

1.0 Hz to 102.4 kHz  
8-Bit Programmable

### Description

The D828 Series are digitally programmable low-pass and high-pass active filters with differential input that are tunable over a 256:1 frequency range. D828 filters are available with any one of five standard factory-set tuning ranges or 8-bit custom ranges from 1.0 Hz to 102.4 kHz. These units contain 8 CMOS logic inputs.

All D828 Series models are convenient, low profile, easy to use fully finished filters which require no external components or adjustments. They feature low harmonic distortion, and near theoretical phase and amplitude characteristics. D828 filters operate from non-critical ± 12 to ± 18 Vdc power supplies, have a 10 kΩ (min.) input and a 10 Ω (max.) output impedance.

### Features/Benefits:

- Compact 2" x 2" design minimizes board space requirements.
- Low harmonic distortion and wide signal-to-noise ratio to 16 bit resolution.
- Digitally programmable corner frequency allows selecting cut-off frequencies specific to each application.
- Plug-in ready-to-use, reducing engineering design and manufacturing cycle time.
- Factory-set tuning range, no external clocks or adjustments needed
- Broad range of transfer characteristics and corner frequencies to meet a wide range of applications.

### Applications

- Anti-alias filtering
- Data acquisition systems
- Communication systems and electronics
- Medical electronics equipment and research
- Aerospace, navigation and sonar applications
- Sound and vibration testing
- Real and compressed time data analysis
- Noise elimination
- Signal reconstruction

## Digital Tuning & Control Characteristics

### 8-Bit Programmable Filters

#### Digital Tuning Characteristics

The digital tuning interface circuits are a parallel set of eight (8) 4053 CMOS switches which accept CMOS compatible inputs for the eight tuning bits (D<sub>0</sub> - D<sub>7</sub>).

Filter tuning follows the tuning equation given below:

$$f_c = (f_{max}/256) [ 1 + D_7 \times 2^7 + D_6 \times 2^6 + D_5 \times 2^5 + D_4 \times 2^4 + D_3 \times 2^3 + D_2 \times 2^2 + D_1 \times 2^1 + D_0 \times 2^0 ]$$

where D<sub>1</sub> - D<sub>7</sub> = "0" or "1", and

f<sub>max</sub> = Maximum tuning frequency;

f<sub>c</sub> = corner frequency;

Minimum tunable frequency = f<sub>max</sub>/256 (D<sub>0</sub> thru D<sub>7</sub> = 0);

Minimum frequency step (Resolution) = f<sub>max</sub>/256

#### Data Input Specifications

**Frequency Response**

**1. Normalized Group Delay:**

The above delay data is normalized to a corner frequency of 1.0Hz. The actual delay is the normalized delay divided by the actual corner frequency (fc).

$$\text{Actual Delay} = \frac{\text{Normalized Delay}}{\text{Actual Corner Frequency (fc) in Hz}}$$
