## DATA SHEET

## TDA9150B

Programmable deflection controller
Preliminary specification
File under Integrated Circuits, IC02

PHILIPS

## FEATURES

## General

- $6.75,13.5$ and 27 MHz clock frequency
- Few external components
- Synchronous logic
- $I^{2} C$-bus controlled
- Easy interfacing
- Low power
- ESD protection
- Flash detection with restart
- Two-level sandcastle pulse.

## Vertical deflection

- Self adaptive 16-bit precision vertical scan
- DC coupled deflection to prevent picture bounce
- Programmable fixed compression to $75 \%$
- S-correction can be preset
- S-correction setting independent of the field frequency
- Differential output for high DC stability
- Current source outputs for high EMC immunity
- Programmable de-interlace phase.

## East-West correction

- DC coupled EW correction to prevent picture bounce
- 2nd and 4th order geometry correction can be preset
- Trapezium correction
- Geometry correction settings are independent of field frequency
- Self adaptive Bult generator prevents ringing of the horizontal deflection
- Current source output for high EMC immunity.

## Horizontal deflection

- Phase 2 loop with low jitter
- Internal loop filter
- Dual slicer horizontal flyback input
- Soft start by $\mathrm{I}^{2} \mathrm{C}$-bus
- Over voltage protection/detection with selection and status bit.

## EHT correction

- Input selection between aquadag or EHT bleeder
- Internal filter.

## GENERAL DESCRIPTION

The TDA9150B is a programmable deflection controller contained in a 20-pin DIP package and constructed using BIMOS technology. This high performance synchronization and DC deflection processor has been especially designed for use in both digital and analog based TV receivers and monitors, and serves horizontal and vertical deflection functions for all TV standards. The TDA9150B uses a line-locked clock at $6.75,13.5$ or 27 MHz , depending on the line frequency and application, and requires only a few external components. The device is self-adaptive for a number of functions and is fully programmable via the $\mathrm{I}^{2} \mathrm{C}$-bus.

## FUNCTIONAL DESCRIPTION

## Input signals (pins 12, 13, 14, 17 and 18)

The TDA9150B requires three signals for minimum operation (apart from the supply). These signals are the line-locked clock (LLC) and the two ${ }^{2} \mathrm{C}$-bus signals (SDA and SCL). Without the LLC the device will not operate because the internal synchronous logic uses the LLC as the system clock.
$I^{2} \mathrm{C}$-bus transmissions are required to enable the device to perform its required tasks. Once started the IC will use the $\mathrm{H}_{\mathrm{A}}$ and/or $\mathrm{V}_{\mathrm{A}}$ inputs for synchronization. If the LLC is not present the outputs will be switched off and all operations

discarded (if the LLC is not present the line drive will be inhibited within $2 \mu \mathrm{~s}$, the EW output current will drop to zero and the vertical output current will drop to $20 \%$ of the adjusted value within $100 \mu \mathrm{~s}$ ). The SDA and SCL inputs meet the $\mathrm{I}^{2} \mathrm{C}$-bus specification, the other three inputs are TTL compatible.

The LLC frequency can be divided-by-two internally by connecting LLCS (pin 5) to ground thereby enabling the prescaler.

The LLC timing is given in the Chapter "Characteristics".

## Programmable deflection controller

## $\mathrm{I}^{2} \mathrm{C}$-bus commands

Slave address: 8C HEX = 1000110X BIN

READ MODE
The format of the status byte is: PON PROT 000000 Where:

PON is the status bit for power-on reset (POR) and after power failure:

- Logic 1:
- after the first POR and after power failure; also set to 1 after a severe voltage dip that may have disturbed the various settings
- POR 1 to 0 transition, $\mathrm{V}_{\mathrm{CC}}=6.25 \mathrm{~V}$ (typ.)
- POR 0 to 1 transition, $\mathrm{V}_{\mathrm{CC}}=5.75 \mathrm{~V}$ (typ.)
- Logic 0 :
- after a successful read of the status byte.

PROT is the over voltage detection for the scaled EHT input:

- Logic 1:
- if the scaled EHT rises above the reference value of 3.9 V
- Logic 0:
- after a successful read of the status byte and EHT <3.9 V.

Remark: a read action is considered successful when an End Of Data signal has been detected (i.e. no master acknowledge).

Table 1 Write mode with auto increment; subaddress and data byte format.

## Notes

1. $X=$ don't care.
2. Data bit used in another function.

## Programmable deflection controller

Table 2 Control bits.

| CONTROL BIT | LOGIC | FUNCTION |
| :---: | :---: | :---: |
| LFSS | 0 | Line stop: EW output current becomes zero and the vertical output current is reduced to $20 \%$ of the adjusted value. LFSS becomes logic 0 after a HIGH on PON. |
|  | 1 | Line start enabled: the soft start mechanism is now activated. |
| DINT | 0 | De-interlace on: the $\mathrm{V}_{\mathrm{A}}$ pulse is sampled at a position selected with control bit DIP. |
|  | 1 | De-interlace off: the $\mathrm{V}_{\mathrm{A}}$ pulse is sampled with the system clock and the detected rising edge is used as vertical reset. |
| BLDS | 0 | Aquadag selected. |
|  | 1 | Bleeder selected. |
| GBS | 0 | Becomes logic 0 after power-on. |
|  | 1 | Guard band 48/12 lines. |
| VAP | 0 | Positive $\mathrm{V}_{\mathrm{A}}$ edge detection. |
|  | 1 | Negative $\mathrm{V}_{\mathrm{A}}$ edge detection. |
| FBL | 0 | Horizontal flyback slicing level $=3.9 \mathrm{~V}$. |
|  | 1 | Horizontal flyback slicing level $=1.3 \mathrm{~V}$. |
| CSU | 0 | No clamping suppression, standard mode of operation. |
|  | 1 | Clamping suppression in wait, stop and protection modes (used in systems with e.g. TDA4680/81). |
| PRD | 0 | No defeat of HOUT, the over voltage information is only written in the PROT status bit. |
|  | 1 | HOUT is defeated and status bit PROT is set when over voltage is detected. |
| DIP | 0 | $V_{A}$ is sampled 42 clock pulses after the leading edge of $H_{A}$. |
|  | 1 | $\mathrm{V}_{A}$ is sampled 258 clock pulses after the leading edge of $\mathrm{H}_{\text {A }}$. |
| CPR | 0 | Nominal amplitude. |
|  | 1 | Compression to $75 \%$ of adjusted amplitude, used for display of $16: 9$ standard pictures on 4 : 3 displays. |
| VPR | 0 | Nominal amplitude (100\%) during wait, stop and clipping. |
|  | 1 | Amplitude reduced to 20\% during wait, stop and clipping. |

## Programmable deflection controller

Table 3 Explanation of control bits shown in Table 2.

| CONTROL BITS |  |
| :--- | :--- |
| LFSS | line frame start/stop |
| DINT | de-interlace |
| BLDS | bleeder mode selection |
| GBS | guard band selection |
| VAP | polarity of $\mathrm{V}_{\mathrm{A}}$ edge detection |
| FBL | flyback slicing level |
| CSU | clamping suppression mode |
| PRD | protection/detection mode |
| DIP | de-interlace phase |
| CPR | compression on/off |
| VPR | vertical power reduction mode |

Table 4 Clock frequency control bit (pin 5; note 1).

| CONTROL BIT | LOGIC | FUNCTION |
| :--- | :---: | :--- |
| LLCS | 0 | prescaler on: the internal clock frequency $f_{\text {clk }}=1 / 2 \mathrm{f}_{\text {LLC }}$ |
|  | 1 | prescaler off (default by internal pull-up resistor): the internal clock frequency $\mathrm{f}_{\mathrm{Clk}}=\mathrm{f}_{\text {LLC }}$ |

## Note

1. Switching of the prescaler is only allowed when LFSS is LOW. It is highly recommended to hard wire LLCS to ground or $\mathrm{V}_{\mathrm{Cc}}$. Active switching may damage the output power transistor due to the changing HOUT pulse. This may cause very high currents and large flyback pulses. The permitted combinations of LLC and the prescaler are shown in Table 5.

Table 5 Line duration with prescaler.

| LLC (MHz) | ON $(\mu \mathbf{s})$ | OFF $(\mu \mathbf{s})$ |
| :---: | :---: | :---: |
| 6.75 | note 1 | 64 |
| 13.5 | 64 | 32 |
| 27 | 32 | note 1 |

## Note

1. Combination not allowed.

Fig. 3 Timing relations between LLC, $\mathrm{H}_{\mathrm{A}}$ and line counter.

## Horizontal part (pins 1, 2, 13, 19 and 20)

## SYNCHRONIZATION PULSE

The $\mathrm{H}_{\mathrm{A}}$ input (pin 13) is a TTL-compatible CMOS input. Pulses on this input have to fulfil the timing requirements as illustrated in Fig.6. For correct detection the minimum pulse width for both the HIGH and LOW periods is 2 internal clock periods.

## FLYBACK INPUT PULSE

The HFB input (pin 1 ) is a CMOS input. The delay of the centre of the flyback pulse to the leading edge of the $\mathrm{H}_{\mathrm{A}}$ pulse can be set via the $\mathrm{I}^{2} \mathrm{C}$-bus with the horizontal phase byte (subaddress 08), as illustrated in Fig.7. The resolution is 6 -bit.

## Output pulse

The HOUT pulse (pin 20) is an open-drain NMOS output. The duty factor for this output is typically $52 / 48$ (conducting/non-conducting) during normal operation. A soft start causes the duty factor to increase linearly from 5 to $52 \%$ over a minimum period of 2000 lines in 2000 steps.

## Off-centre shift

The OFCS output (pin 19) is a push-pull CMOS output which is driven by a pulse-width modulated DAC.

By using a suitable interface, the output signal can be used for off-centre shift correction in the horizontal output stage. This correction is required for HDTV tubes with a $16 \times 9$ aspect ratio and is useful for high performance flat square tubes to obtain the required horizontal linearity. For applications where off-centre correction is not required, the output can be used as an auxiliary DAC. The OFCS signal is phase-locked with the line frequency. The off-centre shift can be set via the $\mathrm{I}^{2} \mathrm{C}$-bus, subaddress 09 , with a 6-bit resolution as illustrated in Fig.8.

## SANDCAStLE

The DSC input/output (pin 2) acts as a sandcastle generating output and a guard sensing input. As an output it provides 2 levels (apart from the base level), one for the horizontal and vertical blanking and the other for the video clamping. As an input it acts as a current sensor during the vertical blanking interval for guard detection.

## Clamping pulse

The clamping pulse width is 21 internal clock periods. The shift, with respect to $\mathrm{H}_{\mathrm{A}}$ can be varied from 35 to 49 clock periods in 7 steps via the $\mathrm{I}^{2} \mathrm{C}$-bus, clamp shift byte subaddress 0A, as illustrated in Fig.9. It is possible to suppress the clamping pulse during wait, stop and protection modes with control bit CSU. This will avoid unwanted reset of the TDA4680/81 (only used in those circuits).

## Horizontal blanking

The start of the horizontal blanking pulse is minimum 38 and maximum 41 clock periods before the centre of the flyback pulse, depending on the $\mathrm{f}_{\mathrm{clk}} / \mathrm{f}_{\mathrm{H}}$ ratio K in accordance with 41 - ( $432-\mathrm{K}$ ).
Stop of the horizontal blanking pulse is determined by the trailing edge of the HFB pulse at the horizontal blanking slicing level crossing as illustrated in Fig. 10.

## Vertical blanking

The vertical blanking pulse starts two internal clock pulses after the rising edge of the $\mathrm{V}_{\mathrm{A}}$ pulse. During this interval a small guard pulse, generated during flyback by the vertical power output stage, must be inserted. Stop vertical blanking is effected at the end of the blanking interval only when the guard pulse is present (see Section "Vertical guard").

The start scan setting determines the end of vertical blanking with a 6-bit resolution in steps of one line via the $\mathrm{I}^{2} \mathrm{C}$-bus subaddress 02 (see Figs 11 and 12).

## Vertical guard

In the vertical blanking interval a small unblanking pulse is inserted. This pulse must be filled-in by a blanking pulse or guard pulse from the vertical power output stage which was generated during the flyback period. In this condition the sandcastle output acts as guard detection input and requires a minimum $800 \mu \mathrm{~A}$ input current. This current is sensed during the unblanking period. Vertical blanking is only stopped at the end of the blanking interval when the inserted pulse is present. In this way the picture tube is protected against damage in the event of missing or malfunctioning vertical deflection (see Figs 11 and 12).

## Vertical part (pins 6, 8, 10, 11 and 12)

## SYNCHRONIZATION PULSE

The $\mathrm{V}_{\mathrm{A}}$ input (pin 12) is a TTL-compatible CMOS input. Pulses at this input have to fulfil the timing requirements as illustrated in Fig.6. For correct detection the minimum pulse width for both the HIGH and LOW period is 2 internal clock periods. For further requirements on minimum pulse width see also Section "De-interlace".

## VERTICAL PLACE GENERATOR

With control bit CPR a compress to $75 \%$ of the adjusted values is possible in all modes of operation. This control bit is used to display $16: 9$ standard pictures on $4: 3$ displays. No new adjustment of other corrections, such as corner and S-correction, is required.

With control bit VPR a reduction of the current during clipping, wait and stop modes to $20 \%$ of the nominal value can be selected, which will reduce the dissipation in the vertical drive circuits.

The vertical start-scan data (subaddress 02) determines the vertical placement in the total range of $64 \times 432$ clock periods in 63 steps. The maximum number of synchronized lines per scan is 910 with an equivalent field frequency of 17.2 or 34.4 Hz for $\mathrm{f}_{\mathrm{H}}=15625$ or 31250 Hz respectively.

The minimum number of synchronized lines per scan is 200 with an equivalent field frequency of 78 or 156 Hz for $f_{H}=15625$ or 31250 Hz respectively.
If the $\mathrm{V}_{\mathrm{A}}$ pulse is not present, the number of lines per scan will increase to 910.2. If the LLC is not present the vertical blanking will start within $2 \mu \mathrm{~s}$.

Amplitude control is automatic, with a settling time of 1 to 2 new fields and an accuracy of either 16/12 or 48/12 lines depending on the value of the GBS bit.

Differences in the number of lines per field, as can occur in TXT or in multi-head VTR, will not affect the amplitude setting providing the differences are less than the value selected with GBS. This is called amplitude control guardband. The difference sequence and the difference sequence length are not important.

## De-interlace

With de-interlace on (DINT = logic 0 ), the $\mathrm{V}_{\mathrm{A}}$ pulse is sampled with LLC at a position supplied by control bit DIP (de-interlace phase).

When DIP = logic 0 sampling takes place 42 clock pulses after the leading edge of $H_{A}$ ( $T=T_{\text {line }} \times 42 / 432$ ).

When DIP = logic 1 sampling takes place 258 clock pulses after the leading edge of $\mathrm{H}_{\mathrm{A}}\left(\mathrm{T}=\mathrm{T}_{\text {line }} \times 258 / 432\right)$.

The distance between the two selectable sampling points is $\left(T_{\text {line }} \times(258-42) / 432\right)$ which is exactly half a line, thus de-interlace is possible in two directions.

The duration of the $\mathrm{V}_{\mathrm{A}}$ pulse must, therefore, be sufficient to enable the $\mathrm{H}_{\mathrm{A}}$ pulse to caught, in this event an active time of minimum of half a line (see Fig. 13 which has an integration time of $T_{\text {line }} \times 1 / 4$ for the $V_{A}$ pulse).

With de-interlace off, the $\mathrm{V}_{\mathrm{A}}$ pulse is sampled with the system clock. The leading edge is detected and used as the vertical reset. Selection of the positive or negative leading edge is achieved by the control bit VAP.

## VERTICAL GEOMETRY PROCESSING

The vertical geometry processing is DC-coupled and therefore independent of field frequency. The external resistive conversion ( $\mathrm{R}_{\mathrm{CONv}}$ ) at pin 8 sets the reference current for both the vertical and EW geometry processing. A useful range is 100 to $150 \mu \mathrm{~A}$, the recommended value is $120 \mu \mathrm{~A}$.

## VERTICAL OUTPUTS

The vertical outputs $\mathrm{VOUT}_{\mathrm{A}}$ and $\mathrm{VOUT}_{\mathrm{B}}$ on pins 10 and 11 together form a differential current output. The vertical amplitude can be varied over the range 80 to $120 \%$ in 63 steps via the $\mathrm{I}^{2} \mathrm{C}$-bus (subaddress 00 ). Vertical S-correction is also applied to these outputs and can be set from 0 to $16 \%$ by subaddress 01 with a 6 -bit resolution.
The vertical off-centre shift (OFCS) shifts the vertical deflection current zero crossing with respect to the EW parabola bottom. The control range is -1.5 to $+1.5 \%$ $\left( \pm 1 / 8 \times I_{8}\right)$ in 7 steps set by the least significant nibble at subaddress 03.

## EW GEOMETRY PROCESSING

The EW geometry processing is DC coupled and therefore independent of field frequency. R ${ }_{\text {CoNv }}$ sets the reference current for both the vertical and EW geometry processing.

The EW output is an ESD-protected single-ended current output.

The EW width/width ratio can be set from 100 to $80 \%$ in 63 steps via subaddress 04 and the EW parabola/width ratio from 0 to $20 \%$ via subaddress 05 . The EW corner/EW parabola ratio has a control range of -40 to $0 \%$ in 63 steps via subaddress 06.

The EW trapezium correction can be set from -1.5 to $+1.5 \%$ in 7 steps via the most significant nibble at subaddress 03 .

## BULT GENERATOR

The Bult generator makes the EW waveform continuous (see Fig.20).

## Protection input (pin 3)

The protection input (PROT) is a CMOS input.
The input voltage must be EHT scaled and has the following characteristics:
Two modes of protection are available with the aid of control bit PRD.

- With PRD = logic 1 the protection mode is selected, HOUT will be defeated and the PROT bit in the status word is set if the input voltage is above 3.9 V . Thus the deflection stops and EW output current is zero, while the vertical output current is reduced to $20 \%$ of the adjusted value. A new start of the circuit is $1^{2} \mathrm{C}$-bus controlled with the user software.
- With PRD = logic 0 the detection mode is selected, HOUT will not be defeated and the over voltage information is only written in the PROT status bit and can be read by the $I^{2} \mathrm{C}$-bus.
All further actions, such as a write of the LFSS bit, are achieved by the $\mathrm{I}^{2} \mathrm{C}$-bus. They depend on the configuration used and are defined by user software.

## Flash detection/protection input (pin 9)

The FLASH input is a CMOS input with an internal pull-up current of approximately $8 \mu \mathrm{~A}$.

When a negative-going edge crosses the 0.75 V level a restart will be executed with a soft start of approximately 2000 lines, such as in the soft-start mode. When the function is not used pin 9 can be connected to ground, $\mathrm{V}_{\mathrm{CC}}$ or left open-circuit, the internal pull-up current source will prevent any problems. However a hard wired connection to $\mathrm{V}_{\mathrm{CC}}$ or ground is recommended when the function is not used.

## EHT compensation (pin 7)

The EHT input is a CMOS input.
The EHT compensation input permits scan amplitude modulation should the EHT supply not be perfect. For correct tracking of the vertical and horizontal deflection the gain of the EW output stage, provided by the ratio $R_{\text {CONV-Ew }} / R_{\text {CONV, }}$ must be $1 / 16 \mathrm{~V}_{\text {scan }} \times \mathrm{V}_{\text {ref }}$ (see Fig.14).
The input for EHT compensation can be derived from an EHT bleeder or from the picture tubes aquadag (subaddress 0B, bit BLDS).
EHT compensation can be set via subaddress 07 in 63 steps allowing a scan modulation range from -10 to $+9.7 \%$.

## Notes to the characteristics

1. For all other frequencies the expected supply current will be as shown in Table 6 ( $\mathrm{f}_{\mathrm{clk}}$ is the internal clock frequency, $f_{\text {LLC }}$ is the internal clock frequency applied to pin 14).
2. When the prescaler is on, one in two LLC HIGH periods is omitted.
3. For 16 kHz operation the minimum value of the control range is $5.7 \mu \mathrm{~s}$. With $1 / 2 \mathrm{t}_{\mathrm{FB}}=5.7 \mu \mathrm{~s}$ the minimum storage time is 0 and the maximum is $18 \mu \mathrm{~s}$.
For 32 kHz operation the minimum value of the control range is $0 \mu \mathrm{~s}$. With $1 / 2 \mathrm{t}_{\mathrm{FB}}=2.85 \mu \mathrm{~s}$ the minimum storage time is 0 and the maximum is $9 \mu \mathrm{~s}$.
4. The k factor is defined as the amount of correction of a phase step. Thus with $\mathrm{k}=0.5$ a $50 \%$ correction of the error takes place each line. The resulting step response now becomes $k^{n}$, with $n$ the line number after the step.
5. The sigma value ( $\sigma$ ) of the jitter with respect to $\operatorname{LLC}$ at $f_{\mathrm{H}}=32 \mathrm{kHz}$ and a storage time of $5 \mu \mathrm{~s}$.

Measurement of $\sigma$ is carried out during 200 lines in the active scan, the resulting peak-to-peak value is approximately $6 \sigma$. The visible jitter on the screen will be higher than the peak-to-peak jitter, depending on the deflection stage.
6. DAC values: vertical amplitude $=31$; EHT $=0 ; \mathrm{SHIFT}=3 ; \mathrm{SCOR}=0$.
7. Value is a percentage of $I_{10}-I_{11}$.
8. The linearity error is measured without S-correction and based on the same measurement principle as used for the screen. Measuring method: divide the output signal $I_{10}-I_{11}$ into 22 equal parts, ranging from 1 to 22 inclusive.
Measure the value of two succeeding parts called one block starting with part 2 and 3 (block 1) and ending with part 20 and 21 (block 10). Thus part 1 and 22 are unused.

Linearity error for adjacent blocks $=\frac{a_{k}-a_{(k+1)}}{a_{a v g}}$
Linearity error for non-adjacent blocks $=\frac{a_{\max }-a_{\text {min }}}{a_{\text {avg }}}$
Where $\mathrm{a}=$ amplitude, $\mathrm{a}_{\mathrm{k}}=$ amplitude block k and $\mathrm{a}_{\mathrm{avg}}=$ average amplitude .
9. Minimum available range.
10. Selection of test mode.

When the EW output is pulled above $\mathrm{V}_{\mathrm{Cc}}-0.5 \mathrm{~V}$ a special test mode is entered in which the prescaler and the clock detector are disabled.
11. DAC values: vertical amplitude $=31$; EHT $=0$; WIDTH $=0$.
12. The value of $-40 \%$ (typically $46 \%$ ) corresponds with data 3F (hexadecimal) and implies maximum 4th order compensation.

Table 6 Supply current with prescaler on/off.

| LLC (MHz) | ON (mA) | OFF (mA) |
| :---: | :---: | :---: |
| 6.75 | note 1 | 27 |
| 13.5 | 27 | 38 |
| 27 | 42 | note 1 |

## Note

1. Combination not allowed.

## TEST AND APPLICATION INFORMATION

## PACKAGE OUTLINE

Dimensions in mm.

Fig. 21 Plastic dual in-line package; 20 leads ( 300 mil); DIP20, SOT146-1.

## SOLDERING

## Plastic dual in-line packages

BY DIP OR WAVE
The maximum permissible temperature of the solder is $260^{\circ} \mathrm{C}$; this temperature must not be in contact with the joint for more than 5 s . The total contact time of successive solder waves must not exceed 5 s .

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified storage maximum. If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

## Repairing soldered joints

Apply a low voltage soldering iron below the seating plane (or not more than 2 mm above it). If its temperature is below $300^{\circ} \mathrm{C}$, it must not be in contact for more than 10 s ; if between 300 and $400^{\circ} \mathrm{C}$, for not more than 5 s .

## DEFINITIONS

| Data sheet status |  |
| :--- | :--- |
| Objective specification | This data sheet contains target or goal specifications for product development. |
| Preliminary specification | This data sheet contains preliminary data; supplementary data may be published later. |
| Product specification | This data sheet contains final product specifications. |
| Limiting values | Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or <br> more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation <br> of the device at these or at any other conditions above those given in the Characteristics sections of the specification <br> is not implied. Exposure to limiting values for extended periods may affect device reliability. |

## Application information

Where application information is given, it is advisory and does not form part of the specification.

## LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.

## PURCHASE OF PHILIPS I²C COMPONENTS

Purchase of Philips $I^{2} \mathrm{C}$ components conveys a license under the Philips' ${ }^{2} \mathrm{C}$ patent to use the components in the $\mathrm{I}^{2} \mathrm{C}$ system provided the system conforms to the $\mathrm{I}^{2} \mathrm{C}$ specification defined by Philips. This specification can be ordered using the code 939839340011.
