

PBL 3726/18

Universal Speech Circuit

Description

PBL 3726/18 is a standard version of the PBL 3726 family of the mask-programmable, monolithic integrated speech circuits for use in electronic telephones.

It is designed for use with a low impedance microphone. Transmitting and receiving gain is regulated with line length. Different regulation for various current feeds can be set by external resistors. Typical current feeds as 48 V, 2 • 200 ohm, 48 V 2 • 400 ohm and 36 V 2 • 500 ohm can be handled. Application dependent parameters such as line balance, side tone level, amplification and frequency response are set by external components. Parameters are set independently which means easy adaption for various market needs.

This version of PBL 3726 is developed for use with CMOS-type dialler ICs. A separate DTMF input is switched in when the circuit is muted, and an adjustable DC supply is provided for feeding an external CMOS device.

Key Features

- Minimum number of inexpensive external components, 5 capacitors and 11 resistors.
- Mute function for operation with DTMF-generator.
- Transmit and receive gain regulation for automatic loop loss compensation.
- Extended current and voltage range 5 - 130 mA, down to 2 V.
- Differential microphone input for good balance to ground.
- Balanced receiver output stage.
- Short start-up time.
- Stabilized DC-supply for low current CMOS dialers and/or electret microphones.
- DTMF-input controlled by mute.

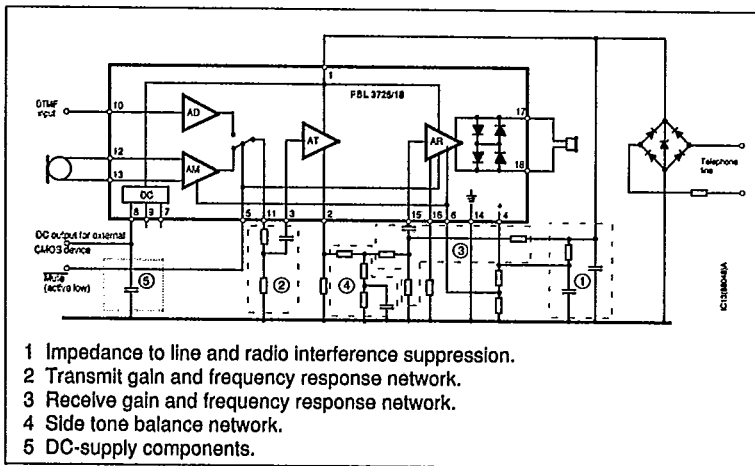

Figure 1. Functional diagram.

Maximum Ratings

Parameter	Symbol	Min	Max	Unit
Line voltage, $t_p = 2$ s	V_L	0	22	V
Line current, continuous	I_L	0	130	mA
Operating temperature range	T_{Amb}	-40	+70	°C
Storage temperature range	T_{Stg}	-55	+125	°C

Transmitter input impedance pin 3	2	1 kHz		17		kohm
Transmitter dynamic output	2	200 Hz-3.4 kHz $\leq 2\%$ distortion, $I_L = 20 - 100\text{ mA}$		1.5		V_p
Transmitter max output	2	200 Hz-3.4 kHz $I_L = 0 - 100\text{ mA}$, $V_3 = 0 - 1\text{ V}$		3		V_p
Receiver output impedance	2	1 kHz, note 3		3(+310)		ohm
Receiver dynamic output note 2	2	200 Hz-3.4 kHz $\leq 2\%$ distortion, $I_L = 20 - 100\text{ mA}$		0.5		V_p
Receiver max output	3	Measured with line rectifier 200 Hz-3.4 kHz, $I_L = 0 - 100\text{ mA}$, $V_1 = 0 - 50\text{ V}$		0.9		V_p
Transmitter output noise	2	Psol-weighting, Rel 1 V_{rms} , $R_L = 0$		-75		dB _{Psol}
Receiver output noise	2	A-weighting, Rel 1 V_{rms} , with cable 0-5 km, $\varnothing = 0.5\text{ mm}$, 0-3 km, $\varnothing = 0.3\text{ mm}$		-85		dB _A
Mute input voltage at mute (active low)	2				0.3	V
DC-supply voltage	2	$I_L = 10 - 100\text{ mA}$ $I_{DC} = 0\text{ mA}$ $I_{DC} = 2\text{ mA}$		2.35 2.2		V V
DC-supply current, pin 8.	2		2			mA
DC-output pin 8 input leakage current (no supply)	4	$V_{DC} = 2.35\text{ V}$		0.1		μA
DTMF transmitting gain	2	$V_M = 0.3\text{ V}$	24.5	26.5	28.5	dB

Notes

- Adjustable to both higher and lower values with external components.
- The dynamic output can be doubled, see applications information.
- External resistor in the test set up.

Pin Descriptions

Refer to figure 5.

Pin	Name	Function
1	+L	Output of the DC-regulator and transmit amplifier. This pin is connected to the line through a polarity guard and diode bridge.
2	TO	Output of the transmit amplifier. This pin is connected through a resistor of 47 to 100 ohm to -L, which sets the DC-resistance of the circuit. The output has a low AC output impedance and the signal is used to drive a side tone balancing network.
3	TI	Input of transmit amplifier. Input impedance 17 k Ω \pm 20 %.
4	+C	This pin is the positive power supply terminal for most of the circuitry inside the PBL 3726/18 (about 1 mA current consumption). The +C-pin shall be connected to a decoupling capacitor of 47 μ F to 150 μ F.
5	Mute	When low, speech circuit is muted and the DTMF input is enabled. Maximum voltage (at mute) is 0.3 V, current sink requirement of external driver is 50 μ A.
6	GR	This pin is control input for the gain regulation circuitry.
7	DCS	This pin is the sense input to the DC-supply.
8	DCO	This pin is the output from the DC-supply.
9	DCC	This pin is the control output from the DC-supply.
10	DI	This pin is the input for the DTMF-signal. Input impedance is 25 kohm \pm 20%.
11	MO	Output of the microphone amplifier or DTMF-amplifier.
12	MI 1	Input to the microphone amplifier. Input impedance 1.7 kohm \pm 20 %.
13	MI 2	
14	-L	The negative power terminal, connected to the line through a polarity guard diode bridge.
15	RI	Input of receiver amplifier. Input impedance is approximately 38 kohm \pm 20%.
16	DR	This pin is the control input for the receiver amplifier driving capability.
17	RE 1	Receiver amplifier outputs. Output impedance is approximately 3 ohm.
18	RE 2	

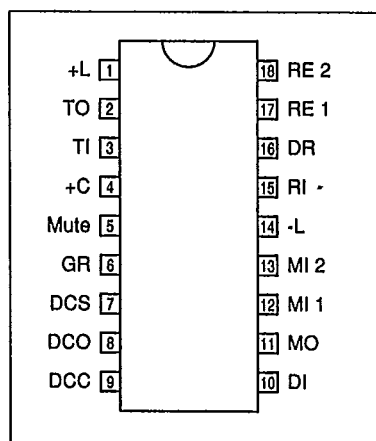

Figure 5. Pin configuration.

Functional Description

General

The gain of the transmitting and receiving amplifiers are continuously and equally changed with the line length. The starting point for the gain regulation is externally set. The gain regulation can be cut-off externally, see table under gain regulation below.

The outputs of the transmitting and receiving amplifiers have internal limitations of the output amplitudes.

The circuit includes a temperature independent voltage reference used for regulation of the DC line voltage and for the transmitting and receiving gain regulation. The DC voltage is very fast settled to its final value with a minimum of overshoot.

The circuit uses a minimum of external components. In a normal practical case only 5 external capacitors of which only one is an electrolytic/tantalum filter capacitor. The other capacitors are needed as radio interference suppression capacitor over the line, one capacitor in the side-tone balancing network and one capacitor for low frequency cut-off in each of the transmitting and receiving amplifiers. The frequency response is, except for that, flat for both amplifiers.

The circuit will with external components get a very good return loss behavior, both against purely resistive lines as for instance 600 ohm and against

complex networks as 900 ohm in parallel with 30 nF.

To get a good CMRR the microphone input is balanced.

It is possible to add a push-button controlled cut-off of the transmitting

amplifier to the circuit without any disturbance of the other circuit functions.

A mute input is included in the circuit. It gives:

1. Cut-off the microphone amplifier.

Figure 6. Block interconnections.

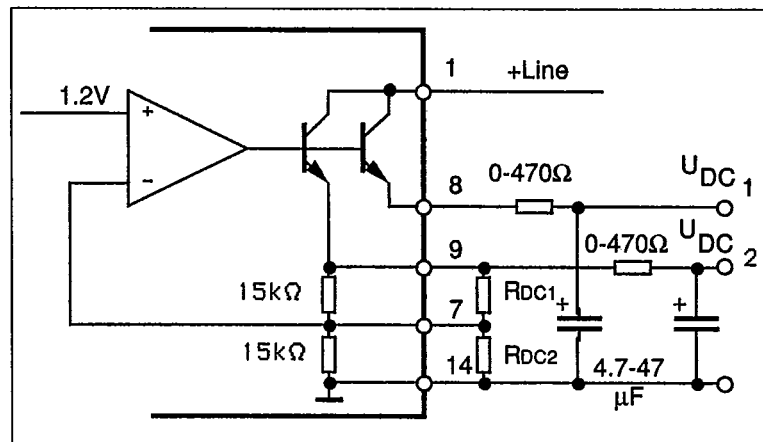

Figure 7. DC regulator for external CMOS devices.

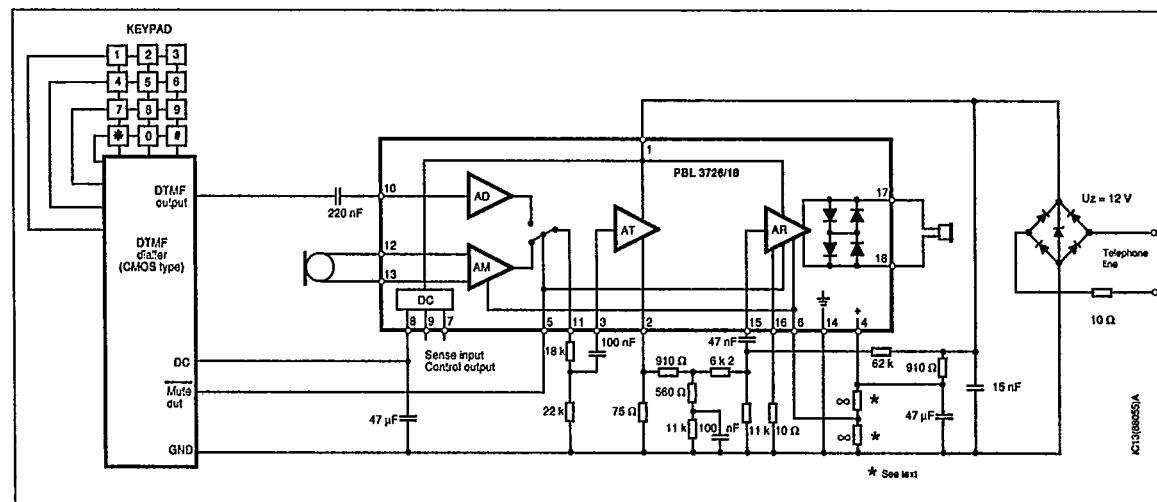

Figure 8. Typical tone dialling telephone.

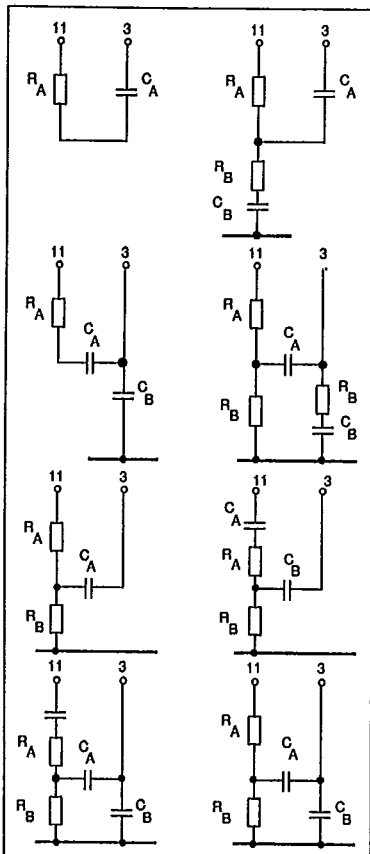

Figure 9. Examples of network "2".

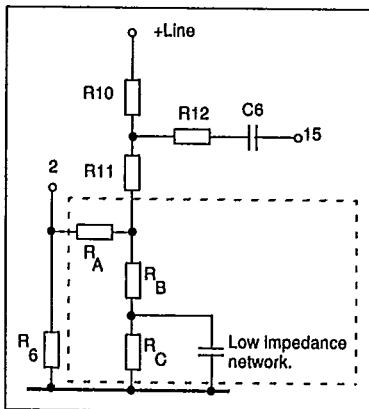

Figure 11. Typical sidetone network.

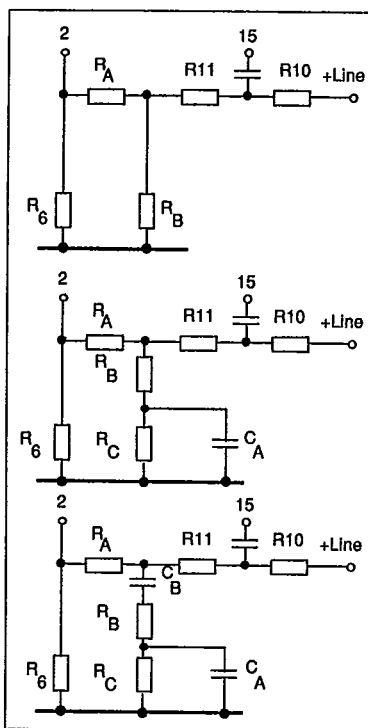

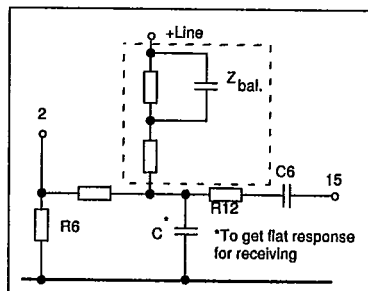

Figure 10. Examples of network "4".

Figure 12. Sidetone network especially suited for applications with a high line current, when R_6 has a low value.

2. Reduced gain in the receiving amplifier.
3. Connection of the DTMF input.

The receiver amplifier is equipped with a high impedance input stage. This gives a less expensive RC-network on the input.

Only resistive elements are used to set the receiving gain.

A push-pull power stage in the receiving amplifier gives a high output swing.

To get the extended low current and voltage range two resistors have to be connected from microphone input to ground.

The side-tone balanced can be set by a RC-network without influence on other parameters. An inexpensive solution requires only one capacitor while more capacitors can give better performance.

In fig. 6 ①②③ and ④ are RC-links with the following functions:

- 1 For radio interference suppression and to give the correct return loss behavior.
- 2 To set the gain and frequency response for transmitting.
- 3 To set the gain and frequency response for receiving.
- 4 To set the side-tone level

A stabilized DC output, with a pre-set output voltage of 2.35 Volts, is provided to facilitate interfacing to external CMOS dialler ICs. The voltage is adjustable with two resistors, as indicated in figure 7. The output requires some filtering to avoid distortion on the telephone line. Note that a high current consumption of the external device will alter the DC characteristics of the speech circuit.

Applications Information

Refer to figure 8.

Gain regulation(R_1 , R_2):

These resistors set the starting point for the gain- and side tone regulation.

Input impedance pin 6 is about 5.5 kohm $\pm 20\%$.

Below are some typical values for R_1 and R_2 , for some different supplies from telephone stations.

Battery feed	R1	R2	R6
No regulation.	22 k Ω	47-100 Ω	
Set for short line gain.			
All feedings.			
Regulation:			
48 V, 2 \cdot 200 Ω	∞	∞	47 Ω
48 V, 2 \cdot 400 Ω	∞	∞	75 Ω
36 V, 2 \cdot 500 Ω		180 k Ω	100 Ω

Previous users of PBL 3726/6 to 3726/15 may note that the two resistors works the opposite way and that only one or none of them is necessary.

Impedance to line (R3, C1, C2):

C1 in series with R3 and those in parallel with C2 give the impedance to the line from the set.

C2 must normally be there for the radio interference too.

The network is optimized with regard to the return loss.

The time constant R3, C1 cannot be allowed to be too small. If the time constant is too small, distortion at low frequencies may be generated.

If R3 is changed this will change the DC-characteristic too, which is set by the voltage at pin 4. The input current at pin 4 is about 1 mA.

Microphone selection (M1, R16):

The microphone can be either dynamic, magnetic or electret. See figures 14, 16 and 17.

The input impedance between pin 12 and 13 is about 1.7 kohm with typical variation $\pm 20\%$.

Transmitting gain and frequency response (R4, R5, C3, C4):

The network gives the amplification and frequency response for the transmitter. R5 is used when a greater reduction of the gain is wanted. Input impedance at pin 3 is about 17 kohm with typical variation $\pm 20\%$. The sum of the resistors R4 and R5 must not be less than 35 kohm because of DC-current to ground. Below is some simple variations of this network. (See figure 9).

DC-characteristics (R6):

Sets the DC-characteristic and take care of some of the supplied power. The resistor have also function with the protection of the circuit, the transmitter, the gain regulation and the side tone. Common values are 47 ohm to 100 ohm.

ERICSSON

T-77-13

Slide tone level, receiving gain and frequency response.(R7, R8, R9, R10, R11, C5):

The network sets the slide tone balance. The network in the application is one of many possibilities. R10 and R11 balance together the signals that go two different ways from the transmitter output stage one from pin 1 and the other from pin 2. The balance network consist of R8, R9 and C5.

The example is not optimized to any specified line, it is only given to show the principle.

Fig. 10, 11 and 12 are examples of balance networks. Fig. 12 is especially suited for lines with high current supply.

R12, R13, C6, (R10, R11):

The networks gives the gain and frequency response for the receiver.

Input impedance at pin 15 is about 38 kohm with a typical variation of $\pm 20\%$. For different possibilities for the design of the network, see the network for the transmittor (R4, R5, C3).

REC, R14:

R14 generates the output impedance to the magnetic earphone (fig.13). If a dynamic earphone is used it should be placed between pin 17 and 18. See figure 18.

IC4 (88087) A-Ue

© Ericsson Components AB 1987

R15:

This resistor is used to set the driving capability of the receiver output amplifier. Common values are 0 ohm to 50 ohm. Setting it for low driving capability results in function at lower line current. Breaking up pin 16 will give lower power consumption and total mute of the receiver when muting the circuit. Disconnecting pin 15 will of course also give total receiver mute.

D1, D2, D3, D4, D5:

Rectifier bridge and overvoltage protector. The zener voltage at D5 should be as low as possible. Common values are between 12 V - 16 V.

R_{DC1}, R_{DC2}:

Refer to figure 7.

The pre-set output voltage of 2.35 V can easily, if needed, be changed to another value by applying one or two resistor (RDC1, RDC2) in parallel with the internal resistors (each 15k Ω \pm 20%). It is possible to get a rather high voltage and current from the DC-supply as long as the high current and voltage is available from the line. The DC voltage has to be filtered by a capacitor and this can, at high DC-voltage and low line current, interfere with the signal on the line and cause distortion. You can minimize the interference, with a resistor in series with the filter capacitor. The DC voltage will, of course, be more dependent of the DC-supply current. The DC-output pin has a very low input leak current, to allow stand-by feeding of the dialer. It is also possible to use pin 9 to feed microphones etc. that do not need stand-by feeding, without interfering with the stand-by feeding on pin 8. Note that a high current consumption by the external device will alter the DC characteristics of the speech circuit.

Design procedure:

1. Circuit impedance to the line.
2. DC-characteristic
3. Gain regulation.
4. Transmitter gain and frequency response.
5. Receiver gain and frequency response.
6. Side-tone.
7. Components to suppress radio interference, specially the wires up to the handset.

Others:

The circuit can be placed either in the telephone or in the handset.

Cut off the transmitter can be done at F1 without interference of other functions of the circuit.

When using the extended low current and low voltage range (5 mA, 2 V), two resistors have to be connected from the microphone inputs to ground as shown in figure 15.
