512 K (65536 words × 8 bits) Pseudo-SRAM

Preliminary

Overview

The LC33864 series is composed of pseudo static RAM that operate on a single 5 V power supply and is organized as 65536 words × 8 bits. By using memory cells each composed of a single transistor and capacitor, together with peripheral CMOS circuitry, this series achieves ease of use with high density, high speed, and low power dissipation. Since the LC33864 series products provide refresh counter and timer on chip, this series can easily accomplish auto-refresh and self-refresh by means of $\overline{RFSH}$ input. The available packages are the 32-pin DIP with a width of 600 mil, and the 32-pin SOP with a width of 525 mil.

Notes: 3. All current values are measured at minimum cycle rate. Since current flows immoderately, if cycle time is longer than shown here, current value becomes smaller. A bypass capacitor of 0.01 µF or larger should be inserted between VCC and GND for each memory chip to suppress power supply noise (voltage drops) due to transient currents.

4. Dependent on output load. Maximum value is value during free state.

Refresh time (512 cycles, A0 to A8)	t_{REF}		8		8		8	ms	
Rise or fall times	t_T	3	50	3	50	3	50	ns	

Note: 5. To accomplish internal initialization, $\overline{CE}$ is fixed at V_{IH} for an interval of 100 µs when V_{CC} reaches the specified voltage after power is switched on. At least eight cycles must be executed following that period.

6. Measured at t_T = 5 ns.
7. When measuring input signal timing, V_{IH} (min) and V_{IL} (max) are reference levels.
8. Measured using an equivalent of 100 pF and two standard TTL loads.
9. t_{CHZ}, t_{OHZ} and t_{WHZ} are defined as the time until output enters the open circuit state and the output voltage level becomes immeasurable.
10. As with ordinary static RAM, write data is incorporated at the rise of $\overline{WE}$ input or $\overline{CE}$ input, whichever is earlier, and write data is therefore held during t_{DSW}, t_{DSC}, t_{DHW}, or t_{DHC}.
11. Because address input is incorporated at the fall of $\overline{CE}$, the address is maintained during t_{ASC} or t_{AHC}.
12. Auto-refresh and self-refresh are determined by $\overline{RFSH}$ pulse width when $\overline{CE}$ = V_{IH}, and are defined as auto-refresh when below t_{FAP} (max), or as self-refresh when above t_{FAS} (min). In order to activate $\overline{CE}$ after the completion of each refresh, t_{FCE} must be assured for auto-refresh, or t_{FRS} must be assured for self-refresh.
Similarly, if self-refresh timing ($\overline{RFSH}$ = Low) is used after power is switched on, t_{FRS} must be assured.
