

486 SYSTEM/CACHE/ISA BUS CONTROLLER

FEATURES

- Fully compatible with 486-based ISA bus systems
- Power-on reset option selects various operational modes
- Up to 40 MHz CPU operation
- Replaces the following peripheral logic on the motherboard:
 - Two 82C37A DMA controllers
 - 74LS612 memory mappers (extended to support 64 MB)
 - Two 82C59A interrupt controllers
 - 82C54 timer
 - 82284 clock generator and ready interface
 - 82288 bus controller
- Memory controller features include:
 - Up to 64 MB system memory
 - 256K, 1M or 4M DRAM
 - Double-sided SIMMs
- Page Mode DRAM access
- Two-way interleave support
- Programmable RAS#/CAS# timing
- Burst read and write support
- Parity generation/checking for on-board DRAM
- Staggered RAS# refresh
- Supports:
 - One to four banks 32 bits wide
 - 8- or 16-bit wide BIOS ROM
 - Shadow RAM in the 640K-1M area
 - Asynchronous ISA bus operation up to 16 MHz
 - Relocation of slot ROMs
 - Access to devices residing on the local bus
 - Weitek 4167 numeric coprocessor
- 0.8-micron CMOS technology
- 208-lead MQFP (metric quad flat pack)
- Includes:
 - Memory/refresh controller
 - Port A, B, and NMI logic
 - Bus steering logic
 - Turbo control
 - Hidden refresh
 - Three-stateable outputs for board testing
- Selectable slow DRAM refresh saves power
- On-chip write-back cache controller:
 - External tags
 - Direct map
 - Separate "dirty" RAM not required
 - 2-1-1-1 reads with two banks, 2-2-2-2 with one bank
 - 32 KB to 1 MB cache size
 - One wait state writes on cache-hits
 - Optional zero wait state writes
 - Optional one wait state reads

VL82C480-BASED ISA BUS SYSTEM DIAGRAM

ORDER INFORMATION

Part Number	Package
VL82C480-FC	Metric Quad Flat Pack

Note: Operating temperature range is 0°C to +70°C.

**FEATURES (Cont.)**

- Other features:
 - Programmable for 10- or 16-bit internal I/O addressing
 - Programmable drive on the DRAM and ISA bus signals
 - Programmable memory access to define "fast-bus", local bus, slot bus, non-cacheable and write-protect areas
 - Input pin defines access to local bus devices

VL82C480 BLOCK DIAGRAM

OVERVIEW

The VL82C480 controller is designed to control 486DX or 486SX/487SX-based ISA bus systems operating at up to 40 MHz. It replaces the following devices on the motherboard:

- Two 82C37A DMA controllers
- Two 82C59A interrupt controllers
- 82C54 timer
- 74LS612 memory mapper
- 82284 clock generator and ready interface
- 82288 bus controller

The following controller blocks are also included on-chip:

- Memory/refresh controller
- Port B and NMI logic
- Bus steering logic
- Turbo Mode control logic
- Parity checking logic
- Parity generation logic
- Write-back look-aside cache controller

The VL82C480 supports the Weitek 4167 Numeric Coprocessor.

The memory controller logic is capable of accessing up to 64 MB. There can be up to four banks of 256K, 1M, or 4M DRAMs used in a system. The VL82C480 can drive two banks without external buffering. Built-in Page Mode operation and up to two-way interleaving allow the PC designer to maximize system performance using low-cost DRAMs. Programmable DRAM timing is provided for RAS# precharge, RAS-to-CAS delay, and CAS# pulse width.

The VL82C480 write-back cache controller logic supports one or two bank direct map write-back cache with external tag storage. The cache controller can perform 2-1-1-1 reads with two banks or 2-2-2-2 reads with one bank. The VL82C480 can perform one wait state writes on cache-hits. An optional zero wait state write mode is provided for use with fast cache SRAMs. The cacheable DRAM range includes 2 MB up to 64 MB utilizing cache data SRAM sizes of 32 KB through 1 MB, respectively.

Shadowing features are supported on 16K boundaries between A0000h and FFFFFh (640 KB to 1 MB). Simultaneous use of shadowed ROM and direct system board access is possible in a non-overlapping fashion throughout this memory space. Control over four access options is provided:

1. Access ROM or slot bus for reads and writes.
2. Access system board DRAM for reads and writes.
3. Access system board DRAM for reads and slot bus for writes.
4. Shadow setup mode. Read ROM or slot bus, write system board DRAM.

Three special programmable address regions are provided. The Fast Bus Clock Region allows accesses to certain memory regions at a faster ISA bus clock rate for fast on-board or off-board devices. A Non-Cacheable Region and/or a Write-Protected Region may be defined by a set of six registers that allow memory in the region 640 KB to 1 MB to be marked as non-cacheable and/or write-protected in increments of 16 KB. A further set of registers allows a memory range anywhere in the first 64 MB of memory to be marked as a DRAM region, an ISA bus region, or a local bus region, either cacheable or non-cacheable in increments of 2 KB, 64 KB, or 1 MB.

Further support for devices that reside on the local bus is provided through use of the LBA# (Local Bus Access) input, which deselects the VL82C480 during CPU cycles. Also, a memory range anywhere in the first 64 MB of memory can be programmed via the internal mapping registers to make the VL82C480 access a local bus device as a CPU bus memory device during DMA or Master Mode transfers, and deselect the VL82C480 during CPU cycles.

The VL82C480 handles system board refresh directly and also controls the timing of slot bus refresh. Refresh may be performed in Synchronous, Asynchronous, or Decoupled Mode. In the Synchronous Mode, slot bus and on-board DRAM refresh cycles proceed simultaneously with all memory cycles held until both have completed. The Asynchronous Mode allows on- and off-board refreshes to be initiated simultaneously, but to complete asynchronously, allowing earlier access to DRAM. In the Decoupled Mode, a separate refresh counter is used for slot bus refresh, allowing on-board DRAM and system refreshes to proceed independently, with DRAM

refreshes initiated during bus idle cycles. CAS-before-RAS refresh is also supported. Refreshes are staggered to minimize power supply loading and attenuate noise on the VDD and VSS pins. The VL82C480 supports the ISA bus standard refresh period of 15.625 μ s as well as 125 μ s.

The interrupt controller logic consists of two 82C59A megacells with eight interrupt request lines each. The two megacells are cascaded internally and three of the interrupt request inputs are connected to internal circuitry, so a total of 13 external interrupt request lines are available. These 13 interrupt request lines plus the Weitek interrupt request line, the ten-channel check line, and the Turbo/Non-Turbo line are scanned in through one pin on the VL82C480. Two external 74LS166s are required for scanning in these 16 signals.

The interval timer includes one 82C54 counter/timer megacell. The counter/timer has three independent 16-bit counters and six programmable counter modes.

The two DMA controllers are 82C37A compatible. Each controls data transfers between an I/O channel and on- or off-board memory. The DMA controllers can transfer data over the full 64 MB range available. Internal latches are provided for latching the middle address bits output by the 82C37A megacells on the data bus. The 74LS612 memory mappers are integrated to generate the upper address bits.

The VL82C480 can be programmed for asynchronous or synchronous operation of the ISA bus.

The VL82C480 also performs all of the data buffer control functions required for a 486-based ISA bus system. Under the control of the CPU, the VL82C480 routes data to and from the CPU's D bus, the internal XD bus, and the slots (SD bus). During CPU ISA bus reads, the data is latched for synchronization with the CPU. Parity is checked for D bus DRAM read operations. The chip does not generate parity for CPU writes to DRAM, but does generate cache write-back cycles. Even parity is generated and checked.

When the DMA requestor or external bus master is the bus owner, the VL82C480 allows data transfer between the slot SD bus and the CPU local D bus. The chip also performs low-to-high and high-to-low byte swaps on the 16-bit

SD bus. Parity is generated by the VL82C480 during DMA or Master Mode writes to on-board DRAM.

The VL82C480 Controller functions are programmable via a set of internal configuration registers. The state of various

interface pins at reset is used to determine the default configuration.

The VL82C480 also provides a single input, SPKR/TRI#, to disable all of its outputs for board level testability.

VL82C480 PIN DIAGRAM

TABLE 1. PIN TYPE BY OPERATIONAL STATE

Pin #	Pin Name	Pin Type	Input Type	Drive (mA)	Pin #	Pin Name	Pin Type	Input Type	Drive (mA)

Notes: (1) These pins are input only during POR (power-on reset).

(2) These pins require an external pull-up resistor.

Legend: CMOS CMOS-compatible input

I Input-only pin

IO Bidirectional pin

GND Ground pin

O Output pin

OD Open drain

PWR Power supply pin

TTL TTL-compatible input

-PD Indicates a high-impedance with $\approx 10\text{ K}\Omega$ minimum resistance to VSS (internal pull-down resistor on pin).

-PU Indicates a high-impedance with $\approx 10\text{ K}\Omega$ minimum resistance to VDD (internal pull-up resistor on pin).

-S Indicates a Schmitt-trigger input with hysteresis for noise immunity.

**SIGNAL DESCRIPTIONS**

Signal Name	Pin Number	Signal Type	Signal Description
CPU INTERFACE SIGNALS			
A[31], A[26], A[25], A[24], A[23], A[22:18], A[17:2]	143, 114, 142, 140, 139, 137:133, 131:116	IO-T	Address bus bits 31, 26 through 21, and 19 through 2 - The bidirectional address bus is driven by the bus master. It is driven out by the VL82C480 during Non-Master Mode DMA and refresh cycles when HLDA is active and MASTER# is inactive. The signals A[25:2] allow access to 64 MB of system memory. A[31] and A[26] are used for disabling DRAM access so that system ROM and the Weitek numeric coprocessor can be accessed. A[31] A[26] 0 0 = normal memory access, up to 64MB DRAM selected 0 1 = other bus slaves (VL82C480 is deselected, 7 μs time-out) 1 0 = Weitek coprocessor access (VL82C480 is deselected, conditional 7 μs time-out) 1 1 = ROM and aliased ISA bus access A[26:24] and A[31] need external 10K ohm pull-down resistors.
A[20]	135	IO-TPU	Address bus bit 20 - This pin is driven by the bus master. It is driven out by the VL82C480 during DMA and refresh cycles. This pin has an internal pull-up resistor.
ADS#	75	IO-T	Address Status - Active low ADS# is driven by the CPU as an indication that the address and control signals currently supplied by the CPU are valid. This signal is used internally to indicate that the data and command are valid and determine the beginning of a memory or I/O cycle. ADS# is driven by the VL82C480 when HLDA is active and is made low for one CPU clock cycle at the beginning of DMA or Master Mode cycles when a local bus region is selected by the PMR Registers.
BE[3:0]#	84:81	IO-T	Byte Enable bits 3 through 0 - These signals are normally inputs to the VL82C480 and indicate which bytes on D[31:0] are involved in a memory or I/O access. They are ignored during all DRAM reads. They are driven by the VL82C480 when HLDA is active and indicate which one or two bytes are involved in an 8- or 16-bit DMA or Master Mode transfer between slot I/O and a local bus device.
BLAST#	57	I-T	Burst Last - This is an input to the VL82C480 indicating when to terminate the current burst cycle, if the length of the burst cycle is less than four double-words. It is driven low by the VL82C480 when HLDA is active, however, the VL82C480 does not support the burst mode during DMA or Master Mode cycles.
A20M#	79	I-TPU	A20 Mask - This asserted output signal instructs the CPU to mask address bit 20 for all operations. This pin has an internal pull-up resistor.
BRDY#	59	IO-TPU	Burst Ready - The active low BRDY# signal indicates to the CPU that the current DRAM cycle is complete. It is driven low when valid data has been presented to the CPU in response to a read command or when data has been accepted in response to a write command from the CPU. The VL82C480 drives BRDY# on all local bus DRAM and cache read accesses. It never drives it in response to slot bus accesses (see RDY# definition). The VL82C480 enables the BRDY# three-state output only when it needs to drive it low, and leaves it enabled for just one CPU clock cycle after it has driven it high again. When HLDA is active, BRDY# is an input to the VL82C480 and may be driven by a local bus device to terminate Local Bus DMA or Master Mode cycles. This pin has an internal pull-up resistor

**SIGNAL DESCRIPTIONS (Cont.)**

Signal Name	Pin Number	Signal Type	Signal Description
NC	60		No Connect
CLK1	62	O	1X Clock - This output is a CMOS level pulse train whose frequency is normally one-half that of the TCLK2 signal. It is used by the VL82C480, 486, and other on-board logic. Its frequency can be programmed to slower rates for Non-Turbo Mode operation.
CLKIN	63	I-C	Input Clock - CLKIN is the fundamental clock input to the VL82C480. It must be the same clock as that supplied to the 486.
M/IO#_DK0	74	IO-T	Memory Input/Output and DMA Acknowledge 0 - When HLDA is low, M/IO#_DK0 is driven by the local bus master and is decoded with D/C#_DK1 and W/R#_DK2 to indicate the type of bus cycle requested. When HLDA is high, this is an output signal which, along with D/C#_DK1 and W/R#_DK2, represents the encoded channel number being serviced at the beginning of DMA acknowledge cycles. If the VL82C480 makes ADS# active during DMA or Master Mode cycles (for local bus accesses) this signal is forced high.
D/C#_DK1	73	IO-T	Data/Control and DMA Acknowledge 1 - When HLDA is low, D/C#_DK1 is driven by the local bus master and is decoded with M/IO#_DK0 and W/R#_DK2 to indicate the type of bus cycle requested. When HLDA is high, this is an output signal which, along with M/IO#_DK0 and W/R#_DK2, represents the encoded channel number being serviced at the beginning of DMA acknowledge cycles. If the VL82C480 makes ADS# active during DMA or Master Mode cycles (for local bus accesses) this signal is forced high.
W/R#_DK2	72	IO-T	Write/Read and DMA Acknowledge 2 - When HLDA is low, W/R#_DK2 is driven by the local bus master and is decoded with D/C#_DK1 and M/IO#_DK0 to indicate the type of bus cycle requested. When HLDA is high, this is an output signal which, along with D/C#_DK1 and M/IO#_DK0, represents the encoded channel number being serviced at the beginning of DMA acknowledge cycles. If the VL82C480 makes ADS# active during DMA or Master Mode cycles (for local bus accesses) this signal indicates whether a local bus read or local bus write cycle is required.
D[31:0]	21:25, 27:31, 33:36, 38:47, 49:56	IO-T	CPU Data bus bits 31 through 0 - This is the data bus directly connected to the CPU and other external devices.
EADS#	69	IO-T	External Address [POR input] - This signal indicates a primary cache invalidation address is on the address bus. It is driven low by the VL82C480 to perform primary cache invalidations during DMA and Master Mode cycles and is also driven low for one cycle during the first T2 of a local bus write to a write-protected memory location. It is also modulated for implementation of the Non-Turbo Mode. At power-on reset (POR), this pin is used to set the polarity of the DKEN input.
FERR#	65	I-TPU	Floating Point Error - The FERR# input indicates a floating point error. When active, it generates an interrupt IRQ13 internal to the VL82C480. This input pin is active low. FERR# has an internal pull-up resistor.
HLDA	70	I-T	Hold Acknowledge - The active high HLDA signal is issued by the CPU in response to the HOLD driven by the VL82C480. It indicates that the CPU is floating its outputs to the high impedance state so that another master can take control of the bus.
HOLD	71	O	Hold Request - The active high HOLD pin is driven by the VL82C480 to the CPU. It indicates that a bus master, such as a DMA or refresh controller, is requesting control of the bus. This signal is synchronized to CLKIN.

**SIGNAL DESCRIPTIONS (Cont.)**

Signal Name	Pin Number	Signal Type	Signal Description
IGNNE#	64	IO-T	Ignore Numeric Error Output [POR input] - This active low output instructs the CPU to ignore the present numeric error. It is enabled when a dummy write is performed to either port F0h or F1h while FERR# is active. At power-on reset (POR), this pin is used to set SA[1] timing.
INTR	160	O	Interrupt Request - An active high output used to interrupt the CPU. It is generated by the 82C59A megacells any time a valid interrupt request input is received.
KEN#	76	O-TPD	Cache Enable - The KEN# signal is an output which determines whether the current cycle is cacheable in the primary cache. This signal is normally low, but is driven inactive during the second and subsequent T2 cycles of all CPU memory accesses defined as non-cacheable, except when local bus CPU cycles are selected by the PMR Registers; in this case it is made inactive during the first and subsequent T2's of the local bus cycle. This pin has an internal pull-down resistor.
NMI	80	O	Non-Maskable Interrupt - An active high output which indicates to the CPU that an external non-maskable interrupt has been generated. This signal is asserted by either a parity error or an I/O channel error. The NMI output is enabled by resetting the MSB (most significant bit) of I/O port 70h. NMI is disabled on reset.
RDY#	58	IO-TPU	Non-Burst Ready - The active low RDY# signal is driven by the VL82C480 as an indication that the current memory or I/O slot bus cycle or cache write cycle is complete. The VL82C480 enables the RDY# three-state output only when it needs to drive it low and leaves it enabled for just one CPU clock cycle after it has driven it high again. When HLDA is active, RDY# is an input to the VL82C480 and may be driven by local bus devices to terminate DMA and Master Mode cycles. This pin has an internal pull-up resistor.
RESCPU	68	O	Reset CPU - This active high signal is used to reset the CPU and is asserted in response to one of the following: 1. A dummy read from I/O port EFh. 2. The LSB (least significant bit) of Port A is set to '1' by an active write. 3. The POWERGOOD signal changes state. 4. Shutdown command. RESCPU is synchronized to CLKIN.
TCLK2	66	I-C	Clock - This input is connected to a crystal oscillator whose frequency is twice the system frequency. The signal is divided down in frequency and sent to the CLK output.

ON-BOARD MEMORY SYSTEM INTERFACE SIGNALS

CASX[3:0]#, CASY[3:0]#	89:86, 94:91	O-PU	Column Address Strokes - The CASX[3:0]# and CASY[3:0]# signals generate active low column address strobes for DRAM banks during on-board memory bus cycles. The active period for these signals is determined by the number of wait states and the configuration mode. These pins have internal pull-up resistors.
MA[10:1]	108:105, 103:99, 97	O	Memory Address bus bits 10 through 1 - The MA[10:1] address bits are the row and column addresses sent to on-board memory. They are buffered and multiplexed versions of the local CPU bus address. They allow addressing of up to 64 MB of memory by the VL82C480.
MA0X	98	O	Memory Address bus bit 0, Banks 0 and 2 - MA0X is a multiplexed row/column address bit for Banks 0 and 2. It is interleaved with MA0Y to ensure that DRAM setup and hold times are met for A[3] during fast burst mode interleave.

**SIGNAL DESCRIPTIONS (Cont.)**

Signal Name	Pin Number	Signal Type	Signal Description
MA0Y	95	O	Memory Address bus bit 0, Banks 1 and 3 - MA0Y is a multiplexed row/column address bit for banks 1 and 3. It is interleaved with MA0X to ensure that DRAM setup and hold times are met for A[3] during fast burst mode interleave.
MDEN#	166	IO	Memory Data Word Enable - An active low signal which enables the output of the memory data buffers.
PAR[3:0]	165:162	IO-T	Parity bits 0 through 3 - Each parity bit signal is associated with one byte of the data bus. Even parity is generated on PAR[3:0] and written to memory along with their corresponding bytes during DMA, master and cache write-back operations. During write operations to memory, the parity bit pins are three-stated because the 486 generates parity. During memory read operations these pins become inputs and are used along with their respective data bytes to determine whether a parity error has occurred.
RAMW#/EAL#	78	IO-T	RAM Write (output) and Early Address Latch Enable [POR input] - This active low output controls DRAM memory write enable and buffer direction, except during ISA bus cycles and refresh cycles. During ISA bus cycles and at the start of refresh, this signal functions as Early Address Latch Enable. RAMW#/EAL# is forced low during the start of a refresh cycle or ISA bus cycle; it is driven high when BALE is high for all CPU slot ISA bus cycles. At power-on reset (POR) this pin is used to set system and slot BIOS ROM location (ROMMOV2, ROMSET[6] Register).
RAS[3:0]#	110:113	O	Row Address Strobe bits 3 through 0 - These signals are sent to each of the four DRAM banks to strobe in the row address during on-board memory bus cycles.

CACHE CONTROLLER INTERFACE SIGNALS

TAG[8:0]	10:2	IO-T	Tag Data bus bits 8 through 0 - A private bus for communication of tags between the VL82C480 and the tag RAM. TAG[8] has an internal pull-up resistor.
CWE[3:0]#	11:14	O	Cache Write Enable bits - These four signals enable writes to the cache SRAMs. Banks A and B (one enable per byte).
TAGWE#	15	O	Cache Tag Write Enable - This active low signal enables writes to the tag SRAM for updates during line-fills or clean-writes.
CA3A	1	O-TPU	Cache Address 3, Bank A (output) - This output signal drives the cache Bank A, Address 3. This pin has an internal pull-up resistor.
CA3BA2	207	IO-TPU	Cache Address 3, Bank B or Cache Address 2, Bank A (output) - In Double Cache Data Bank Mode, this output signal drives the cache Bank B Address 3. In Single Cache Data Bank Mode, this output drives the cache Bank A Address 2. This pin has an internal pull-up resistor.
CCSA#	17	IO-T	Chip Select, Cache Bank A [POR Input] - This active low output signal enables the cache data SRAMs in Bank A during read/write access. At power-on reset (POR), this pin is used along with CCSB# to set the DRAM interface output drive current.
CCSB#	18	IO-T	Chip Select, Cache Bank B [POR Input] - This active low output signal enables the cache data SRAMs in Bank B during read/write access. At power-on reset (POR), this pin is used along with CCSA# to set the DRAM interface output drive current.
COEA#	19	IO-T	Cache Output Enable, Bank A [POR Input] - This active low output signal enables the bus drive circuitry of cache data SRAMs in Bank A.

**SIGNAL DESCRIPTIONS (Cont.)**

Signal Name	Pin Number	Signal Type	Signal Description
COEB#	20	O	At power-on reset (POR), this pin selects the frequency operation mode of the VL82C480 CPU interface. A low on COEA# at power-up selects a clock frequency operation mode of 25 MHz or less. A high on COEA# at POR selects 33 MHz or 40 MHz operation. Cache Output Enable, Bank B - This active low output signal enables the bus drive circuitry of cache data SRAMs in Bank B.
PERIPHERAL INTERFACE SIGNALS			
LBA#	144	I-T	Local Bus Access - On CPU accesses, this signal must be made low by a local bus device before one-half way through the first T2 cycle of any CPU bus cycle that normally accesses on-board DRAM, or before the end of the first T2 for any other type of cycle, if a CPU access is to a local bus device. When active, it causes the VL82C480 to be deselected.
ROMCS#/PCS#	161	IO	ROM Chip Select and Peripheral Chip Select - During ISA bus CPU cycles, this signal is used as the ROM chip select. All other times, it is used as the peripheral chip select for the keyboard controller and real-time clock.
POWERGOOD	176	I-TS	System Power-On Reset - An active high input which indicates that the power to the board is stable. A Schmitt-trigger input is used. This allows the input to be connected directly to an RC network.
SPKR/TRI#	85	IO-TPU	Speaker and Three-state - The active high SPKR output drives an externally buffered speaker. This signal is an input when the POWERGOOD input is low. If sampled low, it forces the VL82C480 into the Three-State Mode where all outputs and bidirectional pins are driven to a high impedance state. This pin has an internal pull-up resistor.
BUS INTERFACE SIGNALS			
AEN	181	O	Address Enable - AEN is an active high output that indicates a DMA transfer cycle to the I/O resources on the bus. It is asserted only when the DMA controller is the bus owner (HLDA = '1, MASTER# = '1). The I/O resource with an active DMA acknowledge signal should only respond to the I/O command lines and all the other I/O resources should ignore the commands.
BALE	180	O	Bus Address Latch Enable - BALE is an active high pulse which is generated at the beginning of any bus cycle initiated by the CPU. It indicates when the SA[19:0], LA[23:17], AEN, and SBHE# signals are valid. BALE is forced high any time HLDA is high.
BUSOSC	155	I-TPU	System Bus Clock - This signal is supplied by an external oscillator. It has a nominal 50% duty cycle and normally a frequency of 16 MHz. It is used for ISA bus operations. If an oscillator is connected to this pin, SYSCLK can be programmed to be BUSOSC ÷2, ÷4, ÷6, or ÷8. If SYSCLK is to be derived from TCLK2, the BUSOSC is held high or low and is used in conjunction with the CLKCTL Register to determine the clock divider value. BUSOSC has an internal pull-up resistor.
DKEN	178	IO-T	DMA Acknowledge Enable (output) [POR input] - DKEN enables an external 3-to-8 decoder for the generation of the DMA acknowledge signals from M/IO#_DK0, D/C#_DK1 and W/R#_DK2 when these signals are valid at the beginning of a DMA cycle. If a local bus cycle is started during a DMA cycle, then DKEN must also be used to latch the DMA acknowledges when active. It is active high when EADS# is pulled high during power-on reset (POR) and active low when EADS# is pulled low during POR. At POR, this pin is used to set BIOS ROM width (ROMWID, ROMSET[7]).

**SIGNAL DESCRIPTIONS (Cont.)**

Signal Name	Pin Number	Signal Type	Signal Description
DRQ[7:5], DRQ[3:0]	200:202, 203:206	I-TSPU	DMA Request bits 7 through 5 and 3 through 0 - The asynchronous DMA request inputs are used by external devices to indicate when they need service from the internal DMA controllers. DRQ[3:0] are used for transfers between 8-bit I/O adapters and system memory. DRQ[7:5] are used for transfers between 16-bit I/O adapters and system memory. DRQ[4] is not available externally as it is used to cascade the two DMA controllers together. All DRQ pins have internal pull-up resistors.
IOCHRDY	151	IO-TOD	I/O Channel Ready - The IOCHRDY input is pulled low in order to extend the read or write cycles of any bus access when required. The cycle can be initiated by the CPU, DMA controllers or refresh controller. The default number of wait states for cycles initiated by the CPU are four wait states for 8-bit peripherals, one wait state for 16-bit peripherals and three wait states for ROM cycles. One DMA wait state is inserted as the default for all DMA cycles. Any peripheral that can not present read data or strobe in write data in this amount of time must use IOCHRDY to extend these cycles. In DMA Mode, this pin is always driven low by the VL82C480 that generate local bus cycles to allow for local bus latency; the VL82C480 never drives IOCHRDY high, but three-states it when not driven low. This pin requires an external 10K pull-up resistor
IOCS16#	146	I-T	16-Bit I/O Chip Select - This input determines when a 16-to-8 bit conversion is needed for CPU accesses. A conversion is done any time the VL82C480 requests a 16-bit I/O cycle and IOCS16# is sampled high. A command delay of one BUSOSC cycle is inserted and the cycle becomes four wait states long when a conversion is needed. If sampled low, an I/O access is performed in one wait state with one command delay inserted. The IOCS16# signal is ignored by the DMA and refresh controller for DMA and refresh cycles, respectively.
IOW# IOR#	158 159	IO-T IO-T	I/O Read I/O Write IOR# and IOW# are active low inputs when an external bus master is in control (HLDA = '1, MASTER# = '0). They function as outputs at all other times. When HLDA is low, they are driven by the internal ISA bus controller. During DMA transfer cycles (HLDA = '1, MASTER# = '1), they are driven by the 82C37A DMA controllers. They are inactive during a refresh cycle. Both the pins require external 10K pull-up resistors.
IRQSDIN	153	I-T	Interrupt Request Data In - This input signal accepts the scanned asynchronous interrupt requests [IRQs] from external 74LS166 shift registers into the 82C59A megacells. IRQ[0], IRQ[2] and IRQ[13] are not available as external inputs because they are used internally. All IRQ inputs pins except IRQ[8]# are active high. NMI is not a scanned input. The following interrupt requests are captured by the scan input: • IRQ[15], IRQ[14], IRQ[12:9], IRQ[8]#, IRQ[7:1] • WEIRQ - Weitek numeric coprocessor error • TURBO - Determines CPU speed. Low = slow, high = full speed. Its state may be read from the NTBREF Register. The hold signals to the 486 are continuously generated in order to slow its operation. • IOCHCK# - I/O bus error. If I/O checking enabled, IOCHCK# assertion by a peripheral device generates an NMI to the CPU if bit 3 of Port B is set to '0. The state of the IOCHCK# signal can be read as data bit 6 (CHAN_CHK) in Port B.
IRQCLK	167	I-T	Interrupt Request Scan Clock - This signal is the input clock to the interrupt request scanner within the VL82C480. It is the same signal used to clock the external 74LS166 shift registers to shift the captured interrupt information into the VL82C480.

SIGNAL DESCRIPTIONS (Cont.)

Signal Name	Pin Number	Signal Type	Signal Description
IRQSH/LD#	150	IO-T	Interrupt Request Load and Shift Control [POR input] - When low, this signal causes the external 74LS166 interrupt shift registers to load new interrupt information when clocked; when high, it causes the shift registers to shift when clocked. Load (IRQSH/LD# low) occurs once every seventeenth IRQCLK. At power-on reset (POR), this pin is used to set the slot drive current (SLTDRV, BUSCTL[5]).
MASTER#	179	I-T	Master - This active low input is driven by an external device to disable the VL82C480's DMA controllers and obtain access to the system bus. When asserted, it indicates that an external bus master has control of the bus.
MEMCS16#	145	I-T	16-Bit Memory Chip Select - This active low input is used to determine when a 16-to-8 bit conversion is needed for CPU accesses. A conversion is done anytime the VL82C480 requests a 16-bit memory cycle and MEMCS16# is sampled high. If sampled high with the BUSCTL Register in the default configuration, a command delay of one BUSOSC cycle is inserted and the cycle becomes four wait states long. If sampled low, a memory access is performed in one wait state with no command delays inserted. The MEMCS16# signal is ignored by the DMA and refresh controller for DMA and refresh cycles, respectively.
MEMR#	175	IO-T	Memory Read
MEMW#	177	IO-T	Memory Write
			The active low signals MEMR# and MEMW# are inputs when an external bus master is in control (HLDA = '1, MASTER# = '0). They are outputs at all other times. When HLDA is low MEMW# is driven from the ISA bus controller. They are driven by internal 82C37A DMA controllers during DMA cycles. Both the pins require external 10K pull-up resistors.
OSC	149	I-T	Oscillator Input - OSC is the buffered input of the external 14.31818 MHz oscillator with a duty cycle of 45-55%.
REFRESH#	154	IO-TSOD	Memory Refresh - The REFRESH# signal is pulled low whenever a refresh cycle is initiated. An external bus master activates this signal when it requires a refresh cycle from the refresh controller. The internal refresh controller activates this line every 15.6 μs to prevent loss of DRAM data. REFRESH# is an open-drain output capable of sinking 24 mA and requires an external pull-up resistor.
RSTDRV	170	O	Reset - This active high output is a system reset generated from the POWERGOOD input. RSTDRV is synchronized to the BUSOSC input. On reset, this signal remains high for at least as long as the RESCPU signal. It may therefore be used to drive the 486's AHOLD input to initiate a 486 self-test sequence on power-on reset only.
SA[1:0]	147:148	IO-T	System Address bus bits 1 and 0 - These signals represent the lower two bits of the system address bus. They act as inputs when an external bus master is in control (HLDA = '1, MASTER# = '0) and are outputs at all other times. When HLDA is low, SA[1:0] are generated by decoding the CPU byte enables, BE[3:0]#. They are driven by the 82C37A DMA controllers during DMA transfer cycles. SA[0] is always connected directly to the ISA bus. SA[1] is connected to the ISA bus if discrete SA buffers are used. If the VL82C113A is used, then SA[1] is connected only to the A[1] input of the VL82C113A (which then drives the ISA bus SA[1] signal). IGNNE# is used to set SA[1] timing at power-on reset for use with/without the VL82C113A.
SBHE#	169	IO-T	System Byte High Enable - An active low SBHE# indicates that valid data is on the upper byte of system data bus, SD[15:8]. Its functionality is similar to that of the SA[1:0] signals. SBHE# is forced low during 16-bit DMA cycles and is the complement of SA[0] during 8-bit DMA cycles.

**SIGNAL DESCRIPTIONS (Cont.)**

Signal Name	Pin Number	Signal Type	Signal Description
SD[15:0]	182:186, 188:192, 194:199	IO-T	System Data bus bits 15 through 0 - The bidirectional SD[15:0] signals and directly connected to the slots.
SMEMR#	171	O	System Memory Read
SMEMW#	174	O	System Memory Write
			The SMEMR# and SMEMW# outputs are active during memory read and write cycles, respectively, when the address is below 1 MB.
			Both the pins require external 10K pull-up resistors.
SYSCLK	173	O	System Clock - The SYSCLK output is 1/2, 1/3, 1/4, 1/6, or 1/8 the frequency of TCLK2 or BUSOSC depending on the BUSOSC pin status and the five lower bits in the CLKCTL Register. The bus control signals BALE, IOR#, IOW#, MEMR#, and MEMW# are synchronized to SYSCLK.
TC	157	O	Terminal Count - This active high output indicates that one of the DMA channels has transferred all data.
WS0#	152	I-T	Wait State Terminate - An active low input which indicates a shorter access cycle. It is pulled low by a peripheral on the slot bus to terminate a CPU controlled bus cycle earlier than the default values defined internally on the chip.
POWER AND GROUND			
VSSI	138	GND	Core Ground Connection - 0 volts.
VSSR	16, 32, 48, 61, 77, 90, 104, 115, 132, 156, 168, 187, 208	GND	Ring Ground Connection - 0 volts.
VDDI	26	PWR	Core Power connection - Nominally +5 volts.
VDDR	37, 67, 96, 109, 141, 172, 193	PWR	Ring Power connection - Nominally +5 volts.

**REGISTER SUMMARY****SYSTEM CONFIGURATION**

The VL82C480 offers hardware configured options to ensure that it resets to a usable state with the various physical configurations available. During reset, the output pins listed in Table become

inputs and their value is loaded into the configuration registers as shown or are used to configure the system. There is no internal default for these bits, therefore the pins shown must be set to the required value during reset. Table 3 details the mapping.

INDEXED CONFIGURATION REGISTER FORMATS

Table 2 shows the Indexed Configuration Register formats. Power-on reset values are shown above the diagrams for each register or set of registers.

TABLE 1. SYSTEM CONFIGURATION INITIALIZATION

Pin	Register		Bit Name	Functional Description
	Name	Bit

**TABLE 4. DEDICATED I/O CONTROL REGISTERS**

Port Addr	Name	Access	Functional Description
61h	Port B	R/W	Miscellaneous control bits
70h	NMI Enable	W	Enables non-maskable interrupts.
92h	Port A	R/W	Fast A20 and reset control.
ECh	Configuration Index Port	R/W	Contains the address of one of the Configuration Registers mention in Table 3.
EDh	Configuration Data Port		Contains the data written to the Configuration Register selected by the Configuration Index Port.
EEh*+	Fast A20 Register	R/W	A dummy read enables Fast A20. A dummy write disables Fast A20.
EFh*+	Fast CPU Reset Register	R	A dummy read resets the CPU.
F0h	Coprocessor Busy Register	W	A dummy write clears IRQ[13] and sets BSCPU#.
F1h	Coprocessor Reset Register	W	A dummy write clears IRQ[13] and sets BSCPU#.
F4h+	Slow CPU Register	W	A dummy write enables the Fast Clock and Turbo Mode for the CPU.
F5h+	Fast CPU Register	W	A dummy write enables the Fast Clock and Turbo Mode for the CPU.
F9h+	Configuration Enable Register	W	A dummy write disables access to the Configuration Registers.
FBh+	Configuration Enable Register	W	A dummy write disables access to the Configuration Registers.

* Also can be activated through Port 92h for PS/2 compatibility.

+ These decodes can be disabled by setting the MSB of the BUSCTL Register in case of conflict.

tA1_SACD ⁽¹⁾	HLDA High to SA[1:0] CMD# ⁽³⁾ Active	3	30	ns	8	CL = 200 pF

**AC CHARACTERISTICS (Cont.)**

Symbol	Parameter	Min	Max	Unit	Fig	Conditions
INTERRUPT TIMING						
tD1_INTR	FERR# to INTR Delay	5	150	ns	8	CL = 50 pF
tD3_INTR ⁽¹⁾	OSC to INTR Delay	5	130	ns	9	CL = 50 pF
tD1_ISLD	IRQCLK to IRQSH/LD# Delay	3	10	ns	5	CL = 50 pF
tS1_ISDI	IRQSDIN to IRQCLK Setup Time	5		ns	5	
tH1_ISDI	IRQSDIN from IRQCLK Hold Time	3		ns	5	
MISCELLANEOUS TIMING						
tS1_PWG ⁽¹⁾	POWERGOOD to OSC Setup Time	15		ns	9	
tH1_PWG ⁽¹⁾	POWERGOOD from OSC Hold Time	10		ns	9	
tD1_RSD	CLKIN to RSTDRV Delay	-10	20	ns	5	CL = 200 pF
tD2_SPKR ⁽¹⁾	OSC to SPKR Delay	5	120	ns	9	CL = 50 pF
tA1_DRAM ⁽¹⁾	CLKIN to MA[10:1], MA0X, MA0Y, RAS[3:0]#, CASX[3:0]#, CASY[3:0]# Active	4	50	ns	4	Following fourth ADS# after power-on reset

1 These timing specifications are guaranteed by design.

2 These timing specifications apply to zero wait state write systems only. These timings are characterized, but not tested in production. To support zero wait state writes at 25/33 MHz, the following glue logic components are needed in the system:

A) Two minimum skew clock buffers on CLK1.

B) Two octal address latches for data SRAMs to allow CWE# late turn-off time during zero wait state write-hits.

3 CMD# refers to the signals MEMR#, MEMW#, IOR#, and IOW#

4 SCMD# refers to the signals SMEMR# and SMEMW#.

5 CMD# refers to the signals MEMR# and MEMW#.
