

**GENERAL DESCRIPTION**

The SX8646 is an ultra low power, fully integrated 8-channel solution for capacitive touch-buttons and applications. Unlike many capacitive touch solutions, the SX8646 features dedicated capacitive sense inputs (that requires no external components) in addition to 8 general purpose I/O ports (GPIO). Each GPIO is typically configured as LED driver with independent PWM source for enhanced lighting control such as intensity and fading.

The SX8646 includes a capacitive 10 bit ADC analog interface with automatic compensation up to 100pF. The high resolution capacitive sensing supports a wide variety of touch pad sizes and shapes and allows capacitive buttons to be created using thick overlay materials (up to 5mm) for an extremely robust and ESD immune system design.

The SX8646 incorporates a versatile firmware that was specially designed to simplify capacitive touch solution design and offers reduced time-to-market. Integrated multi-time programmable memory provides the ultimate flexibility to modify key firmware parameters (gain, threshold, scan period, auto offset compensation... ) in the field without the need for new firmware development.

The SX8646 supports the 400 kHz I<sup>2</sup>C serial bus data protocol and includes a field programmable slave address. The tiny 4mm x 4mm footprint makes it an ideal solution for portable, battery powered applications where power and density are at a premium.

**KEY PRODUCT FEATURES**

- ◆ Complete eight Sensors Capacitive Touch Controller for Buttons
  - Pre-configured for eight Buttons
  - Eight LED Drivers with Individual Intensity, Fading Control and Autolight Mode
  - 256 steps PWM Linear and Logarithmic control
- ◆ High Resolution Capacitive Sensing
  - Up to 100pF of Offset Capacitance Compensation at Full Sensitivity
  - Capable of Sensing through Overlay Materials up to 5mm thick
- ◆ Extremely Low Power Optimized for Portable Application
  - 8uA (typ) in Sleep Mode
  - 80uA (typ) in Doze Mode (Scanning Period 195ms)
  - 175uA (typ) in Active Mode (Scanning Period 30ms)
- ◆ Programmable Scanning Period from 15ms to 1500ms
- ◆ Auto Offset Compensation
  - Eliminates False Triggers due to Environmental Factors (Temperature, Humidity)
  - Initiated on Power-up and Configurable Intervals
- ◆ Multi-Time In-Field Programmable Firmware Parameters for Ultimate Flexibility
  - On-chip user programmable memory for fast, self contained start-up
- ◆ "Smart" Wake-up Sequence for Easy Activation from Doze
- ◆ No External Components per Sensor Input
- ◆ Internal Clock Requires No External Components
- ◆ Differential Sensor Sampling for Reduced EMI
- ◆ 400 KHz Fast-Mode I<sup>2</sup>C Interface with Interrupt
- ◆ -40°C to +85°C Operation

**TYPICAL APPLICATION CIRCUIT**

**APPLICATIONS**

- ◆ Notebook/Netbook/Portable/Handheld computers
- ◆ Cell phones, PDAs
- ◆ Consumer Products, Instrumentation, Automotive
- ◆ Mechanical Button Replacement

GPP	General Purpose PWM
MTP	Multiple Time Programmable
NVM	Non Volatile Memory
PWM	Pulse Width Modulation
QSM	Quick Start Memory
SPM	Shadow Parameter Memory

## 2 ELECTRICAL CHARACTERISTICS

### 2.1 Absolute Maximum Ratings

Stresses above the values listed in “Absolute Maximum Ratings” may cause permanent damage to the device.

This is a stress rating only and functional operation of the device at these, or any other conditions beyond the “Recommended Operating Conditions”, is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Parameter	Symbol	Min.	Max.	Unit
Supply Voltage	VDD	-0.5	3.9	V
Input voltage (non-supply pins)	V <sub>IN</sub>	-0.5	3.9	V
Input current (non-supply pins)	I <sub>IN</sub>		10	mA
Operating Junction Temperature	T <sub>JCT</sub>		125	°C
Reflow temperature	T <sub>RE</sub>		260	°C
Storage temperature	T <sub>STOR</sub>	-50	150	°C
ESD HBM (Human Body model) <sup>(i)</sup>	ESD <sub>HBM</sub>	3		kV
Latchup <sup>(ii)</sup>	I <sub>LU</sub>	± 100		mA

(ii) Tested to JEDEC standard JESD78

### 2.2 Recommended Operating Conditions

Parameter	Symbol	Min.	Max.	Unit
Supply Voltage	VDD	2.7V	3.6	V
Supply Voltage Drop <sup>(iii, iv, v)</sup>	VDD <sub>drop</sub>		100	mV
Supply Voltage for NVM programming	VDD	3.0V	3.6	V
Ambient Temperature Range	T <sub>A</sub>	-40	85	°C

Table 3 Recommended Operating Conditions

(iii) Performance for 2.6V < VDD < 2.7V might be degraded.

(iv) Operation is not guaranteed below 2.6V. Should VDD briefly drop below this minimum value, then the SX8646 may require;

- a hardware reset issued by the host using the RESETB pin
- a software reset issued by the host using the I2C interface

(v) In the event the host processor is reset or undergoes a power OFF/ON cycle, it is recommended that the host also resets the SX8646 and assures that parameters are re-written into the SPM (should these differ to the parameters held in NVM).

### 3 FUNCTIONAL DESCRIPTION

#### 3.1 Quickstart Application

The SX8646 is preconfigured (Quickstart Application) for an application with eight buttons and eight LED drivers using logarithmic PWM fading.

Implementing a schematic based on Figure 6 will be immediately operational after powering without programming the SX8646 (even without host).

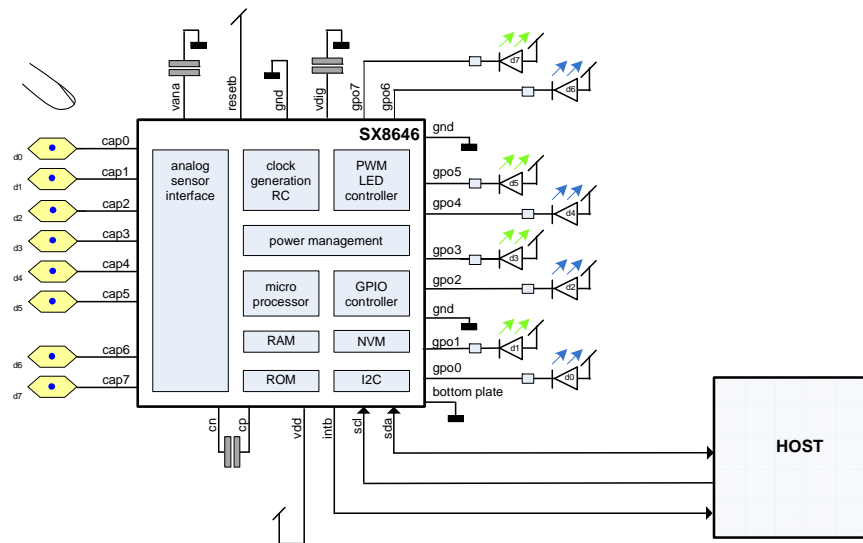

Figure 6 Quickstart Application

Touching the sensor on the CAP0 pin will enable automatically the LED connected to GPIO0. When the CAP0 sensor is released the LED on GPIO0 will slowly fade-out using smooth logarithmic fading.

All other sensors (CAP1 to CAP7) have their own LED associated on a GPIO pin showing a touch or a release.

The sensor detection and the LED fading described above are operational without any host interaction.

This is made possible using the SX8646 Autolight feature described in the following sections.

#### 3.2 Introduction

##### 3.2.1 General

The SX8646 is intended to be used in applications which require capacitive sensors covered by isolating overlay material. A finger approaching the capacitive sensors will change the charge that can be loaded on the sensors. The SX8646 measures the change of charge and converts that into digital values (ticks). The larger the charge on the sensors, the larger the number of ticks will be. The charge to ticks conversion is done by the SX8646 Analog Sensor Interface (ASI).

The ticks are further processed by the SX8646 and converted in a high level, easy to use information for the user's host.

The information between SX8646 and the user's host is passed through the I2C interface with an additional interrupt signal indicating that the SX8646 has new information. For buttons this information is simply touched or released.

### 3.2.2 GPIOs

A second path of feedback to the user is using General Purpose Input Output (GPIO) pins. The SX8646 offers eight individual configurable GPIO pins. The GPIO can e.g. be set as a LED driver which slowly fade-in when a finger touches a button and slowly fade-out when the button is released. Fading intensity variations can be logarithmic or linear. Interval speed and initial and final light intensity can be selected by the user. The fading is done using a 256 steps PWM. The SX8646 has eight individual PWM generators, one for each GPIO pin.

The LED fading can be initiated automatically by the SX8646 by setting the SX8646 Autolight feature. A simple touch on a sensor and the corresponding LED will fade-in without any host interaction over the I2C.

In case the Autolight feature is disabled then the host will decide to start a LED fading-in period, simply by setting the GPO pin to 'high' using one I2C command. The SX8646 will then slowly fade-in the LED using the PWM autonomously.

In case the host needs to have full control of the LED intensity then the host can set the GPIO in GPP mode. The host is then able to set the PWM pulse width freely at the expense of an increased I2C occupation.

The GPIOs can be set further in the digital standard Input mode (GPI).

### 3.2.3 Parameters

The SX8646 has many low level built-in, fixed algorithms and procedures. To allow a lot of freedom for the user and adapt the SX8646 for different applications these algorithms and procedures can be configured with a large set of parameters which will be described in the following sections. Examples of parameters are which sensors are buttons, which GPIO is used for outputs or LEDs and which GPIO is mapped to which button.

Sensitivity and detection thresholds of the sensors are part of these parameters. Assuming that overlay material and sensors areas are identical then the sensitivities and thresholds will be the same for each sensor. In case sensors are not of the same size then sensitivities or thresholds might be chosen individually per sensor.

So a smaller size sensor can have a larger sensitivity while a big size sensor may have the lower sensitivity.

### 3.2.4 Configuration

During a development phase the parameters can be determined and fine tuned by the users and downloaded over the I2C in a dynamic way. The parameter set can be downloaded over the I2C by the host each time the SX8646 boots up. This allows a flexible way of setting the parameters at the expense of I2C occupation.

In case the parameters are frozen they can be programmed in Multiple Time Programmable (MTP) Non Volatile Memory (NVM) on the SX8646. The programming needs to be done once (over the I2C). The SX8646 will then boot up from the NVM and additional parameters from the host are not required anymore.

In case the host desires to overwrite the boot-up NVM parameters (partly or even complete) this can be done by additional I2C communications.

### 3.3 Scan Period

The basic operation Scan period of the SX8646 sensing interface can be split into three periods over time. In the first period (Sensing) the SX8646 is sensing all enabled CAP inputs, from CAP0 towards CAP7. In the second period (Processing) the SX8646 processes the sensor data, verifies and updates the GPIO and I2C status registers. In the third period (Timer) the SX8646 is set in a low power mode and waits until a new cycle starts.

Figure 7 shows the different SX8646 periods over time.

*Figure 7 Scan Period*

The scan period determines the minimum reaction time of the SX8646. The scan period can be configured by the host from 15ms to values larger than a second. The reaction time is defined as the interval between a touch on the sensor and the moment that the SX8646 generates the interrupt on the INTB pin. The shorter the scan period the faster the reaction time will be. Very low power consumption can be obtained by setting very long scan periods with the expense of having longer reaction times.

**Important:** All external events like GPIO, I2C and INTB are updated in the processing period, so once every scan period. If e.g. a GPI would change state directly after the processing period then this will be reported with a delay of one scan period later in time.

### 3.4 Operation modes

The SX8646 has 3 operation modes. The main difference is found in the reaction time (corresponding to the scan period) and power consumption.

Active mode offers fast scan periods. The typical reaction time is 30ms. All enabled sensors are scanned and information data is processed within this interval.

Doze mode increases the scan period time which increases the reaction time to 195ms typical and at the same time reduces the operating current.

Sleep mode turns the SX8646 OFF, except for the I2C and GPI peripheral, minimizing operating current while maintaining the power supplies. In Sleep mode the SX8646 does not do any sensor scanning.

The user can specify other scan periods for the Active and Doze mode and decide for other compromises between reaction time and power consumption.

In most applications the reaction time needs to be fast when fingers are present, but can be slow when no person uses the application. In case the SX8646 is not used for a specific time it can go from Active mode into Doze mode and power will be saved. This time-out is determined by the Passive Timer which can be configured by the user or turned OFF if not required.

To leave Doze mode and enter Active mode this can be done by a simple touch on any button.

For some applications a single button touch might cause undesired waking up and Active mode would be entered too often.

The SX8646 offers therefore a smart wake-up sequence feature in which the user needs to touch and release a correct sequence of buttons before Active mode will be entered. This is explained in more detail in the Wake-Up Sequence section.

The host can decide to force the operating mode by issuing commands over the I2C (using register CompOpMode) and take fully control of the SX8646.

The diagram in Figure 8 shows the available operation modes and the possible transitions.

Figure 8 Operation modes

### 3.5 Sensors on the PCB

The capacitive sensors are relatively simple copper areas on the PCB connected to the eight SX8646 capacitive sensor input pins (CAP0...CAP7). The sensors are covered by isolating overlay material (typically 1mm...3mm). The area of a sensor is typically one square centimeter which corresponds about to the area of a finger touching the overlay material.

The capacitive sensors can be setup as ON/OFF buttons (see example Figure 9).

Figure 9 PCB top layer of four sensors for buttons (surrounded by a ground plane)

### 3.6 Button Information

#### 3.6.1 Button Information

The buttons have two simple states (see Figure 10): ON (touched by finger) and OFF (released and no finger press).

Figure 10 Buttons

A finger is detected as soon as the number of ticks from the ASI reaches a user-defined threshold plus a hysteresis.

A release is detected if the ticks from the ASI go below the threshold minus a hysteresis. The hysteresis around the threshold avoids rapid touch and release signaling during transients.

### 3.7 Analog Sensing Interface

The Analog Sensing Interface (ASI) converts the charge on the sensors into ticks which will be further digitally processed. The basic principle of the ASI will be explained in this section.

The ASI consists of a multiplexer selecting the sensor, analog switches, a reference voltage, an ADC sigma delta converter, an offset compensation DAC and an external integration capacitor (see Figure 11).

Figure 11 Analog Sensor Interface

To get the ticks representing the charge on a specific sensor the ASI will execute several steps.

The charge on a sensor cap (e.g. CAP0) will be accumulated multiple times on the external integration capacitor, C<sub>int</sub>.

This results in an increasing voltage on C<sub>int</sub> proportional to the capacitance on CAP0.

At this stage the offset compensation DAC is enabled. The compensation DAC generates a voltage proportional to an estimation of the external capacitance. The estimation is obtained by the offset compensation procedure executed e.g. at power-up.

The difference between the DAC output and the charge on C<sub>int</sub> is the desired signal. In the ideal case the difference of charge will be converted to zero ticks if no finger is present and the number of ticks becomes high in case a finger is present.

The difference of charge on C<sub>int</sub> and the DAC output will be transferred to the ADC (Sigma Delta Integrator).

After the charge transfer to the ADC the steps above will be repeated.

The larger the number the cycles are repeated the larger the signal out of the ADC with improved SNR. The sensitivity is therefore directly related to the number of cycles.

The SX8646 allows setting the sensitivity for each sensor individually in applications which have a variety of sensors sizes or different overlays or for fine-tuning performances. The optimal sensitivity is depending heavily on the final application. If the sensitivity is too low the ticks will not pass the thresholds and it is not possible to detect fingers. In case the sensitivity is set too large a finger hovering above the sensors will already be detected before the finger really touches the overlay resulting in false detections.

Once the ASI has finished the first sensor, the ticks are stored and the ASI will start measuring the next sensor until all (enabled) sensors pins have been treated.

In case some sensors are disabled then these result in lower power consumption simply because the ASI is active for a shorter period and the following processing period will be shorter.

The ticks from the ASI will then be handled by the digital processing.

### 3.8 Offset Compensation

The capacitance at the CAP pins is determined by an intrinsic capacitance of the integrated circuit, the PCB traces, ground coupling and the sensor planes. This capacitance is relatively large and might become easily some tens of pF. This parasitic capacitance will vary only slowly over time due to environmental changes.

A finger touch is in the order of one pF. If the finger approaches the sensor this occurs typically fast.

The ASI has the difficult task to detect and distinguish a small, fast changing capacitance, from a large, slow varying capacitance. This would require a very precise, high resolution ADC and complicated, power consuming, digital processing.

The SX8646 features a 16 bit DAC which compensates for the large, slow varying capacitance already in front of the ADC. In other words the ADC converts only the desired small signal. In the ideal world the ADC will put out zero ticks even if the external capacitance is as high as 100pF.

At each power-up of the SX8646 the Digital Compensation Values (DCV) are estimated by the digital processing algorithms. The algorithm will adjust the compensation values such that zero ticks will be generated by the ADC.

Once the correct compensation values are found these will be stored and used to compensate each CAP pin.

If the SX8646 is shut down the compensation values will be lost. At a next power-up the procedure starts all over again. This assures that the SX8646 will operate under any condition. Powering up at e.g. different temperatures will not change the performance of the SX8646 and the host does not have to do anything special.

The DCVs do not need to be updated if the external conditions remain stable.

However if e.g. temperature changes this will influence the external capacitance. The ADC ticks will drift then slowly around zero values basically because of the mismatch of the compensation circuitry and the external capacitance.

In case the average value of the ticks become higher than the positive noise threshold (configurable by user) or lower than the negative threshold (configurable by user) then the SX8646 will initiate a compensation procedure and find a new set of DCVs.

Compensation procedures can as well be initiated by the SX8646 on periodic intervals. Even if the ticks remain within the positive and negative noise thresholds the compensation procedure will then estimate new sets of DCVs.

Finally the host can initiate a compensation procedure by using the I2C interface (in Active or Doze mode). This is e.g. required after the host changed the sensitivity of sensors.

### 3.9 Processing

The first processing step of the raw ticks, coming out of the ASI, is low pass filtering to obtain an estimation of the average capacitance: tick-ave (see Figure 12). This slowly varying average is important in the detection of slowly changing environmental changes.

Figure 12 Processing

The difference of the tick average and the raw ticks, tick-diff, is a good estimation of rapid changing input capacitances.

The tick-diff, tick-ave and the configuration parameters in the SPM are then processed and determines the sensor information, I2C registers status and PWM control.

### 3.10 Configuration

Figure 13 shows the building blocks used for configuring the SX8646.

Figure 13 Configuration

The default configuration parameters of the SX8646 are stored in the Quick Start Memory (QSM). This configuration data is setup to a very common application for the SX8646 with eight buttons. Without any programming or host interaction the SX8646 will startup in the Quick Start Application.

The QSM settings are fixed and can not be changed by the user.

In case the application needs different settings than the QSM settings then the SX8646 can be setup and/or programmed over the I2C interface.

The configuration parameters of the SX8646 can be stored in the Multiple Time Programmable (MTP) Non Volatile Memory (NVM). The NVM contains all those parameters that are defined and stable for the application. Examples are the number of sensors enabled, sensitivity, active and Doze scan period. The details of these parameters are described in the next chapters.

At power up the SX8646 checks if the NVM contains valid data. In that case the configuration parameter source becomes the NVM. If the NVM is empty or non-valid then the configuration source becomes the QSM. In the next step the SX8646 copies the configuration parameter source (QSM or NVM) into the Shadow Parameter Memory (SPM). The SX8646 is operational and uses the configuration parameters of the SPM.

During power down or reset event the SPM loses all content. It will automatically be reloaded (from QSM or NVM) following power up or at the end of the reset event.

The host will interface with the SX8646 through the I2C bus.

The I2C of the SX8646 consists of 16 registers. Some of these I2C registers are used to read the status and information of the button. Other I2C registers allow the host to take control of the SX8646. The host can e.g. decide to change the operation mode from Active mode to Doze mode or go into Sleep (according to Figure 8).

Two additional modes allow the host to have an access to the SPM or indirect access to the NVM.

These modes are required during development, can be used in real time or in-field programming.

Figure 14 shows the Host SPM mode. In this mode the host can decide to overwrite the SPM. This is useful during the development phases of the application where the configuration parameters are not yet fully defined and as well during the operation of the application if some parameters need to be changed dynamically.

*Figure 14 Host SPM mode*

The content of the SPM remains valid as long as the SX8646 is powered and no reset is performed. After a power down or reset the host needs to re-write the SPM if relevant for the application.

Figure 15 shows the Host NVM mode. In this mode the host will be able to write the NVM.

Figure 15 Host NVM mode

The writing of the host towards the NVM is not done directly but done in 2 steps (Figure 15).

In the first step the host writes to the SPM (as in Figure 14). In the second step the host signals the SX8646 to copy the SPM content into the NVM.

Initially the NVM memory is empty and it is required to determine a valid parameter set for the application. This can be done during the development phase using dedicated evaluation hardware representing the final application. This development phase uses probably initially the host SPM mode which allows faster iterations.

Once the parameter set is determined this can be written to the NVM over the I2C using the 2 steps approach by the host or a dedicated programmer for large volumes production (as described in the paragraphs 6.6 and 6.7).

### 3.11 Power Management

The SX8646 uses on-chip voltage regulators which are controlled by the on-chip microprocessor. The regulators need to be stabilized with an external capacitor between VANA and ground and between VDIG and ground (see Table 5). Both regulators are designed to only drive the SX8646 internal circuitry and must not be loaded externally.

### 3.12 Clock Circuitry

The SX8646 has its own internal clock generation circuitry that does not require any external components. The clock circuitry is optimized for low power operation and is controlled by the on-chip microprocessor. The typical operating frequency of the oscillating core is 16.7MHz from which all other lower frequencies are derived.

### 3.13 I2C interface

The I2C interface allows the communication between the host and the SX8646.

The I2C slave implemented on the SX8646 is compliant with the standard (100kb/s) and fast mode (400kb/s). The default SX8646 I2C address equals 0b010 1011.

A different I2C address can be programmed by the user in the NVM.

### 3.14 Reset

The reset can be performed by 3 sources:

- power up,
- RESETB pin,
- software reset.

#### 3.14.1 Power up

During power up the INTB is kept low. Once the power up sequence is terminated the INTB is released autonomously. The SX8646 is then ready for operation.

Figure 16 Power Up vs. INTB

During the power on period the SX8646 stabilizes the internal regulators, RC clocks and the firmware initializes all registers.

During the power up the SX8646 is not accessible and I2C communications are forbidden. As soon as the INTB rises the SX8646 will be ready for I2C communication.

#### 3.14.2 RESETB

When RESETB is driven low the SX8646 will reset and start the power up sequence as soon as RESETB is driven high or pulled high.

In case the user does not require a hardware reset control pin then the RESETB pin can be connected to VDD.

Figure 17 Hardware Reset

**3.14.3 Software Reset**

To perform a software reset the host needs to write 0xDE followed by 0x00 at the SoftReset register at address 0xB1.

*Figure 18 Software Reset*

### 3.15 Interrupt

#### 3.15.1 Power up

During power up the INTB is kept low. Once the power up sequence is terminated the INTB is released autonomously. The SX8646 is then ready for operation.

Figure 19 Power Up vs. INTB

During the power on period the SX8646 stabilizes the internal regulators, RC clocks and the firmware initializes all registers.

During the power up the SX8646 is not accessible and I2C communications are forbidden. As soon as the INTB rises the SX8646 will be ready for I2C communication.

#### 3.15.2 Assertion

INTB is updated in Active or Doze mode once every scan period.

The INTB will be asserted: at the following events:

- if a Button event occurred (touch or release if enabled). I2C register CapStatLsb show the detailed status of the Buttons,
- if a GPI edge occurred (rising or falling if enabled). I2C register GpiStat shows the detailed status of the GPI pins,
- when actually entering Active or Doze mode either through automatic wakeup or via host request (may be delayed by 1 scan period). I2C register CompOpmode shows the current operation mode,
- once compensation procedure is completed either through automatic trigger or via host request (may be delayed by 1 scan period),
- once SPM write is effective (may be delayed by 1 scan period),
- once NVM burn procedure is completed (may be delayed by 1 scan period),
- during reset (power up, hardware RESETB, software reset).

#### 3.15.3 Clearing

INTB is updated in Active or Doze mode once every scan period.

The clearing of the INTB is done as soon as the host performs a read to the IrqSrc I2C register or reset is completed.

### 3.15.4 Example

A typical example of the assertion and clearing of the INTB and the I2C communication is shown in Figure 20.

Figure 20 Interrupt and I2C

When a button is touched the SX8646 will assert the interrupt (1). The host will read the IrqSrc information over the I2C and this clears the interrupt (2).

If the finger releases the button the interrupt will be asserted (3). The host reading the IrqSrc information will clear the interrupt (4).

In case the host does not react to an interrupt this results in a missing touch.

## 3.16 General Purpose Input and Outputs

### 3.16.1 Introduction and Definitions

The SX8646 offers eight General Purpose Input and Outputs (GPIO) pins which can be configured in any of these modes:

- GPI (General Purpose Input)
- GPP (General Purpose PWM)
- GPO (General Purpose Output)

Each of these modes is described in more details in the following sections.

The polarity of the GPP and GPO pins is defined as in figure below, driving an LED as example. It has to be set accordingly in SPM parameter GpioPolarity.

Figure 21 Polarity definition, (a) normal, (b) inverted

The PWM blocks used in GPP and GPO modes are 8-bits based and clocked at 2MHz typ. hence offering 256 selectable pulse width values with a granularity of 128us typ.

Figure 22 PWM definition, (a) small pulse width, (b) large pulse width

### 3.16.2 GPI

GPIOs configured as GPI will operate as digital inputs with standard low and high logic levels.

Optional pull-up/down and debounce can be enabled. Each GPI is individually edge programmable for INTB generation which will also exit Sleep/Doze mode if relevant.

SPM/I2C parameters applicable in GPI mode are listed in table below. Please refer to the relevant SPM/I2C parameters sections for more details.

		GPI
<b>SPM</b>	GpioMode	X
	GpioPullUpDown	X
	GpioInterrupt	X
	GpioDebounce	X
<b>I2C</b>	IrqSrc[4]	X
	GpiStat	X

Table 7 SPM/I2C Parameters Applicable in GPI Mode

### 3.16.3 GPP

GPIOs configured as GPP will operate as PWM outputs directly controlled by the host. A typical application is LED dimming.

Typical GPP operation is illustrated in figure below.

Figure 23 LED control in GPP mode

SPM/I2C parameters applicable in GPP mode are listed in table below. Please refer to the relevant SPM/I2C parameters sections for more details.

		GPP
SPM	GpioMode	X
	GpioOutPwrUp	X <sup>1</sup>
	GpioPolarity	X
	GpioIntensityOn	X <sup>1</sup>
	GpioIntensityOff	X <sup>1</sup>
	GpioFunction	X
I2C	GppPinId	X
	GppIntensity	X <sup>1</sup>

<sup>1</sup> At power up, GppIntensity of each GPP pin is initialized with GpioIntensityOn or GpioIntensityOff depending on GpioOutPwrUp corresponding bits value.

Table 8 SPM/I2C Parameters Applicable in GPP Mode

### 3.16.4 GPO

GPIOs configured as GPO will operate as digital outputs which can generate both standard low/high logic levels and PWM low/high duty cycles levels. Typical application is LED ON/OFF control.

Transitions between ON and OFF states can be triggered either automatically in Autolight mode or manually by the host. This is illustrated in figures below.

Figure 24 LED Control in GPO mode, Autolight OFF

Figure 25 LED Control in GPO mode, Autolight ON (mapped to Button)

Additionally these transitions can be configured to be done with or without fading following a logarithmic or linear function. This is illustrated in figures below.

Figure 26 GPO ON transition (LED fade in), normal polarity, (a) linear, (b) logarithmic

Figure 27 GPO ON transition (LED fade in), inverted polarity, (a) linear, (b) logarithmic

The fading out (e.g. after a button is released) is identical to the fading in but an additional off delay can be added before the fading starts (Figure 28 and Figure 29).

Figure 28 GPO OFF transition (LED fade out), normal polarity, (a) linear, (b) logarithmic

Figure 29 GPO OFF transition (LED fade out), inverted polarity, (a) linear, (b) logarithmic

Please note that standard high/low logic signals are just a specific case of GPO mode and can also be generated simply by setting inc/dec time to 0 (ie OFF) and programming intensity OFF/ON to 0x00 and 0xFF.

SPM/I2C parameters applicable in GPO mode are listed in table below.

		GPO
<b>SPM</b>	GpioMode	X
	GpioOutPwrUp	X <sup>1</sup>
	GpioAutoligh	X
	GpioPolarity	X
	GpioIntensityOn	X
	GpioIntensityOff	X
	GpioFunction	X
	GpioIncFactor	X
	GpioDecFactor	X
	GpioIncTime	X
	GpioDecTime	X
	GpioOffDelay	X
	<b>I2C</b>	GpoCtrl

<sup>1</sup> Only if Autolight is OFF, else must be left to 0 (default value)

<sup>2</sup> Only if Autolight is OFF, else ignored

*Table 9 SPM/I2C Parameters Applicable in GPO Mode*

ADVANCED COMMUNICATIONS & SENSING DATASHEET

3.16.5 Intensity index vs PWM pulse width

Tables below are used to convert all intensity indexes parameters GpioIntensityOff, GpioIntensityOn and GppIntensity but also to generate fading in GPO mode  
During fading in(out), the index is automatically incremented(decremented) at every Inc(Dec)Time x Inc(Dec)Factor until it reaches the programmed GpioIntensityOn(Off) value.

Table 10 Intensity index vs. PWM pulse width (normal polarity). A table with 16 columns (Index, Lin/Log) and 32 rows of data.

Table 10 Intensity index vs. PWM pulse width (normal polarity)

Table 11 Intensity index vs. PWM pulse width (inverted polarity). A table with 16 columns (Index, Lin/Log) and 32 rows of data.

Table 11 Intensity index vs. PWM pulse width (inverted polarity)

Recommended/default settings are inverted polarity (to take advantage from high sink current capability) and logarithmic mode (due to the non-linear response of the human eye).

### 3.17 Smart Wake Up

The SX8646 offers a smart wake up mechanism which allows waking-up from the Doze low power mode to the Active mode in a secure/controlled way and not by any unintentional sensor activation.

Until the full correct wake-up sequence is entered, the SX8646 will remain in Doze mode. Any wrong key implies the whole sequence to be entered again.

A sequence of up to 6 keys can be defined. Each key must be followed by a release to be validated.

The smart wake-up mechanism can also be disabled which implies that Doze mode can hence only be exited from GPI or I2C command.

## 4 PIN DESCRIPTIONS

### 4.1 Introduction

This chapter describes briefly the pins of the SX8646, the way the pins are protected, if the pins are analog, digital, require pull up or pull down resistors and show control signals if these are available.

### 4.2 ASI pins

#### CAP0, CAP1, ..., CAP7

The capacitance sensor pins (CAP0, CAP1, ..., CAP7) are connected directly to the ASI circuitry which converts the sensed capacitance into digital values.

The capacitance sensor pins which are not used should be left open.

The enabled CAP pins need be connected directly to the sensors without significant resistance (typical below some ohms, connection vias are allowed).

The capacitance sensor pins are protected to VANA and GROUND.

Figure 30 shows the simplified diagram of the CAP0, CAP1, ..., CAP7 pins.

Figure 30 Simplified diagram of CAP0, CAP1, ..., CAP7

#### CN, CP

The CN and the CP pins are connected to the ASI circuitry. A 1nF sampling capacitor between CP and CN needs to be placed as close as possible to the SX8646.

The CN and CP are protected to VANA and GROUND.

Figure 31 shows the simplified diagram of the CN and CP pins.

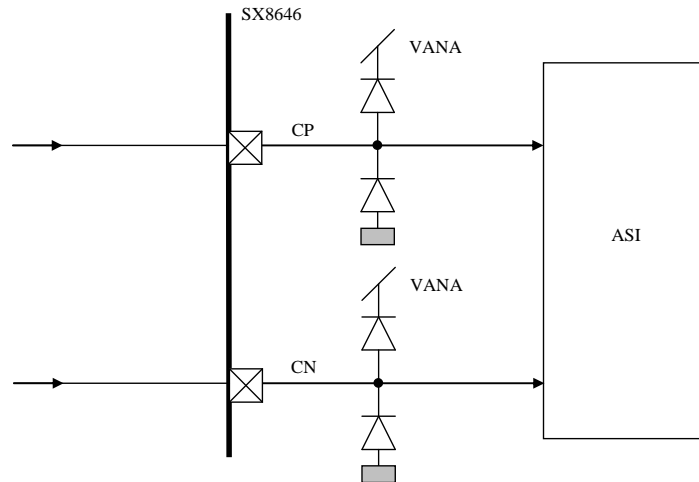

Figure 31 Simplified diagram of CN and CP

### 4.3 Host interface pins

The host interface consists of the interrupt pin INTB, a reset pin RESETB and the standard I2C pins: SCL and SDA.

#### INTB

The INTB pin is an open drain output that requires an external pull-up resistor (1..10 kOhm). The INTB pin is protected to VDD using dedicated devices. The INTB pin has diode protected to GROUND.

Figure 32 shows a simplified diagram of the INTB pin.

Figure 32 Simplified diagram of INTB

**SCL**

The SCL pin is a high impedance input pin. The SCL pin is protected to VDD, using dedicated devices, in order to conform to standard I2C slave specifications. The SCL pin has diode protected to GROUND. An external pull-up resistor (1..10 kOhm) is required on this pin.

Figure 33 shows the simplified diagram of the SCL pin.

*Figure 33 Simplified diagram of SCL*

**SDA**

SDA is an IO pin that can be used as an open drain output pin with external pull-up resistor or as a high impedance input pin. The SDA IO pin is protected to VDD, using dedicated devices, in order to conform to standard I2C slave specifications. The SDA pin has diode protected to GROUND. An external pull-up resistor (1..10 kOhm) is required on this pin.

Figure 34 shows the simplified diagram of the SDA pin.

*Figure 34 Simplified diagram of SDA*

**RESETB**

The RESETB pin is a high impedance input pin. The RESETB pin is protected to VDD using dedicated devices. The RESETB pin has diode protected to GROUND.

Figure 35 shows the simplified diagram of the RESETB pin controlled by the host.

*Figure 35 Simplified diagram of RESETB controlled by host*

Figure 36 shows the RESETB without host control.

*Figure 36 Simplified diagram of RESETB without host control*

#### 4.4 Power management pins

The power management pins consist of the Power, Ground and Regulator pins.

##### VDD

VDD is a power pin and is the main power supply for the SX8646.  
 VDD has protection to GROUND.

Figure 37 shows a simplified diagram of the VDD pin.

Figure 37 Simplified diagram of VDD

##### GND

The SX8646 has four ground pins all named GND. These pins and the package center pad need to be connected to ground potential.

The GND has protection to VDD.

Figure 38 shows a simplified diagram of the GND pin.

Figure 38 Simplified diagram of GND

**VANA, VDIG**

The SX8646 has on-chip regulators for internal use (pins VANA and VDIG).

VANA and VDIG have protection to VDD and to GND.

The output of the regulators needs to be de-coupled with a small 100nF capacitor to ground.

Figure 39 shows a simplified diagram of the VANA and VDIG pin.

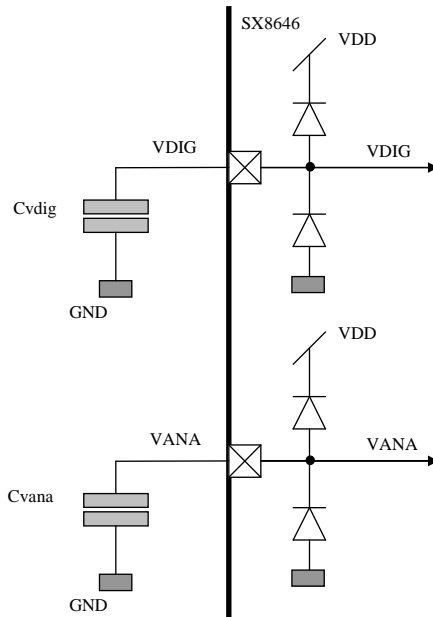

Figure 39 Simplified diagram of VANA and VDIG

**4.5 General purpose IO pins**

The SX8646 has 8 General purpose input/output (GPIO) pins.

All the GPIO pins have protection to VDD and GND.

The GPIO pins can be configured as GPI, GPO or GPP.

Figure 40 shows a simplified diagram of the GPIO pins.

Figure 40 Simplified diagram of GPIO pins

**5 DETAILED CONFIGURATION DESCRIPTIONS****5.1 Introduction**

The SX8646 configuration parameters are taken from the QSM or the NVM and loaded into the SPM as explained in the chapter 'functional description'.

This chapter describes the details of the configuration parameters of the SX8646.

The SPM is split by functionality into 5 configuration sections:

- General section: operating modes,
- Capacitive Sensors section: related to lower level capacitive sensing,
- Button: related to the conversion from sensor data towards button information,
- Mapping: related to mapping of button information towards wake-up and GPIO pins,
- GPIO: related to the setup of the GPIO pins.

The total address space of the SPM and the NVM is 128 bytes, from address 0x00 to address 0x7F.

Two types of memory addresses, data are accessible to the user.

- 'application data': Application dependent data that need to be configured by the user.
- 'reserved': Data that need to be maintained by the user to the QSM default values (i.e. when NVM is burned).

The Table 12 and Table 13 resume the complete SPM address space and show the 'application data' and 'reserved' addresses, the functional split and the default values (loaded from the QSM).

Address	Name	default QSM value	
0x00	Reserved	0xxx

Capacitive Sensors Parameters			
Address	Name	Bits	Description
0x1F	CapPerComp	7:4	Reserved
		3:0	Periodic Offset Compensation Defines the periodic offset compensation. 0x0: OFF (default) 0x1: 1 second 0x2: 2 seconds ... 0x7: 7 seconds 0x8: 16 seconds 0x9: 18 seconds ... 0xE: 28 seconds 0xF: 60 seconds

*Table 15 Capacitive Sensors Parameters*
**CapModeMisc**

By default the ASI is using a common sensitivity for all capacitive sensors as in the usual case overlay material and sensors sizes are about equal. The register bits CapSensitivity0\_1[7:4] determine the sensitivity for all sensors in common sensitivity mode.

In special applications it might be required to have a different, individual, sensitivity for each CAP pin. This can be obtained by setting bit CapModeMisc[2]. The individual sensitivity mode results in longer sensing periods than required in common sensitivity mode.

**CapMode7\_4, CapMode3\_0:**

The CAP pins can be set as a button or disabled depending on the application.

	minimum	default	maximum
buttons	one	eight	eight

*Table 16 Possible CAP pin modes*

Buttons and disabled CAP pins can be attributed freely (examples in Figure 41).

*Figure 41 Button examples*

**CapSensitivity0\_1, CapSensitivity2\_3, CapSensitivity4\_5, CapSensitivity6\_7:**

The sensitivity of the sensors can be set between 8 values. The higher the sensitivity is set the larger the value of the ticks will be.

The minimum sensitivity can be used for thin overlay materials and large sensors, while the maximum sensitivity is required for thicker overlay and smaller sensors.

The required sensitivity needs to be determined during a product development phase. Too low sensitivity settings result in missing touches. Too high sensitivity settings will result in fault detection of fingers hovering above the sensors.

The sensitivity is identical for all sensors in common sensitivity mode using the bits CapSensitivity0\_1[7:4] and can be set individually using register CapModeMisc[2].

The maximum number of ticks that can be obtained depends on the selected sensitivity as illustrated in Table 17.

Sensitivity	Approximate Maximum Tick Level
0	1000
1	2000
2	3000
3	4000
4	5000
5	6000
6	7000
7	8000

*Table 17 ASI Maximum Tick Levels*

CapThresh0, CapThresh1, CapThresh2, CapThresh3, CapThresh4, CapThresh5, CapThresh6, CapThresh7:

For each CAP pin a threshold level can be set individually.

The threshold levels are used by the SX8646 for making touch and release decisions on e.g. touch or no-touch.

The details are explained in the sections for buttons.

CapPerComp:

The SX8646 offers a periodic offset compensation for applications which are subject to substantial environmental changes. The periodic offset compensation is done at a defined interval and only if buttons are released.

## 5.4 Button Parameters

Button Parameters			
Address	Name	Bits	Description
0x21	BtnCfg	7:6	Defines the buttons events reporting method. 00: Multiple reporting of all touches and releases (default) 01: Single reporting of the first button touch. Next button touches and releases are ignored until release of the first button. 10: Reserved 11: Reserved
		5:4	Defines the buttons interrupt (for all buttons) 00 : Interrupts masked 01 : Triggered on Touch 10 : Triggered on Release 11 : Triggered on Touch and Release (default)
		3:2	Defines the number of samples at the scan period for determining a release 00: OFF, use incoming sample (default) 01: 2 samples debounce 10: 3 samples debounce 11: 4 samples debounce
		1:0	Defines the number of samples at the scan period for determining a touch 00: OFF, use incoming sample (default) 01: 2 samples debounce 10: 3 samples debounce 11: 4 samples debounce
0x22	BtnAvgThresh	7:0	Defines the positive threshold for disabling the processing filter averaging. If ticks are above the threshold, then the averaging is suspended 0x00: 0 0x01: 4 ... 0x50: 320 (default) ... 0xFF: 1020
0x23	BtnCompNegThresh	7:0	Defines the negative offset compensation threshold. 0x00: 0 0x01: 4 ... 0x50: 320 (default) ... 0xFF: 1020
0x24	BtnCompNegCntMax	7:0	Defines the number of ticks (below the negative offset compensation threshold) which will initiate an offset compensation. 0x00: Reserved 0x01: 1 sample (default) ... 0xFF-> samples
0x25	BtnHysteresis	7:0	Defines the button hysteresis corresponding to a percentage of the CAP thresholds (defined in Table 18). 0x00: 0% ... 0x0A: 10% (default) ... 0x64: 100% All buttons use the same hysteresis
0x26	BtnStuckAtTimeout	7:0	Defines the stuck at timeout. 0x00: OFF (default)

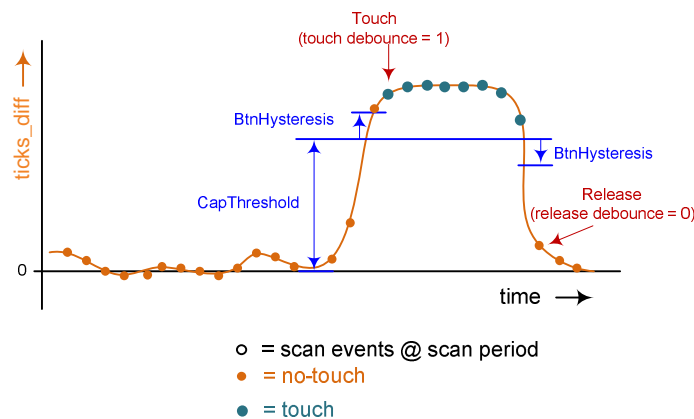

Button Parameters			
Address	Name	Bits	Description
			0x01: 1 second ... 0xFF: 255 seconds

*Table 18 Button Configuration Parameters*

A reliable button operation requires a coherent setting of the registers.

Figure 42 shows an example of a touch and a release. The ticks will vary slightly around the zero idle state.

When the touch occurs the ticks will rise sharply. At the release of the button the ticks will go down rapidly and converge to the idle zero value.

*Figure 42 Touch and Release Example*

As soon as the ticks become larger than the CAP thresholds (see registers of the previous section) plus the hysteresis (defined in register BtnHysteresis) the debounce counter starts.

In the example of Figure 42 the touch is validated after 2 samples (BtnCfg [1:0] = 01).

The release is detected immediately (BtnCfg [3:2] = 00) at the first sample which is below the threshold minus the hysteresis.

#### BtnCfg

The SX8646 can report all touches of multiple fingers or the SX8646 can be set to report only the first detected touch. In the later case all succeeding touches are ignored. The very first touch should be released before a next touch will be detected.

The user can select to have the interrupt signal on touching a button, releasing a button or both

In noisy environments it may be required to debounce the touch and release detection decision.

In case the debounce is enabled the SX8646 will count up to the number of debounce samples BtnCfg [1:0], BtnCfg [3:2] before taking a touch or release decision. The sample period is identical to the scan period.

#### BtnAvgThresh

Small environmental and system noise cause the ticks to vary slowly around the zero idle mode value.

In case the ticks get slightly positive this is considered as normal operation. Very large positive tick values indicate a valid touch. The averaging filter is disabled as soon as the average reaches the value defined by

BtnAvgThresh. This mechanism avoids that a valid touch will be averaged and finally the tick difference becomes zero.

In case three or more sensors reach the BtnAvgThresh value simultaneously then the SX8646 will start an offset compensation procedure.

Small environmental and system noise cause the ticks to vary slowly around the zero idle mode value. In case the ticks get slightly negative this is considered as normal operation. However large negative values will trigger an offset compensation phase and a new set of DCVs will be obtained. The decision to trigger a compensation phase based on negative ticks is determined by the value in the register BtnCompNegThresh and by the number of ticks below the negative thresholds defined in register BtnCompNegCntMax. An example is shown in Figure 43.

Figure 43 Negative Ticks Offset Compensation Trigger

#### BtnCompNegThresh

Small negative ticks are considered as normal operation and will occur very often. Larger negative ticks however need to be avoided and a convenient method is to trigger an offset compensation phase. The new set of DCV will assure the idle ticks will be close to zero again. A trade-off has to be found for the value of this register. A negative threshold too close to zero will trigger a compensation phase very often. A very negative threshold will never trigger.

#### BtnCompNegCntMax

As soon as the ticks get smaller than the Negative Threshold the Negative Counter starts to count. If the counter goes beyond the Negative Counter Max then the offset compensation phase is triggered. The recommended value for this register is '1' which means that the offset compensation starts on the first tick below the negative threshold.

#### BtnHysteresis

The hysteresis percentage is identical for all buttons.  
 A touch is detected if the ticks are getting larger as the value defined by:  
 $\text{CapThreshold} + \text{CapThreshold} * \text{hysteresis}$ .

A release is detected if the ticks are getting smaller as the value defined by:  
 $\text{CapThreshold} - \text{CapThreshold} * \text{hysteresis}$ .

#### BtnStuckAtTimeout

The stuckat timer can avoid sticky buttons.

If the stuckat timer is set to one second then the touch of a finger will last only for one second and considered released, even if the finger remains on the button for a longer time. After the actual finger release the button can be touched again and will be reported as usual.

In case the stuckat timer is not required it can be set to zero.

**ADVANCED COMMUNICATIONS & SENSING      DATASHEET**

### 5.5 Mapping Parameters

Mapping Parameters			
Address	Name	Bits	Description
0x33	MapWakeupSize	7:3	Reserved
		2:0	Doze -> Active wake up sequence size. 0: Any sensor event (default) 1: key0 2: key0, key1 ... 6: key0, key1,...key5 7: No sensor event, only GPI or I2C cmd can exit Doze mode  Each key must be followed by a release to be validated. Any other sensor event before the release is ignored. Any wrong key implies the whole sequence to be entered again.
0x34	MapWakeupValue0	7:4	key5
		3:0	key4
0x35	MapWakeupValue1	7:4	key3
		3:0	key2
0x36	MapWakeupValue2	7:4	key1
		3:0	key0
0x37	MapAutoLight0	7:4	GPIO[7]
		3:0	GPIO[6]
0x38	MapAutoLight1	7:4	GPIO[5]
		3:0	GPIO[4]
0x39	MapAutoLight2	7:4	GPIO[3]
		3:0	GPIO[2]
0x3A	MapAutoLight3	7:4	GPIO[1]
		3:0	GPIO[0]
0x3B	MapAutoLightGrp0Msb	7:0	Reserved
0x3C	MapAutoLightGrp0Lsb	7	Btn7
		6	Btn6
		5	Btn5
		4	Btn4
		3	Btn3
		2	Btn2
		1	Btn1
		0	Btn0
			Defines Group0 sensor events: 0: OFF (default) 1: ON  If any of the enabled sensor events occurs the Group0 event will occur as well.  All sensors events within the group can be independently set.
0x3D	MapAutoLightGrp1Msb	7:0	Reserved
0x3E	MapAutoLightGrp1Lsb	7	Btn7
		6	Btn6
		5	Btn5
			Defines Group1 sensor events: 0: OFF (default) 1: ON

Mapping Parameters			
Address	Name	Bits	Description
		4	Btn4
		3	Btn3
		2	Btn2
		1	Btn1
		0	Btn0
			<p>If any of the enabled sensor events occurs the Group0 event will occur as well.</p> <p>All sensors events within the group can be independently set.</p>

*Table 19 Mapping Parameters*
**MapWakeupSize**

The number of keys defining the wakeup sequence can be set from 1 to 6.  
 If the size is set to 0 then wakeup is done on any sensor event.  
 if the size is set to 6 then wakeup is done only by GPI or an I2C command.

**MapWakeupValue0, MapWakeupValue1, MapWakeupValue2**

For the wakeup sequence Btn2 -> Btn5 -> Btn6 -> Btn0 the required register settings are:

- MapWakeupSize set to 0x04,
- key0 = 0x2
- key1 = 0x5
- => MapWakeupValue2 set to 0x52
- key2 = 0x6
- key3 = 0x0
- => MapWakeupValue2 set to 0x06

**MapAutoLight0, MapAutoLight1, MapAutoLight2, MapAutoLight3**
**MapAutoLightGrp0Msb, MapAutoLightGrp0Lsb, MapAutoLightGrp1Msb, MapAutoLightGrp1Lsb**

These registers define the mapping between the GPO pins (with Autolight ON) and the sensor information which will control its ON/OFF state.

The mapping can be done to a specific sensor event but also on groups (in this case any sensor event in the group will control the GPO).

Table 20 defines for each selectable sensor event, which action will trigger corresponding GPO to switch ON or OFF.

MapAutoLight	GPO ON	GPO OFF
BtnX	Touch	Release

*Table 20 Autolight Mapping, Sensor Information*

Examples:

- If GPO[0] should change state accordingly to Btn4 then MapAutoLight3[3:0] should be set to 0x04.
- If GPO[0] should change state accordingly to Btn0 or Btn1 then Group0 can be used as following:
  - MapAutoLight3[3:0] should be set to 0x0C (ie Group0).
  - MapAutoLightGrp0 should be set to 0x0003 (ie Btn0 or Btn1)

**5.6 GPIO Parameters**

GPIO Parameters					
Address	Name	Bits	Description		
0x40	GpioMode7_4	7:6	GPIO[7] Mode	Defines the GPIO mode. 00: GPO (default) 01: GPP 10: GPI 11: Reserved	
		5:4	GPIO[6] Mode		
		3:2	GPIO[5] Mode		
		1:0	GPIO[4] Mode		
0x41	GpioMode3_0	7:6	GPIO[3] Mode		
		5:4	GPIO[2] Mode		
		3:2	GPIO[1] Mode		
		1:0	GPIO[0] Mode		
0x42	GpioOutPwrUp	7:0	GPIO[7] Output Value at Power Up	Defines the values of GPO and GPP pins after power up ie default values of I2C parameters GpoCtrl and GppIntensity respectively. 0: OFF(GPO) / IntensityOff (GPP) (default) 1: ON (GPO) / IntensityOn (GPP)	
			GPIO[6] Output Value at Power Up		
			GPIO[5] Output Value at Power Up		
			GPIO[4] Output Value at Power Up		
			GPIO[3] Output Value at Power Up		Bits corresponding to GPO pins with Autolight ON should be left to 0.
			GPIO[2] Output Value at Power Up		
			GPIO[1] Output Value at Power Up		Before being actually initialized GPIOs are set as inputs with pull up.
			GPIO[0] Output Value at Power Up		
0x43	GpioAutoLight	7:0	GPIO[7] AutoLight	Enables Autolight in GPO mode 0 : OFF 1 : ON (default)	
			GPIO[6] AutoLight		
			GPIO[5] AutoLight		
			GPIO[4] AutoLight		
			GPIO[3] AutoLight		
			GPIO[2] AutoLight		
			GPIO[1] AutoLight		
			GPIO[0] AutoLight		
0x44	GpioPolarity	7:0	GPIO[7] Output Polarity	Defines the polarity of the GPO and GPP pins. 0: Inverted (default) 1: Normal	
			GPIO[6] Output Polarity		
			GPIO[5] Output Polarity		
			GPIO[4] Output Polarity		
			GPIO[3] Output Polarity		
			GPIO[2] Output Polarity		
			GPIO[1] Output Polarity		
			GPIO[0] Output Polarity		
0x45	GpioIntensityOn0	7:0	ON Intensity Index	Defines the ON intensity index 0x00: 0 0x01: 1	
0x46	GpioIntensityOn1				
0x47	GpioIntensityOn2				

GPIO Parameters				
Address	Name	Bits	Description	
0x48	GpioIntensityOn3			... 0xFF: 255 (default)
0x49	GpioIntensityOn4			
0x4A	GpioIntensityOn5			
0x4B	GpioIntensityOn6			
0x4C	GpioIntensityOn7			
0x4D	GpioIntensityOff0	7:0	OFF Intensity Index	Defines the OFF intensity index 0x00: 0 (default) 0x01: 1 ... 0xFF: 255
0x4E	GpioIntensityOff1			
0x4F	GpioIntensityOff2			
0x50	GpioIntensityOff3			
0x51	GpioIntensityOff4			
0x52	GpioIntensityOff5			
0x53	GpioIntensityOff6			
0x54	GpioIntensityOff7			
0x56	GpioFunction	7:0	GPIO[7] Function	Defines the intensity index vs PWM pulse width function. 0: Logarithmic (default) 1: Linear
			GPIO[6] Function	
			GPIO[5] Function	
			GPIO[4] Function	
			GPIO[3] Function	
			GPIO[2] Function	
			GPIO[1] Function	
			GPIO[0] Function	
0x57	GpioIncFactor	7:0	GPIO[7] Fading Increment Factor	Defines the fading increment factor. 0: 1, intensity index incremented every increment time (default) 1: 16, intensity index incremented every 16 increment times
			GPIO[6] Fading Increment Factor	
			GPIO[5] Fading Increment Factor	
			GPIO[4] Fading Increment Factor	
			GPIO[3] Fading Increment Factor	
			GPIO[2] Fading Increment Factor	
			GPIO[1] Fading Increment Factor	
			GPIO[0] Fading Increment Factor	
0x58	GpioDecFactor	7:0	GPIO[7] Fading Decrement Factor	Defines the fading decrement factor. 0: 1, intensity index decremented every decrement time (default) 1: 16, intensity index decremented every 16 decrement times
			GPIO[6] Fading Decrement Factor	
			GPIO[5] Fading Decrement Factor	
			GPIO[4] Fading Decrement Factor	
			GPIO[3] Fading Decrement Factor	
			GPIO[2] Fading Decrement Factor	
			GPIO[1] Fading Decrement Factor	
			GPIO[0] Fading Decrement Factor	
0x59	GpioIncTime7_6	7:4	GPIO[7] Fading Increment Time	Defines the fading increment time.

GPIO Parameters				
Address	Name	Bits	Description	
0x5A	GpioIncTime5_4	3:0	GPIO[6] Fading Increment Time	0x0: OFF (default)
		7:4	GPIO[5] Fading Increment Time	0x1: 0.5ms
		3:0	GPIO[4] Fading Increment Time	0x2: 1ms
0x5B	GpioIncTime3_2	7:4	GPIO[3] Fading Increment Time	...
		3:0	GPIO[2] Fading Increment Time	0xF: 7.5ms
		7:4	GPIO[1] Fading Increment Time	The total fading in time will be: GpioIncTime*GpioIncFactor*
0x5C	GpioIncTime1_0	7:4	GPIO[1] Fading Increment Time	(GpioIntensityOn – GpioIntensityOff)
		3:0	GPIO[0] Fading Increment Time	
0x5D	GpioDecTime7_6	7:4	GPIO[7] Fading Decrement Time	Defines the fading decrement time.
		3:0	GPIO[6] Fading Decrement Time	0x0: OFF
0x5E	GpioDecTime5_4	7:4	GPIO[5] Fading Decrement Time	0x1: 0.5ms
		3:0	GPIO[4] Fading Decrement Time	0x2: 1ms
0x5F	GpioDecTime3_2	7:4	GPIO[3] Fading Decrement Time	...
		3:0	GPIO[2] Fading Decrement Time	0x4: 2.0ms (default)
0x60	GpioDecTime1_0	7:4	GPIO[1] Fading Decrement Time	...
		3:0	GPIO[0] Fading Decrement Time	0xF: 7.5ms
0x61	GpioOffDelay7_6	7:4	GPIO[7] OFF Delay	The total fading out time will be: GpioDecTime*GpioDecFactor*
		3:0	GPIO[6] OFF Delay	(GpioIntensityOn – GpioIntensityOff)
0x62	GpioOffDelay5_4	7:4	GPIO[5] OFF Delay	Defines the delay after GPO OFF trigger before fading out starts.
		3:0	GPIO[4] OFF Delay	0x0: OFF (default)
0x63	GpioOffDelay3_2	7:4	GPIO[3] OFF Delay	0x1: 200ms
		3:0	GPIO[2] OFF Delay	0x2: 400ms
0x64	GpioOffDelay1_0	7:4	GPIO[1] OFF Delay	...
		3:0	GPIO[0] OFF Delay	0xF: 3000ms
0x65	GpioPullUpDown7_4	7:6	GPIO[7] Pullup/down	Enables pullup/down resistors for GPI pins.
		5:4	GPIO[6] Pullup/down	00 : None (default)
		3:2	GPIO[5] Pullup/down	01 : Pullup
		1:0	GPIO[4] Pullup/down	10 : Pulldown
0x66	GpioPullUpDown3_0	7:6	GPIO[3] Pullup/down	11 : Reserved
		5:4	GPIO[2] Pullup/down	
		3:2	GPIO[1] Pullup/down	
		1:0	GPIO[0] Pullup/down	
0x67	GpioInterrupt7_4	7:6	GPI[7] Interrupt	Defines the GPI edge which will trigger INTB falling edge and exit Sleep/Doze modes if relevant.
		5:4	GPI[6] Interrupt	00 : None (default)
		3:2	GPI[5] Interrupt	01 : Rising
		1:0	GPI[4] Interrupt	10 : Falling
0x68	GpioInterrupt3_0	7:6	GPI[3] Interrupt	11 : Both
		5:4	GPI[2] Interrupt	
		3:2	GPI[1] Interrupt	

GPIO Parameters												
Address	Name	Bits	Description									
		1:0	GPI[0] Interrupt									
0x69	GpioDebounce	7:0	<table border="1"> <tr> <td>GPI[7] Debounce</td> <td rowspan="8">Enables the GPI debounce (done on 10 consecutive samples at 1ms). 0 : OFF (default) 1 : ON</td> </tr> <tr> <td>GPI[6] Debounce</td> </tr> <tr> <td>GPI[5] Debounce</td> </tr> <tr> <td>GPI[4] Debounce</td> </tr> <tr> <td>GPI[3] Debounce</td> </tr> <tr> <td>GPI[2] Debounce</td> </tr> <tr> <td>GPI[1] Debounce</td> </tr> <tr> <td>GPI[0] Debounce</td> </tr> </table>	GPI[7] Debounce	Enables the GPI debounce (done on 10 consecutive samples at 1ms). 0 : OFF (default) 1 : ON	GPI[6] Debounce	GPI[5] Debounce	GPI[4] Debounce	GPI[3] Debounce	GPI[2] Debounce	GPI[1] Debounce	GPI[0] Debounce
GPI[7] Debounce	Enables the GPI debounce (done on 10 consecutive samples at 1ms). 0 : OFF (default) 1 : ON											
GPI[6] Debounce												
GPI[5] Debounce												
GPI[4] Debounce												
GPI[3] Debounce												
GPI[2] Debounce												
GPI[1] Debounce												
GPI[0] Debounce												

Table 21 GPIO Parameters

Table 22 resumes the applicable SPM and I2C parameters for each GPIO mode.

		GPI	GPP	GPO
<b>SPM</b>	GpioMode	X	X	X
	GpioOutPwrUp		X <sup>1</sup>	X <sup>2</sup>
	GpioAutoligth			X
	GpioPolarity		X	X
	GpioIntensityOn		X <sup>1</sup>	X
	GpioIntensityOff		X <sup>1</sup>	X
	GpioFunction		X	X
	GpioIncFactor			X
	GpioDecFactor			X
	GpioIncTime			X
	GpioDecTime			X
	GpioOffDelay			X
	GpioPullUpDown	X		
	GpioInterrupt	X		
	GpioDebounce	X		
<b>I2C</b>	IrqSrc[4]	X		
	GpiStat	X		
	GpoCtrl			X <sup>3</sup>
	GppPinId		X	
	GppIntensity		X <sup>1</sup>	

<sup>1</sup> At power up, GppIntensity of each GPP pin is initialized with GpioIntensityOn or GpioIntensityOff depending on GpioOutPwrUp corresponding bits value.

<sup>2</sup> Only if Autolight is OFF, else must be left to 0 (default value)

<sup>3</sup> Only if Autolight is OFF, else ignored

Table 22 Applicable SPM/I2C Parameters vs. GPIO Mode

## 6 I2C INTERFACE

The I2C implemented on the SX8646 is compliant with:

- standard (100kb/s), fast mode (400kb/s)
- slave mode
- 7 bit address (default 0x2B). The default address can be changed in the NVM at address 0x04.

The host can use the I2C to read and write data at any time. The effective changes will be applied at the next processing phase (section 3.3).

Three types of registers are considered:

- status (read). These registers give information about the status of the capacitive buttons, GPIOs, operation modes etc...
- control (read/write). These registers control the soft reset, operating modes, GPIOs and offset compensation.
- SPM gateway (read/write). These registers are used for the communication between host and the SPM. The SPM gateway communication is done typically at power up and is not supposed to be changed when the application is running. The SPM needs to be re-stored each time the SX8646 is powered down. The SPM can be stored permanently in the NVM memory of the SX8646. The SPM gateway communication over the I2C at power up is then not required.

The I2C will be able to read and write from a start address and then perform read or writes sequentially, and the address increments automatically.

The supported I2C access formats are described in the next sections.

### 6.1 I2C Write

The format of the I2C write is given in Figure 44.

After the start condition [S], the slave address (SA) is sent, followed by an eighth bit ('0') indicating a Write. The SX8646 then Acknowledges [A] that it is being addressed, and the Master sends an 8 bit Data Byte consisting of the SX8646 Register Address (RA). The Slave Acknowledges [A] and the master sends the appropriate 8 bit Data Byte (WD0). Again the Slave Acknowledges [A]. In case the master needs to write more data, a succeeding 8 bit Data Byte will follow (WD1), acknowledged by the slave [A]. This sequence will be repeated until the master terminates the transfer with the Stop condition [P].

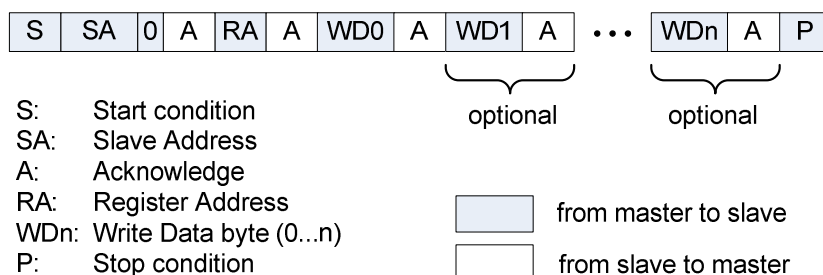

Figure 44 I2C write

The register address is incremented automatically when successive register data (WD1...WDn) is supplied by the master.

## 6.2 I2C read

The format of the I2C read is given in Figure 45.

After the start condition [S], the slave address (SA) is sent, followed by an eighth bit ('0') indicating a Write. The SX8646 then Acknowledges [A] that it is being addressed, and the Master responds with an 8 bit Data consisting of the Register Address (RA). The Slave Acknowledges [A] and the master sends the Repeated Start Condition [Sr]. Once again, the slave address (SA) is sent, followed by an eighth bit ('1') indicating a Read.

The SX8646 responds with an Acknowledge [A] and the read Data byte (RD0). If the master needs to read more data it will acknowledge [A] and the SX8646 will send the next read byte (RD1). This sequence can be repeated until the master terminates with a NACK [N] followed by a stop [P].

*Figure 45 I2C read*

### 6.3 I2C Registers Overview

Address	Name	R/W	Description
0x00	IrqSrc	read	Interrupt Source
0x01	Reserved		
0x02	CapStatLsb	read	Button Status LSB
0x03	Reserved		
0x04	Reserved		
0x05	Reserved		
0x06	Reserved		
0x07	GpiStat	read	GPI Status
0x08	SpmStat	read	SPM Status
0x09	CompOpMode	read/write	Compensation and Operating Mode
0x0A	GpoCtrl	read/write	GPO Control
0x0B	GppId	read/write	GPP Pin Selection
0x0C	GppIntensity	read/write	GPP Intensity
0x0D	SpmCfg	read/write	SPM Configuration
0x0E	SpmBaseAddr	read/write	SPM Base Address
0x0F	Reserved		
0xAC	SpmKeyMsb	read/write	SPM Key MSB
0xAD	SpmkeyLsb	read/write	SPM Key LSB
0xB1	SoftReset	read/write	Software Reset

*Table 23 I2C Registers Overview*

## 6.4 Status Registers

Address	Name	Bits	Description
0x00	IrqSrc	7	Reserved
		6	NVM burn interrupt flag
		5	SPM write interrupt flag
		4	GPI interrupt flag
		3	Reserved
		2	Buttons interrupt flag
		1	Compensation interrupt flag
		0	Operating Mode interrupt flag

*Table 24 Interrupt Source*

The delay between the actual event and the flags indicating the interrupt source may be one scan period.

IrqSrc[6] is set once NVM burn procedure is completed.

IrqSrc[5] is set once SPM write is effective.

IrqSrc[4] is set if a GPI edge as programmed in GpioInterrupt occurred. GpiStat shows the detailed status of the GPI pins.

IrqSrc[2] is set if a Button event occurred (touch or release if enabled). CapStatLsb show the detailed status of the Buttons.

IrqSrc[1] is set once compensation procedure is completed either through automatic trigger or via host request.

IrqSrc[0] is set when actually entering Active or Doze mode either through automatic wakeup or via host request. CompOpmode shows the current operation mode.

**ADVANCED COMMUNICATIONS & SENSING      DATASHEET**

Address	Name	Bits	Description
0x02	CapStatLsb	7	Button 7 Touched
		6	Button 6 Touched
		5	Button 5 Touched
		4	Button 4 Touched
		3	Button 3 Touched
		2	Button 2 Touched
		1	Button 1 Touched
		0	Button 0 Touched
			Button Touch status 0: Released (default) 1: Touched

*Table 25, Button status LSB*

Address	Name	Bits	Description
0x07	GpiStat	7:0	GPI[7:0] Status Status of each individual GPI pin 0: Low 1: High Bits of non-GPI pins are set to 0.

*Table 26 I2C GPI status*

Address	Name	Bits	Description
0x08	SpmStat	7:4	reserved
		3	NvmValid Indicates if the current NVM is valid. 0: No – QSM is used 1: Yes – NVM is used
		2:0	NvmCount Indicates the number of times NVM has been burned: 0: None – QSM is used (default) 1: Once – NVM is used if NvmValid = 1, else QSM. 2: Twice – NVM is used if NvmValid = 1, else QSM. 3: Three times – NVM is used if NvmValid = 1, else QSM. 4: More than three times – QSM is used

*Table 27 I2C SPM status*

## 6.5 Control Registers

Address	Name	Bits	Description
0x09	CompOpMode	7:3	Reserved*, write only '00000'
		2	Compensation Indicates/triggers compensation procedure 0: Compensation completed (default) 1: read -> compensation running ; write -> trigger compensation
		1:0	Operating Mode Indicates/programs** operating mode 00: Active mode (default) 01: Doze mode 10: Sleep mode 11: Reserved

Table 28 I2C compensation, operation modes

\* The reading of these reserved bits will return varying values.

\*\* After the operating mode change (Active/Doze) the host should wait for INTB or 300ms before performing any I2C read access.

Address	Name	Bits	Description
0x0A	GpoCtrl	7:0	GpoCtrl[7:0] Triggers ON/OFF state of GPOs when Autolight is OFF 0: OFF (ie go to IntensityOff) 1: ON (ie go to IntensityOn) Default is set by SPM parameter GpioOutPwrUp Bits of non-GPO pins are ignored.

Table 29 I2C GPO Control

Address	Name	Bits	Description
0x0B	GppPinId	7:3	Reserved, write only '00000'
		2:0	GPP Pin Identifier  Defines the GPP pin to which the GppIntensity is assigned for the following read/write operations 0x0 = GPP0 (default) 0x1 = GPP1 ... 0x7 = GPP7  GPPx refers to pin GPIOx configured as GPP

*Table 30 I2C GPP Pin Identifier*

Address	Name	Bits	Description
0x0C	GppIntensity	7:0	Defines the intensity index of the GPP pin selected in GppPinId 0x00: 0 0x01: 1 ... 0xFF: 255  Reading returns the intensity index of the GPP pin selected in GppPinId. Default value is IntensityOn or IntensityOff depending on GpioOutPwrUp.

*Table 31 I2C GPP Intensity*

Address	Name	Bits	Description
0xB1	SoftReset	7:0	Writing 0xDE followed by 0x00 will reset the chip.

*Table 32 I2C Soft Reset*

## 6.6 SPM Gateway Registers

The SX8646 I2C interface offers two registers for exchanging the SPM data with the host.

- SpmCfg
- SpmBaseAddr

Address	Name	Bits	Description
0x0D	SpmCfg	7:6	00: Reserved
		5:4	Enables I2C SPM mode 00: OFF (default) 01: ON 10: Reserved 11: Reserved
		3	Defines r/w direction of SPM 0: SPM write access (default) 1: SPM read access
		2:0	000: Reserved

*Table 33 SPM access configuration*

Address	Name	Bits	Description
0x0E	SpmBaseAddr	7:0	SPM Base Address (modulo 8). The lowest address is 0x00 (default). The highest address is 0x78.

*Table 34 SPM Base Address*

The exchange of data, read and write, between the host and the SPM is always done in bursts of eight bytes. The base address of each burst of eight bytes is a modulo 8 number, starting at 0x00 and ending at 0x78.

The registers SpmKeyMsb and SpmKeyLsb are required for NVM programming as described in section 6.7.

Address	Name	Bits	Description
0xAC	SpmKeyMsb	7:0	SPM to NVM burn Key MSB Unlock requires writing data: 0x62

*Table 35 SPM Key MSB*

Address	Name	Bits	Description
0xAD	SpmKeyLsb	7:0	SPM to NVM burn Key LSB Unlock requires writing data: 0x9D

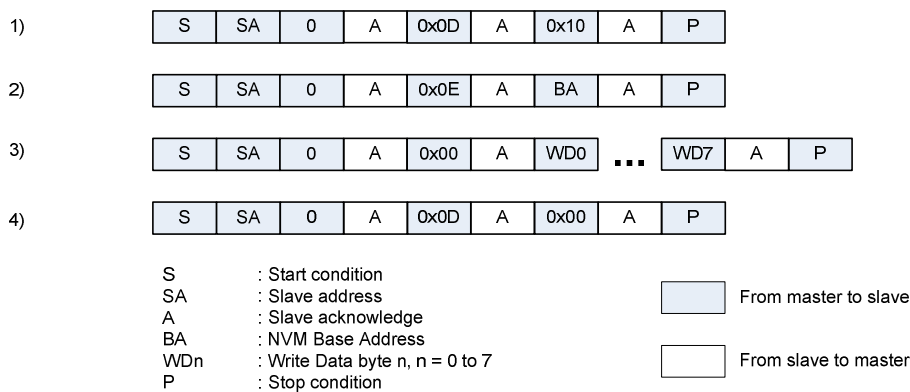

*Table 36 SPM Key LSB*

**6.6.1 SPM Write Sequence**

The SPM write can be done in any mode (Active, Doze, Sleep). Writing the SPM in Sleep is useful to avoid potential transient behaviors.

The SPM must always be written in blocks of 8 bytes. The sequence is described below:

1. Set the I2C in SPM mode by writing "01" to SpmCfg[5:4] and SPM write access by writing '0' to SpmCfg[3].
2. Write the SPM base address to SpmBaseAddr (The base address needs to be a value modulo 8).
3. Write the eight consecutive bytes to I2C address 0, 1, 2, ...7
4. Terminate by writing "000" to SpmCfg[5:3].

*Figure 46: SPM Write Sequence*

The complete SPM can be written by repeating 16 times the cycles shown in Figure 46 using base addresses 0x00, 0x08, 0x10, ..., 0x70, 0x78. Between each sequence the host should wait for INTB (Active/Doze) or 30ms in Sleep.

In Active or Doze mode, once the SPM write sequence is actually applied, the INTB pin will be asserted and IrqSrc[5] set. In Sleep mode the SPM write can be actually applied with a delay of 30ms.

The host clears the interrupt and IrqSrc[5] by reading the IrqSrc register.

### 6.6.2 SPM Read Sequence

The SPM read can be done in any mode (Active, Doze, Sleep).

The SPM must always be read in blocks of 8 bytes. The sequence is described below:

1. Set the I2C in SPM mode by writing "01" to SpmCfg[5:4] and SPM read access by writing '1' to SpmCfg[3].
2. Write the SPM base address to SpmBaseAddr (The base address needs to be a value modulo 8).
3. Read the eight consecutive bytes from I2C address 0, 1, 2, ...7
4. Terminate by writing "000" to SpmCfg[5:3].

*Figure 47: SPM Read Sequence*

The complete SPM can be read by repeating 16 times the cycles shown in Figure 47 using base addresses 0x00, 0x08, 0x10, ..., 0x70, 0x78.

## 6.7 NVM burn

The content of the SPM can be copied permanently (burned) into the NVM to be used as the new default parameters. The burning of the NVM can be done up to three times and must be done only when the SPM is completely written with the desired data. The NVM burn must be done in Active or Doze mode.

Once the NVM burn process is terminated IrqSrc[6] will be set and INTB asserted.

After a reset the burned NVM parameters will be copied into the SPM.

The number of times the NVM has been burned can be monitored by reading NvmCount from the I2C register SpmStat[2:0].

Figure 48 Simplified Diagram NvmCount

Figure 48 shows the simplified diagram of the NVM counter. The SX8646 is delivered with empty NVM and NvmCount set to zero. The SPM points to the QSM.

Each NVM burn will increase the NvmCount. At the fourth NVM burn the SX8646 switches definitely to the QSM.

The burning of the SPM into the NVM is done by executing a special sequence of four I2C commands.

- |  |                                    |
|--|------------------------------------|
| 1. Write the data 0x62 to the I2C register I2CKeyMsb.      | Terminate the I2C write by a STOP. |
| 2. Write the data 0x9D to the I2C register I2CKeyLsb.      | Terminate the I2C write by a STOP. |
| 3. Write the data 0xA5 to the I2C register I2CSpmBaseAddr. | Terminate the I2C write by a STOP. |
| 4. Write the data 0x5A to the I2C register I2CSpmBaseAddr. | Terminate the I2C write by a STOP. |

This is illustrated in Figure 49.

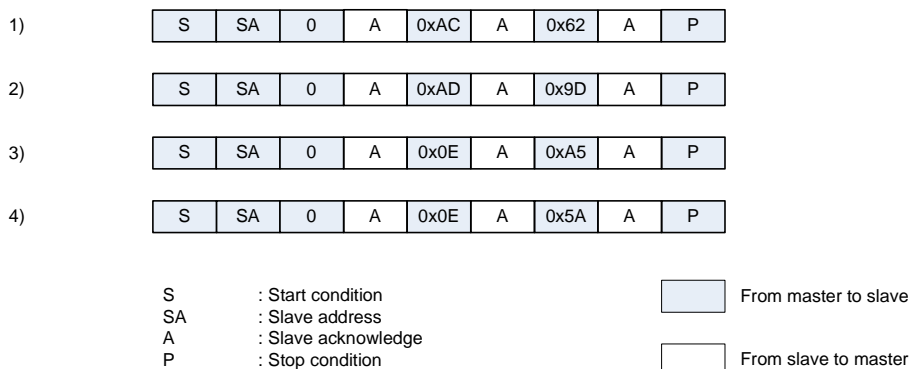

Figure 49: NVM burn procedure

**7 APPLICATION INFORMATION**

A typical application schematic is shown in Figure 50.

*Figure 50 Typical Application*

## 8 PACKAGING INFORMATION

### 8.1 Package Outline Drawing

SX8646 is assembled in a MLPQ-UT28 package as shown in Figure 51.

Figure 51 Package Outline Drawing

### 8.2 Land Pattern

The land pattern of MLPQ-UT28 package, 4 mm x 4 mm is shown in Figure 52.
