

High Performance HDMI™/DVI Transmitter

AD9889

FEATURES

HDMI/DVI transmitter compatible with HDMI 1.1 and HDCP 1.1

Single 1.8 V power supply

Video/audio inputs are 3.3 V tolerant

80-lead, Pb-free LQFP

Digital video

80 MHz operation supports all video formats from 480i to 1080i and 720p

Programmable 2-way color space converter

Supports RGB, YCbCr, DDR, ITU656 formats

Auto input video format detection

Digital audio

Supports standard S/PDIF for stereo or compressed audio up to 192 kHz

8-channel LPCM I²S audio up to 192 kHz

Special features for easy system design

On-chip MPU to perform HDCP operations

On-chip I²C master to handle EDID reading

5 V tolerant I²C and MPD I/Os, no extra device needed

No audio master clock needed for S/PDIF support

APPLICATIONS

DVD players and recorders

Digital set-top boxes

AV receivers

Digital cameras and camcorders

GENERAL DESCRIPTION

The AD9889 is an 80 MHz, high-definition multimedia interface (HDMI™ 1.1) transmitter. It supports HDTV formats up to 1080i and 720p, and graphic resolutions up to XGA (1024 × 768 @ 75 Hz). With the inclusion of HDCP, the AD9889 allows the secure transmission of protected content as specified by the HDCP 1.1 protocol.

The AD9889 supports both S/PDIF and 8-channel I²S audio. Its high fidelity 8-channel I²S can transmit either stereo or 7.1 surround audio at 192 kHz. The S/PDIF can carry stereo LPCM (linear pulse code modulation) audio or compressed audio including Dolby® Digital, DTS®, and THX®.

FUNCTIONAL BLOCK DIAGRAM

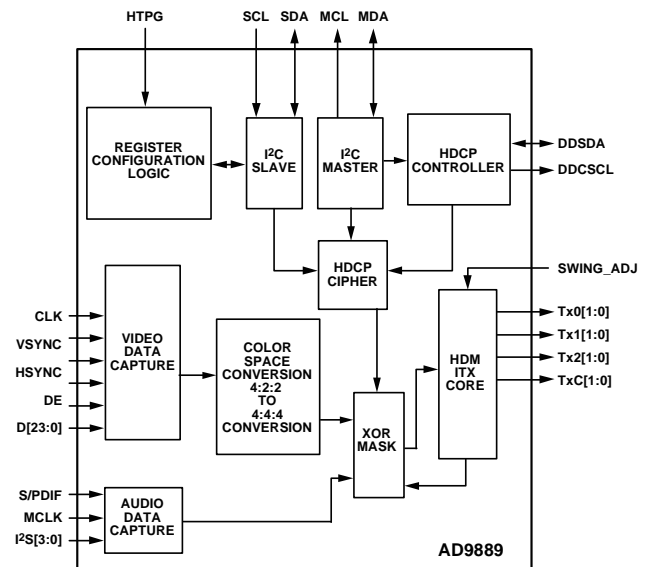

Figure 1.

The AD9889 helps to reduce system design complexity and cost by incorporating such features as HDCP master, I²C master for EDID reading, a single 1.8 V power supply, and 5 V tolerance on I²C and hot plug detect pins.

Fabricated in an advanced CMOS process, the AD9889 is provided in a space-saving, 80-lead, surface-mount, Pb-free plastic LQFP and is specified over the 0°C to 70°C temperature range.

EVALUATION KITS AND OTHER RESOURCES

Evaluation kits, reference design schematics, software quick start guide, and codes are available from Analog Devices local sales and marketing personnel.

ABSOLUTE MAXIMUM RATINGS

Table 2.

Parameter	Rating
Digital Inputs	5 V to 0.0 V
Digital Output Current	20 mA
Operating Temperature Range	−40°C to +85°C
Storage Temperature Range	−65°C to +150°C
Maximum Junction Temperature	150°C
Maximum Case Temperature	150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

EXPLANATION OF TEST LEVELS

Table 3.

Level	Test
I	100% production tested.
II	100% production tested at 25°C and sample tested at specified temperatures.
III	Sample tested only.
IV	Parameter is guaranteed by design and characterization testing.
V	Parameter is a typical value only.
VI	100% production tested at 25°C; guaranteed by design and characterization testing.
VII	Limits defined by HDMI specification.

www.DataSheet4U.com

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

	44	DDCSCL	Serial Port Data Clock to Receiver	3.3 V CMOS

Table 5. Pin Function Descriptions

Pin Mnemonic	Description
OUTPUTS	
TxC+	Differential Clock Output at Pixel Clock Rate; Transition Minimized Differential Signaling (TMDS).
TxC-	Differential Clock Output Complement.
Tx2+	Differential Output of the Red Data at 10× the Pixel Clock Rate; TMDS.
Tx2-	Differential Red Output Complement.
Tx1+	Differential Output of the Green Data at 10× the Pixel Clock Rate; TMDS.
Tx1-	Differential Green Output Complement.
Tx0+	Differential Output of the Blue Data at 10× the Pixel Clock Rate; TMDS.
Tx0-	Differential Blue Output Complement.
INT	Monitor Sense.
SERIAL PORT (2-WIRE)	
SDA	Serial Port Data I/O.
SCL	Serial Port Data Clock.
DDSDA	Serial Port Data I/O Master to Receiver.
DDCSCL	Serial Port Data Clock Master to Receiver.
MDA	Serial Port Data I/O Master to HDCP Keys.
MCL	Serial Port Data Clock Master to HDCP Keys.
	For a full description of the 2-wire serial register and how it works, refer to the 2-Wire Serial Control Port section.
INPUTS	
D[23:0]	Digital Input in RGB or YCbCr Format.
CLK	Video Clock Input.
DE	Data Enable for Video Data.
HSYNC	Horizontal Sync Input.
VSYNC	Vertical Sync Input. This is the input for vertical sync.
EXT_SW	Swing Adjust Sets the Differential Output Voltage or Swing. An 887 Ω resistor (1% tolerance) should be placed between this pin and ground.
HPD	Hot Plug Detect. This indicates to the interface whether the receiver is connected.
S/PDIF	S/PDIF Audio Input. This is the audio input from a Sony/Philips Digital Interface.
MCLK	Audio Reference Clock. Set either to 128 × fs or 256 × fs.
I ² S[3:0]	I ² S Audio Inputs. These represent the eight channels of audio (two per input) available through I ² S.
I ² S CLK	I ² S Audio Clock.
LRCLK	Left/Right Channel Selection.
PD/A0	Power Down.

AD9889

Pin Mnemonic	Description
POWER SUPPLY	
DV _{DD}	Main Power Supply. These pins supply power to the main elements of the circuit. They should be filtered and as quiet as possible.
AV _{DD}	Output Power Supply
PV _{DD}	Clock Generator Power Supply. The most sensitive portion of the AD9889 is the clock generation circuitry. These pins provide power to the clock PLL (phase-locked loop) and help the user design for optimal performance. The designer should provide quiet, noise-free power to these pins.
GND	Ground. The ground return for all circuitry on-chip. It is recommended that the AD9889 be assembled on a single solid ground plane, with careful attention given to ground current paths.

I²C ADDRESSES

The SDA/SCL programming address is 0x72 or 0x7A based on whether A0 is pulled high (10 kΩ resistor = 0x7A) or pulled low (10 kΩ resistor = 0x72).

The MDA/MCL EEPROM address is 0xA0.

The EDID EEPROM on the receiver is expected to have an address of 0xA0.

LIST OF REFERENCE DOCUMENTS

Table 6.

Document	Description
EIA/CEA-861B	Describes audio and video infoframes as well as the E-EDID structure for HDMI.
HDMI V1.1	Defining document for HDMI Version 1.1. Can be located at www.hdmi.org .
HDCPv1.0	Defining document for HDCP Version 1.1. Can be located at www.digital-cp.com .
ITU-R BT.656-3	Defining document for BT656.

FORMAT STANDARDS

In this document, data is represented in a variety of ways.

Table 7.

Data Type	Format
0xNN	Hexadecimal (base-16) numbers are represented using the C language notation, preceded by 0x.
0bNN	Binary (base-2) numbers are represented using the C language notation, preceded by 0b.
NN	Decimal (base-10) numbers are represented using no additional prefixes or suffixes.
Bit	Bits are numbered in little-endian format, that is, the least significant bit (LSB) of a byte or word is referred to as Bit 0.

DESIGN GUIDE

GENERAL DESCRIPTION

The AD9889 HDMI transmitter provides a high bandwidth digital content protected (HDCP) digital link between a wide range of digital input formats—both audio and video (see Table 8) and output formats (see Table 9). Video and audio data are captured and prepared for transmission while three separate I²C buses (two of which are masters) are used to program and provide content protection for the data to be transmitted.

VIDEO DATA CAPTURE

The AD9889 can accept video data from as few as eight pins (YCbCr DDR) representing 8-bit data or as many as 24 pins representing 12-bit data. The AD9889 is capable of detecting all of the 34 video formats defined in the EIA/CEA-861B specification. If video ID (VID) 32, 33, or 34 is present, the user needs to set Register R0x15[0] to 0b1, as these modes have V_{REF} frequencies of 30 Hz or less. The user can read the detected video format at R0x3E[7:2]. Formats outside the EIA/CEA-861B specification can be read in R0x3F[7:5]. Detailed line count differences for 240p and 288p modes can be read from R0x3F[4:3]. In order to distinguish between an aspect ratio of 4:3 and one of 16:9, R0x17[1] should be set accordingly.

Figure 3. Timing for Data Input

05675-014

AD9889

Normal 4:4:4 Input Format (RGB or YCbCr) Input ID = 0

An input format of RGB 4:4:4 or YCbCr 4:4:4 can be selected by setting the input ID (R0x15[3:1]) to 0b000. The input color space (CS) must be selected by setting R0x16[0] to 0b0 for RGB or 0b1 for YCbCr. There is no need to set the input style (R0x16[3:2]).

Table 10.

Input Format	Data<23:0>																						
	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
RGB 4:4:4	R[7:0]							G[7:0]							B[7:0]								
YCbCr 4:4:4	Cr[7:0]							Y[7:0]							Cb[7:0]								

YCbCr 4:2:2 Formats (24 Bits, 20 Bits, or 16 Bits) with Separate Sync, Input ID = 1

An input with YCbCr 4:2:2 with separate syncs can be selected by setting the Input ID (R0x15[3:1]) to 0b001. The input CS (R0x16[0]) must be set to 0b1 for proper operation. The data bit width (24 bits, 20 bits, or 16 bits) must be set with R0x16[5:4]. The three input pin assignment styles are shown in Table 11. The input style can be set in R0x16[3:2].

Table 11.

Input Format	Data <23:0>																							
	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Style 1																								
YCbCr 4:2:2 Sep. Sync (24 bit)	Cb[11:4]							Y[11:4]							Cb[3:0]			Y[3:0]						
	Cr[11:4]							Y[11:4]							Cr[3:0]			Y[3:0]

	Y[7:0]							Cr[7:0]																

YCbCr 4:2:2 Formats (24 Bits, 20 Bits, or 16 Bits) with Embedded Syncs, Input ID = 2

An input with YCbCr 4:2:2 with embedded syncs can be selected by setting the input ID (R0x15[3:1]) to 0b010. HS YNC and VSYNC are embedded as Start of Active Video (SAV) and End of Active Video (EAV). The input CS (R0x16[0]) must be set to 0b1 for proper operation. The data bit width (24 = 12 bits, 20 = 10 bits, or 16 = 8 bits) must be set with R0x16[5:4]. The three input pin assignment styles are shown in Table 12. The input style can be set in R0x16[3:2]. The only difference between Input ID 1 and Input ID 2 is that the syncs on ID 2 are embedded in the data much like ITU 656 running at 1× clock and double width.

Table 12.

Input Format	Data <23:0>																								
	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

YCbCr 4:2:2 Formats (Double Data Rate) Formats (12, 10, or 8 bits) with Separate Syncs, Input ID = 3

An input with YCbCr 4:2:2 DDR data and separate syncs can be selected by setting the input ID (R0x15[3:1]) to 0b011. The input CS (R0x16 [0]) must be set to 0b1. The data bit width (12 bits, 10 bits, or 8 bits) must be set with R0x16[5:4]. The two input pin assignment styles are shown in Table 13. The input style can be set in R0x16[3:2].

AD9889

YCbCr 4:2:2 DDR (Double Data Rate) Formats (12 Bits, 10 Bits, or 8 Bits) with Embedded Syncs. Input ID = 4

An input with YCbCr 4:2:2 DDR data and embedded syncs (ITU 656) can be selected by setting the input ID (R0x15[3:1]) to 0b100. The input CS (R0x16[0]) must be set to 0b1. The data bit width (12 bits, 10 bits, or 8 bits) must be set with R0x16[5:4]. The two input pin assignment styles are shown in Table 14. The input style can be set in R0x16[3:2]. The order of data input is the order in the table (for example, 12-bit data is accepted as Cb0, Y0, Cr0, Y1, Cb2, Y2, Cr2, Y3).

Table 14.

YCbCr 4:2:2 Formats (24, 20, or 16 bits) DDR with Separate Sync, Input ID = 6

An input format of YCbCr 4:2:2 DDR can be selected by setting the input ID (R0x15[3:1]) to 0b110. The three different input pin assignment styles are shown in Table 16. The input style can be set in R0x16[3:2]. The input CS (R0x16[0]) must be set to 0b1. The data bit width (12, 10, or 8 bits) must be set to with R0x16[5:4].

The 1st or the 2nd edge may be the rising or falling edge. The data input edge is defined in R0x16[1]. 0b0 = rising edge; 0b1 = falling edge. Pixel 0 is the first pixel of the 4:2:2 word and should be where DE starts.

AD9889

4:2:2 TO 4:4:4 DATA CONVERSION

The AD9889 has the ability to convert YCbCr video from 4:4:4 to 4:2:2 and 4:2:2 to 4:4:4. To convert from 4:4:4 to 4:2:2, the video data goes through a filter first to remove any artificial downsampling noise. To convert from 4:2:2 to 4:4:4, the AD9889 utilizes either the zero-order upconversion (pixel repetition) or first-order upconversion (linear interpolation). The upconversion and downconversion are used when the video output timing format does not match the video input timing format. The video output format is set by Register R0x16[7:6]. The video input format is set by the video ID (R0x15[3:1]) and video color space (R0x16[0]). The default mode for upconversion is pixel repetition. To use linear interpolation, set Register R0x17[2] to 1.

HORIZONTAL SYNC, VERTICAL SYNC, AND DEGENERATION

When transmitting video data across the TMDS interface, it is necessary to have an HSYNC, VSYNC, and data enable (DE) defined for the image. ITU-656 based sources have start of active video (SAV) and end of active video (EAV) signals built in, but the HSYNC and VSYNC must be generated (the DE is implied by the SAV and EAV signals). Other sources (with separate syncs) have HSYNC, VSYNC, and DE supplied at the same time as the pixel data.

DEGENERATION

The AD9889 offers a choice of DE from an external pin, or an internally generated DE. To activate the internal DE generation, set Register R0x17[0] to 1. Register R0x35 to Register R0x3A are used to define the DE. R0x35 and R0x36[7:6] define the number of pixels from the HS leading edge to the DE leading edge. R0x36[5:0] are the number of HSYNCs between the leading edge of VS and DE. R0x37[7:5] defines the difference of HS counts during VS blanking for interlace video. R0x37[4:0] and R0x38[7:1] indicate the width of the DE. R0x39 and R0x3A[7:4] are the number of lines of active video (see Figure 4).

HSYNC AND VSYNC GENERATION

For video with embedded HSYNC and VSYNC, such as EAV and SAV, found in ITU 656 format, it is necessary to reconstruct HSYNC and VSYNC. This is done with Register R0x30 to Register R0x34. R0x30 and R0x31[7:6] specify the number of pixels between the HSYNC leading edge and the trailing edge of DE. Register R0x31[5:0] and Register R0x32[7:4] are the duration of the HSYNC in pixel clocks. R0x32[3:0] and R0x33[7:2] are the number of HS pulses between the trailing edge of the last DE and the leading edge of the VSYNC pulse. Register R0x33[1:0] and Register R0x34[7:0] are the duration of VSYNC in units of HSYNCs. HSYNC and VSYNC polarity can be specified by setting R0x17[6] (for VSYNC) and R0x17[5] (for HSYNC).

AD9889

COLOR SPACE CONVERSION MATRIX (CSC)

The color space conversion matrix in the AD9889 consists of three identical processing channels. In each channel, three input values are multiplied by three separate coefficients. Also included are an offset value for each row of the matrix and a scaling multiple for all values. Each value is 13-bit, twos complement resolution to ensure the signal integrity is maintained. The CSC is designed to run at speeds up to 80 MHz supporting resolutions up to 1080i at 60 Hz and UXGA at 60 Hz. With any-to-any color space support, RGB, YUV, YCbCr, and other formats are supported by the CSC.

The main inputs, R_{IN} , G_{IN} , and B_{IN} come from the 8-bit to 12-bit inputs from each channel. These inputs are based on the input format detailed in Table 10 to Table 16. The mapping of these inputs to the CSC inputs is shown in Table 17.

Table 17. CSC Port Mapping

Input Channel	CSC Input Channel
R/Cr	R_{IN}
Gr/Y	G_{IN}
B/Cb	B_{IN}

One of the three channels is represented in Figure 7. In each processing channel the three inputs are multiplied by three separate coefficients marked a_1 , a_2 , and a_3 . These coefficients are divided by 4096 to obtain nominal values ranging from -0.9998 to $+0.9998$. The variable labeled a_4 is used as an offset control. The CSC_Mode setting is the same for all three processing channels. This multiplies all coefficients and offsets by a factor of 2^{CSC_Mode} .

The functional diagram for a single channel of the CSC as per Figure 7 is repeated for the remaining G and B channels. The coefficients for these channels are b_1 , b_2 , b_3 , b_4 , c_1 , c_2 , c_3 , and c_4 .

A programming example and register settings for several common conversions are listed in the Color Space Converter (CSC) Common Settings section.

For a detailed functional description and more programming examples, refer to AN-795, *The AD9880 Color Space Converter User's Guide*.

AUDIO DATA CAPTURE

The AD9889 is capable of receiving audio data in either I²S or S/PDIF format for packetization and transmission over the HDMI interface.

I²S AUDIO

The AD9889 can accommodate from two to eight channels of I²S audio at up to a 192 kHz sampling rate. Selection of I²S audio mode (vs. S/PDIF) is set with R0x0A[4] = 0. The detected sampling frequency (from 32 kHz to 192 kHz) can be read in R0x04[7:4]. The output sampling frequency (from 32 kHz to 192 kHz) can be selected with R0x15[7:4]. The number of channels and the specific channels can be selected in R0x0C[5:2] and R0x50[7:5]. If all eight channels (I²S0 to I²S3) are required, setting all bits of R0x0C[5:2] to 1 selects eight channels. If I²S0 only is needed, setting R0x0C[2] to 1 selects this. The placement of these packets with respect to their output can be specified in Register R0x0E to Register R0x11. Default settings place all channels in their respective position (I²S0 left channel in Channel 0 left position, I²S3 right channel in Channel 3 right position), but this mapping is completely programmable.

The AD9889 supports standard I²S, left-justified I²S, and right-justified I²S formats via R0x0C[1:0] and sample word lengths between 16 bits and 24 bits (R0x14[3:0]).

S/PDIF AUDIO

The AD9889 is capable of accepting two channel LPCM and encoded audio up to a 192 kHz sampling rate via the S/PDIF. S/PDIF audio input is selected by setting R0x0A[4] = 1. The AD9889 is capable of accepting S/PDIF with or without an MCLK input. When no MCLK is present, the AD9889 makes the determination of the CTS value (N/CTS determines the MCLK frequency).

CTS GENERATION

Audio data being carried across the HDMI link, which is driven by a TMDS (video) clock only, does not retain the original audio sample clock.

The task of recreating this clock at the sink is called audio clock regeneration. There are a variety of clock regeneration methods that can be implemented in an HDMI sink, each with a different set of performance characteristics. The HDMI specification does not attempt to define exactly how these mechanisms operate. It does, however, present a possible configuration and it does define the data items that the HDMI source supplies to the HDMI sink in order to allow the HDMI sink to adequately regenerate the audio clock. It also defines how that data is generated. In many video source devices, the audio and video clocks are generated from a common clock (coherent clocks). In this situation, there exists a rational (integer divided by integer) relationship between these two clocks. The HDMI clock regeneration architecture can take advantage of this rational relationship and can also work in an environment where there is no such relationship between these two clocks, that is, where the two clocks are truly asynchronous or where their relationship is unknown.

Figure 8 shows the system architecture model used by HDMI for audio clock regeneration. The source determines the fractional relationship between the video clock and an audio reference clock ($128 \times$ audio sample rate) and passes the numerator and denominator for that fraction to the sink across the HDMI link. The sink can then recreate the audio clock from the TMDS clock by using a clock divider and a clock multiplier. The exact relationship between the two clocks is

$$128 \times f_s = f_{TMDS_clock} \times N/CTS$$

The source determines the value of the numerator N as stated in Section 7.2.1 of the HDMI specification. Typically, this value N is used in a clock divider to generate an intermediate clock that is slower than the $128 \times f_s$ clock by the factor N. The source typically determines the value of the denominator cycle time stamp (CTS) by counting the number of TMDS clocks in each of the $128 \times f_s/N$ clocks.

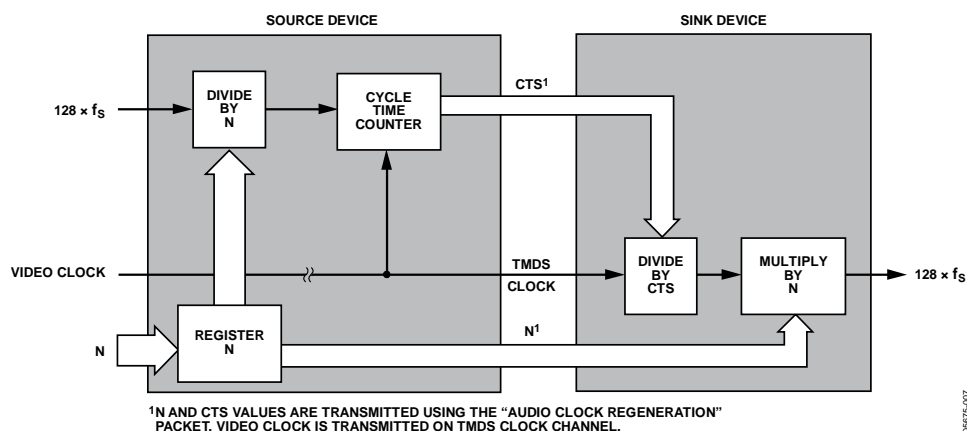

Figure 8. Audio Clock Regeneration

Rev. 0 | Page 17 of 48

AD9889

N PARAMETER

N shall be an integer number that meets the following restriction: $128 \times fs/1500 \text{ Hz} \leq N \leq 128 \times fs/300 \text{ Hz}$ with a recommended optimal value of $128 \times fs/1000 \text{ Hz}$ equals N. For coherent audio and video clock sources, use Table 18 to Table 20 to determine the value of N. For noncoherent sources or sources where coherency is not known, use the equations previously described.

CTS PARAMETER

CTS is an integer number that satisfies the following:

$$(\text{Average CTS Value}) = (f_{TMD5_clock} \times N) / (128 \times fs)$$

Recommended N and Expected CTS Values

The recommended value of N for several standard pixel clocks is given in Table 18 to Table 20. It is recommended that sources with noncoherent clocks use the values listed for the pixel clock type labeled Other.

Table 18. Recommended N and Expected CTS Values for 32 kHz Audio

The AD9889 has two modes for CTS generation: manual mode and auto mode. In manual mode, the user can program the CTS number directly into the chip (R0x07 to R0x09) and select this external mode by setting R0x0A[7] to 1. In auto mode, the chip computes the CTS based on the actual audio and video rates. This can be selected by setting R0x0A[7] to 0, and the results can be read from R0x04 to R0x06. Manual mode is good for coherent audio and video, where the audio and video clock are generated from the same crystal; thus CTS should be a fixed number. The auto mode is good for incoherent audio-video, where there is no simple integer ratio between the audio and video clock. A filter is available (R0x0A[6:5]) to stabilize the chip-generated CTS. The 20-bit N value can be programmed into the AD9889 in Register R0x01 to Register R0x03.

PACKET CONFIGURATION

The AD9889 supports all the packets listed in the HDMI 1.1 specification. Each packet can be separately enabled and disabled. Based on the audio and video input, the packets are added to the HDMI link at the earliest time, so that a minimum delay is incurred. Notice the ISRC1 packet has one bit to enable the ISRC2 packet. For the general control packet, remember to clear or reset the bits to avoid system lock-up.

PIXEL REPETITION

Due to HDMI specification and bandwidth requirements, sometimes it is necessary to set clock multiplication by 2× and 4× in order to maintain the minimum TMDS clock frequency. The AD9889 offers three choices for the user to implement this function: auto mode, manual mode, and max mode (R0x3B[6:5]).

For the auto mode (R0x3B[6:5] = 00), based on the input video format (either programmed by user, or chip detection) and audio sampling rate, AD9889 automatically sets the pixel repetition factor (R0x3D[7:6]).

For manual mode (R0x3B[6:5] = 1×), the user programs the pixel repetition factor in R0x3B[4:3].

For max mode (R0x3B[6:5] = 01), based on the input video format, the AD9889 selects the maximum repetition factor. The advantage of the max mode is that it is independent of the audio sampling rate.

Table 21. Pixel Repetition—Valid Pixel Repeat Values for Each Format

Video Code	Video Description	EIA/CEA-861B Pixel Repeat Values	HDMI Pixel Repeat Values
1	640 × 480p @ 60 Hz	No repetition	No repetition
2, 3	720 × 480p @ 59.94/60 Hz	No repetition	No repetition
4	1280 × 720p @ 59.94/60 Hz	No repetition	No repetition

34	1920 × 1080p @ 29.9/30 Hz	No repetition	No repetition

¹ Denotes change from EIA/CEA-861B valid values. Pixel repetition is required to support some audio formats at 720 × 480p and 720 × 576p video format timings.

AD9889

HDCP HANDLING

The AD9889 has a built-in microcontroller to handle HDCP transmitter states, including handling downstream HDCP repeaters. To activate HDCP from a system level, the main controller needs to set R0xAF[7] to 1 to inform AD9889 that the video stream should be encrypted. The AD9889 takes control from there and implements all remaining tasks defined by the HDCP 1.1 specification.

The system controller should monitor the status of HDCP by reading Register R0xB8[6] (indicating the HDCP link has been established). There are also some error flags (R0xC5[7] and R0xC8[7:4]) to help debug the system.

The AD9889 also supports AV functions to suspend HDCP temporarily. To set AV mute, clear R0x45[7] and set R0x45[6] to 1. To clear AV mute, clear R0x45[6] and set R0x45[7] to 1. (Note that it is invalid to set the two mute bits at the same time.)

For more information, refer to application note AN-810, *EDID and HDCP Controller User Guide for the AD9889*.

EDID READING

The AD9889 has an I²C master (DDC Pin 44 and Pin 45) to read the EDID based on system need. It buffers segment 0 once HPD is detected. The system can request other segments by programming Register R0xC4. An interrupt bit (R0x96[2]) indicates the completion of EDID rebuffering.

To read EDID data from the AD9889, use the AD9889 programming bus (Pin 46 and Pin 47) with I²C Address 0x7E. This is the default address but can be changed by writing the desired address into Register R0x43.

For more information, refer to application note AN-810, *EDID and HDCP Controller User Guide for the AD9889*.

INTERRUPTS

The AD9889 has interrupts to help with the system design: hot plug detection, receiver sense, VS detection, audio FIFO overflow, ITU 656 error, EDID ready, HDCP error, and BKSV ready. Interrupts can be cleared by writing 1 into the interrupt register (R0x96, R0x97). There are read-only registers (R0xC5, R0xC6) to show the state of these signals. Masks (R0x94, R0x95) are available to let the user selectively activate each interrupt. To enable a specific interrupt register, write 1 to the corresponding mask bit.

POWER MANAGEMENT

The AD9889 power-down pin polarity depends on the AD9889's I²C address selection. To use 0x72, the PD pin is high active. To use 0x7A, the PD pin is low active. At any time, the power-down pin polarity can be verified by reading Register R0x42[7].

The AD9889 can be powered down or reset either by Pin 33 or by Register R0x41[6]. During power-down mode, all the circuits are inactive except the I²C slave and some circuits related to mode and activity detection. During power-down mode, the chip status can still be read through the I²C slave. To enter normal power-down mode, either drive Pin 33 to 1, or set R0x41[6] to 1. To further reduce power consumption, disable the receiver sense detection by setting Register R0xA4[2] to 1.

For HDCP security reasons, the I²C power-down bit is also reset by the power-down pin. Anytime after power down, the user needs to drive the PD pin back to 0 and set R0x41[6] to 0 to activate the chip.

2-WIRE SERIAL REGISTER MAP

The AD9889 is initialized and controlled by a set of registers that determine the operating modes. An external controller is employed to write and read the control registers through the two-line serial interface port.

Table 22. Control Register Map

Hex Address	Read/Write or Read Only	Bits	Default Value	Register Name	Description
0x00	Read	[7:0]	00000000	Chip Revision	Revision of the chip, start from 0.
0x01	Read/Write	[3:0]	****0000	N[19:16]	20-bit N used with cycle time stamp (CTS) (see Table 18 to Table 20 for appropriate settings) to regenerate the audio clock in the receiver. For remaining bits, see R0x02 and R0x03. Used only with I ² S audio, not S/PDIF.
0x02	Read/Write	[7:0]	00000000	N[15:8]	The middle byte of N.
0x03	Read/Write	[7:0]	00000000	N[7:0]	The lower byte of N.
0x04	Read	[7:4]	0000****	S/PDIF_SF	S/PDIF sampling frequency for S/PDIF audio decoded from hardware. This information is used by both the audio Rx and the pixel repetition. 0011 = 32 kHz. 0000 = 44.1 kHz. 0010 = 48 kHz. 1000 = 88.2 kHz. 1010 = 96 kHz. 1100 = 176.4 kHz. 1110 = 192 kHz. Default = 0x0.
		[3:0]	****0000	CTS_Int[19:16]	CTS measured (internal). This 20-bit value is used in the receiver with the N value to regenerate an audio clock. For remaining bits, see R0x05 and R0x06.
0x05	Read	[7:0]	00000000	CTS_Int[15:8]	Middle byte of measured CTS.
0x06	Read	[7:0]	00000000	CTS_Int[7:0]	Low byte of measured CTS.
0x07	Read/Write	[3:0]	****0000	CTS_Ext[19:16]	CTS (external). This 20-bit value is used in the receiver with the N value to regenerate an audio clock. For remaining bits see R0x08 and R0x09.
0x08	Read/Write	[7:0]	00000000	CTS_Ext[15:8]	Middle byte of external CTS.
0x09	Read/Write	[7:0]	00000000	CTS_Ext[7:0]	Low byte of external CTS.
0x0A	Read/Write	[7]	0*****	CTS_Sel	CTS source select. 0 = internal CTS. 1 = external CTS. Default = 0.
		[6:5]	*10*****	Avg_Mode	CTS filter mode. 00 = no filter. 01 = divide by 4. 10 = divide by 8. 11 = divide by 16. Default = 10.
		[4]	***0****	Audio_Sel	Audio type select. 0 = I ² S. 1 = S/PDIF. Default = 0.
		[3]	****0***	MCLK_SP	MCLK for S/PDIF. 1 = MCLK active. 0 = MCLK inactive. Default = 0.
		[2]	*****0**	MCLK_I ² S	MCLK for I ² S. 1 = I ² S MCLK active. 0 = I ² S MCLK inactive. Default = 0.
		[1:0]	*****01	MCLK_Ratio	MCLK ratio.

AD9889

Hex Address	Read/Write or Read Only	Bits	Default Value	Register Name	Description
					00 = × 128 fs. 01 = × 256 fs. 10 = × 384 fs. 11 = × 512 fs. Default = 01.
0x0B	Read/Write	[6]	*0*****	MCLK_Pol	MCLK polarity. 0 = rising edge. 1 = falling edge. Default = 0.
		[5]	**0*****	Flat_Line	Flat line. 1 = flat line audio (audio sample not valid). 0 = normal. Default = 0.
		[4:0]	****0111	Test bits	Must be set to 0x7 for proper operation.
0x0C	Read/Write	[5:2]	**1111**	I ² S enable	I ² S enable for the four I ² S pins (active). 0001 = I ² S0. 0010 = I ² S1. 0100 = I ² S2. 1000 = I ² S3. Default = 1111 for all.
		[1:0]	*****00	I ² S Format	I ² S format. 00 = standard I ² S mode. 01 = right-justified I ² S mode. 10 = left-justified I ² S mode. 11 = raw IEC60958 mode. Default = 0.
0x0D	Read/Write	[4:0]	***11000	I ² S_bit_width	I ² S bit width. For right justified audio only. Default is 24. Not valid for widths greater than 24.
0x0E	Read/Write	[5:3]	**000***	SUBPKT0_L_src	Registers 0x0E-0x11 should be set based on the speaker mapping information obtained from EDID Source of sub packet 0, left channel. Default = 000.
		[2:0]	*****001	SUBPKT0_R_src	Source of sub packet 0, right channel. Default = 001.
0x0F	Read/Write	[5:3]	**010***	SUBPKT1_L_src	Source of sub packet 1, left channel. Default = 010.
		[2:0]	*****011	SUBPKT1_R_src	Source of sub packet 1, right channel. Default = 011.
0x10	Read/Write	[5:3]	**100***	SUBPKT2_L_src	Source of sub packet 2, left channel. Default = 100.
		[2:0]	*****101	SUBPKT2_R_src	Source of sub packet 2, right channel. Default = 101.
0x11	Read/Write	[5:3]	**110***	SUBPKT3_L_src	Source of sub packet 3, left channel. Default = 110.
		[2:0]	*****111	SUBPKT3_R_src	Source of sub packet 3, right channel. Default = 111.
0x12	Read/Write	[5]	*0*****	CR_bit	Copyright bit. 0 = copyright. 1 = not copyright protected.
		[4:2]	***000**	a_info	Additional information for channel status bits. 000 = 2 audio channels without pre-emphasis. 100 = 2 audio channels with 50/15 μs pre-emphasis. 010 = reserved. 110 = reserved. Default = 000.
		[1:0]	*****00	Clk_Acc	Clock accuracy. 00 = Level II, normal accuracy ±1000 × 10 ⁻⁶ . 01 = Level III, variable pitch shifted clock. 10 = Level I, high accuracy ±50 × 10 ⁻⁶ . 11 = reserved. Default = 00.
0x13	Read/Write	[7:0]	00000000	Category Code	Category code for audio infoframe; see IEC 60958

Hex Address	Read/Write or Read Only	Bits	Default Value	Register Name	Description
0x14	Read/Write	[7:4] [3:0]	0000**** ****0000	Source Number Word Length	Source number. Audio word length. 0000 = not specified. 0100 = 16 bits. 0011 = 17 bits. 0010 = 18 bits. 0001 = 19 bits. 0101 = 20 bits. 1000 = not specified. 1100 = 20 bits. 1011 = 21 bits. 1010 = 22 bits. 1001 = 23 bits. 1101 = 24 bits. Default = 0x0.

		[5]	**0*****	MSEN_state	State of the monitor connection. 0 = HDMI clock termination not detected. 1 = HDMI clock termination detected.
0x43	Read/Write	[7:0]	01111110	EDID_ID	The I ² C address for EDID memory. Default = R0x7E.
0x44	Read/Write	[7]	0*****	spdif_en	1 = enable S/PDIF receiver. Default = 0.
		[6]	*1*****	N_CTS_pkt_en	1 = enable N_CTS packet. Default = 1.
		[5]	**1*****	audio_sample_pkt_en	1 = enable audio sample packet. Default = 1.
		[4]	***1****	aviIF_pkt_en	1 = enable avi info frame. Default = 1.
		[3]	****1***	audioIF_pkt_en	1 = enable audio info frame. Default = 1.
0x45	Read/Write	[7]	0*****	clear_avmute	1 = clear av mute. Default = 0.
		[6]	*0*****	set_avmute	1 = set av mute. Default = 0.
		[5:4]	**00****	Y1Y0	Output format, should be written when R0x16[7:6] is written. 00 = RGB. 01 = YCbCr 4:2:2. 10 = YCbCr 4:4:4. 11 = reserved. Default = 00.
		[3]	****0***	Active Format Information Status	Active format information present. 0 = no data. 1 = active format information valid. Default = 0.
		[2:1]	****00*	Bar Information	B[1:0]. 00 = no bar information. 01 = horizontal bar information valid. 10 = vertical bar information valid. 11 = horizontal and Vertical bar information valid. Default = 00.
0x46	Read/Write	[7:6]	00*****	Scan Information	S[1:0]. 00 = no information. 01 = overscanned (television). 10 = underscanned (computer). 11 = undefined. Default = 00.

AD9889

Hex Address	Read/Write or Read Only	Bits	Default Value	Register Name	Description
		[5:4]	**00****	Colorimetry	C[1:0]. 00 = no data. 01 = SMPTE 170M, ITU601. 10 = ITU709. 11 = undefined. Default = 00.
		[3:2]	****00**	Picture Aspect Ratio	M[1:0]. 00 = no data. 01 = 4:3. 10 = 16:9. 11 = undefined. Default = 00.
		[1:0]	*****00	Nonuniform Picture Scaling	SC[1:0]. 00 = No known nonuniform scaling. 01 = picture has been scaled horizontally. 10 = picture has been scaled vertically. 11 = picture has been scaled horizontally and vertically. Default = 00.
0x47	Read/Write	[7:4]	0000****	Active Format Aspect Ratio	R[3:0]. 1000 = same as picture aspect ratio. 1001 = 4:3 (center). 1010 = 16:9 (center). 1011 = 14:9 (center). Default = 0x0.
0x48	Read/Write	[7:0]	00000000	Active Line Start LSB	This represents the line number at the end of the top horizontal bar. If 0, there is no horizontal bar.
0x49	Read/Write	[7:0]	00000000	Active Line Start MSB	
0x4A	Read/Write	[7:0]	00000000	Active Line End LSB	This represents the line number at the beginning of a lower horizontal bar. If greater than the number of active video lines, there is no lower horizontal bar..
0x4B	Read/Write	[7:0]	00000000	Active Line End MSB	
0x4C	Read/Write	[7:0]	00000000	Active Pixel Start LSB	This represents the last pixel in a vertical pillar bar at the left side of the picture. If 0, there is no left bar.
0x4D	Read/Write	[7:0]	00000000	Active Pixel Start MSB	
0x4E	Read/Write	[7:0]	00000000	Active Pixel End LSB	This represents the first horizontal pixel in a vertical pillar bar at the right side of the picture. If greater than the maximum number of horizontal pixels, there is no vertical bar.
0x4F	Read/Write	[7:0]	00000000	Active Pixel End MSB	
0x50	Read/Write	[7:5]	000*****	audio_IF_CC	Channel count. 000 = refer to stream header. 001 = 2 channels. 010 = 3 channels. ... 111 = 8 channels. Default = 000.
		[4]	***0****	audio_IF_DM_INH	Down-mix inhibit. 0 = permitted or no information about this. 1 = prohibited. Default = 0.
		[3:0]	****0000	Level Shift	LSV[3:0]. Level Shift Values with attenuation information. 0000 = 0 dB attenuation. 0001 = 1 dB attenuation. ... 1111 = 15 dB attenuation. Default = 0x0.
0x51	Read/Write	[7:0]	00000000	Speaker Mapping	CA[7:0]. Speaker mapping or placement for up to 8 channels (see Table 24). Default = 0x00.

Hex Address	Read/Write or Read Only	Bits	Default Value	Register Name	Description
0x52	Read/Write	[7:0]	00000000	Source Product Description Infoframe Byte 1. (SPD_B1)	Vendor name character 1 (VN1).
0x53	Read/Write	[7:0]	00000000	SPD_B2	VN2.
0x54	Read/Write	[7:0]	00000000	SPD_B3	VN3.
0x55	Read/Write	[7:0]	00000000	SPD_B4	VN4.
0x56	Read/Write	[7:0]	00000000	SPD_B5	VN5.

2-WIRE SERIAL CONTROL REGISTER DETAIL CHIP IDENTIFICATION

0x00—Bits[7:0] Chip Revision

An 8-bit register that represents the silicon revision.

0x01—Bits[3:0] N[19:16]

These are the most significant four bits of a 20-bit word used along with the 20-bit CTS term in the receiver to regenerate the audio clock.

0x02—Bits[7:0] N[15:8]

0x03—Bits[7:0] [(7-0)]

0x04—Bits[3:0] CTS_Int[19:16]

These are the most significant four bits of a 20-bit word used along with the 20-bit N term in the receiver to regenerate the audio clock. This is the measured or internal CTS. The internal or external CTS can be selected via R0x0A Bit 7.

0x05—Bits[7:0] CTS_Int[15:8]

0x06—Bits[7:0] CTS_In[7:0]

0x07—Bits[3:0] CT_Ext[19:16]

These are the most significant four bits of a 20-bit word used along with the 20-bit N term in the receiver to regenerate the audio clock. This is the external CTS. The internal or external CTS can be selected via R0x0A Bit 7.

0x08—Bits[7:0] CTS_Ext[15:8]

0x09—Bits[7:0] CTS_Ext[7:0]

0x0A—Bits[7] CTS_Sel

When internal CTS is selected, the CTS is calculated by the AD9889.

- 0 = internal CTS
- 1 = external CTS

0x0A—Bits[6:5] Avg_Mode

- 00 = no filter
- 01 = divide by 4
- 10 = divide by 8
- 11 = divide by 16
- Default = 10

0x0A—Bit[4] Audio_Sel

- 0 = I²S
- 1 = S/PDIF
- Default = 0

0x0A—Bit[3] MCLK_SP

If MCLK is available for S/PDIF, it is used for bit recovery; otherwise, internal circuitry is used.

- 1 = MCLK active
- 0 = MCLK inactive
- Default = 0

0x0A—Bit[2] MCLK_I²S

- 1 = I²S MCLK active
- 0 = I²S MCLK inactive
- Default = 0

If MCLK is available for I²S, it is used for bit recovery; otherwise, internal circuitry is used.

0x0A—Bits[1:0] MCLK_Ratio

- 00 = ×128 fs
- 01 = ×256 fs
- 10 = ×384 fs
- 11 = ×512 fs
- Default = 01

0x0B—Bit[6] MCLK_Pol

- 0 = rising edge
- 1 = falling edge
- Default = 0

0x0B—Bit[5] Flat_Line

- 1 = flat line audio (audio sample not valid)
- 0 = normal
- Default = 0

0x0C—Bits[5:2] I²S enable

- 0001 = I²S0
- 0010 = I²S1
- 0100 = I²S2
- 1000 = I²S3
- Default = 1111 for all

0x0C—Bits[1:0] I²S Format

- 00 = standard I²S mode
- 01 = right-justified I²S mode
- 10 = left-justified I²S mode
- 11 = raw IEC60958 mode
- Default = 00

0x0D—Bits[4:0] I²S bit width

For right-justified audio only. Default is 11000 (24). Not valid for widths greater than 24.

0x0E—Bits[5:3] SUBPKT0_L_src

Source of audio subpacket 0 (left channel) data. Default is 000.

AD9889

Table 23. Source of Subpacket Audio

Field Code	Channel (0 to 3) and Left/Right
000	Channel 0 Left
001	Channel 0 Right
010	Channel 1 Left
011	Channel 1 Right
100	Channel 2 Left
101	Channel 2 Right
110	Channel 3 Left
111	Channel 3 Right

0x0E—Bits[2:0] SUBPKT0_R_src

Default is 001 (see Table 27).

0x0F—Bits[5:3] SUBPKT1_L_src

Default is 010 (see Table 27).

0x0F—Bits[2:0] SUBPKT1_R_src

Default is 011 (see Table 27).

0x10—Bits[5:3] SUBPKT2_L_src

Default is 100 (see Table 27).

0x10—Bits[2:0] SUBPKT2_R_src

Default is 101 (see Table 27).

0x11—Bits[5:3] SUBPKT3_L_src

Default is 110 (see Table 27).

0x11—Bits[2:0] SUBPKT3_R_src

Default is 111 (see Table 27).

0x18—Bits[4:0] CSC_A1_MSB

These five bits form the 5 MSBs of the Color Space Conversion coefficient a1. Combined with the 8 LSBs of the following register, they form a 13-bit, twos complement coefficient that is user programmable. The equation takes the form of

$$R_{OUT} = (a1 \times R_{IN}) + (a2 \times G_{IN}) + (a3 \times B_{IN}) + a4$$

$$G_{OUT} = (b1 \times R_{IN}) + (b2 \times G_{IN}) + (b3 \times B_{IN}) + b4$$

$$B_{OUT} = (c1 \times R_{IN}) + (c2 \times G_{IN}) + (c3 \times B_{IN}) + c4$$

The default value for the 13-bit, a1 coefficient is 0x0662.

0x19—Bits[7:0] CSC_A1_LSB

See Register 0x18.

0x1A—Bits[4:0] CSC_A2_MSB

These five bits form the 5 MSBs of the Color Space Conversion coefficient a2. This combined with the 8 LSBs of the following register form a 13-bit, twos complement coefficient that is user programmable. The equation takes the form of

$$R_{OUT} = (a1 \times R_{IN}) + (a2 \times G_{IN}) + (a3 \times B_{IN}) + a4$$

$$G_{OUT} = (b1 \times R_{IN}) + (b2 \times G_{IN}) + (b3 \times B_{IN}) + b4$$

$$B_{OUT} = (c1 \times R_{IN}) + (c2 \times G_{IN}) + (c3 \times B_{IN}) + c4$$

The default value for the 13-bit a2 coefficient is 0x04A8.

0x1B—Bits[7:0] CSC_A2_LSB

See Register 0x1A.

0x1C—Bits[4:0] CSC_A3_MSB

The default value for the 13-bit a3 is 0x0000.

0x1D—Bits[7:0] CSC_A3_LSB**0x1E—Bits[4:0] CSC_A4_MSB**

The default value for the 13-bit a4 is 0x1C84.

0x1F—Bits[7:0] CSC_A4_LSB**0x20—Bits[4:0] CSC_B1_MSB**

The default value for the 13-bit b1 is 0x1CBF.

0x21—Bits[7:0] CSC_B1_LSB**0x22—Bits[4:0] CSC_B2_MSB**

The default value for the 13-bit b2 is 0x04A8.

0x23—Bits[7:0] CSC_B2_LSB**0x24—Bits[4:0] CSC_B3_MSB**

The default value for the 13-bit b3 is 0x1E70.

0x25—Bits[7:0] CSC_B3_LSB**0x26—Bits[4:0] CSC_B4_MSB**

The default value for the 13-bit b4 is 0x021E.

0x27—Bits[7:0] CSC_B4_LSB**0x28—Bits[4:0] CSC_C1_MSB**

The default value for the 13-bit c1 is 0x0000.

0x29—Bits[7:0] CSC_C1_LSB**0x2A—Bits[4:0] CSC_C2_MSB**

The default value for the 13-bit c2 is 0x04A8.

0x2B—Bits[7:0] CSC_C2_LSB**0x2C—Bits[4:0] CSC_C3_MSB**

The default value for the 13-bit c3 is 0x0812.

0x2D—Bits[7:0] CSC_C3_LSB**0x2E—Bits[4:0] CSC_C4_MSB**

The default value for the 13-bit c4 is 0x1BAC.

0x2F—Bits[7:0] CSC_C4_LSB

0x3C—Bits[5:0] ext_VID_to_Rx

This is a programmable I²C address from which the EDID information (1 to 256 segment) can be read. Default is 0x7E.

0x48—Bits[7:0] Active Line Start LSB

Combined with the MSB in Register 0x49, these bits indicate the beginning line of active video. All lines before this comprise a top horizontal bar. This is used in letter-box modes. If the 2-byte value is 0x00, there is no horizontal bar.

0x49—Bits[7:0] Active Line Start MSB

See Register 0x48.

0x4A—Bits[7:0] Active Line End LSB

Combined with the MSB in Register 0x4B, the bits indicate the last line of active video. All lines past this comprise a lower horizontal bar. This is used in letter-box modes. If the 2-byte value is greater than the number of lines in the display, there is no lower horizontal bar.

0x4B—Bits[7:0] Active Line End MSB

See Register 0x4A.

0x4C—Bits[7:0] Active Pixel Start LSB

Combined with the MSB in Register 0x4D, these bits indicate the first pixel in the display that is active video. All pixels before this comprise a left vertical bar. If the 2-byte value is 0x00, there is no left bar.

0x4D—Bits[7:0] Active Pixel Start MSB

See Register 0x4C.

0x4E—Bits[7:0] Active Pixel End LSB

Combined with the MSB in Register 0x4F, these bits indicate the last active video pixel in the display. All pixels past this comprise a right vertical bar. If the 2-byte value is greater than the number of pixels in the display, there is no vertical bar.

0x4F—Bits[7:0] Active Pixel End MSB

See Register 0x4E.

0xC8—Bits[7:4] HDCP Controller Error

When an error occurs in the HDCP flow, it is reported here after setting the error flag (0xC5[7]).

Table 28.

Error Code	Error Condition
0000	No error
0001	Bad receiver BKSv
0010	Ri mismatch
0011	Pj mismatch
0100	I ² C error (usually a no acknowledge)
0101	Timed out waiting for downstream repeater
0110	Maximum cascade of repeaters exceeded
0111	SHA-1 hash check of BKSv list failed
1000	Too many devices connected to repeater tree

0xC8—Bits[3:0] HDCP Controller State

This information is used in troubleshooting the HDCP controller.

0xC9—Bits[3:0] EDID Read Tries

These bits define the number of times the EDID attempts to be read if unsuccessful.

AD9889

2-WIRE SERIAL CONTROL PORT

A 2-wire serial interface is provided. Up to two AD9889 devices can be connected to the 2-wire serial interface, with each device having a unique address.

The 2-wire serial interface comprises a clock (SCL) and a bidirectional data (SDA) pin. The analog flat panel interface acts as a slave for receiving and transmitting data over the serial interface. When the serial interface is not active, the logic levels on SCL and SDA are pulled high by external pull-up resistors.

Data received or transmitted on the SDA line must be stable for the duration of the positive going SCL pulse. Data on SDA must change only when SCL is low. If SDA changes state while SCL is high, the serial interface interprets that action as a start or stop sequence.

There are five components to serial bus operation:

- Start signal
- Slave address byte
- Base register address byte
- Data byte to read or write
- Stop signal

When the serial interface is inactive (SCL and SDA are high) communications are initiated by sending a start signal. The start signal is a high-to-low transition on SDA while SCL is high. This signal alerts all slave devices that a data transfer sequence is coming.

The first 8 bits of data transferred after a start signal comprise a 7-bit slave address (the first 7 bits) and a single $\overline{R/W}$ bit (the eighth bit). The $\overline{R/W}$ bit indicates the direction of data transfer, read from (1) or write to (0) the slave device. If the transmitted slave address matches the address of the device, the AD9889 acknowledges by bringing SDA low on the ninth SCL pulse. If the addresses do not match, the AD9889 does not acknowledge.

Table 29. Serial Port Addresses

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1
A ₆ (MSB)	A ₅	A ₄	A ₃	A ₂	A ₁	A ₀
0	1	1	1	0	0	0
0	1	1	1	0	0	1

Figure 11. Serial Port Read/Write Timing

DATA TRANSFER VIA SERIAL INTERFACE

For each byte of data read or written, the MSB is the first bit of the sequence.

If the AD9889 does not acknowledge the master device during a write sequence, the SDA remains high so the master can generate a stop signal. If the master device does not acknowledge the AD9889 during a read sequence, the AD9889 interprets this as the end of data. The SDA remains high so the master can generate a stop signal.

Writing data to specific control registers of the AD9889 requires that the 8-bit address of the control register of interest be written to after the slave address has been established. This control register address is the base address for subsequent write operations. The base address auto-increments by one for each byte of data written after the data byte intended for the base address.

Data is read from the control registers of the AD9889 in a similar manner. Reading requires two data transfer operations:

- The base address must be written with the $\overline{R/W}$ bit of the slave address byte low to set up a sequential read operation.
- Reading (the $\overline{R/W}$ bit of the slave address byte high) begins at the previously established base address. The address of the read register auto-increments after each byte is transferred.

To terminate a read/write sequence to the AD9889, a stop signal must be sent. A stop signal comprises a low-to-high transition of SDA while SCL is high.

A repeated start signal occurs when the master device driving the serial interface generates a start signal without first generating a stop signal to terminate the current communication. This is used to change the mode of communication (read, write) between the slave and master without releasing the serial interface lines.

SERIAL INTERFACE READ/WRITE EXAMPLES

Write to one control register:

- Start signal
- Slave address byte (R/\overline{W} bit = low)
- Base address byte
- Data byte to base address
- Stop signal
- Write to four consecutive control registers
- Start signal
- Slave address byte (R/\overline{W} bit = low)
- Base address byte
- Data byte to base address
- Data byte to (base address + 1)
- Data byte to (base address + 2)
- Data byte to (base address + 3)
- Stop signal

Read from one control register:

- Start signal
- Slave address byte (R/\overline{W} bit = low)
- Base address byte
- Start signal
- Slave address byte (R/\overline{W} bit = high)
- Data byte from base address
- Stop signal

Read from four consecutive control registers:

- Start signal
- Slave address byte (R/\overline{W} bit = low)
- Base address byte
- Start signal
- Slave address byte (R/\overline{W} bit = high)
- Data byte from base address
- Data byte from (base address + 1)
- Data byte from (base address + 2)
- Data byte from (base address + 3)
- Stop signal

Figure 12. Serial Interface—Typical Byte Transfer

AD9889

PCB LAYOUT RECOMMENDATIONS

The AD9889 is a high precision, high speed analog device. As such, to get the maximum performance out of the part, it is important to have a well laid out board. The following is a guide for designing a board using the AD9889.

POWER SUPPLY BYPASSING

It is recommended to bypass each power supply pin with a 0.1 μF capacitor. The exception is when two or more supply pins are adjacent to each other. For these groupings of powers/grounds, it is necessary to have only one bypass capacitor. The fundamental idea is to have a bypass capacitor within about 0.5 cm of each power pin. Also, avoid placing the capacitor on the opposite side of the PC board from the AD9889, as that interposes resistive vias in the path.

The bypass capacitors should be physically located between the power plane and the power pin. Current should flow from the power plane to the capacitor to the power pin. Do not make the power connection between the capacitor and the power pin. Placing a via underneath the capacitor pads, down to the power plane, is generally the best approach.

It is particularly important to maintain low noise and good stability of PV_{D} (the clock generator supply). Abrupt changes in PV_{D} can result in similarly abrupt changes in sampling clock phase and frequency. This can be avoided by careful attention to regulation, filtering, and bypassing. It is highly desirable to provide separate regulated supplies for each of the analog circuitry groups (V_{D} and PV_{D}).

Some graphic controllers use substantially different levels of power when active (during active picture time) and when idle (during horizontal and vertical sync periods). This can result in a measurable change in the voltage supplied to the analog supply regulator, which can in turn produce changes in the regulated analog supply voltage. This can be mitigated by regulating the analog supply, or at least PV_{D} , from a different, cleaner power source (for example, from a 12 V supply).

It is also recommended to use a single ground plane for the entire board. Experience has shown repeatedly that noise performance is the same or better with a single ground plane. Using multiple ground planes can be detrimental because each separate ground plane is smaller, and long ground loops can result.

In some cases, using separate ground planes is unavoidable, so it is recommended to place a single ground plane under the AD9889. The location of the split should be at the receiver of the digital outputs. For this case, it is even more important to place components wisely because the current loops are much longer (current takes the path of least resistance). Figure 13 shows an example of a current loop.

Figure 13. Current Loop

DIGITAL INPUTS

The digital inputs on the AD9889 were designed to work with 1.8 V signals but are tolerant of 3.3 V signals. Therefore, no extra components need to be added if using 3.3 V logic.

Any noise that gets onto the HSYNC input trace adds jitter to the system. Therefore, minimize the trace length and do not run any digital or other high frequency traces near it.
