

# AN8245K, AN8245SCR

## Laser Disk Spindle Motor Controller

### Overview

The AN8245K and AN8245SCR are speed control drive ICs of the brushless motors by means of the 3-phase full-wave current drive system. They are suitable for controlling/driving the laser disk spindle motors, LBP polygon mirror motors, and so on.

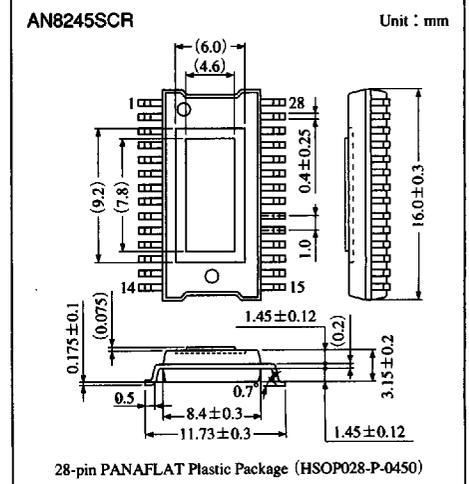

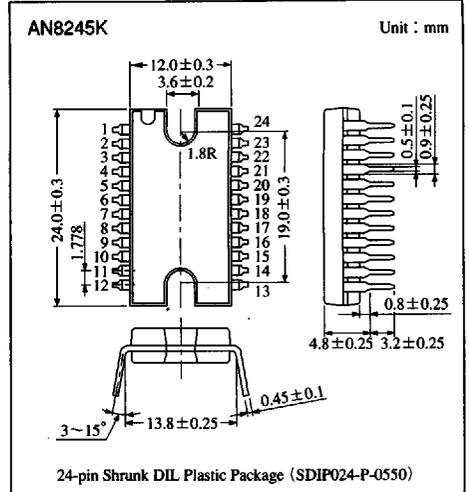

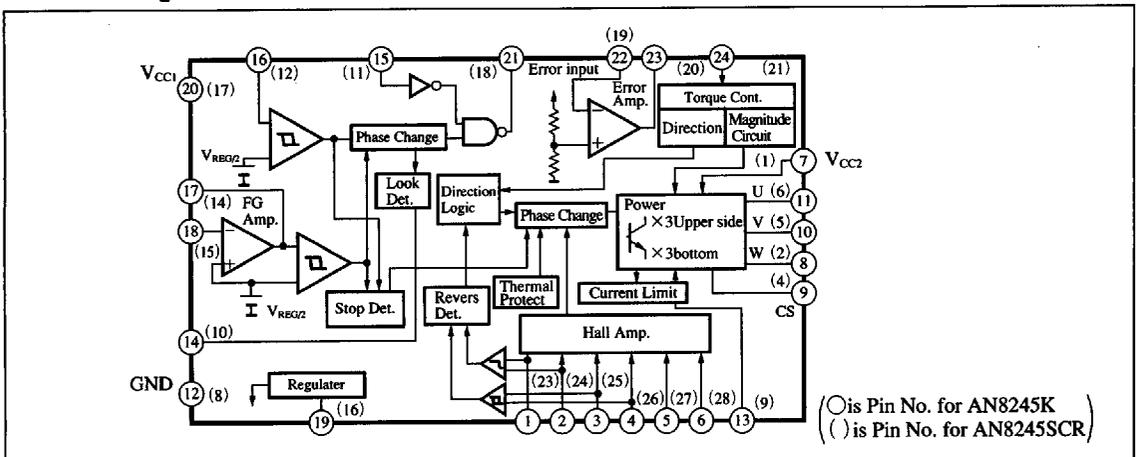

### Features

- Operating supply voltage range :  $V_{CC1} = 10.8$  to  $13.2V$   
 $V_{CC2} = 10.8$  to  $22V$
- 3-sensor 3-phase full-wave current drive ; power transistor built-in
- Maximum motor drive current :  $I_{Mmax} = 1.5A$
- Digital PLL control
- Bidirectional torque control
- Provided with reverse detector and stop detector
- Synchronizing signal and stop signal output
- Built-in thermal protective and current limiter functions

### Applications

Control and drive of the Hall motors such as laser disk spindle motors, LBP polygon motors, and so on

### Block Diagram

## Supplementary Explanation

The AN8245K and AN8245SCR have been developed as single-chip ICs for controlling and driving the laser spindle motors. They can be also available for controlling and driving the 3-phase brushless motors. Their functions and features are described below.

### 1. Drive block

- 3-phase full-wave drive (1.5A)
- Current drive (current feedback available)
- Built-in motor current limiter (current limiter level variable)\*<sup>1</sup>
- Built-in thermal protective function
- Reverse rotation torque brake\*<sup>2</sup>
- Built-in reverse detector

### 2. Control block

- PLL speed control method\*<sup>3</sup>
- Digital phase comparator
- Start/brake control pin
- Phase lock detection pin

\*<sup>1</sup> A motor current is detected by the resistor R<sub>CS</sub> between the Pin<sup>⑨</sup> (4) and GND. Since the potential of the Pin<sup>⑨</sup> (4) (CS pin) is controlled so that a value may not exceed a specified voltage (current limiter level) V<sub>L</sub>, the maximum motor current can be specified by V<sub>L</sub>/R<sub>CS</sub>. Because of the voltage of the Pin<sup>⑬</sup> (9) (CLL pin) = V<sub>L</sub>, V<sub>L</sub> can be made variable by connecting a resistor between GNDs via the Pin<sup>⑬</sup> (9).

\*<sup>2</sup> As the potentials of the torque command and DTC pin (Pin<sup>⑳</sup> (21)) go below 1/2 · V<sub>reg</sub>, a torque is to be generated in the reverse rotating direction. As a result, the motor load with large inertia can be stopped and transient response can be improved.

To prevent the motor from rotating in the reverse direction, the following functions are provided :

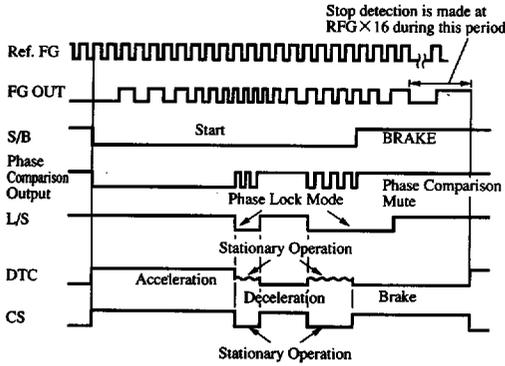

- Motor current OFF function : When detecting a stop
- Forward full torque function : when detecting reverse rotation

\*<sup>3</sup> The reference pulse to be input from the Pin<sup>⑯</sup> (12) (Ref.FG pin) and the pulse due to FG amp. waveform shaping are compared as to their digital phases to control the PLL speed. PLL of these ICs consists of a phase loop only in the from that dumping is obtained through the filters around the error amplifier.

■ Supplementary Description (Cont.)

Operational Chart of Pins

• Setting the External Parts (Refer to Product Specifications and Block Diagram)

1. Drive block

- C<sub>8</sub>~C<sub>10</sub> : Connected between the phases of 3-phase coils or GNDs for absorbing the voltage spike of drive output by current drive (120 deg. conducted) or preventing oscillation of drive output. When oscillation tends to occur, it is recommended to insert a resistor of 10 to 500Ω in series with C (several μF as a capacity value).
- R<sub>8</sub>, R<sub>9</sub> : Determine the Hall element current. It is recommend to set the Hall element output to about typ. 100 to 200mVpp.
- R<sub>C5</sub> : Determine the control system gain and the maximum motor current.
- C<sub>4</sub>, C<sub>5</sub>, C<sub>11</sub> : Used for decoupling the power supply and stabilized voltage output.

2. Control block

- R<sub>6</sub>, R<sub>7</sub>, C<sub>6</sub>, C<sub>7</sub> : Set the filter for eliminating noise of a speed detecting FG signal and the FG amp. gain.

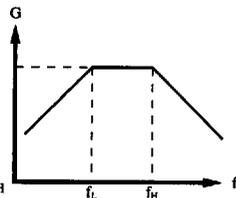

FG amp. gain  $G_{FG} = R7/R6$

Filter constant

$$f_L = \frac{1}{2\pi C_6 R_6} \text{ (Hz)}$$

$$f_H = \frac{1}{2\pi C_7 R_7} \text{ (Hz)}$$

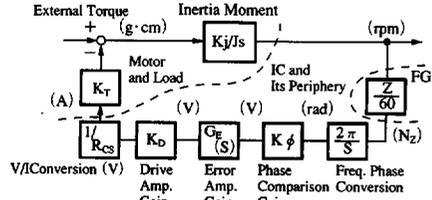

FC frequency  $f_{FG} = f_L < f_{FG} < f_H$

- R<sub>1</sub>~R<sub>4</sub>, C<sub>1</sub>, C<sub>2</sub> : Constitute the dumping filter for the control system and the ripple filter for phase comparison output.
- R<sub>5</sub> : Connects 10kΩ as the current control load of the transistor switch (operated at start and reverse motor drive detection) which is connected to the Pin⑳ (21) in the IC.

3. Design of the control system

The following describes the important points when designing the speed control system with these ICs. The control system is shown in the following block diagram.

- K<sub>T</sub> : Motor torque constant (gcm/A)
- J : Sum (gcm<sup>2</sup>) of inertia moment of the motor and load (disc, etc.)
- S : Laplacian operator
- K<sub>J</sub> : Coefficient for changing a torque (gcm) into a motor speed (r.p.m.)  $9.36 \times 10^3$
- Z : Number of FG teeth
- Kφ : IC phase comparison gain  $8/2\pi$  (V/rad)
- G<sub>E</sub> (S) : Dumping of the error amp. block and the gain of the ripple filter
- K<sub>D</sub> : IC drive amp. gain 0.4 to 0.6
- 1/R<sub>C5</sub> : V/I conversion gain by the IC and external resistor  $R_{C5}1/R_{C5}$  (A/V).

Make the following calculation, using the constants above.

$$A(S) = K_J/J_S$$

$$B(S) = \frac{Z}{60} \cdot \frac{2\pi}{S} K_\phi \cdot G_E(S) \cdot K_D \cdot \frac{1}{R_{C5}} \cdot K_T$$

At this time, the motor speed change ΔN for disturbance torque ΔT is as follows.

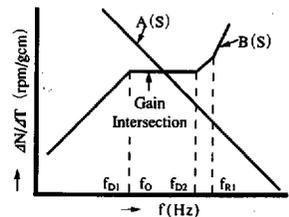

$$\frac{\Delta N}{\Delta T} = \frac{A(S)}{1 + A(S)B(S)} = \frac{1}{1/A(S) + B(S)}$$

When  $1/A(S) \gg B(S)$ ,  $\frac{\Delta N}{\Delta T} \approx A(S)$ , and when  $1/A(S) \ll B(S)$ ,  $\frac{\Delta N}{\Delta T} \approx 1/B(S)$ .

If shown in the figure, it will be almost as shown in the right one.

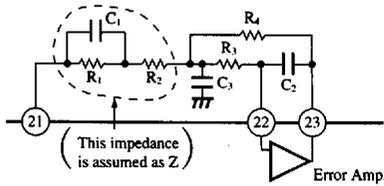

It is better for stable operation to satisfy the following conditions.

- $f_{D2} \geq 3 \cdot f_0$
- $f_{R1} \geq 5 \cdot f_0$
- $f_{D1} \leq f_0/3$
- $f_{FG}$  (FG frequency)  $\geq 20f_0$

■ Supplementary Description (Cont.)

$f_{D1}$ ,  $f_{D2}$ , and  $f_{R1}$  are determined as follows.

The figure above shows an example of the external circuit around the error amplifier. This block constitutes the damping filter for the control system and the ripple filter for phase comparison output.

$$G_E(S) = \frac{R_4}{Z} \cdot \frac{1}{1 + sC_2R_3R_4 \left( \frac{1}{Z} + \frac{1}{R_3} + \frac{1}{R_4} \right) + s^2C_2C_3R_3R_4}$$

$$Z = (R_1 + R_2) \frac{1 + sC_1(R_1/R_2)}{1 + sC_1R_1}$$

The transfer function  $G_E(S)$  of these filters are represented by the following expression, indicating the characteristics of the damping filter in Item 1 and of the ripple filter in Item 2.

Damping filter :  $f_{D1} = 1 / (2\pi C_1 R_1)$

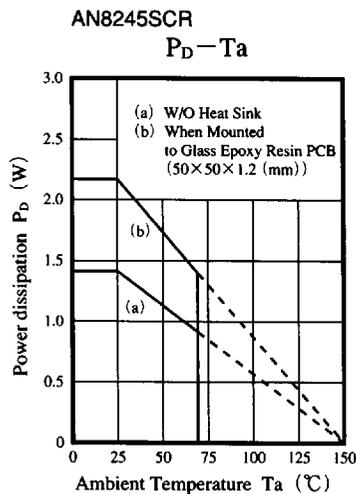

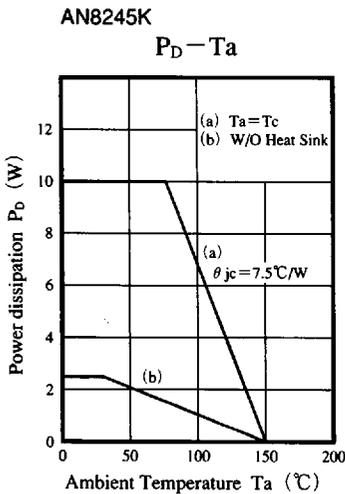

$$f_{D2} = 1 / \{ 2\pi C_1 (R_1/R_2) \}$$

Ripple filter :

$$f_{R1} = 1 / 2\pi \sqrt{C_2 C_3 R_3 R_4}$$

$$\zeta = \left\{ C_2 C_3 C_4 \left( \frac{1}{Z} + \frac{1}{R_3} + \frac{1}{R_4} \right) \right\} / 2 \sqrt{C_2 C_3 R_3 R_4}$$
