Description

IBM11T1640LP is an industry standard 144-pin 8-byte Small Outline Dual In-line Memory Module (SO DIMM) which is organized as a 1Mx64 high speed memory array designed for use in non-parity applications. The SO DIMM uses 4 1Mx16 DRAMs in TSOP packages.

This card uses *serial presence detects* implemented via a serial EEPROM using the two pin I²C Protocol. This communication protocol uses CLOCK (SCL) and DATA I/O (SDA) lines to synchronously clock data between the master (ex: The System Micropro-

cessor) and the slave EEPROM device. The device address for the EEPROM is set to zero at the card. The first 128 bytes are utilized by the SO DIMM manufacturer and the second 128 bytes are available to the end user.

All IBM 144-pin SO DIMMs provide a high performance, flexible 8-byte interface in a 2.66" long space-saving footprint. Related products are the 2Mx64 Fast Page Mode and the 1Mx64, 2Mx64, 4Mx64 and the x72 (ECC) EDO SO DIMMs.

AC Characteristics $(T_A = 0 \text{ to } +70^\circ\text{C}, V_{CC} = 3.3 \pm 0.3\text{V})$

1. An initial pause of 200 μs is required after power-up followed by 8 $\overline{\text{RAS}}$ only refresh cycles before proper device operation is achieved. In case of using the internal refresh counter, a minimum of 8 $\overline{\text{CAS}}$ before $\overline{\text{RAS}}$ refresh cycles instead of 8 $\overline{\text{RAS}}$ only refresh cycles is required.
2. AC measurements assume $t_T=5\text{ns}$.
3. $V_{IH}(\text{min.})$ and $V_{IL}(\text{max.})$ are reference levels for measuring timing of input signals. Also, transition times are measured between V_{IH} and V_{IL} .
4. When both $\overline{\text{LCAS}}$ and $\overline{\text{UCAS}}$ (REFERENCE BLOCK DIAGRAM, PAGE 5) go low at the same time, all 16 bits of data are read/written into the device. $\overline{\text{LCAS}}$ and $\overline{\text{UCAS}}$ cannot be staggered within the same read/write cycle.

1. When using Self Refresh mode, the following refresh operations must be performed to ensure proper DRAM operation: If row addresses are being refreshed in an EVENLY DISTRIBUTED manner over the refresh interval using CBR refresh cycles, then only one CBR cycle must be performed immediately after exit from Self Refresh. If row addresses are being refreshed in any other manner (ROR - Distributed/Burst; or CBR-Burst) over the refresh interval, then a full set of row refreshes must be performed immediately before entry to and immediately after exit from Self Refresh. 2. If $t_{RASS} > t_{CHD}$ (min) then t_{CHD} applies. If $t_{RASS} \leq t_{CHD}$ (min) then t_{CHS} applies.

1. The write cycle time(t_{WR}) is the time from a valid stop condition of a write sequence to the end of the internal erase/program cycle. During the write cycle, the bus interface circuits are disabled, SDA is allowed to remain high per the bus-level pull-up resistor, and the device does not respond to its slave address.

NOTE : $\overline{\text{WE}}$, $\overline{\text{OE}}$ and D_{IN} are "H" or "L"

NOTE: Address is "H" or "L"

Hidden Refresh Cycle (Read)

Hidden Refresh Cycle (Write)

Self Refresh Cycle (Sleep Mode)

: "H" or "L"

NOTES:

1. Address and $\overline{OE}$ are "H" or "L"
2. Once $\overline{RAS}$ (min) is provided and $\overline{RAS}$ remains low, the DRAM will be in Self Refresh, commonly known as "Sleep Mode."
3. If $t_{RASS} > t_{CHD}$ (min) then t_{CHD} applies.
If $t_{RASS} \leq t_{CHD}$ (min) then t_{CHS} applies.

Presence Detect (EEPROM) Bus Timing

Presence Detect Operation

Clock and Data Conventions: Data states on the SDA line can change only during SCL low. SDA state changes during SCL HIGH are reserved for indicating start and stop conditions (Figure 1 & Figure 2).

Start Condition: All commands are preceded by the start condition, which is a HIGH to LOW transition of SDA when SCL is high. The serial PD device continuously monitors the SDA and SCL lines for the start condition and will not respond to any command until this condition has been met.

Stop Condition: All communications are terminated by a stop condition, which is a LOW to HIGH transition of SDA when SCL is HIGH. The stop condition is also used to place the serial PD device into standby power mode.

Acknowledge: Acknowledge is a software convention used to indicate successful data transfers. The transmitting device, either master or slave, will release the bus after transmitting eight bits. During the ninth clock cycle the receiver will pull the SDA line LOW to acknowledge that it received the eight bits of data (Figure 3).

The PD device will always respond with an acknowledge after recognition of a start condition and its slave address. If both the device and a write operation have been selected, The PD device, will respond with an acknowledge after the receipt of each subsequent eight bit word. In the read mode the PD device will transmit eight bits of data, release the SDA line and monitor the line for an acknowl-

edge. If an acknowledge is detected and no stop condition is generated by the master, the slave will continue to transmit data. If an acknowledge is not detected, the slave will terminate further data transmissions and await the stop condition to return to standby power mode.
