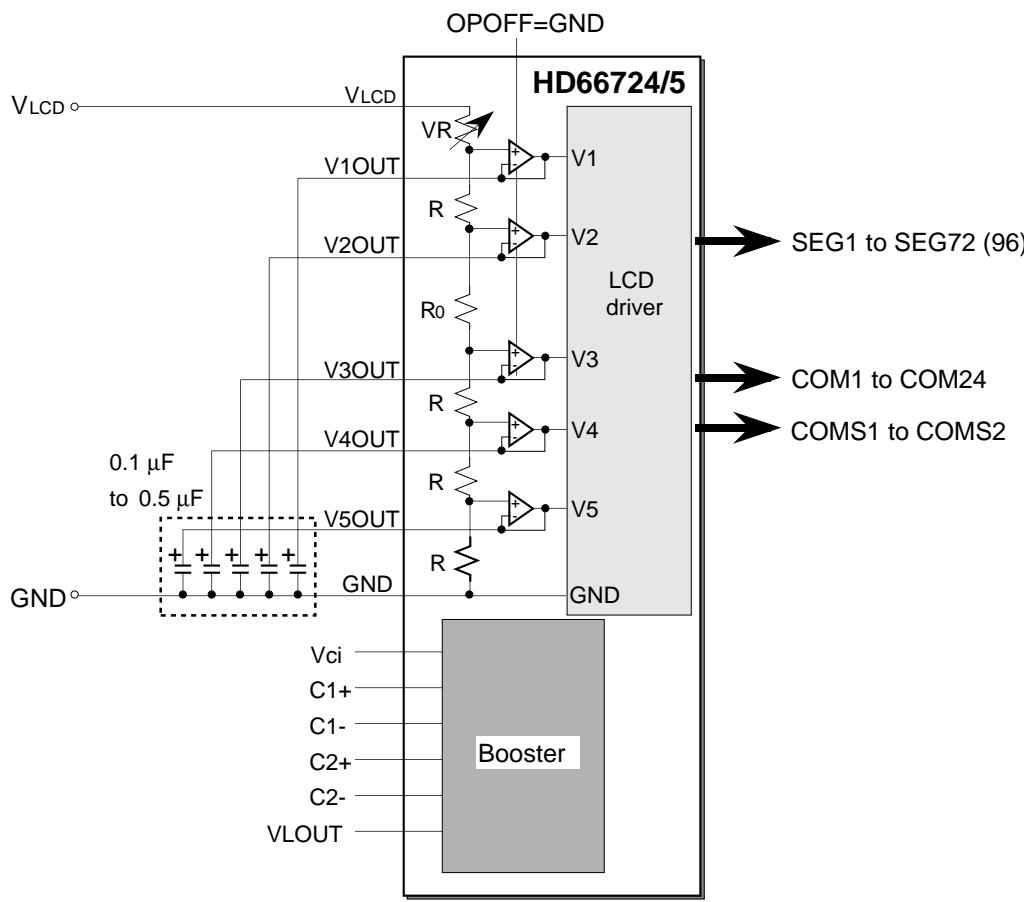

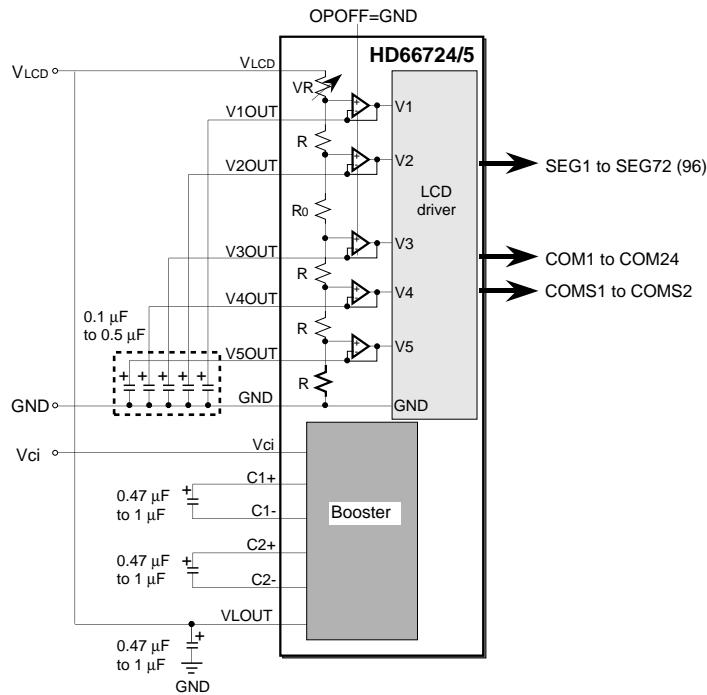

Figure 36 External Power Supply Circuit for LCD Drive Voltage Generation

When an Internal Booster and Internal Operational Amplifiers are Used

To supply LCD drive voltage using the internal booster, circuits should be connected as shown in figure 37. Here, contrast can be adjusted through the CT bits of the contrast control instruction. Temperature can be compensated either through the CT bits or by controlling the reference voltage for the booster (V_{ci} pin) using a thermistor.

Note that V_{ci} is both a reference voltage and power supply for the booster. The reference voltage must therefore be adjusted using an emitter-follower or a similar element so that sufficient current can be supplied. In this case, V_{ci} must be equal to or smaller than the V_{CC} level.

The HD66724/HD66725 incorporate a voltage-follower operational amplifier for each of V_1 to V_5 to reduce current flowing through the internal bleeder-resistors, which generate different liquid-crystal drive voltages. Thus, the potential differences between V_{LCD} and V_1 and between V_5 and GND must be 0.1 V or higher. Note that the $OPOFF$ pin must be grounded when using the operational amplifiers. Place a capacitor of about $0.1 \mu F$ to $0.5 \mu F$ between each internal operational amplifier V_{1out} to V_{5out} output and GND and stabilize the output level of the operational amplifier.

- Notes:
1. The reference voltage input (V_{ci}) must be adjusted so that the output voltage after boosting will not exceed the absolute maximum rating for the liquid-crystal power supply voltage (7 V). Particularly, V_{ci} must be 2.3 V or less for triple boosting.
 2. V_{ci} is both a reference voltage and power supply for the booster; connect it to V_{cc} directly or combine it with a transistor so that sufficient current can be obtained.
 3. V_{ci} must be smaller than V_{cc} .
 4. When using up to the double booster, no capacitors are required between C_{2+} and C_{2-} .
 5. Polarized capacitors must be connected correctly.
 6. Circuits for temperature compensation should be based on the sample circuit below.

Figure 37 Internal Booster Circuit for LCD Drive Voltage Generation

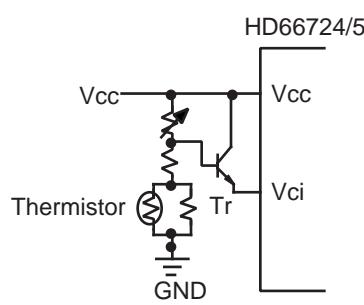

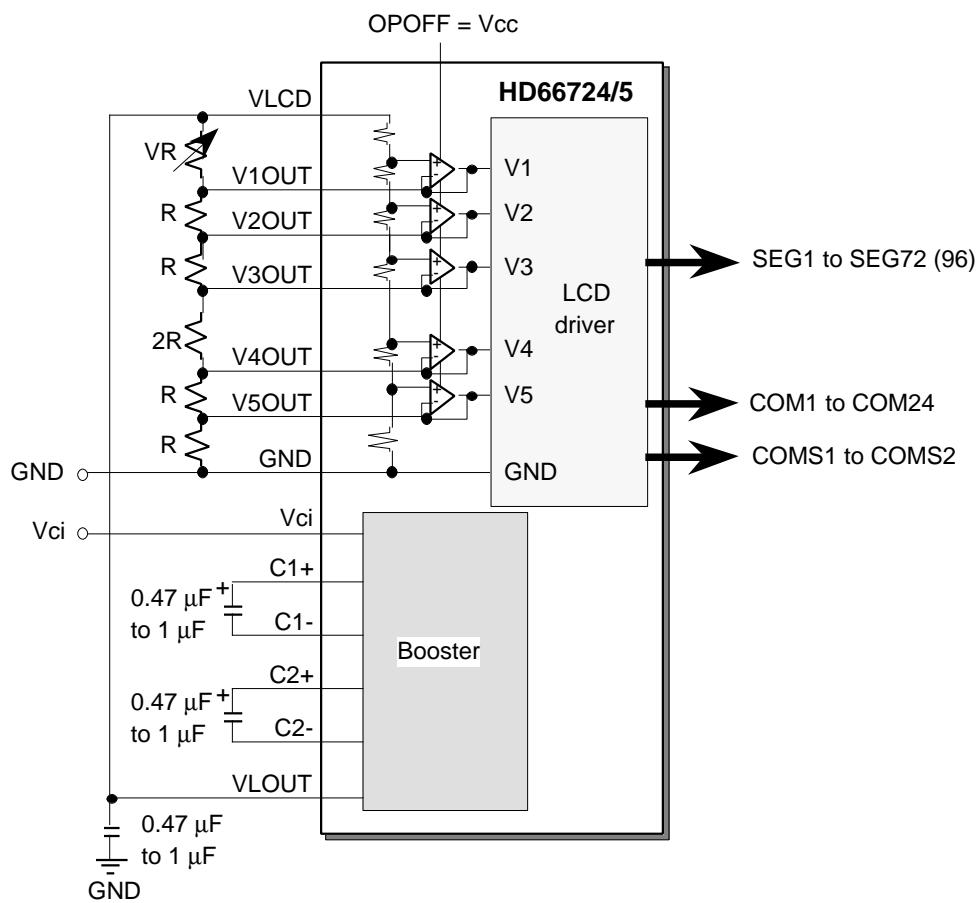

Figure 38 External Power Supply Circuit for LCD Drive Voltage Generation

When an Internal Booster and External Bleeder-Resistors are Used

When internal operational amplifiers cannot fully drive the LCD panel used, V1 to V5 voltages can be supplied through external bleeder-resistors (figure 39). Here, the OPOFF pin must be set to the V_{CC} level to turn off the internal operational amplifiers. Since the internal contrast adjuster is disabled, contrast must be adjusted externally. Connection of external bleeder-resistors can specify a given bias value from 1/2 to 1/6. Figure 39 shows connection for 1/6-bias drive voltage generation. Double- and triple-boosters can be used as they are.

- Notes:
1. Resistance of each external bleeder resistor should be $4.7\text{ k}\Omega$ to $25\text{ k}\Omega$.
 2. The bias current value for driving LCDs can be varied by adjusting the resistance ($2R$) between the V3OUT and V4OUT pins.
 3. The internal contrast adjuster is disabled; contrast must be adjusted either by controlling the external variable resistor between VLCD and V1 for the booster.
 4. Vci is both a reference voltage and power supply for the booster; connect it to V_{CC} directly or combine it with a transistor so that sufficient current can be obtained.
 5. Vci must be smaller than V_{CC} .

Figure 39 Circuit Using External Bleeder-Resistors

Contrast Adjuster

Contrast for an LCD can be adjusted by varying the liquid-crystal drive voltage (potential difference between V_{LCD} and V1) through the CT bits of the contrast control instruction (electron volume function). See figure 40 and table 37. The value of a variable resistor (VR) can be adjusted within a range from $0.1 \times R$ through $3.2 \times R$, where R is a reference resistance obtained by dividing the total resistance between V_{LCD} and V1.

The HD66724/HD66725 incorporate a voltage-follower operational amplifier for each of V1 to V5 to reduce current flowing through the internal bleeder-resistors, which generate different liquid-crystal drive voltages. Thus, CT4-0 bits must be adjusted so that the potential differences between V_{LCD} and V1 and between V5 and GND are 0.1 V or higher when liquid-crystal drives.

Liquid Crystal Display Drive Bias Selector Circuit

An optimum liquid crystal display bias value can be selected using BS2-0 bits, according to the liquid crystal drive duty ratio setting (NL2-0 bits). Liquid crystal display drive duty ratio and bias value can be displayed while switching software applications to match the LCD panel display status. The optimum bias value calculated using the following expression is an ideal value where the optimum contrast is obtained. Driving by using a lower value than the optimum bias value provides lower contrast and lower liquid crystal display voltage (potential difference between V1 and GND). When the liquid crystal display voltage is insufficient even if a triple booster is used or output voltage is lowered because the battery life has been reached, the display can be made easier to see by lowering the liquid crystal bias.

The liquid crystal display can be adjusted by using the contrast adjustment register (CT4-0 bits) and selecting the booster output level (BT1/0 bits).

$$\text{Optimum bias value for } 1/N \text{ duty ratio drive voltage} = \frac{1}{\sqrt{N + 1}}$$

Table 39 Optimum Drive Bias Values

LCD drive duty ratio (NL2-0 set value)	1/26 duty ratio (NL2-0 = 011)	1/18 duty ratio (NL2-0 = 010)	1/10 duty ratio (NL2-0 = 001)	1/2 duty ratio (NL2-0 = 000)
Optimum drive bias value (BS2-0 set value)	1/6 bias (BS2-0 = 001)	1/5 bias (BS2-0 = 011)	1/4 bias (BS2-0 = 101)	1/4 bias (BS2-0 = 101)

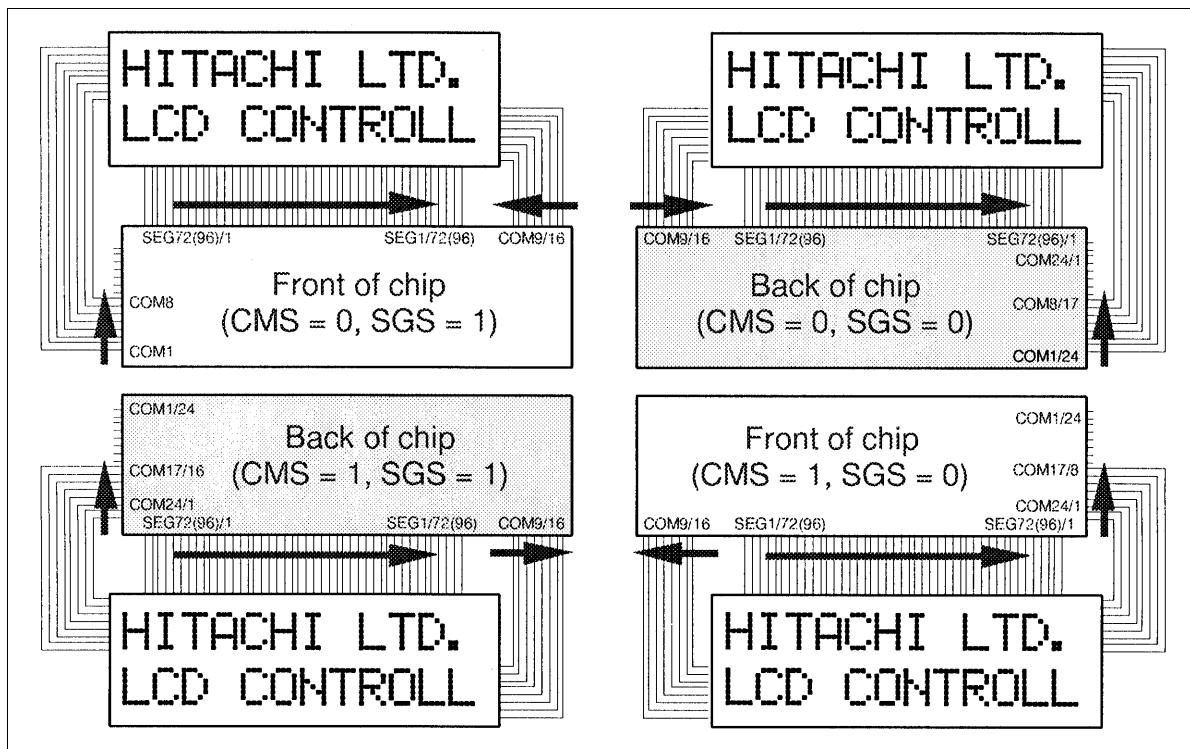

Figure 43 2-Line Display Pattern Wiring

CGROM Bank Switching Function

The HD66724/HD66725 incorporate two pages of CGROM. Switching the memory bank using the CGROM bank switching bit (ROM) can display a total of 432 font patterns. Multinational fonts, special symbols, and icons can be displayed. Note that the number of fonts simultaneously displayed is CGROM: 240 + CGRAM: 16 when memory bank 0 is selected, and CGROM: 192 + CGRAM: 64 when memory bank 1 is selected. Font displays for CGRAM (1) to (16) are used in common with memory bank 0 and memory bank 1.

Graphics Display Function

The HD66724/HD66725 have a character display mode (GR = 0) where CGRAM or CGROM is used to display font patterns, and a graphics display mode (GR = 1) where bit pattern data is set to CGRAM to display given patterns. In the character display mode, an LCD panel display can easily be provided by sending byte-per-character character codes to DDRAM, but any pattern not set to CGROM or CGRAM cannot be displayed. In the graphics display mode, all bit pattern data to be displayed must be sent although any pattern can be displayed. The HD66724/HD66725 support both of these modes which can easily be switched using the GR bit.

In the graphics display mode, kanji characters, special symbols, and graphic icons can be displayed. In the HD66724, up to a 72 x 26-dot display is allowed using CGRAM and SEGREGAM. Thus, for a 12 x 12-dot kanji font, up to a 2-line x 6-character kanji display is allowed. In the HD66725, up to a 96 x 26-dot display is allowed, and up to a 2-line x 8-character kanji display is allowed for a 12 x 12-dot kanji font.

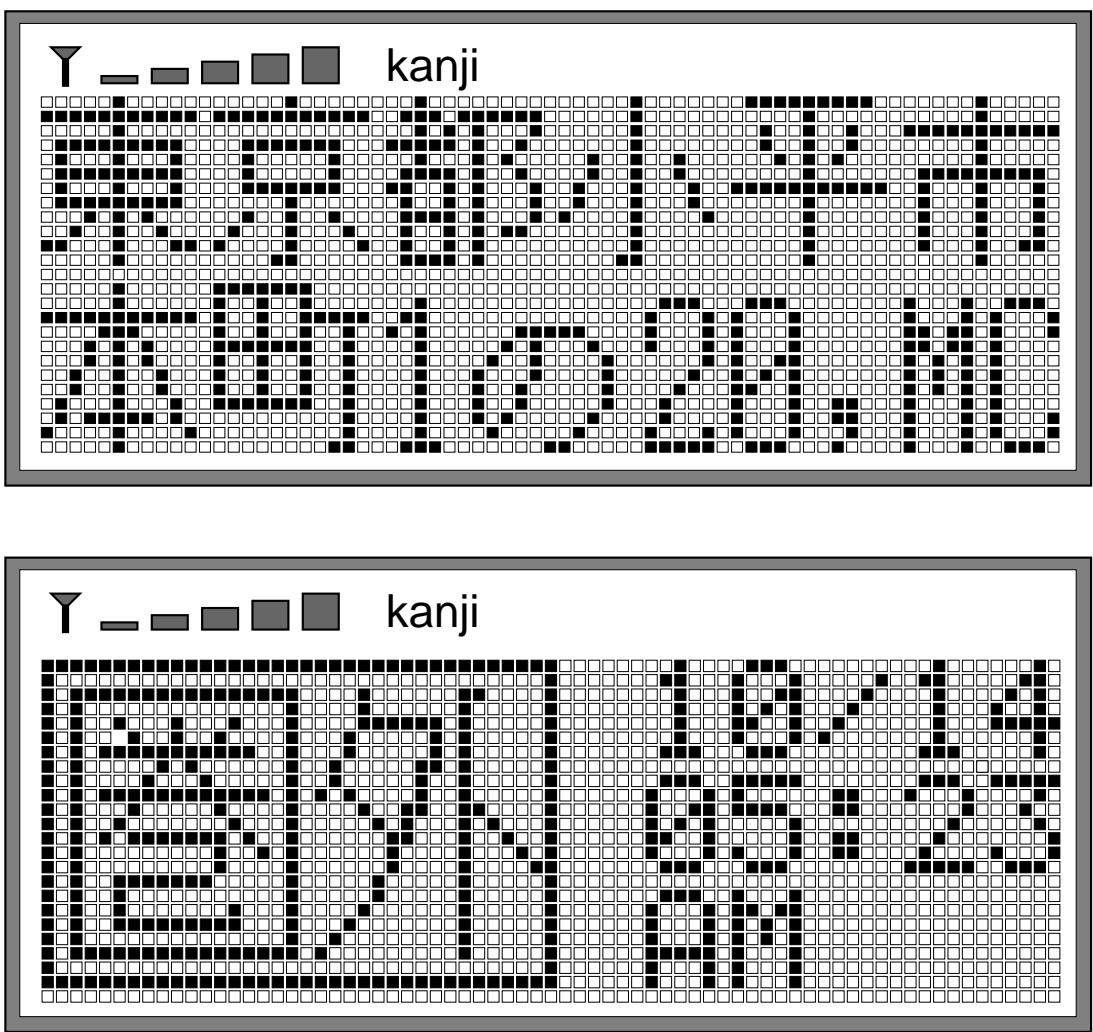

Figure 44 Kanji Display in Graphics Display Mode

Vertical Smooth Scroll

The HD66724/HD66725 can scroll vertically in units of raster-rows. In character display mode (GR = 0), this is achieved by writing character codes into a DDRAM area that is not being used for display. In other words, since DDRAM corresponds to a 5-line × 16-character display, two lines can be used to achieve continuous smooth vertical scroll even in a 3-line display. Here, after the fifth line is displayed, the first line is displayed again. In the graphics display mode (GR = 1), a 96 x 32-dot area is assigned as CGRAM. Thus a non-display area other than the 72 x 24-dot display area can be used to provide consecutive, smooth scroll display. Segment (mark) display is system-fixed and the scroll function cannot be used.

Specifically, this function is controlled by incrementing or decrementing the value in the display-start line bits (SL2 to SL0) and display-start raster-row bits (SN2/1/0) by 1. For example, to smoothly scroll up, first set line bits SN2 to SN0 to 000, and increment SL2 to SL0 by 1 from 000 to 111 to scroll seven raster-rows. Then increment line bits SN2 to SN0 to 001, and again increment SL2 to SL0 by 1 from 000 to 111. To start displaying and scrolling from the first raster-row of the second line, update the first line of DDRAM or CGRAM data as desired during its non-display period.

Figure 47 Setting Instructions for Vertical Smooth Scroll (Graphics Display Mode)

Horizontal Smooth Scroll

The HD66724/HD66725 perform the horizontal smooth scroll in 3-dot units. In the character display mode (GR = 0), an area of 16 characters x 5 lines is assigned as DDRAM. In the graphics display mode (GR = 1), a 96 x 32-dot area is assigned as CGRAM. These non-display areas are used to provide a horizontal smooth scroll display. When the HD66725 displays 16 characters or 96 dots, there are no non-display areas and horizontal scrolling cannot be done.

Display lines for horizontal scroll can be separately specified using the horizontal scroll bits (SE4-1), allowing a scroll of the whole display or specified lines. Horizontal scroll dots can be specified using the horizontal scroll dot bits (SQ2-0), allowing up to a 21-dot scroll at a time. For further scrolls, data in the DDRAM or CGRAM must be overwritten.

Double-Height Display

The HD66724/HD66725 can double the height of any desired line from the first to third lines. A line can be selected by the DL3 to DL1 bits as listed in table 41. All the standard font characters stored in the CGROM and CGRAM can be doubled in height, allowing easy recognition. Note that there should be no space between the lines for double-height display (figure 50).

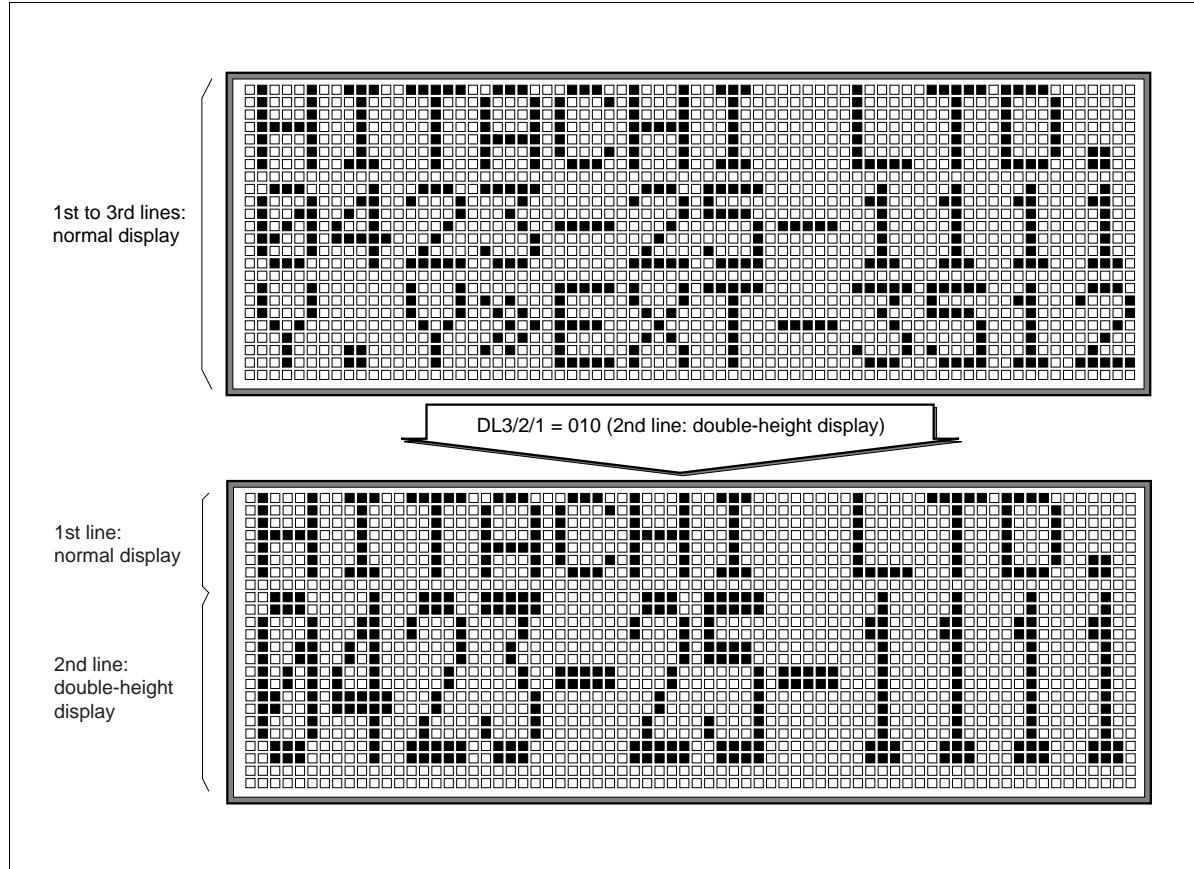

Figure 50 Double-Height Display

Blink Mark Display

The HD66724/HD66725 have a grayscale display and blink display based on 144 (192) individual segments (marks). Forty-eight (sixty-four) of these are for grayscale display and the remainder are for blink display.

These 48 (64) segments can also control a grayscale display, providing simple grayscale on specific pictograms or marks. For example, the battery no charge alarm uses this display. The above display uses a curtailed frame grayscale system, and flicker may result in quick-response liquid crystal materials. Tables 42 and 43 show the relationship between set data in SEGRAM and effective applied voltage during frame curtailing operation.

The remaining 96 (128) segments are responsible for normal blinking and double-speed blinking. Normal blinking (b & w) is achieved by repeatedly turning on each segment for 32 frames and turning it off for the next 32 frames. Double-speed blinking (b & w) is achieved by repeatedly turning on each segment for 16 frames and turning it off for the next 16 frames, that is, double the speed of normal blinking.

3. Double-speed blinking is achieved by repeatedly turning on the segment for 16 frames and turning it off for the next 16 frames.

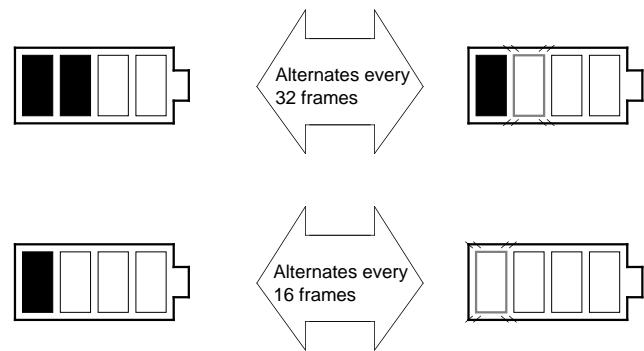

Figure 52 Blinking Control Segment Display

Line-Cursor Display

The HD66724/HD66725 can assign a cursor attribute to an entire line corresponding to the address counter value by setting the LC bit to 1. One of three line-cursor modes can be selected: a black-white inverting cursor ($B/W = 1$), an underline cursor ($C = 1$), and a blink cursor ($B = 1$). The cycle for a blink cursor is 32 frames. These line-cursors are suitable for highlighting an index and/or marker, or for indicating an item in a menu with a cursor or an underline.

Table 46 Address Counter Value and Line-Cursor

Address Counter Value (AC)	Selected Line for Line-Cursor
00H to 0FH	Entire 1st line (16 characters)
10H to 1FH	Entire 2nd line (16 characters)
20H to 2FH	Entire 3rd line (16 characters)
30H to 3FH	Entire 4th line (16 characters)
40H to 4FH	Entire 5th line (16 characters)

Partial-Display-On Function

The HD66724/HD66725 can program the liquid crystal display drive duty ratio setting (NL2-0 bits), liquid crystal display drive bias value selection (BS2-0 bits), boost output level selection (BT1/0 bit) and contrast adjustment (CT4-0 bits). In the three-line display mode (1/26 duty ratio), the HD66724/HD66725 can drive only one line in the center of the screen by combining these register functions and the centering display (CEN bit) function. This is called partial-display-on. Lowering the liquid crystal display drive duty ratio as required saves the liquid crystal display drive voltage, thus reducing internal current consumption. This is suitable for calendar or time display, which needs to be continuous in the system standby state with minimal current consumption. Here, the non-displayed lines are constantly driven by the deselection level voltage, thus turning off the LCD for the lines.

In general, lowering the liquid crystal display drive duty ratio decreases the optimum liquid crystal display drive voltage and liquid crystal display drive bias value.

Table 47 Partial-Display-On Function

Item	Normal 3-Line Display	Partially-On Display
Character display	1st to 3rd lines displayed	Only one line in the center of the screen
Segment display	Possible (144)	Possible (144)
Centering display	Not necessary (CEN = 0)	Possible (CEN = 1)
LCD drive duty ratio	1/26 (NL2/1/0 = 011)	1/10 (NL2/1/0 = 001) possible
LCD drive bias value (optimum)	1/6 (BS2-0 = 001)	1/4 (BS2-0 = 101)
LCD drive voltage	Adjustable using BT1/0 and CT4-0	Adjustable using BT1/0 and CT4-0
Frame frequency (fosc = 32 kHz)	77 Hz	80 kHz

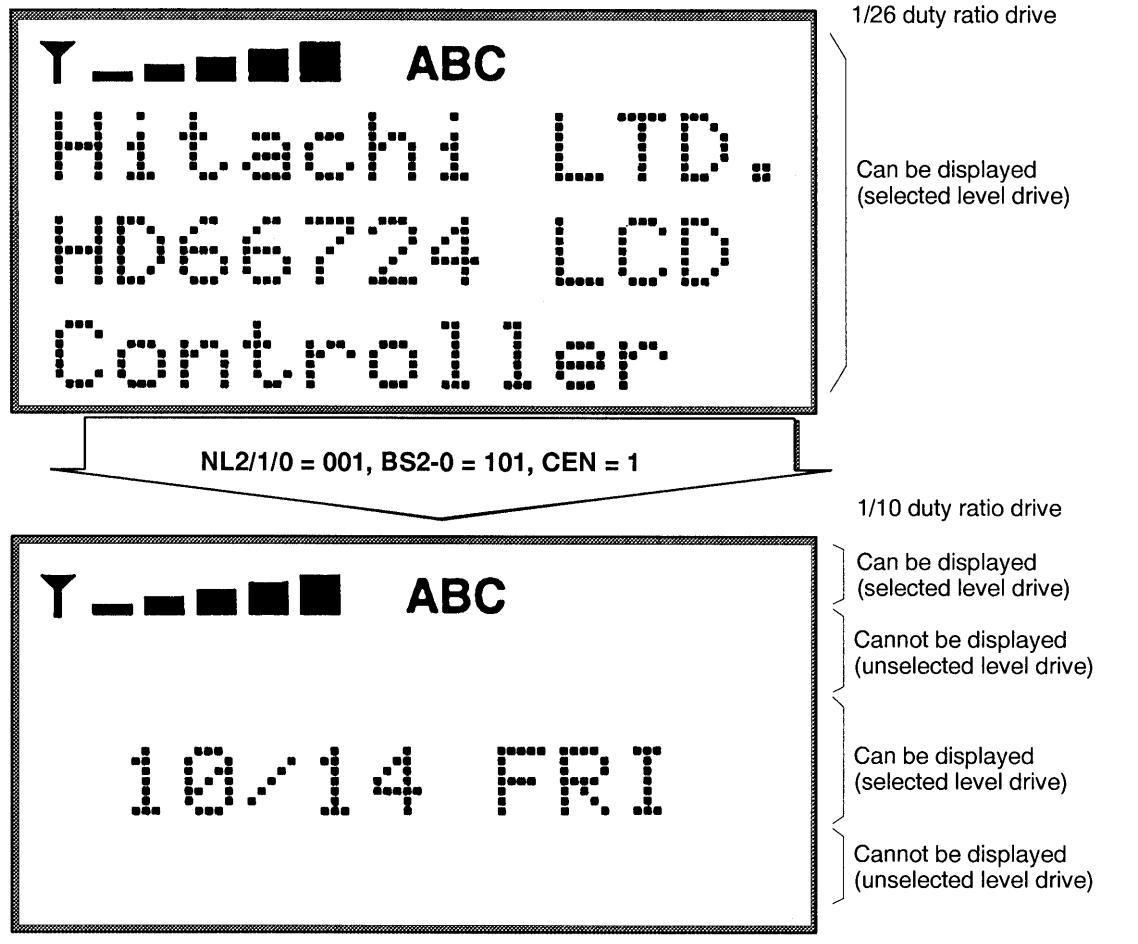

Figure 57 Partial-On Display (Date and Time Indicated)

Sleep Mode

Setting the sleep mode bit (SLP) to 1 puts the HD66724/HD66725 in the sleep mode, where the device stops all internal display operations except for key scan operations, thus reducing current consumption. Specifically, LCD drive is completely halted. Here, all the SEG (SEG1 to SEG72 (96)) and COM (COM1 to COM24, COMS1/2) pins output the GND level, resulting in no display. If the AMP bit is set to 0 in the sleep mode, the LCD drive power supply can be turned off, reducing the total current consumption of the LCD module.

The key scan circuit operates normally in the sleep mode, thus allowing normal key scan and key scan interrupt generation. For details, refer to the Key Scan Control section and Key Scan Interrupt (Wake-up Function) section.

Table 48 Comparison of Sleep Mode and Standby Mode

Function	Sleep Mode (SLP = 1)	Standby Mode (STB = 1)
Character display	Turned off	Turned off
Segment display	Turned off	Turned off
R-C oscillation	Operates normally	Halted
Key scan	Can operate normally	Halted but IRQ* can be generated

Standby Mode

Setting the standby mode bit (STB) to 1 puts the HD66724/HD66725 in the standby mode, where the device stops completely, halting all internal operations including the R-C oscillator, thus further reducing current consumption compared to that in the sleep mode. Specifically, character and segment displays, which are controlled by the multiplexing drive method, are completely halted. Here, all the SEG (SEG1 to SEG72 (96)) and COM (COM1 to COM24, COMS1/2) pins output the GND level, resulting in no display. If the AMP bit is set to 0 in the standby mode, the LCD drive power supply can be turned off.

During the standby mode, no instructions can be accepted other than those for the start-oscillator instruction and the key scan interrupt generation enable instruction. To cancel the standby mode, issue the start oscillator instruction to stabilize R-C oscillation before setting the STB bit to 0.

Although key scan is halted in the standby mode, the HD66724/HD66725 can detect eight key inputs connected with strobe signal KST0, thus generating key scan interrupt (IRQ*). This means, the system can be activated from a completely inactive state. For details, refer to the Key Scan Interrupt (Wake-Up Function) section.

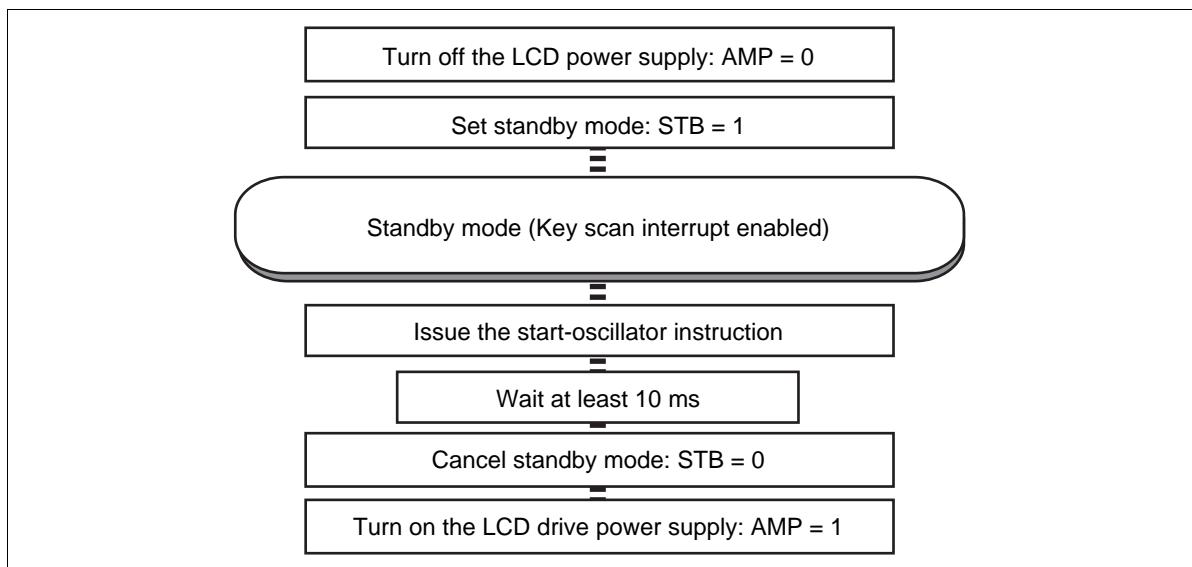

Figure 58 Procedure for Setting and Canceling Standby Mode

Absolute Maximum Ratings *

Item	Symbol	Unit	Value	Notes*
Power supply voltage (1)	V _{CC}	V	–0.3 to +7.0	1
Power supply voltage (2)	V _{LCD} – GND	V	–0.3 to +7.0	1, 2
Input voltage	V _t	V	–0.3 to V _{CC} + 0.3	1
Operating temperature	T _{OPR}	°C	–40 to +85	
Storage temperature	T _{STG}	°C	–55 to +110	4

Note: If the LSI is used above these absolute maximum ratings, it may become permanently damaged. Using the LSI within the following electrical characteristics limits is strongly recommended for normal operation. If these electrical characteristic conditions are also exceeded, the LSI will malfunction and cause poor reliability.

DC Characteristics ($V_{CC} = 1.8$ to 5.5 V, $T_a = -40$ to $+85^\circ\text{C}$ ³⁾

Item	Symbol	Min	Typ	Max	Unit	Test Condition	Notes

Reset Timing Characteristics ($V_{CC} = 1.8$ to 5.5 V)

Item	Symbol	Min	Typ	Max	Unit	Test Condition
Reset low-level width	t_{RES}	1	—	—	ms	Figure 68

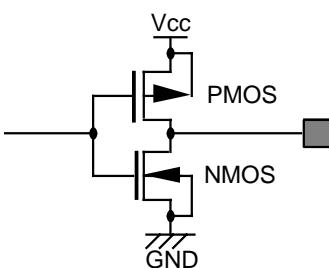

Electrical Characteristics Notes

1. All voltage values are referred to GND = 0 V. If the LSI is used above the absolute maximum ratings, it may become permanently damaged. Using the LSI within the given electrical characteristic is strongly recommended to ensure normal operation. If these electrical characteristics are exceeded, the LSI may malfunction or exhibit poor reliability.
2. VLCD > GND must be maintained.
3. For bare die products, specified at 85°C.
4. For bare die products, specified by the common die shipment specification.
5. The following three circuits are I/O pin configurations (figure 59).

Pins: RESET*, CS*, E/WR*/SCL, RS,
OSC1, OPOFF, IM2/1, IM0/ID, TEST

Pins: KST3 to KST0, IRQ*
PORT2 to PORT0, OSC2

Pin: RW/RD*/SDA

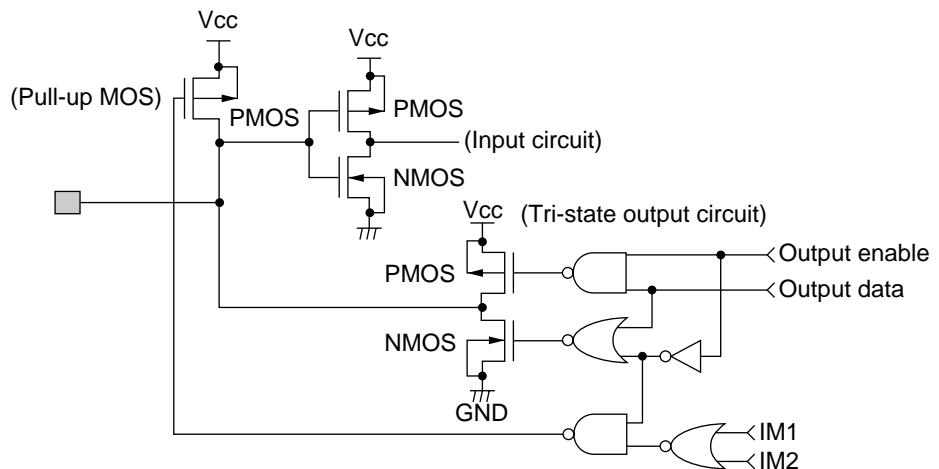

Figure 59 I/O Pin Configuration

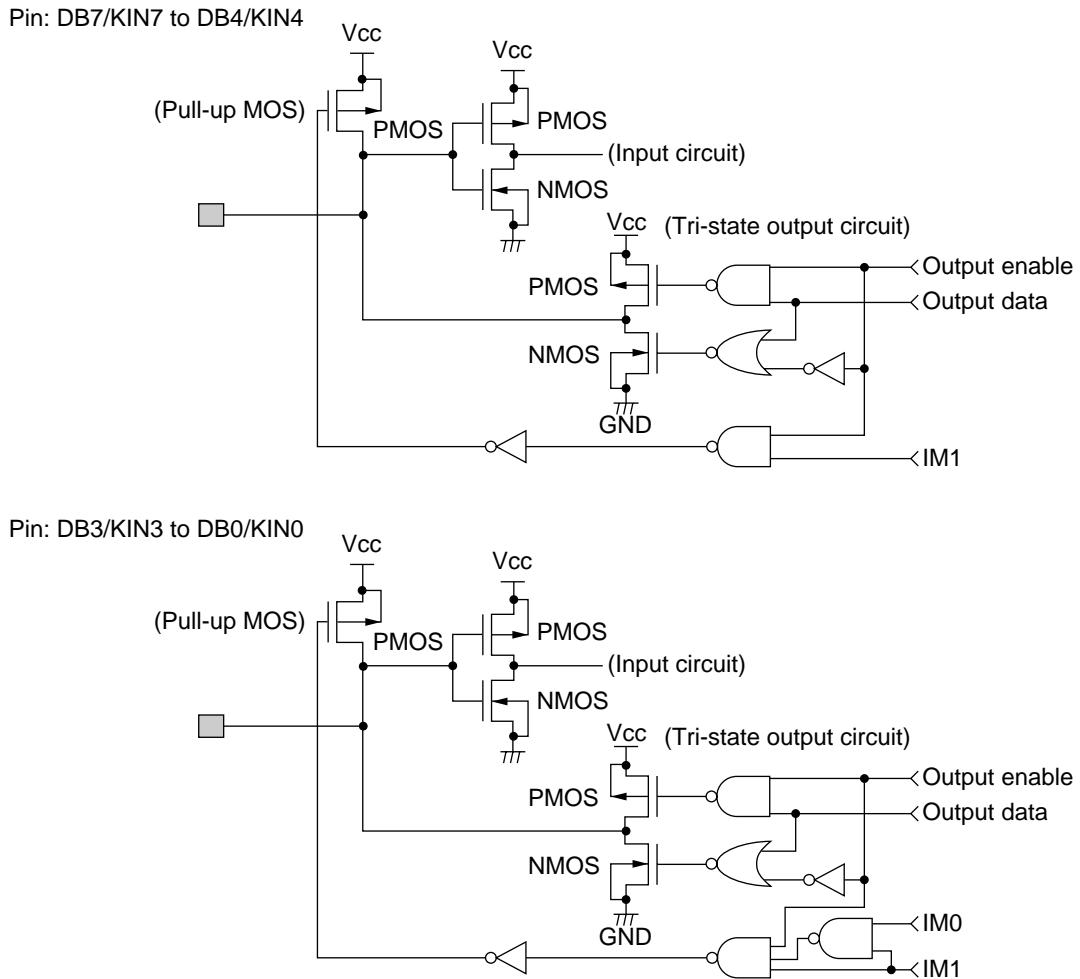

Figure 59 I/O Pin Configuration (cont)

6. The TEST pin must be grounded and the IM2/1, IM0/ID, and OPOFF pins must be grounded or connected to Vcc.
7. Corresponds to the high output for clock-synchronized serial interface.
8. Applies to the resistor value (RCOM) between power supply pins V1OUT, V2OUT, V5OUT, GND and common signal pins (COM1 to COM24, COMS1 and COMS2), and resistor value (RSEG) between power supply pins V1OUT, V3OUT, V4OUT, GND and segment signal pins (SEG1 to SEG72 (96)), when current Id is flown through all driver output pins.
9. This excludes the current flowing through pull-up MOSs and output drive MOSs.
10. This excludes the current flowing through the input/output units. The input level must be fixed high or low because through current increases if the CMOS input is left floating.
11. The following shows the relationship between the operation frequency (fosc) and current consumption (Icc) (figure 60).

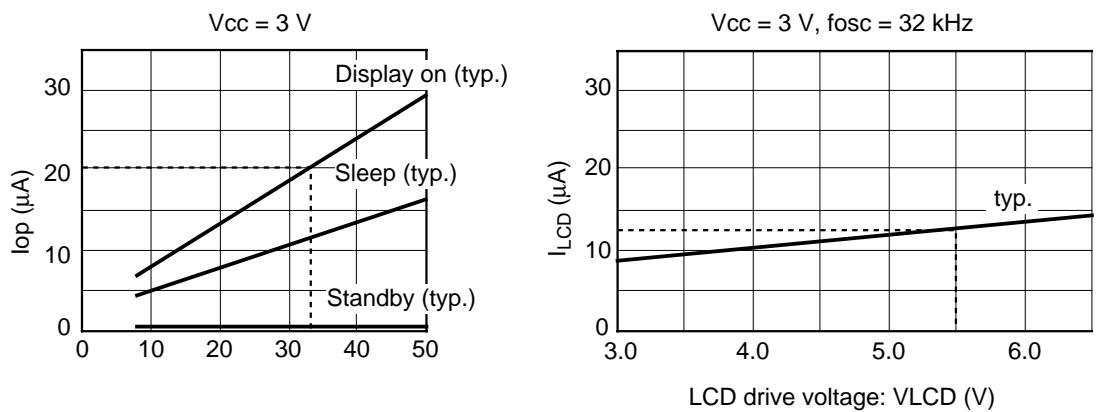

Figure 60 Relationship between the Operation Frequency and Current Consumption

12. Each COM and SEG output voltage is within ±0.15 V of the LCD voltage (V_{CC}, V₁, V₂, V₃, V₄, V₅) when there is no load.
13. Applies to the external clock input (figure 61).

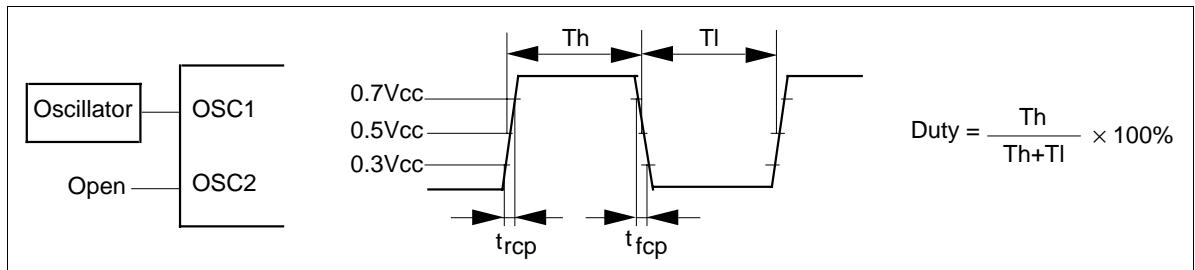

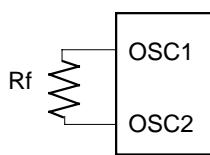

Figure 61 External Clock Supply

HD66724/HD66725

14. Applies to the internal oscillator operations using oscillation resistor Rf (figure 62).

Since the oscillation frequency varies depending on the OSC1 and OSC2 pin capacitance, the wiring length to these pins should be minimized.

External resistance (Rf)	CR oscillation frequency : fosc				
	Vcc = 1.8 V	Vcc = 2.2 V	Vcc = 3.0 V	Vcc = 4.0 V	Vcc = 5.0 V
390 kΩ	40 kHz	45 kHz	48 kHz	50 kHz	51 kHz
510 kΩ	33 kHz	36 kHz	38 kHz	40 kHz	41 kHz
560 kΩ	30 kHz	33 kHz	35 kHz	36 kHz	37 kHz
620 kΩ	28 kHz	30 kHz	32 kHz	33 kHz	33 kHz
680 kΩ	26 kHz	29 kHz	30 kHz	31 kHz	31 kHz
750 kΩ	24 kHz	27 kHz	28 kHz	29 kHz	29 kHz

Figure 62 Internal Oscillation

15. Booster characteristics test circuits are shown in figure 63.

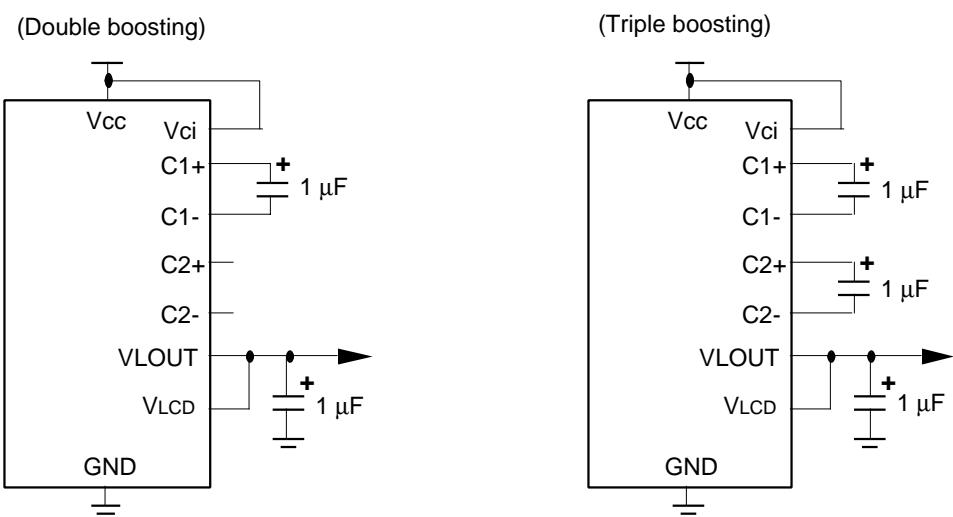

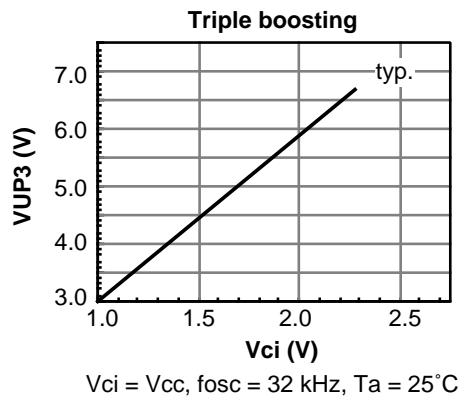

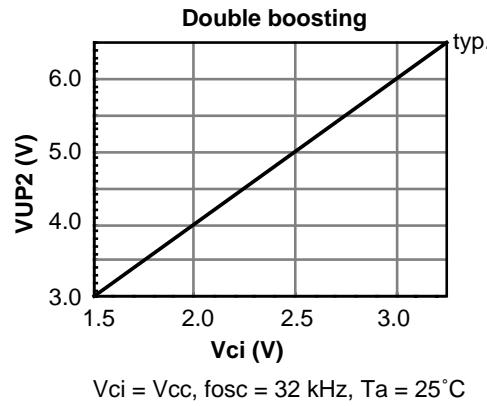

Figure 63 Booster

Referential data

VUP2 = VLCD – GND; VUP3 = VLCD – GND

(i) Relation between the obtained voltage and input voltage

(ii) Relation between the obtained voltage and temperature <T.B.D.>

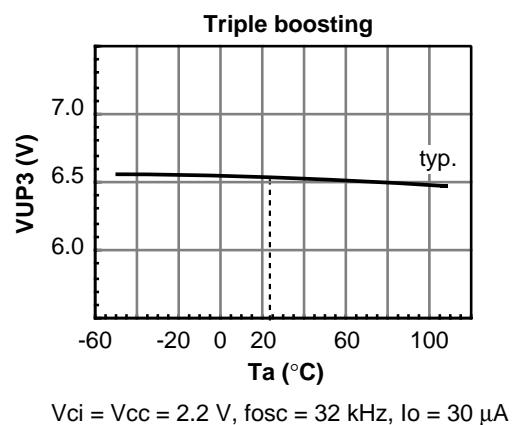

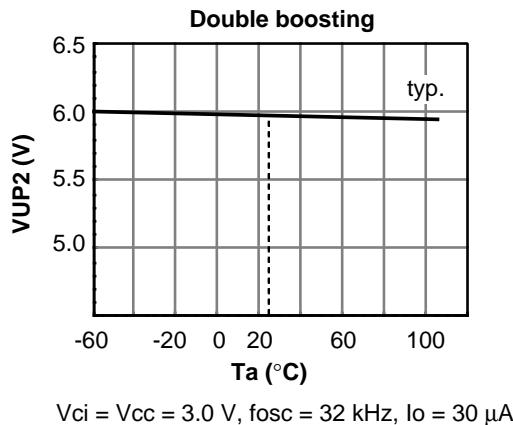

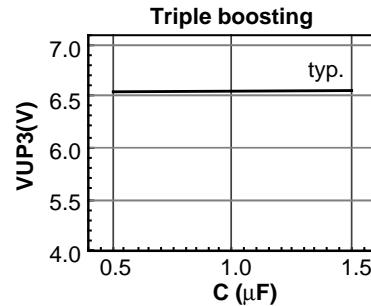

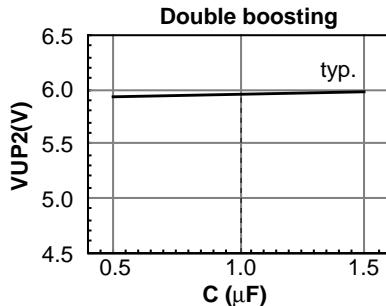

Figure 63 Booster (cont)

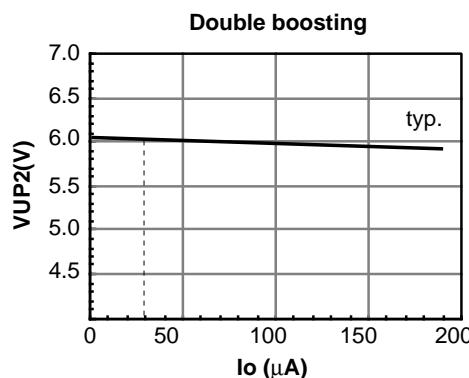

(iii) Relation between the obtained voltage and capacitance

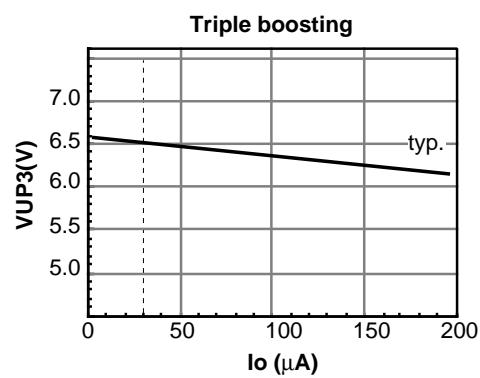

V_{ci} = V_{cc} = 3.0 V, fosc = 32 kHz, I_o = 30 μ A

V_{ci} = V_{cc} = 2.2 V, fosc = 32 kHz, I_o = 30 μ A

(iv) Relation between the obtained voltage and current <T.B.D.>

V_{ci} = V_{cc} = 3.0 V, fosc = 32 kHz, Ta = 25°C

V_{ci} = V_{cc} = 2.2 V, fosc = 32 kHz, Ta = 25°C

Cautions

1. Hitachi neither warrants nor grants licenses of any rights of Hitachi's or any third party's patent, copyright, trademark, or other intellectual property rights for information contained in this document. Hitachi bears no responsibility for problems that may arise with third party's rights, including intellectual property rights, in connection with use of the information contained in this document.
2. Products and product specifications may be subject to change without notice. Confirm that you have received the latest product standards or specifications before final design, purchase or use.
3. Hitachi makes every attempt to ensure that its products are of high quality and reliability. However, contact Hitachi's sales office before using the product in an application that demands especially high quality and reliability or where its failure or malfunction may directly threaten human life or cause risk of bodily injury, such as aerospace, aeronautics, nuclear power, combustion control, transportation, traffic, safety equipment or medical equipment for life support.
4. Design your application so that the product is used within the ranges guaranteed by Hitachi particularly for maximum rating, operating supply voltage range, heat radiation characteristics, installation conditions and other characteristics. Hitachi bears no responsibility for failure or damage when used beyond the guaranteed ranges. Even within the guaranteed ranges, consider normally foreseeable failure rates or failure modes in semiconductor devices and employ systemic measures such as fail-safes, so that the equipment incorporating Hitachi product does not cause bodily injury, fire or other consequential damage due to operation of the Hitachi product.
5. This product is not designed to be radiation resistant.
6. No one is permitted to reproduce or duplicate, in any form, the whole or part of this document without written approval from Hitachi.
7. Contact Hitachi's sales office for any questions regarding this document or Hitachi semiconductor products.
