INFORMATION IN THIS DOCUMENT IS PROVIDED IN CONNECTION WITH INTEL® PRODUCTS. NO LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE, TO ANY INTELLECTUAL PROPERTY RIGHTS IS GRANTED BY THIS DOCUMENT. EXCEPT AS PROVIDED IN INTEL'S TERMS AND CONDITIONS OF SALE FOR SUCH PRODUCTS, INTEL ASSUMES NO LIABILITY WHATSOEVER, AND INTEL DISCLAIMS ANY EXPRESS OR IMPLIED WARRANTY, RELATING TO SALE AND/OR USE OF INTEL PRODUCTS INCLUDING LIABILITY OR WARRANTIES RELATING TO FITNESS FOR A PARTICULAR PURPOSE, MERCHANTABILITY, OR INFRINGEMENT OF ANY PATENT, COPYRIGHT OR OTHER INTELLECTUAL PROPERTY RIGHT. Intel products are not intended for use in medical, life saving, life sustaining, critical control or safety systems, or in nuclear facility applications.

Intel may make changes to specifications and product descriptions at any time, without notice.

Intel Corporation may have patents or pending patent applications, trademarks, copyrights, or other intellectual property rights that relate to the presented subject matter. The furnishing of documents and other materials and information does not provide any license, express or implied, by estoppel or otherwise, to any such patents, trademarks, copyrights, or other intellectual property rights.

Designers must not rely on the absence or characteristics of any features or instructions marked "reserved" or "undefined." Intel reserves these for future definition and shall have no responsibility whatsoever for conflicts or incompatibilities arising from future changes to them.

Intel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. See [http://www.intel.com/products/processor\\_number](http://www.intel.com/products/processor_number) for details.

Contact your local Intel sales office or your distributor to obtain the latest specifications and before placing your product order.

Copies of documents which have an order number and are referenced in this document, or other Intel literature may be obtained by calling 1-800-548-4725 or by visiting Intel's website at <http://www.intel.com>.

Intel, Intel logo, Intel StrataFlash and Pentium are trademarks or registered trademarks of Intel Corporation or its subsidiaries in the United States and other countries.

## Product Features

- **System on a Chip (SoC)**
  - Integrated Intel® Architecture (IA) processor and chipset (MCH/ICH) technology
  - Extensive integration of standard Intel architecture communications interfaces provide cost, power and board area savings (Gigabit Ethernet (GbE), Time Division Multiplexing (TDM)<sup>†</sup> processing, Security Services Unit (SSU),<sup>‡</sup> and Acceleration Services Units (ASU)<sup>‡</sup>)
- **SKU Support<sup>1</sup>**
  - Embedded: Intel architecture compatibility and high-speed interfaces (GbEs, PCI Express\*)
  - Application Services: Security — Packet security compatibility and IP Telephony packet security, TDM, and High-Level Data Link Control (HDLC)
- **Intel Architecture Processor**
  - Low-power and high-performance architecture based on Intel Architecture (IA-32) processor
  - Three operating frequency SKUs:
    - 600 MHz, 1066 MHz, or 1200 MHz
  - 256 KB L2 data coherent cache (2 way)
- **Integrated Memory Control Hub (IMCH) and Integrated I/O Control Hub (IICH) Compatible**
  - Enhanced DMA (EDMA) controller
  - Two SATA Gen1 or Gen2 interfaces
  - Two USB 1.1 or USB 2.0 ports
  - Two integrated, 16550-compatible UARTs
  - LPC 1.1 interface
  - Serial Peripheral Interface (SPI)<sup>†</sup>
  - Two SMBus 2.0 compliant interfaces
  - GPIOs
  - Watchdog Timer
  - One 32/64-bit and two 32-bit high-precision event timers
- **Acceleration Services Unit (ASU)<sup>‡</sup>**
  - High performance accelerator on-chip engines for packet processing
  - Support capabilities for commonly used protocol implementations such as TCP/IP, UDP, IPSec, SSL, NAT, and SRTP
- **Security Services Unit (SSU)<sup>‡</sup>**
  - High-performance on-chip Crypto Accelerator
  - Support capabilities for commonly used cryptographic protocol implementations
- **Single-Channel Double-Data-Rate (DDR) SDRAM Memory**
  - Supports DDR2 at 400/533/667/800 MT/s
  - Supports 32 or 64-bit interfaces
  - Error correction code (ECC): single-bit correct/double-bit detect (SEC/DED) coverage
  - Addressable from Intel architecture processor and PCI Express
- **Three Gigabit Ethernet MACs**
  - Three 10/100/1000 ports with RGMII/RMII interfaces
  - MDIO interface for external PHY configuration
  - Serial EEPROM interface supports network boot and wake-on LAN
- **Industry Standard PCI Express Interface**
  - Supports 1x8, 2x4, or 2x1 configurations as a root complex
- **Integrated Serial ATA (SATA) Host Controllers**
  - Independent DMA operation on two ports
  - Data transfer rates up to 3.0 Gb/s
  - Alternate Device ID
- **Integrated High-speed Serial Interface (TDM)<sup>†</sup>**
  - Supports up to 12 external T1/E1 and codecs
  - Supports up to 128 HDLC channels
- **Local Expansion Bus (LEB)**
  - Supports up to eight chip selects
  - 25-bit address and 16-bit data
  - Supports HPI-8 and HPI-16
- **Dual Controller Area Network (CAN)**
  - Supports two CAN 2.0b interfaces
- **Single Synchronous Serial Port (SSP) Compatible**
- **IEEE 1588-2008 Hardware Assistance**
  - Supports two GbE and two CAN interfaces
  - Time master/target support
- **1088-Ball FCBGA package**
  - Dimensions of 37.5 mm x 37.5 mm
  - 1.092-mm solder ball pitch
  - Lead-free only — RoHS 5/6 compliant
- **Typical Applications**
  - Embedded, Security and/or IP Telephony applications

<sup>†</sup> Intel recommends using the SPI for Pre-boot firmware due to the reduced availability of LPC FW.

<sup>‡</sup> Feature must be enabled with EP80579 software. Refer to the EP80579 software documentation for more information.

1. For complete information about product features and SKUs, please refer to [Chapter 47.0, "SKUs, Power Savings and Pre-Boot Firmware"](#).

| 5.2.2      | Software Usage Model .....                                | 141        |
| 5.3        | Error Reporting by the IMCH .....                         | 141        |
| 5.3.1      | Overview of the First and Next Error Architecture .....   | 141        |
| 5.3.2      | Global Error Events .....                                 | 142        |
| 5.3.3      | Unit-Level Errors from the Buffer Unit .....              | 143        |
| 5.3.4      | Unit-Level Errors from the DRAM Interface .....           | 143        |
| 5.3.5      | Unit-Level Errors from the FSB Interface .....            | 144        |
| 5.3.6      | Unit-Level Errors from the NSI .....                      | 145        |
| 5.3.7      | Unit-Level Errors from the EDMA Engine.....               | 146        |
| 5.3.8      | Unit-Level Errors from PCI Express* Ports A0 and A1 ..... | 147        |
| 5.4        | Error Reporting by the IICH .....                         | 149        |
| 5.4.1      | SMBus Interface .....                                     | 149        |
| 5.4.2      | LPC Interface.....  | 150        |
| 5.4.3      | USB 1.1 Interface .....                                   | 151        |
| 5.4.4      | USB 2.0 Interface .....                                   | 151        |
| 5.4.5      | SATA Interface .....                                      | 152        |
| 5.4.6      | Serial I/O Interface .....                                | 153        |
| 5.5        | Error Reporting by the System Memory Controller .....     | 153        |
| 5.5.1      | Handling Out-of-Bounds Addresses.....                     | 154        |
| 5.5.2      | IMCH - Memory Controller.....                             | 154        |
| 5.6        | Error Reporting by AIOC Devices .....                     | 155        |
| 5.6.1      | Gigabit Ethernet MAC .....                                | 155        |
| 5.6.2      | CAN Interface.....  | 156        |
| 5.6.3      | SSP Interface .....                                       | 157        |
| 5.6.4      | Local Expansion Bus .....                                 | 158        |
| 5.6.5      | IEEE 1588, and GCU.....                                   | 159        |
| <b>6.0</b> | <b>Reset and Power Management.....</b>                    | <b>161</b> |
| 6.1        | Reset and Powergood Distribution .....                    | 161        |
| 6.1.1      | Types of Reset.....                                       | 161        |
| 6.1.1.1    | Powergood Implementation.....                             | 161        |
| 6.1.1.2    | Hard Reset Implementation.....                            | 162        |
| 6.1.1.3    | Software Controlled Reset.....                            | 162        |
| 6.1.1.4    | CPU Only Reset Implementation .....                       | 162        |
| 6.1.1.5    | S-state Wake Events .....                                 | 163        |
| 6.1.1.6    | Targeted Reset Implementation.....                        | 163        |
| 6.1.2      | Platform Reset and Powergood.....                         | 163        |
| 6.1.2.1    | Platform Powergood .....                                  | 163        |
| 6.1.2.2    | Platform Reset.....                                       | 163        |
| 6.1.2.3    | Reset and Powergood Distribution .....                    | 164        |
| 6.1.3      | EP80579 Power Sequencing and Reset Sequence.....          | 167        |
| 6.2        | BIOS Boot Flow (Initialization) .....                     | 175        |
| 6.2.1      | Memory Configuration.....                                 | 176        |
| 6.2.2      | Memory Initialization .....                               | 176        |
| 6.2.3      | Boot from Network .....                                   | 176        |
| 6.3        | Power Management .....                                    | 177        |
| 6.3.1      | Power Management States .....                             | 177        |
| 6.3.2      | Power Management Support .....                            | 179        |
| 6.3.2.1    | Transitioning Between Power States .....                  | 181        |
| 6.3.2.2    | Power State Transition Timing Diagrams .....              | 181        |
| 6.3.3      | Thermal Sensor .....                                      | 182        |
| 6.3.4      | ACPI Implementation.....                                  | 182        |
| <b>7.0</b> | <b>Register Summary .....</b>                             | <b>183</b> |
| 7.1        | Overview of Register Descriptions and Summaries .....     | 183        |

- 7.1.1 Register Description Tables ..... 183
- 7.1.2 Register Field Access Attributes ..... 189
- 7.1.3 Register Nomenclature and Values ..... 189
- 7.1.4 “Sticky” Register Fields..... 190
- 7.2 IA-32 core Registers ..... 190
- 7.3 IMCH and IICH Registers ..... 191
  - 7.3.1 IMCH Registers: Bus 0, Device 0, Function 0 ..... 191
  - 7.3.2 IMCH Error Reporting Registers: Bus 0, Device 0, Function 1 ..... 195
  - 7.3.3 EDMA Engine Registers: Bus 0, Device 1, Function 0 ..... 197
  - 7.3.4 PCI Express\* Port A Registers: Bus 0, Device 2, Function 0 ..... 200
  - 7.3.5 PCI Express\* Port A1 Registers: Bus 0, Device 3, Function 0 ..... 203
  - 7.3.6 USB (1.1) Controller: Bus 0, Device 29, Functions 0 ..... 206
  - 7.3.7 USB (2.0) Controller: Bus 0, Device 29, Function 7 ..... 207

| 35.11.1    | Register Details .....   | 1305 |
| 35.11.1.1  | Offset 00h: VID – Vendor Identification Register .....                               | 1306 |
| 35.11.1.2  | Offset 02h: DID – Device Identification Register .....                               | 1306 |
| 35.11.1.3  | Offset 04h: PCICMD – Device Command Register .....                                   | 1306 |
| 35.11.1.4  | Offset 06h: PCISTS – Device Status Register .....                                    | 1307 |
| 35.11.1.5  | Offset 08h: RID – Revision ID Register .....   | 1308 |
| 35.11.1.6  | Offset 09h: CC – Class Code Register .....   | 1308 |
| 35.11.1.7  | Offset 0Eh: HDR – Header Type Register .....   | 1309 |
| 35.11.1.8  | Offset 10h: CSRBAR – Control and Status Registers Base Address Register .....        | 1309 |
| 35.11.1.9  | Offset 2Ch: SVID – Subsystem Vendor ID Register .....                                | 1310 |
| 35.11.1.10 | Offset 2Eh: SID – Subsystem ID Register .....  | 1310 |
| 35.11.1.11 | Offset 34h: CP – Capabilities Pointer Register .....                                 | 1310 |
| 35.11.1.12 | Offset 3Ch: IRQL – Interrupt Line Register .....                                     | 1311 |
| 35.11.1.13 | Offset 3Dh: IRQP – Interrupt Pin Register .....                                      | 1311 |
| 35.11.1.14 | Offset DCh: PCID – Power Management Capability ID Register .....                     | 1312 |
| 35.11.1.15 | Offset DDh: PCP – Power Management Next Capability Pointer Register .....            | 1312 |
| 35.11.1.16 | Offset DEh: PMCAP – Power Management Capability Register .....                       | 1313 |
| 35.11.1.17 | Offset E0h: PMCS – Power Management Control and Status Register .....                | 1313 |
| 35.11.1.18 | Offset E4h: SCID – Signal Target Capability ID Register .....                        | 1314 |
| 35.11.1.19 | Offset E5h: SCP – Signal Target Next Capability Pointer Register .....               | 1314 |
| 35.11.1.20 | Offset E6h: SBC – Signal Target Byte Count Register .....                            | 1314 |
| 35.11.1.21 | Offset E7h: STYP – Signal Target Capability Type Register .....                      | 1315 |
| 35.11.1.22 | Offset E8h: SMIA – Signal Target IA Mask Register .....                              | 1315 |
| 35.11.1.23 | Offset E9h: Reserved Register .....  | 1315 |
| 35.11.1.24 | Offset EAh: Reserved Register .....  | 1315 |
| 35.11.1.25 | Offset Ech: SINT – Signal Target Raw Interrupt Register .....                        | 1316 |
| 35.11.1.26 | Offset F0h: MCID – Message Signalled Interrupt Capability ID Register .....          | 1316 |
| 35.11.1.27 | Offset F1h: MCP – Message Signalled Interrupt Next Capability Pointer Register ..... | 1317 |
| 35.11.1.28 | Offset F2h: MCTL – Message Signalled Interrupt Control Register .....                | 1317 |
| 35.11.1.29 | Offset F4h: MADR – Message Signalled Interrupt Address Register .....                | 1318 |

- 35.11.1.30 Offset F8h: MDATA – Message Signalled Interrupt Data Register..... 1318
- 35.12 Expansion Bus Configuration Space: Bus M, Device 8, Function 0 ..... 1319
  - 35.12.1 Register Details..... 1319
    - 35.12.1.1 Offset 00h: VID – Vendor Identification Register..... 1320
    - 35.12.1.2 Offset 02h: DID – Device Identification Register ..... 1320
    - 35.12.1.3 Offset 04h: PCICMD – Device Command Register ..... 1321
    - 35.12.1.4 Offset 06h: PCISTS – Device Status Register ..... 1321
    - 35.12.1.5 Offset 08h: RID – Revision ID Register ..... 1322
    - 35.12.1.6 Offset 09h: CC – Class Code Register ..... 1323
    - 35.12.1.7 Offset 0Eh: HDR – Header Type Register ..... 1323
    - 35.12.1.8 Offset 10h: CSRBAR – Control and Status Registers Base Address Register ..... 1323
    - 35.12.1.9 Offset 14h: MMBAR – Expansion Bus Base Address Register ..... 1324
    - 35.12.1.10 Offset 2Ch: SVID – Subsystem Vendor ID Register ..... 1325
    - 35.12.1.11 Offset 2Eh: SID – Subsystem ID Register ..... 1325
    - 35.12.1.12 Offset 34h: CP – Capabilities Pointer Register..... 1326
    - 35.12.1.13 Offset 3Ch: IRQL – Interrupt Line Register..... 1326
    - 35.12.1.14 Offset 3Dh: IRQP – Interrupt Pin Register ..... 1327
    - 35.12.1.15 Offset 40h: LEBCTL – LEB Control Register ..... 1327
    - 35.12.1.16 Offset DCh: PCID – Power Management Capability ID Register ..... 1327
    - 35.12.1.17 Offset DDh: PCP – Power Management Next Capability Pointer Register ..... 1328
    - 35.12.1.18 Offset DEh: PMCAP – Power Management Capability Register ..... 1328
    - 35.12.1.19 Offset E0h: PMCS – Power Management Control and Status Register ..... 1329
    - 35.12.1.20 Offset E4h: SCID – Signal Target Capability ID Register ..... 1329
    - 35.12.1.21 Offset E5h: SCP – Signal Target Next Capability Pointer Register ..... 1330
    - 35.12.1.22 Offset E6h: SBC – Signal Target Byte Count Register ..... 1330
    - 35.12.1.23 Offset E7h: STYP – Signal Target Capability Type Register ..... 1330
    - 35.12.1.24 Offset E8h: SMIA – Signal Target IA Mask Register ..... 1331
    - 35.12.1.25 Offset E9h: Reserved Register..... 1331
    - 35.12.1.26 Offset EAh: Reserved Register ..... 1331
    - 35.12.1.27 Offset ECh: SINT – Signal Target Raw Interrupt Register ..... 1331
    - 35.12.1.28 Offset F0h: MCID – Message Signalled Interrupt Capability ID Register ..... 1332
    - 35.12.1.29 Offset F1h: MCP – Message Signalled Interrupt Next Capability Pointer Register ..... 1332
    - 35.12.1.30 Offset F2h: MCTL – Message Signalled Interrupt Control Register ..... 1333
    - 35.12.1.31 Offset F4h: MADR – Message Signalled Interrupt Address Register ..... 1333
    - 35.12.1.32 Offset F8h: MDATA – Message Signalled Interrupt Data Register..... 1334
- 36.0 AIOC Interfaces** ..... 1335
  - 36.1 Overview ..... 1335
  - 36.2 Gigabit Ethernet (GbE) ..... 1335
    - 36.2.1 Integrated DMA Features ..... 1336
    - 36.2.2 MAC Features..... 1336
    - 36.2.3 Host Off-Loading Features ..... 1337
    - 36.2.4 Interfaces..... 1337
    - 36.2.5 Power Management ..... 1337
    - 36.2.6 Serial EEPROM Interface ..... 1338
  - 36.3 Local Expansion Bus Interface (LEB)..... 1338
  - 36.4 Serial Synchronous Port (SSP)..... 1339
  - 36.5 Controller Area Network (CAN) ..... 1339
  - 36.6 IEEE 1588 Time Synchronization Hardware Assist ..... 1340
- 37.0 Gigabit Ethernet Controller** ..... 1341
  - 37.1 Overview ..... 1341

- 37.1.1 Terminology and Conventions ..... 1341
  - 37.1.1.1 Register and Bit References ..... 1341
  - 37.1.1.2 Byte and Bit Designations ..... 1341
  - 37.1.1.3 Numbering ..... 1341
  - 37.1.1.4 Memory Alignment Terminology ..... 1342
  - 37.1.1.5 Alignment and Byte Ordering ..... 1342
  - 37.1.1.6 Packet Buffer ..... 1342
- 37.1.2 Wake On LAN ..... 1343
- 37.2 Feature List ..... 1343
- 37.3 Functional Block Diagram ..... 1344
- 37.4 Usage Model ..... 1345
  - 37.4.1 Protocol Translation ..... 1346
  - 37.4.2 Power Management ..... 1346
  - 37.4.3 Software Initialization and Diagnostics ..... 1346
    - 37.4.3.1 Power Up State ..... 1346
    - 37.4.3.2 Memory Initialization ..... 1347
    - 37.4.3.3 General Configuration ..... 1348
    - 37.4.3.4 Link Setup Mechanisms and Control/Status Bit Summary ..... 1348
    - 37.4.3.5 Receive Initialization ..... 1348
    - 37.4.3.6 Transmit Initialization ..... 1349
    - 37.4.3.7 Initialization of Statistics ..... 1350
    - 37.4.3.8 GbE Line Rate Configuration Change ..... 1350
    - 37.4.3.9 Network Boot ..... 1350
    - 37.4.3.10 Diagnostics ..... 1351
- 37.5 Functional Description ..... 1351
  - 37.5.1 Ethernet Addressing ..... 1351
  - 37.5.2 Interrupt Control & Tuning ..... 1352
    - 37.5.2.1 Interrupt Cause Set/Read Registers ..... 1353
    - 37.5.2.2 Interrupt Mask Set (Read)/Clear Registers ..... 1353
    - 37.5.2.3 Interrupt Throttling Register ..... 1353
  - 37.5.3 Hardware Acceleration Capability ..... 1353
    - 37.5.3.1 Checksum Off-Loading ..... 1353
    - 37.5.3.2 TCP Segmentation ..... 1354
  - 37.5.4 Buffer and Descriptor Structure ..... 1354
  - 37.5.5 Packet Reception ..... 1354
    - 37.5.5.1 Packet Address Filtering ..... 1354
    - 37.5.5.2 Receive Data Storage ..... 1355
    - 37.5.5.3 Receive Descriptor Format ..... 1355
    - 37.5.5.4 Receive Descriptor Fetching ..... 1358
    - 37.5.5.5 Receive Descriptor Write-Back ..... 1358
    - 37.5.5.6 Receive Descriptor Queue Structure ..... 1359
    - 37.5.5.7 Receive Interrupts ..... 1360
    - 37.5.5.8 Receive Packet Checksum Off loading ..... 1363
  - 37.5.6 Packet Transmission ..... 1365
    - 37.5.6.1 Transmit Data Storage ..... 1365
    - 37.5.6.2 Transmit Descriptor Formats ..... 1365
    - 37.5.6.3 Legacy Transmit Descriptor Format ..... 1366
    - 37.5.6.4 TCP/IP Context Transmit Descriptor Format ..... 1369
    - 37.5.6.5 TCP/IP Data Descriptor Format ..... 1373
    - 37.5.6.6 Transmit Descriptor Structure ..... 1375
    - 37.5.6.7 Transmit Descriptor Fetching ..... 1377
    - 37.5.6.8 Transmit Descriptor Write-back ..... 1377
    - 37.5.6.9 Transmit Interrupts ..... 1378
    - 37.5.6.10 Transmit Checksum Off loading ..... 1379
  - 37.5.7 TCP Segmentation ..... 1380
    - 37.5.7.1 Assumptions ..... 1381
    - 37.5.7.2 Transmission Process ..... 1381
    - 37.5.7.3 TCP Segmentation Performance ..... 1382

- 37.5.7.4 Packet Format ..... 1382
- 37.5.7.5 TCP Segmentation Indication ..... 1383
- 37.5.7.6 TCP Segmentation Data Descriptors ..... 1383
- 37.5.7.7 IP and TCP/UDP Headers ..... 1384
- 37.5.7.8 Transmit Checksum Off loading with TCP Segmentation ..... 1388
- 37.5.7.9 IP/TCP/UDP Header Updating ..... 1389
- 37.5.7.10 Data Flow ..... 1391
- 37.5.8 Ethernet Interfaces ..... 1391
  - 37.5.8.1 MAC/PHY GMII/MII Interface ..... 1392
  - 37.5.8.2 Duplex Operation ..... 1393
  - 37.5.8.3 Physical Layer Auto-Negotiation & Link Setup Features ..... 1394
  - 37.5.8.4 10/100Mbps Specific Performance Enhancements ..... 1396
  - 37.5.8.5 Flow Control ..... 1397
- 37.5.9 802.1q VLAN Support ..... 1400
  - 37.5.9.1 Transmitting and Receiving 802.1q Packets ..... 1401
  - 37.5.9.2 802.1q VLAN Packet Filtering ..... 1401
- 37.5.10 Wake on LAN ..... 1402
  - 37.5.10.1 Advanced Power Management Wakeup ..... 1402
  - 37.5.10.2 ACPI Power Management Wakeup ..... 1403
  - 37.5.10.3 Wake-up Packets: Pre-defined Filters ..... 1404
  - 37.5.10.4 Wake-up Packets: Flexible Filters ..... 1409
- 37.5.11 Serial EEPROM ..... 1412
  - 37.5.11.1 EEPROM Device ..... 1412
  - 37.5.11.2 Software Accesses ..... 1412
  - 37.5.11.3 Signature Field ..... 1413
  - 37.5.11.4 EEPROM Map ..... 1413
  - 37.5.11.5 Hardware Accessed Words ..... 1415
  - 37.5.11.6 Software Accessed Words ..... 1417
- 37.5.12 Error Handling ..... 1418
  - 37.5.12.1 CSR (Target) Accesses ..... 1418
  - 37.5.12.2 DMA Host (Master) Accesses ..... 1418
  - 37.5.12.3 Internal Memories ..... 1419
- 37.5.13 Reset Operation ..... 1420
  - 37.5.13.1 Soft Reset ..... 1422
  - 37.5.13.2 MAC Disable ..... 1422
- 37.5.14 Endianness ..... 1422
- 37.6 GbE Controller Register Summary ..... 1425
  - 37.6.1 Registers Overview ..... 1425
    - 37.6.1.1 Memory-Mapped Access to Internal Registers and Memories ..... 1436
    - 37.6.1.2 I/O-Mapped Access to Internal Registers and Memories ..... 1436
    - 37.6.1.3 Register Conventions ..... 1437
  - 37.6.2 General Registers: Detailed Descriptions ..... 1438
    - 37.6.2.1 CTRL – Device Control Register ..... 1438
    - 37.6.2.2 STATUS – Device Status Register ..... 1441
    - 37.6.2.3 CTRL\_EXT – Extended Device Control Register ..... 1442
    - 37.6.2.4 CTRL\_AUX – Auxiliary Device Control/Status Register ..... 1444
    - 37.6.2.5 EEPROM\_CTRL – EEPROM Control Register ..... 1446
    - 37.6.2.6 EEPROM\_RR – EEPROM Read Register ..... 1448
    - 37.6.2.7 FCAL – Flow Control Address Low Register ..... 1449
    - 37.6.2.8 FCAH – Flow Control Address High Register ..... 1450
    - 37.6.2.9 FCT – Flow Control Type Register ..... 1451
    - 37.6.2.10 VET – VLAN EtherType Register ..... 1452
    - 37.6.2.11 FCTTV – Flow Control Transmit Timer Value Register ..... 1452
    - 37.6.2.12 PBA – Packet Buffer Allocation Register ..... 1453
  - 37.6.3 Interrupt Registers: Detailed Descriptions ..... 1454
    - 37.6.3.1 ICRO – Interrupt 0 Cause Read Register ..... 1454
    - 37.6.3.2 ITR0 – Interrupt 0 Throttling Register ..... 1457
    - 37.6.3.3 ICSO – Interrupt 0 Cause Set Register ..... 1458

|           |   |      |
|-----------|---|------|
| 37.6.3.4  | IMSO – Interrupt 0 Mask Set/Read Register .....                   | 1459 |
| 37.6.3.5  | IMCO – Interrupt 0 Mask Clear Register .....                      | 1460 |
| 37.6.3.6  | ICR1 – Interrupt 1 Cause Read Register .....                      | 1462 |
| 37.6.3.7  | ICS1 – Interrupt 1 Cause Set Register .....                       | 1464 |
| 37.6.3.8  | IMS1 – Interrupt 1 Mask Set/Read Register .....                   | 1466 |
| 37.6.3.9  | IMC1 – Interrupt 1 Mask Clear Register .....                      | 1467 |
| 37.6.3.10 | ICR2 – Error Interrupt Cause Read Register .....                  | 1469 |
| 37.6.3.11 | ICS2 – Error Interrupt Cause Set Register .....                   | 1471 |
| 37.6.3.12 | IMS2 – Error Interrupt Mask Set/Read Register .....               | 1472 |
| 37.6.3.13 | IMC2 – Error Interrupt Mask Clear Register .....                  | 1473 |
| 37.6.4    | Receive Registers: Detailed Descriptions .....                    | 1474 |
| 37.6.4.1  | RCTL – Receive Control Register .....                             | 1474 |
| 37.6.4.2  | FCRTL: Flow Control Receive Threshold Low Register .....          | 1478 |
| 37.6.4.3  | FCRTH – Flow Control Receive Threshold High Register .....        | 1479 |
| 37.6.4.4  | RDBAL – Receive Descriptor Base Address Low Register .....        | 1480 |
| 37.6.4.5  | RDBAH – Receive Descriptor Base Address High Register .....       | 1480 |
| 37.6.4.6  | RDLEN – Receive Descriptor Length Register .....                  | 1481 |
| 37.6.4.7  | RDH – Receive Descriptor Head Register .....                      | 1481 |
| 37.6.4.8  | RDT – Receive Descriptor Tail Register .....                      | 1482 |
| 37.6.4.9  | RDTR – RX Interrupt Delay Timer (Packet Timer) Register .....     | 1482 |
| 37.6.4.10 | RXDCTL – Receive Descriptor Control Register .....                | 1483 |
| 37.6.4.11 | RADV – Receive Interrupt Absolute Delay Timer Register .....      | 1485 |
| 37.6.4.12 | RSRPD – Receive Small Packet Detect Interrupt Register .....      | 1486 |
| 37.6.4.13 | RXCSUM – Receive Checksum Control Register .....                  | 1487 |
| 37.6.4.14 | MTA[0-127] – 128 Multicast Table Array Registers .....            | 1488 |
| 37.6.4.15 | RAL[0-15] – Receive Address Low Register .....                    | 1488 |
| 37.6.4.16 | RAH[0-15] – Receive Address High Register .....                   | 1489 |
| 37.6.4.17 | VFTA[0-127] – 128 VLAN Filter Table Array Registers .....         | 1490 |
| 37.6.5    | Transmit Registers: Detailed Descriptions .....                   | 1491 |
| 37.6.5.1  | TCTL – Transmit Control Register .....                            | 1491 |
| 37.6.5.2  | TIPG – Transmit IPG Register .....                                | 1493 |
| 37.6.5.3  | AIT – Adaptive IFS Throttle Register .....                        | 1495 |
| 37.6.5.4  | TDBAL – Transmit Descriptor Base Address Low Register .....       | 1496 |
| 37.6.5.5  | TDBAH – Transmit Descriptor Base Address High Register .....      | 1496 |
| 37.6.5.6  | TDLEN – Transmit Descriptor Length Register .....                 | 1497 |
| 37.6.5.7  | TDH – Transmit Descriptor Head Register .....                     | 1497 |
| 37.6.5.8  | TDT – Transmit Descriptor Tail Register .....                     | 1498 |
| 37.6.5.9  | TIDV – Transmit Interrupt Delay Value Register .....              | 1499 |
| 37.6.5.10 | TXDCTL – Transmit Descriptor Control Register .....               | 1500 |
| 37.6.5.11 | TADV – Transmit Absolute Interrupt Delay Value Register .....     | 1502 |
| 37.6.5.12 | TSPMT – TCP Segmentation Pad and Minimum Threshold Register ..... | 1503 |
| 37.6.6    | Statistical Registers: Detailed Descriptions .....                | 1505 |
| 37.6.6.1  | CRCERRS – CRC Error Count Register .....                          | 1505 |
| 37.6.6.2  | ALGNERRC – Alignment Error Count Register .....                   | 1506 |
| 37.6.6.3  | RXERRC – Receive Error Count Register .....                       | 1506 |
| 37.6.6.4  | MPC – Missed Packet Count Register .....                          | 1507 |
| 37.6.6.5  | SCC – Single Collision Count Register .....                       | 1507 |
| 37.6.6.6  | ECOL – Excessive Collisions Count Register .....                  | 1508 |
| 37.6.6.7  | MCC – Multiple Collision Count Register .....                     | 1508 |

| 1-4  | Glossary Table .....   | 98  |
| 2-1  | EP80579 External Interface Summary .....   | 106 |
| 2-2  | IA-32 core / FSB Frequency Ratios (depends on SKU and configuration) .....       | 107 |
| 2-3  | Memory Controller Frequencies .....  | 107 |
| 2-4  | Summary of Communication.....  | 107 |
| 2-5  | DMA and Peer-to-Peer Data Transfer Options .....                                 | 109 |
| 3-1  | Main Memory DRAM Organization .....  | 112 |
| 3-2  | Basic CMI Platform Address Space Requirements for IMCH and IICH Devices.....     | 115 |
| 3-3  | Memory Regions .....   | 116 |
| 3-4  | Supported Operations by Memory Type .....  | 117 |
| 3-5  | Supported Operations by Memory Type .....  | 118 |
| 3-6  | Device Exposure from an IA-attached Memory Map Perspective.....                  | 119 |
| 3-7  | Address Space Sizes of AIOC-attached Devices .....                               | 119 |
| 3-8  | Expansion Bus Byte Ordering for Inbound Transactions using LEBCTL register ..... | 119 |
| 3-9  | IMCH and IICH PCI Device Summary .....   | 122 |
| 3-10 | AIOC PCI Device Summary .....  | 123 |
| 3-11 | PCI Configuration Header Support for Type 0 Headers in AIOC Devices .....        | 125 |
| 3-12 | PCI Configuration Header Support for Type 1 Headers in AIOC Devices .....        | 127 |
| 4-1  | Supported Inter-Agent Signaling .....  | 134 |
| 5-1  | Summary of IMCH Global Error Conditions.....                                     | 142 |
| 5-2  | Summary of IMCH Buffer Unit Error Conditions.....                                | 143 |
| 5-3  | Summary of IMCH Buffer Unit Error Reporting Capabilities .....                   | 143 |
| 5-4  | Summary of IMCH FSB Error Conditions .....                                       | 144 |
| 5-5  | Summary of IMCH FSB Error Reporting Capabilities .....                           | 144 |
| 5-6  | Summary of IMCH NSI Error Conditions .....                                       | 145 |
| 5-7  | Summary of IMCH NSI Error Reporting Capabilities.....                            | 146 |
| 5-8  | Summary of IMCH EDMA Error Conditions .....                                      | 146 |

- 5-9 Summary of IMCH EDMA Error Reporting Capabilities ..... 147
- 5-10 Summary of IMCH PCI-Express Error Conditions ..... 148
- 5-11 Summary of IMCH PCI-Express Error Reporting Capabilities..... 149
- 5-12 Summary of SMBus Interface Error Conditions..... 150
- 5-13 Summary of SMBus Controller Error Reporting Capabilities ..... 150
- 5-14 Summary of LPC Interface Error Conditions ..... 150
- 5-15 Summary of LPC Interface Error Reporting Capabilities ..... 150
- 5-16 Summary of USB 1.1 Interface Error Conditions..... 151
- 5-17 Summary of USB 1.1 Interface Error Reporting Capabilities ..... 151
- 5-18 Summary of USB 2.0 Interface Error Conditions..... 152
- 5-19 Summary of USB 2.0 Interface Error Reporting Capabilities ..... 152
- 5-20 Summary of SATA Interface Error Conditions..... 152
- 5-21 Summary of SATA Interface Error Reporting Capabilities ..... 153
- 5-22 Summary of Serial I/O Interface Error Conditions..... 153
- 5-23 Summary of Serial I/O Interface Error Reporting Capabilities..... 153
- 5-24 Summary of Memory Controller Error Conditions ..... 154
- 5-25 Summary of Memory Controller Error Reporting Capabilities ..... 155
- 5-26 Summary of Gigabit Ethernet MAC Error Conditions..... 156
- 5-27 Summary of Gigabit Ethernet MAC Error Reporting Capabilities ..... 156
- 5-28 Summary of CAN Error Conditions..... 157
- 5-29 Summary of CAN Error Reporting Capabilities..... 157
- 5-30 Summary of SSP Error Conditions ..... 158
- 5-31 Summary of SSP Error Reporting Capabilities ..... 158
- 5-32 Summary of Local Expansion Bus Error Conditions ..... 158
- 5-33 Summary of Local Expansion Bus Error Reporting Capabilities..... 159
- 6-1 Types of Reset and Wake-up from Power Saving States ..... 161
- 6-2 Power Wells and External Voltages ..... 162
- 6-3 EP80579 Power Supply Pins ..... 168
- 6-4 Power Rail Sequence Signal Timings..... 171
- 6-5 Powergood Reset Timings ..... 173
- 6-6 Hard Reset Timings..... 174
- 6-7 Global Power States ..... 178
- 6-8 Device States..... 178
- 6-9 Sleeping States ..... 179
- 6-10 CPU States ..... 179
- 6-11 ACPI States ..... 180
- 6-12 Power Wells Status for Supported ACPI States\* ..... 180
- 7-1 Definition of the Views Used in Register Description Tables..... 184
- 7-2 View Convention to Describe Single Versus Multiple Physical Registers ..... 185
- 7-3 Offset Convention to Describe Multiple Physical Registers in the Same Device ..... 186
- 7-4 EG\_SINGLE: Example Single Register with Different Views ..... 187
- 7-5 EG\_MULTI\_DIFF: Example Multiple Registers in Different Devices with Different Views..... 187
- 7-6 EG\_MULTI\_SAME[1-2]: Example Multiple Registers in Same Device with Different Views..... 188
- 7-7 EG\_INDEX: Example Single Indexed Register ..... 188
- 7-8 Register Field Access Attributes ..... 189
- 7-9 Bus 0, Device 0, Function 0: Summary of IMCH PCI Configuration Registers ..... 191
- 7-10 Bus 0, Device 0, Function 0: Summary of IMCH Configuration Registers Mapped Through NSIBAR Memory BAR ..... 192
- 7-11 Bus 0, Device 0, Function 0: Summary of IMCH SMRBASE Registers..... 193
- 7-12 Bus 0, Device 0, Function 1: Summary of IMCH Error Reporting PCI Configuration Registers ..... 195
- 7-13 Bus 0, Device 1, Function 0: Summary of EDMA PCI Configuration Registers ..... 197

|      |   |     |
|------|---|-----|
| 7-14 | Bus 0, Device 1, Function 0: Summary of EDMA Configuration Registers Mapped Through EDMALBAR Memory BAR .....                               | 197 |
| 7-15 | Bus 0, Device 2, Function 0: Summary of PCI Express Port A Standard and Enhanced PCI Configuration Registers .....                          | 200 |
| 7-16 | Bus 0, Device 3, Function 0: Summary of PCI Express Port A1 Standard and Enhanced PCI Configuration Registers .....                         | 203 |
| 7-17 | Bus 0, Device 29, Functions 0, Summary of USB (1.1) Controller PCI Configuration Registers .....  | 206 |
| 7-18 | Summary of USB (1.1) Controller Configuration Registers Mapped Through USBIOBAR I/O BAR .....   | 206 |
| 7-19 | Bus 0, Device 29, Function 7: Summary of USB (2.0) Controller PCI Configuration Registers .....   | 207 |
| 7-20 | Bus 0, Device 29, Function 7: Summary of USB (2.0) Controller Configuration Registers Mapped Through MBAR Memory BAR .....                  | 208 |
| 7-21 | Bus 0, Device 31, Function 0: Summary of Root Complex Configuration Registers Mapped Through RCBA Memory BAR.....                           | 209 |
| 7-22 | Bus 0, Device 31, Function 0: Summary of LPC Interface PCI Configuration Registers  | 210 |
| 7-23 | Bus 0, Device 31, Function 0: Summary of LPC Interface Power Management PCI Configuration Registers .....                                   | 211 |
| 7-24 | Bus 0, Device 31, Function 0: Summary of TCO Configuration Registers Mapped Through TCOBASE I/O BAR“ .....                                  | 211 |
| 7-25 | Bus 0, Device 31, Function 0: Summary of LPC Interface Power Management General Configuration Registers Mapped Through PMBASE I/O BAR ..... | 211 |
| 7-26 | Bus 0, Device 31, Function 0: Summary of General Purpose I/O Configuration Registers Mapped Through GBA BAR IO BAR.....                     | 212 |
| 7-27 | Bus 0, Device 31, Function 2: Summary of SATA Controller PCI Configuration Registers .....  | 213 |
| 7-28 | Bus 0, Device 31, Function 2: Summary of SATA Controller Configuration Registers Mapped Through LBAR I/O BAR.....                           | 214 |
| 7-29 | Bus 0, Device 31, Function 2: Summary of SATA Controller Configuration Registers Mapped Through ABAR Memory BAR.....                        | 214 |
| 7-30 | Bus 0, Device 31, Function 3: Summary of SMBus Controller PCI Configuration Registers .....   | 216 |
| 7-31 | Bus 0, Device 31, Function 3: Summary of SMBus Controller Configuration Registers Mapped Through SM_BASE I/O BAR.....                       | 216 |
| 7-32 | Summary of IA-32 Core Interface Registers Mapped in I/O Space .....   | 217 |
| 7-33 | Summary of IMCH PCI Configuration Registers Mapped in I/O Space .....   | 217 |
| 7-34 | Summary of APIC Registers Mapped in Memory Space“ .....   | 217 |
| 7-35 | Summary of APIC Indexed Registers.....  | 218 |
| 7-36 | Summary of 8259 Interrupt Controller (PIC) Registers Mapped in I/O Space .....  | 219 |
| 7-37 | Summary of APM Registers Mapped in I/O Space.....   | 219 |
| 7-38 | Summary of LPC DMA Registers Mapped in I/O Space .....  | 220 |
| 7-39 | 0000h (IO) Base Address Registers in the IA F1 View.....  | 220 |
| 7-40 | 0000h (IO) Base Address Registers in the IA F2 View.....  | 221 |
| 7-41 | Summary of 8254 Timer Registers Mapped in I/O Space.....  | 221 |
| 7-42 | Summary of HPET Registers Mapped in Memory Space .....  | 222 |
| 7-43 | Summary of UART Timer registers in I/O space .....  | 222 |
| 7-44 | Summary of Watchdog Timer Registers in I/O Space.....   | 223 |
| 7-45 | Summary of Real Time Clock Indexed Registers .....  | 223 |
| 7-46 | Bus 0, Device 4, Function 0: Summary of PCI-to-PCI Bridge PCI Configuration Registers .....   | 224 |
| 7-47 | Bus M, Device 0, Function 0: Summary of Gigabit Ethernet MAC Interface PCI Configuration Registers .....                                    | 226 |
| 7-48 | Bus M, Device 1, Function 0: Summary of Gigabit Ethernet MAC Interface PCI Configuration Registers .....                                    | 227 |

- 7-49 Bus M, Device2, Function 0: Summary of Gigabit Ethernet MAC Interface PCI Configuration Registers ..... 228
- 7-50 Bus M, Device 0, Function 0: Gigabit Ethernet MAC I/O Spaces Registers ..... 229
- 7-51 Bus M, Device 1, Function 0: Gigabit Ethernet MAC I/O Spaces Registers ..... 229
- 7-52 Bus M, Device 2, Function 0: Gigabit Ethernet MAC I/O Spaces Registers ..... 229
- 7-53 Bus M, Device 0, Function 0: Summary of Gigabit Ethernet Interface Registers Mapped Through CSRBAR Memory BAR ..... 229
- 7-54 Bus M, Device 1, Function 0: Summary of Gigabit Ethernet Interface Registers Mapped Through CSRBAR Memory BAR ..... 233
- 7-55 Bus M, Devices 2, Function 0: Summary of Gigabit Ethernet Interface Registers Mapped Through CSRBAR Memory BAR ..... 236
- 7-56 Bus M, Device 3, Function 0: Summary of GCU PCI Configuration Registers ..... 240
- 7-57 Bus M, Device 3, Function 0: Summary of GCU Registers Mapped Through CSRBAR Memory BAR ..... 240
- 7-58 Bus M, Device 4, Function 0: Summary of CAN Interface PCI Configuration Registers ..... 242
- 7-59 Bus M, Devices 5, Function 0: Summary of CAN Interface PCI Configuration Registers ..... 243
- 7-60 Bus M, Device 4, Function 0: Summary of CAN Registers Mapped Through CSRBAR Memory BAR ..... 244
- 7-61 Bus M, Device 5, Function 0: Summary of CAN Registers Mapped Through CSRBAR Memory BAR ..... 244
- 7-62 Bus M, Device 6, Function 0: Summary of SSP Controller PCI Configuration Registers ..... 245
- 7-63 Bus M, Device 6, Function 0: Summary of SSP CSRs ..... 246
- 7-64 Bus M, Device 7, Function 0: Summary of IEEE 1588 Timestamp Unit PCI Configuration Registers ..... 247
- 7-65 Bus M, Device 7, Function 0: Summary of IEEE 1588 TSYNC CSRs ..... 248
- 7-66 Bus M, Device 8, Function 0: Summary of Local Expansion Bus PCI Configuration Registers ..... 249
- 7-67 Bus M, Device 8, Function 0: Summary of Local Expansion Bus Registers Mapped Through CSRBAR PCI Memory BAR" ..... 250
- 8-1 Processor Version Identification Signature (CPUID) ..... 254
- 9-1 Supported PCI Express Configurations ..... 257
- 10-1 Regions of Memory Ranges ..... 267
- 10-2 System Memory Space ..... 268
- 10-3 IMCH VGA and MDA Memory Spaces ..... 268
- 10-4 IMCH PAM Memory Address Ranges ..... 270
- 10-5 PAM Associated Attribute Bits ..... 273
- 10-6 TSEG SMM Memory Space ..... 274
- 10-7 PCI Express Enhanced Configuration Aperture ..... 274
- 10-8 IOAPIC Memory Space ..... 275
- 10-9 FSB Interrupt Memory Space ..... 275
- 10-10 High SMM Memory Space ..... 276
- 10-11 Device 2 Memory and Prefetchable Memory ..... 277
- 10-12 Device 3 Memory and Prefetchable Memory ..... 277
- 10-13 Device 4 Memory and Prefetchable Memory ..... 277
- 10-14 EDMA Accesses to Fixed Address Spaces ..... 278
- 10-15 EDMA Accesses to Relocatable Address Spaces ..... 279
- 10-16 Supported SMM Ranges ..... 282
- 10-17 Fixed I/O Ranges Decoded by IICH ..... 284
- 10-18 Variable I/O Decode Ranges ..... 286
- 10-19 IICH Memory Decode Ranges (from IA-32 core Perspective) ..... 287
- 11-1 Supported DDR2 Device Densities and Width ..... 291
- 11-2 Supported DRAM Capacity for 64b Mode ..... 291
- 11-3 Supported DRAM Capacity for 32b Mode ..... 292
- 11-4 Raw Cards Supported by the EP80579 ..... 292
- 11-5 Supported DDR2 Data Speeds ..... 292

|       |  |     |
|-------|--|-----|
| 11-6  | Supported DIMM Populations .....   | 293 |
| 11-7  | Supported Rank Configurations in Single and Dual DIMM mode .....               | 293 |
| 11-8  | 256Mb Addressing .....   | 294 |
| 11-9  | 512Mb Addressing .....   | 294 |
| 11-10 | 1Gb Addressing .....   | 294 |
| 11-11 | 2Gb Addressing .....   | 295 |
| 11-12 | Supported DRAM Timings .....   | 296 |
| 11-13 | DRA Mapping for DQS .....  | 298 |
| 11-14 | DQS to DQ Mapping for x8 Devices .....   | 298 |
| 11-15 | ODT Timing Parameters .....  | 299 |
| 11-16 | Supported DDR2 MR and EMR settings .....                                       | 303 |
| 11-17 | Poisoning Granularity .....  | 305 |
| 12-1  | Channel 0 Memory-mapped Register Set .....                                     | 332 |
| 12-2  | Interrupt Summary .....  | 338 |
| 13-1  | PCI Devices and Functions on Bus 0 .....                                       | 346 |
| 13-2  | Summary of IMCH PCI Configuration Registers Mapped in I/O Space .....          | 354 |
| 13-3  | Offset 0CF8h: CONFIG_ADDRESS: Configuration Address Register .....             | 354 |
| 13-4  | Offset 0CFCh: CONFIG_DATA: Configuration Data Register .....                   | 355 |
| 13-5  | Enhanced Configuration FSB Address Format .....                                | 357 |
| 14-1  | Pseudocode for EDMA Errors .....   | 369 |
| 15-1  | SMBus Register Summary .....   | 372 |
| 15-2  | SMBus Memory-Mapped Register Summary .....                                     | 372 |
| 15-3  | ADDR3 Memory Assignments .....   | 372 |
| 15-4  | Command (CMD) Register .....   | 373 |
| 15-5  | Byte Count Register .....  | 374 |
| 15-6  | Address Byte 3 Register .....  | 374 |
| 15-7  | ADDR2 – Address Byte 2 Register .....  | 375 |
| 15-8  | ADDR1 – Address Byte 1 Register .....  | 375 |
| 15-9  | ADDR0 – Address Byte 0 Register .....  | 375 |
| 15-10 | Offset 04-07: DATA - Data Register .....                                       | 376 |
| 15-11 | Status Register .....  | 376 |
| 15-12 | Relationship Between Link and Device PM States .....                           | 383 |
| 16-1  | Bus 0, Device 0, Function 0: Summary of IMCH PCI Configuration Registers ..... | 389 |
| 16-2  | Offset 00h: VID – Vendor Identification Register .....                         | 391 |
| 16-3  | Offset 02h: DID – Device Identification Register .....                         | 391 |
| 16-4  | Offset 04h: PCICMD: PCI Command Register .....                                 | 392 |
| 16-5  | Offset 06h: PCISTS: PCI Status Register .....                                  | 393 |
| 16-6  | Offset 8h: RID - Revision Identification Register .....                        | 394 |
| 16-7  | Offset 0Ah: SUBC - Sub-Class Code Register .....                               | 394 |
| 16-8  | Offset 0Bh: BCC – Base Class Code Register .....                               | 394 |
| 16-9  | Offset 0Eh: HDR - Header Type Register .....                                   | 395 |
| 16-10 | Offset 14h: SMRBASE - System Memory RCOMP Base Address Register .....          | 396 |
| 16-11 | Offset 2Ch: SVID - Subsystem Vendor Identification Register .....              | 396 |
| 16-12 | Offset 2Eh: SID - Subsystem Identification Register .....                      | 397 |
| 16-13 | Offset 34h: CAPPTR - Capabilities Pointer Register .....                       | 397 |
| 16-14 | Offset 4Ch: NSIBAR - Root Complex Block Address Register .....                 | 397 |
| 16-15 | Offset 50h: CFG0- IMCH Configuration 0 Register .....                          | 398 |
| 16-16 | Offset 51h: IMCH_CFG1 – IMCH Configuration 1 Register .....                    | 399 |
| 16-17 | Offset 53h: CFGNS1 - Configuration 1 (Non-Sticky) Register .....               | 399 |

37-121 TPT: Total Packets Transmitted Register ..... 1529

37-122 PTC64 - Packets Transmitted Count (64 Bytes) Register ..... 1529

37-123 PTC255: Packets Transmitted Count (128-255 Bytes) Register ..... 1530

37-124 PTC511: Packets Transmitted Count (256-511 Bytes) Register ..... 1530

37-125 PTC1023: Packets Transmitted Count (512-1023 Bytes) Register ..... 1531

37-126 PTC1522: Packets Transmitted Count (1024-1522 Bytes) Register ..... 1531

37-127 MPTC: Multicast Packets Transmitted Count Register ..... 1532

37-128 BPTC: Broadcast Packets Transmitted Count Register ..... 1532

37-129 TSCTC: TCP Segmentation Context Transmitted Count Register ..... 1533

37-130 TSCTFC: TCP Segmentation Context Transmit Fail Count Register ..... 1533

37-131 WUC - Wake Up Control Register (0x05800; RW) ..... 1534

37-132 WUFC - Wake Up Filter Control Register (0x05808; RW) ..... 1535

37-133 WUS - Wake Up Status Register (0x05810; RW) ..... 1536

37-134 IPAV - IP Address Valid Register (0x05838; RW) ..... 1537

37-135 IP4AT (0x5840 - 0x5858; RW)[0-3]: IPv4 Address Table Registers ..... 1538

37-136 IPV6\_ADDR0BYTES\_1\_4 – IPv6 Address Table Register (0x5880), Bytes 1 - 4 ..... 1539

37-137 IPV6\_ADDR0BYTES\_5\_8 – IPv6 Address Table Register, Bytes 5 - 8 ..... 1539

37-138 IPV6\_ADDR0BYTES\_9\_12 – IPv6 Address Table Register, Bytes 9 - 12 ..... 1540

37-139 IPV6\_ADDR0BYTES\_13\_16 – IPv6 Address Table Register, Bytes 13 - 16 ..... 1541

37-140 FFLT[0-3] - Flexible Filter Length Table Registers (0x5F00 - 0x5F18; RW) ..... 1542

37-141 Flexible Filter Mask Table ..... 1542

37-142 FFMT[0-127] - Flexible Filter Mask Table Registers (0x9000 - 0x93F8; RW) ..... 1543

37-143 Flexible Filter Mask Table ..... 1543

37-144 FFVT[0-127]: Flexible Filter Value Table Registers ..... 1544

37-145 INTBUS\_ERR\_STAT - Internal Bus Error Status Register ..... 1544

37-146 MEM\_TST - Memory Error Test Register ..... 1546

37-147 MEM\_STS - Memory Error Status Register ..... 1547

37-148 MAC Timing ..... 1556

37-149 GbE Timing Guarantees ..... 1557

38-1 Bus M, Device 3, Function 0: Summary of GCU Registers Mapped Through CSRBAR Memory BAR ..... 1561

38-2 Register-Table Legend ..... 1561

38-3 Offset 0x00000010h: MDIO\_STATUS - MDIO Status Register ..... 1562

38-4 Offset 0x00000014h: MDIO\_COMMAND - MDIO Command Register ..... 1562

38-5 Offset 0x00000018h: MDIO\_DRIVE - MDIO Drive Register ..... 1563

38-6 Offset 0x00000020h: MDC\_DRIVE - MDC Drive Register ..... 1563

38-7 Offset 0x00000024h: GCU\_GBE\_RC\_CTRL - GCU GbE RCOMP Control Register ..... 1564

38-8 Offset 0x00000044h: GCU\_GBE\_RC\_STAT - GCU GbE RCOMP Status Register ..... 1564

38-9 Offset 0x00000050h: GCU\_LEB\_RC\_STAT - GCU Local Expansion Bus RCOMP Status Register ..... 1565

38-10 Offset 0x00000054h: GCU\_LEB\_RC\_CTRL - GCU Local Expansion Bus RCOMP Control Register ..... 1566

38-11 Offset 0x00000060h: SSP\_DRIVE - SSP Drive Register ..... 1566

38-12 Offset 0x00000064h: TDM\_DRIVE\_3 - TDM Drive Register for TDM ports 3 ..... 1567

38-13 Offset 0x00000068h: TDM\_DRIVE\_12 - TDM Drive Register for TDM ports 1 & 2 ..... 1567

38-14 Offset 0x00000028h: CAN\_DRIVE - CAN Drive Register ..... 1568

39-1 CiA Recommended bit rate and timing Parameters ..... 1578

39-2 CAN Recommended Bit Rate and Timing Parameters ..... 1580

39-3 CAN Higher Level Protocol (HLP) Bit Assignment ..... 1583

39-4 Bus M, Device 4, Function 0: Summary of CAN Registers Mapped Through CSRBAR Memory BAR ..... 1585

39-5 Bus M, Device 5, Function 0: Summary of CAN Registers Mapped Through CSRBAR Memory BAR ..... 1586

39-6 Offset 00000000h: Int\_Status - Interrupt Status Register ..... 1587

39-7 Offset 00000004h: Int\_Ebl - Interrupt Enable Register ..... 1588

# Introduction and Overview, Volume 1 of 6

---

## 1.0 Introduction

---

### 1.1 Introduction

The Intel® EP80579 Integrated Processor product line is made up of the Intel® EP80579 Integrated Processor and the Intel® EP80579 Integrated Processor with Intel® QuickAssist Technology. The Intel® EP80579 Integrated Processor product line is an integrated System On a Chip (SoC). The Intel® EP80579 Integrated Processor with Intel® QuickAssist Technology architecture combines Intel Architecture (IA)-based communications processors, a memory hub controller (IMCH), an I/O architecture (IICH), and high speed I/O interfaces (PCI Express\*, Gigabit Ethernet). The Intel® EP80579 Integrated Processor with Intel® QuickAssist Technology also features high-performance packet processing and security capabilities. The Intel® EP80579 Integrated Processor product line architecture is designed to provide best-in-class processing performance, stringent power usage, and reasonable cost targets while maintaining IA implementation and providing the required I/O throughput.

The intended audience for this document is architects, hardware/software design engineers or designer who may need specific technical information for the development and programming of the EP80579 integrated processor SoC. This document is also intended for an audience that has a thorough understanding of IA-32 microprocessor, memory controller and I/O architectures as well as a basic understanding of system software architectures (operating system and pre-boot firmware).

### 1.2 Document Organization

*Note:* The Intel® EP80579 Integrated Processor product line is referred to as the "EP80579". In cases where the features are specific to a given processor we will use Intel® EP80579 Integrated Processor or Intel® EP80579 Integrated Processor with Intel® QuickAssist Technology.

This document first provides an overview of the Intel® EP80579 Integrated Processor product line architecture. The overview chapter provides a block diagram and defines the 's external and internal interfaces. This is followed by a functional description of the following blocks:

- IA Complex (including the IA-32 core, IMCH and IICH).
- Acceleration and I/O Complex (including ASU, SSU, and high-speed I/O interfaces such as Gigabit Ethernet and TDM).
- Test and Debug information, including JTAG.
- Technical Specifications (SKUs, Packaging, Electrical and Thermal).

### 1.3 Referenced Documents and Related Websites

Visit the Intel® EP80579 Integrated Processor product line Website for other information:

## 1.4 Acronyms

This section describes acronyms that are used throughout this document.

Table 1-3. Acronym Table

| Term    | Description   |
|---------|---|
| ACPI    | Advanced Configuration and Power Interface Specification, an industry specification of the common interfaces enabling robust operating system (OS)-directed motherboard device configuration and power management of both devices and entire systems. |
| AHCI    | Advanced Host Controller Interface, an industry specification of the interface between memory and SATA devices.   |
| AIO     | IMCH A-unit I/O Mux Leg   |
| AIOC    | Acceleration and I/O Complex  |
| AMC     | Audio/Modem Codec   |
| ARP     | Address resolution protocol   |
| ASF     | Alert Specification Format. This is the next generation of "Alert on LAN*" implementation.  |
| ASU     | Acceleration Services Unit  |
| BAR     | PCI Base Address Register used to define the base and limit of an I/O or memory region assigned to a PCI device.  |
| BER     | Bit Error Rate  |
| BGA     | Ball Grid Array   |
| CM      | Coherent Memory   |
| CMC     | Common Mode Choke   |
| CMI     | Core (IA-32 core) interface, Memory controller hub, I/O controller hub  |
| CNR     | Communications and Networking Riser   |
| CRC     | See Cyclic Redundancy Check in Table 1-4.   |
| CSMA/CD | Carrier Sense Multiple Access/Carrier Detect  |
| DDP     | Direct Data Placement Protocol  |
| DDR     | DDR SDRAM (Double Data Rate Synchronous Dynamic Random Access Memory) is a system memory technology.  |

Table 1-3. Acronym Table

| Term    | Description   |
|---------|---|
| DED     | Double-bit Error Detect   |
| DMA     | See Direct Memory Access in <a href="#">Table 1-4</a> .   |
| DW      | Double Word. A legacy reference to 32 bits of data on a naturally aligned four-byte boundary (i.e. the least significant two bits of the byte address are b00). This is a legacy term used by PCI and must not be used other than in that context.  |
| ECC     | Error Checking and Correction   |
| EDMA    | Enhanced DMA  |
| EMI     | Electro Magnetic Interference   |
| EMTS    | Electrical Mechanical Thermal Specification used for processor specifications.  |
| EOP/EOF | End Of Packet / End Of Frame  |
| ESD     | Electrostatic Discharge   |
| EXP     | A generic designation for the I/O interconnect technology also known as PCI Express*.   |
| FRU     | Field Replaceable Unit  |
| FS      | Full-speed. Refers to USB.  |
| FSB     | Front Side Bus (a common external interface for IA processors)  |
| FWH     | Firmware Hub. A non-volatile memory device used to store the system BIOS/pre-boot firmware.   |
| GbE     | Gigabit Ethernet controller   |
| GMII    | Gigabit MII   |
| HBA     | Host Bus Adapter - necessary when connecting a peripheral to a computer that doesn't have native support for that peripheral's interface.   |
| HCD     | Host Controller Device - USB interface for programmers  |
| HECBASE | PCI Express* Enhanced Configuration Base Register   |
| HPET    | High Precision Event Time (HPET) - The IA-PC HPET Architecture defines a set of timers that can be used by the operating system. The timers are defined such that the OS may be able to assign specific timers to be used directly by specific applications. Each timer can be configured to generate a separate interrupt. |
| HSI     | High Speed Interface. Refers to USB.  |
| I/O     | 1. Input/Output. 2. When used as a qualifier to a transaction type, specifies that transaction targets Intel Architecture™ specific I/O space (e.g., I/O read).   |
| IA      | Intel Architecture instruction set commonly known as "x86"  |
| IA-CPU  | IA-CPU, IA Complex and IA Processor are the same terminology  |
| ICH     | I/O Controller Hub, ICH and IICH are interchangeable for entire document  |
| IICH    | Integrated I/O Controller Hub, ICH and IICH are interchangeable for entire document   |
| IMCH    | Integrated Memory Controller Hub, MCH and IMCH are interchangeable for the entire document  |
| INTx    | Legacy PCI interrupt architecture that encodes interrupts on one of four side-band signals (INTA, INTB, INTC, and INTD).  |
| IP      | Internet Protocol   |
| ISA     | See Industry Standard Architecture in <a href="#">Table 1-4</a>   |
| LEB     | Local Expansion Bus, or LE Bus  |
| LML     | Latency Measurement Logic   |
| LPC     | Low Pin Count   |
| LS      | Low-speed. Refers to USB.   |
| LSb     | Least Significant Bit   |

Table 1-3. Acronym Table

| Term      | Description   |
|-----------|---|
| LSB       | Least Significant Byte  |
| MCH       | Memory Controller Hub, MCH and IMCH are interchangeable for the entire document   |
| MII       | Media Independent Interface (16 pins per port)  |
| MMIO      | Memory Mapped I/O   |
| MMR       | Memory Mapped Register  |
| MSb       | Most Significant Bit  |
| MSB       | Most Significant Byte   |
| MSI       | Message-signaled interrupt that encodes interrupts as an in-band 32-bit write transaction.  |
| MTBF      | Mean Time Between Failures  |
| NCM       | Non Coherent Memory   |
| NIC       | Network interface controller  |
| NOS       | Network Operating System  |
| NSI       | North South Interface. The designation for the proprietary, internal high-speed serial interconnect between the IMCH and the IICH.  |
| OS        | Operating System.   |
| OSPM      | Operating System directed Power Management  |
| P2P       | See Peer-to-Peer in <a href="#">Table 1-4</a>   |
| PB        | Packet Buffer   |
| PBM       | Packet Buffer Memory  |
| PCI       | Peripheral Component Interconnect Local Bus. A 32- or 64-bit bus with multiplexed address and data lines that is primarily intended for use as an interconnect mechanism within a system between processor/memory and peripheral components or add-in cards.      |
| PCM       | Pulse Code Modulation   |
| PEC       | Packet Error Checking. This is an SMBUS 2.0 feature.  |
| PHY       | Physical Layer Device   |
| POC       | Power-on-configuration  |
| RASUM     | Reliability, Availability, Serviceability, Usability, and Manageability, which are all important characteristics of servers.  |
| RCBA      | Root Complex Base Address register at D31:F0:RegF0h. It specifies the physical address of the CMI Configuration Space. Also used in RCBA + offset xxxhx or RCBA + xxxhx (where xxxhx is the offset) to indicate register location in the CMI Configuration Space. |
| RCRB      | Root Complex Register Block, as defined in the <i>PCI Express* Specification v1.0a</i> . In the IICH context, it refers to a part of the CMI Configuration Space (see RCBA, above).   |
| RDMA      | Remote Direct Memory Access   |
| RFL       | Receive FIFO Level  |
| RGMII     | Reduced GMII  |
| RMII      | Reduced MII (7 pins per port)   |
| RMW       | Read-Modify-Write operation   |
| RTC       | Real-Time Clock   |
| RTCRESET# | Signal that resets the RTC well (but does not clear the RTC RAM memory contents).   |
| RX        | Receive   |
| SATA      | Serial Advanced Technology Attachment   |
| SATA*     | Serial ATA, an industry specification of the interface for storage controllers and devices.   |

**Table 1-3. Acronym Table**

| Term    | Description  |
|---------|--|
| SEC     | Single-bit Error Correct   |
| SEC/DED | Single Error Correct/Double Error Detect - A specific data protection algorithm that distributes data and ECC across 144 bits. Enables correction of single bit errors. Allows detection of double bit errors. |
| SOP/SOF | Start Of Packet / Start Of Frame   |
| SMM     | System Management Mode   |
| SPD     | Serial Presence Detect   |
| SSU     | Security Services Unit   |
| STR     | Suspend To Ram   |
| TAP     | Test Access Port used for testability and debug of the component.  |
| TX      | Transmit   |
| TCO     | Total Cost of Ownership  |
| TCP     | Transmission Control Protocol  |
| TDM     | Time Division Multiplexed  |
| TDR     | Time Domain Reflectometry  |
| TFL     | Transit FIFO Level   |
| TID     | See Transaction Identifier in <a href="#">Table 1-4</a>  |
| USB     | Universal Serial Bus   |
| VCMI    | IA-32 core, IA-32 Core interface, Memory controller hub, I/O controller hub  |
| VLAN    | Virtual Local Area Network   |
| WDT     | Watch Dog Timer  |

## 1.5 Glossary

This section presents a glossary for this document.

**Table 1-4. Glossary Table (Sheet 1 of 5)**

| Term             | Definition  |
|------------------|---|
| µBGA             | Micro Ball Grid Array   |
| AIOC Direct (AD) | AIOC Direct (AD) memory regions are not coherent with IA caches when accessed from AIOC agents. Accesses to these memory regions enter the memory system through the Memory Controller avoiding the IMCH. Memory regions that are not coherent with IA caches need not be accessible to the IA CPU. |
| Agent            | A logical device connected to a bus or shared interconnect that can either initiate accesses or be the target of accesses.  |
| ALT Access Mode  | Mode to allow the reading of write-only registers, usually used when saving/restoring register content for power management sleep state implementations.  |
| Anti-Etch        | Any plane-split, void or cutout in a V <sub>CC</sub> or GND plane is referred to as an anti-etch.   |
| Asserted         | Signal is set to a level that represents logical true.  |
| Asynchronous     | 1. An event that causes a change in state with no relationship to a clock signal. 2. When applied to transactions or a stream of transactions, a classification for those that do not require service within a fixed time interval.   |

Table 1-4. Glossary Table (Sheet 2 of 5)

| Term                    | Definition  |
|-------------------------|---|
| Atomic operation        | A series of two or more transactions to a device by the same initiator which are guaranteed to complete without intervening accesses by a different master. Most commonly required for a read-modify-write (RMW) operation.   |
| Block Locking           | Ability to lock the FWH's blocks to write-protect, read-protect, or open state.   |
| Buffer                  | 1. A random access memory structure. 2. The term I/O buffer is also used to describe a low-level input receiver and output driver combination.  |
| Cx States               | Processor power states (Cx states) are processor power consumption and thermal management states within the global working state, G0. <ul style="list-style-type: none"> <li>• C0: Processor power state - While the processor is in this state, it executes instructions.</li> <li>• C1: Processor power state - This power state has the lowest latency. The hardware latency in this state must be low enough that the operating software does not consider the latency aspect of the state when deciding whether to use it.</li> <li>• C2: Processor power state - This state offers improved power savings over the C1 state. The worst-case hardware latency for this state is provided via the ACPI system firmware and operating software can use this information to determine when the C1 state should be used instead of the C2 state.</li> <li>• C3: Processor power state - This state is not supported. The C3 state offers improved power savings over the C1 and C2 states. The worst-case hardware latency for this state is provided via the ACPI system firmware and the operating software can use this information to determine when the C2 state should be used instead of C3 state. While in the C3 state, the processor's caches maintain state but ignore any snoops.</li> </ul> |
| Cache Line              | The unit of memory that is copied to and individually tracked in a cache. Specifically, 64 bytes of data or instructions aligned on a 64-byte physical address boundary.  |
| Cfg                     | Used as a qualifier for transactions that target PCI configuration address space.   |
| Character               | The raw data Byte in an encoded system (i.e., the 8b value in a 8b/10b encoding scheme). This is the meaningful quantum of information to be transmitted or that is received across an encoded transmission path.   |
| CMI                     | IA-32 Core interface, Memory controller hub, I/O controller hub   |
| Coherent (C)            | Transactions that ensure that the processor's view of memory through the cache is consistent with that obtained through the I/O subsystem. In EP80579 integrated processor, Coherent (C) memory regions are coherent with IA caches when accessed from AIOC agents. Accesses to these memory regions enter the memory system through the IMCH. Memory regions that are coherent with IA caches must be accessible to the IA CPU.  |
| Command                 | The distinct phases, cycles, or packets that make up a transaction. Requests and Completions are referred to generically as Commands.   |
| Completion              | A packet, phase, or cycle used to terminate a Transaction on a interface, or within a component. A Completion will always refer to a preceding Request and may or may not include data and/or other information.  |
| Core Power Well         | Main system power, turns off in S3 – S5   |
| Cyclic Redundancy Check | A number derived from, and stored or transmitted with, a block of data in order to detect corruption. By recalculating the CRC and comparing it to the value originally transmitted, the receiver can detect some types of transmission errors.   |
| Deasserted              | Signal is set to a level that represents logical false.   |
| Deferred Transaction    | A processor bus Split Transaction. The requesting agent receives a Deferred Response which allows other transactions to occur on the bus. Later, the response agent completes the original request with a separate Deferred Reply transaction.  |
| Delayed Transaction     | A transaction where the target retries an initial request, but unknown to the initiator, forwards or services the request on behalf of the initiator and stores the completion or the result of the request. The original initiator subsequently reissues the request and receives the stored completion.   |
| Direct Memory Access    | Method of accessing memory on a system without interrupting the processors on that system.  |
| Downstream              | Describes commands or data flowing away from the processor-memory complex and toward I/O. The terms Upstream and Downstream are never used to describe transactions as a whole. (e.g. Downstream data may be the result of an Outbound Write, or an Inbound Read. The Completion to an Inbound Read travels Downstream.)  |

Table 1-4. Glossary Table (Sheet 3 of 5)

| Term                           | Definition  |
|--------------------------------|---|
| Full Duplex                    | A connection or channel that allows data or messages to be transmitted in opposite directions simultaneously.   |
| Gb/s                           | Gigabits per second (10 <sup>9</sup> bits per second)   |
| GB/s                           | Gigabytes per second (10 <sup>9</sup> bytes per second)   |
| Global visibility              | An operation is said to be globally visible when all side-effects of the operation are visible to every observer in the system. For example, a write to some resource (e.g., memory location, control register, etc.) R achieves global visibility when a read of R by all other agents is guaranteed to return the new value.  |
| Gx States                      | Global system states (Gx states) apply to the entire system and are visible to the user. <ul style="list-style-type: none"> <li>G3: Mechanical off - A computer state that is entered and left by a mechanical switch. It is implied by the entry of this off state through a mechanical means that no electrical current is running through the circuitry and that it can be worked on without damaging the hardware or endangering service personnel.</li> <li>G2/S5: Soft Off - A computer state where the computer consumes a minimal amount of power.</li> <li>G1: Sleeping - A computer state where the computer consumes a small amount of power, user mode threads are not being executed, and the system "appears" to be off (from an end user's perspective, the display is off, and so on).</li> <li>G0: Working - A computer state where the system dispatches user mode (application) threads and they execute. In this state, peripheral devices are having their power state changed dynamically.</li> </ul> |
| Half Duplex                    | A connection or channel that allows data or messages to be transmitted in either direction, but not simultaneously.   |
| Implicit Writeback             | A snoop-initiated data transfer from the bus agent with the modified Cache Line to the memory controller due to an access to that line.   |
| Inbound                        | A transaction where the request destination is the processor-memory complex and is sourced from I/O. The terms Inbound and Outbound refer to transactions as a whole and never to Requests or Completions in isolation. (e.g., an Inbound Read generates Downstream data, whereas an Inbound Write has Upstream data. Even more confusing, the Completion to an Inbound Read travels Downstream.)   |
| Industry Standard Architecture | A 16-bit bus architecture associated with the IBM AT motherboard designed to connect motherboard circuitry to expansion card devices that is now considered Legacy.   |
| Initiator                      | The source of requests. [IBA] An agent sending a request packet on 3GIO is referred to as the Initiator for that Transaction. The Initiator may receive a completion for the Request. [3GIO]  |
| ISA Regime                     | A special legacy mode to support ISA-based devices which have been integrated into the chipset. It opens a dedicated channel from the peripheral device to the processor bus. While in this mode, the legacy device is granted exclusive accesses to memory and the ability to use Tenured Transactions.  |
| Isochronous                    | A classification of transactions or a stream of transactions that require service within a fixed time interval.   |
| Lane                           | A set of differential signal pairs, one pair for transmission and one pair for reception. A by-N Link is composed of N Lanes.   |
| Layer                          | A level of abstraction commonly used in interface specifications as a tool to group elements related to a basic function of the interface within a layer and to identify key interactions between layers.   |
| Legacy                         | Functional requirements handed down from previous chipsets, or PC compatibility requirements from the past.   |
| Link                           | The collection of two Ports and their interconnecting Lanes. A Link is a dual simplex communications path between two components.   |
| LPC Bus                        | Low Pin Count connection used to connect to the super I/O device.   |
| Master                         | A device or logical entity that is capable of initiating transactions. A Master is any potential Initiator.   |
| Mbyte/s                        | Megabytes per second (10 <sup>6</sup> bytes per second)   |
| Mem                            | Used as a qualifier for transactions that target memory space. (For example, a Mem read to I/O.)  |

Table 1-4. Glossary Table (Sheet 4 of 5)

| Term                    | Definition  |
|-------------------------|---|
| Metastability           | A characteristic of flip flops that describes the state where the output becomes non-deterministic. Most commonly caused by a setup or hold time violation.   |
| Multi Media Timer (MMT) | See High Precision Event Timer (HPET) in Table 1-3.   |
| Non-Coherent            | Transactions that may cause the processor's view of memory through the cache to be different than that obtained through the I/O subsystem.  |
| North                   | Usually refers to bridges. The bridge or device that is closer to the processor-memory complex.   |
| Ordering                | Refers to the order in which signals and/or memory accesses to different locations must reach global visibility to ensure some behavior. Note that this excludes the "ordering" necessary to prevent data hazards which are accesses to the same location.  |
| Outbound                | A transaction where the request destination is I/O and is sourced from the processor-memory complex. The terms Inbound and Outbound refer to transactions as a whole and never to Requests or Completions in isolation. (For example, an Outbound Read generates Upstream data, whereas an Outbound Write has Downstream data. Even more confusing, the Completion to an Outbound Read travels Upstream.)   |
| OWord                   | 128 bits of data on a naturally aligned sixteen-byte boundary (e.g., the least significant four bits of the byte address are b"0000"). This is the native size of the IMCH datapath.  |
| Packet                  | The indivisible unit of data transfer and routing, consisting of a header, data, and CRC.   |
| PCI Reset               | PCIRST#. This is the secondary PCI Bus reset signal. It is a logical OR of the primary interface PLTRST# signal and the state of the Secondary Bus Reset bit.   |
| Peer-to-Peer            | Transactions that occur between two devices independent of memory or the processor.   |
| Platform Reset          | IICH asserts PLTRST# to reset devices that reside on the primary PCI bus. The IICH asserts PLTRST# during power-up and when a hard reset sequence is initiated through the CF9h register. PLTRST# is driven inactive a minimum of 1 ms after both PWROK and VRMPWRGD are driven high. PLTRST# is driven for a minimum of 1 ms when initiated through the CF9h register.   |
| Plesiochronous          | From Greek, meaning almost synchronous. Describes signals that have the same nominal digital rate, but are synchronized on different clocks. Any variation in rate is constrained within specified limits, which allows a device to process the data signal without buffer underflow or overflow by making periodic compensating adjustments that repeat or delete dummy data bits. However, there is no limit to the phase difference that can accumulate between the signals over time. |
| Port                    | 1. Logically, an interface between a component and a PCI Express* Link.<br>2. Physically, a group of Transmitters and Receivers located on the same chip that define a Link.  |
| Posted                  | A Transaction that is considered complete by the initiating agent or source before it actually completes at the Target of the Request or destination. All agents or devices handling the Request on behalf of the original Initiator must then treat the Transaction as being system visible from the initiating interface all the way to the final destination. Commonly refers to memory writes.  |
| Push Model              | Method of messaging or data transfer that predominately uses writes instead of reads.   |
| Queue                   | A first-in first-out (FIFO) structure.  |
| Receiver                | 1. The Agent that receives a Packet across an interface regardless of whether it is the ultimate destination of the packet. 2. More narrowly, the circuitry required to convert incoming signals from the physical medium to more perceptible forms.  |
| Request                 | A packet, phase, or cycle used to initiate a Transaction on a interface, or within a component.   |
| Reserved                | The contents or undefined states or information that are not defined at this time. Using any reserved area is not permitted. Reserved register bits must be set to 0. However, when stated, there may be specific instances where a reserved register is either non-zero, or there may be a requirement to make it non-zero.  |
| Resume Power Well       | Trickle from power supply, only turns off when power is disconnected from wall.   |
| Resume Reset            | Signal that resets the parts of the IICH in the resume power well, generated when the trickle supply turns on.  |
| RTC Power Well          | Powered by a coin cell battery and only turns off when the battery is drained. Powers the RTC and some resume events.   |

Table 1-4. Glossary Table (Sheet 5 of 5)

| Term                   | Definition  |
|------------------------|---|
| Sx States              | <p>Sleeping states (Sx states) are types of sleeping states within the global sleeping state, G1.</p> <ul style="list-style-type: none"> <li>• S5: Soft Off state. The main memory power plane is shut down in addition to the clock synthesizer and core well power planes for the processor and CMI. The CMI resume well is still powered.</li> <li>• S4: Sleeping state - This state is only used to transition to or from the S5 state. <b>The S4 state is not a supported power management state in CMI.</b></li> <li>• S3: Suspend to RAM (STR) state - The clock synthesizer and core well power planes for the processor and CMI are shut down, but the main memory power plane and the CMI resume well remain active. All clocks from synthesizers are shut down during the S3 state.</li> <li>• S0: Awake state - Power Management state when all power planes are active.</li> </ul> |
| Simplex                | A connection or channel that allows data or messages to be transmitted in one direction only.   |
| SMBus                  | System Management Bus. A two-wire interface through which various system components may communicate.  |
| Snooping               | A means of ensuring cache coherency by monitoring all memory accesses on a common multi-drop bus to determine if an access is to information resident within a cache.   |
| South                  | Usually refers to bridges. The bridge or device that is further from the processor-memory complex.  |
| South Port             | The PCI Express* downstream root port(s) on the IICH.   |
| Split Lock Sequence    | A sequence of transactions that occurs when the target of a lock operation is split across a processor bus data alignment or Cache Line boundary, resulting in two read transactions and two write transactions to accomplish a read-modify-write operation.  |
| Split Transaction      | A transaction that consists of distinct Request and Completion phases or packets that allow use of bus, or interconnect, by other transactions while the Target is servicing the Request.   |
| Symbol                 | An expanded and encoded representation of a data Byte in an encoded system (e.g., the 10b value in a 8b/10b encoding scheme). This is the value that is transmitted over the physical medium.   |
| Symbol Time            | The amount of time required to transmit a symbol.   |
| Target                 | A device that responds to bus Transactions. The agent receiving a request packet is referred to as the Target for that Transaction.   |
| Tenured Transaction    | A transaction that holds the bus or interconnect until complete, effectively blocking all other transactions while the Target is servicing the Request.   |
| Transaction            | An overloaded term that represents an operation between two or more agents that can be comprised of multiple phases, cycles, or packets.  |
| Transaction Identifier | A multi-bit field used to uniquely identify a transaction. Commonly used to relate a Completion with its originating Request in a Split Transaction system.   |
| Transmitter            | 1. The Agent that sends a Packet across an interface regardless of whether it was the original generator of the packet. 2. More narrowly, the circuitry required to drive signals onto the physical medium.   |
| Upstream               | Describes commands or data flowing toward the processor-memory complex and away from I/O. The terms Upstream and Downstream are never used to describe transactions as a whole. (For example, Upstream data may be the result of an Inbound Write, or an Outbound Read. The Completion to an Outbound Read travels Upstream.)   |
| VCMI                   | IA-32 core, IA-32 Core interface, Memory controller hub, I/O controller hub   |

## 2.0 Architectural Overview

---

### 2.1 Overview

This chapter provides an overview of the Intel® EP80579 Integrated Processor product line architecture. [Section 2.1.1, “Block Summary”](#) gives a high-level summary for each of the major blocks and their internal interfaces. [Section 2.1.2, “External Interfaces”](#) reviews the EP80579’s external chip interfaces.

The block diagrams in [Figure 2-1](#) and [Figure 2-1](#) show the major EP80579 blocks.

#### 2.1.1 Block Summary

- The EP80579 **IA-32 core** runs at 600, 1066, and 1200 MHz with an internal 400 or 533 MHz front-side bus (FSB) interface. The IA-32 core features a 256 Kilobyte 2-way level 2 cache (L2).
- The EP80579 **IMCH** provides the main path to memory for the IA-32 core and all peripherals that perform coherent I/O (e.g. PCI Express\*, the IICH to coherent memory). The IMCH includes the four channel DMA engine as well as a PCI Express\* root complex with 1x8, 2x4, or 2x1 interfaces. The **memory controller** operates at 200-266-333-400 MHz, depending on external DDR and SKU configuration. Depending on SKU, the EP80579 supports a single channel, 64-bit with ECC, memory controller for external DDR-2 memory (400, 533, 667, and 800 MHz). The EP80579 also supports a 32-bit with ECC mode for cost-sensitive applications.
- The EP80579 **IICH** provides a set of PC platform-compatible I/O devices that include two SATA1.0/2.0, one USB1.1/2.0 host controller supporting two USB ports, and two serial 16550 compatible UART interfaces. The IICH complex interfaces to the MCH through the “NSI” internal bus interface.
- The EP80579 **Acceleration and I/O Complex (AIOC)** supports three Gigabit Ethernet media access controllers, MDIO, Local Expansion Bus (LEB), two Controller Area Network (CAN) interfaces, IEEE1588 (2-GbE and 2-CAN ports), and SSP. In addition some SKU have three high-speed serial TDM interfaces that provide up to 12 T1/E1. ASU and SSU provide the high performance packet processing and accelerate common security capability.

## 2.1.2 External Interfaces

Table 2-1 summarizes the key features of the external interfaces.

**Table 2-1. EP80579 External Interface Summary**

| Name                | Qty. | Description  |
|---------------------|------|--|
| External DDR Memory | 1    | Single channel memory controller with an ECC enabled 64-bit interface that, depending on SKU, supports external DDR-2 memory (400, 533, 667 and 800 MHz). Minimum memory size is 128 MB (in 32 bit mode). Maximum memory size is 4GB. The EP80579 integrated processor also supports a 32-bit mode (with ECC) for cost-sensitive applications. |
| PCI Express* (root) | 1    | Supports 1x8, 2x4, or 2x1 configurations as a root complex.  |
| Gigabit Ethernet    | 3    | 10/100/1000 Gigabit Ethernet MACs with RGMII/RMII interface. Two of the three ports support IEEE 1588 hardware assist.   |
| TDM                 | 3    | 8.192 MHz high-speed synchronous serial TDM interfaces that support up to 12 T1/E1 links (SKU dependent) with Intel software driver provided for HDLC support.   |
| Local Expansion Bus | 1    | 25/16-bit 80MHz local expansion bus with 8 programmable chip selects.  |
| USB 2.0             | 1    | Universal Serial Bus 2.0 host controller interface, supports two USB ports (shared with USB1.1 ports)  |
| USB 1.1             | 1    | Universal Serial Bus 1.1 host controller interface, supports two USB ports (shared with USB2.0 ports)  |
| LPC                 | 1    | Low Pin Count Bus (LPC) interface to attached PC compatible boot flash memory up to 64MB.  |
| SPI                 | 1    | Serial Peripheral Interface (SPI).   |
| GPIO                | 36   | Programmable General Purpose I/O (GPIO) pins. Note, Intel recommends using this interface to boot from. Of the 36pins, many have alternate functions defined.  |
| SMBus/I2C           | 2    | I2C compatible SMBus2.0 connections.   |
| UART                | 2    | 16550 compatible asynchronous serial ports that support data rate of at least 115Kbits/sec.  |
| SATA                | 2    | SATA1.0 or 2.0 used to attached external hard drives.  |
| SSP                 | 1    | Synchronous Serial Port  |
| CAN                 | 2    | Controller Area Network interfaces.  |
| MDIO                | 1    | MDIO interface to support the ethernet interfaces.   |
| IEEE-1588           | 1    | IEEE-1588 Hardware Assist  |

### 2.1.3 Frequencies and Gear Ratios

This section discusses frequencies and gear ratios.

The **IA core** used in the EP80579 is an IA-32 core, and can run at frequencies between 600 and 1200 MHz (actually supported CPU frequencies vary by SKU, see [Chapter 47.0, “SKUs, Power Savings and Pre-Boot Firmware”](#)). Based on divider ratios in its PLL design, the IA-32 core imposes a 6:1 minimum core/bus frequency ratio. This limits maximum FSB frequency to 400 or 533 MHz front-side bus (FSB) interface.

The IA-32 core/FSB frequency combinations supported are listed in [Table 2-2](#).

**Table 2-2. IA-32 core / FSB Frequency Ratios (depends on SKU and configuration)**

| IA-32 core [MHz] | FSB [MHz] | Ratio |
|------------------|-----------|-------|
| 600              | 400       | 6:1   |
| 1066             | 533       | 8:1   |
| 1200             | 533       | 9:1   |

[Table 2-3](#) summarizes the memory controller clock ratios.

**Table 2-3. Memory Controller Frequencies**

| DDR Clock [MHz] | DDR Technology |
|-----------------|----------------|
| 200             | DDR2-400       |
| 266             | DDR2-533       |
| 333             | DDR2-667       |
| 400             | DDR2-800       |

## 2.2 Signaling Architecture

As defined in [Table 2-4](#), the EP80579 supports communication between the IA, AIOC devices (ASU, SSU, internal I/O devices) and externally attached bus master (PCI Express\* through different memory types using a variety of operations.

**Table 2-4. Summary of Communication**

| Operation   | Agent           | Targeted Memory Type <sup>a</sup> |                             |
|-------------|-----------------|-----------------------------------|-----------------------------|
|             |                 | External DRAM (Coherent)          | External DRAM (AIOC Direct) |
| Read, Write | IA              | X                                 | X <sup>b</sup>              |
|             | ASU             | X                                 | X                           |
|             | PCI-E DMA, EDMA | X                                 | X <sup>b</sup>              |
|             | GbE             | X                                 | X                           |
| Atomic      | IA              | X                                 | -                           |
|             | ASU             | X                                 | X                           |
|             | PCI-E DMA, EDMA | -                                 | -                           |
|             | GbE             | -                                 | -                           |

a. "X" cells are supported with normal or MMIO accesses and "-" cells are not supported.

- b. Agents in the IA-32 core may access AIOC-Direct memory (non-coherent) via uncacheable 1, 2 or 4-byte IA loads/store, IA MMX 8-byte MOVQ instructions or 64-byte DMA transfers. While such IA-32 core accesses to AIOC-Direct memory are not ordered with respect to other ASU memory traffic, the AIOC-Direct memory supports limited one-way communication in which IA agent (or the Internal PCI agent) is the sole writer and the internal PCI agent (or the IA agent) views such memory locations as read-only. Hardware will ensure that self-aligned 1, 2, 4, 8 and 64-byte updates will be atomically visible to all readers.

The EP80579 allows signaling to occur between IA, AIOC complex, and externally-attached agents in the appropriate native signaling format.

The EP80579 supports basic producer/consumer behavior between agents.

Because the AIOC complex devices are exposed to the IA platform as PCI devices, they follow PCI ordering semantics when interacting with IA. This enables two fundamental producer/consumer models in coherent memory: the polled and interrupt methods.

**For the Polled method:**

1. Producer writes data to location "X" in Coherent Memory.
2. Producer sets flag to location "Y" in Coherent Memory
3. Consumer waits for flag to be set in Coherent Memory
4. Consumer read data from location "X" in Coherent Memory

To ensure this behavior, agents generating traffic into the IMCH must ensure that the writes originating from an agent are globally observable in the same order. In the above case X and Y must be globally observable in the same order.

**For the Interrupt method:**

1. Producer writes data to location "X" in Coherent Memory.
2. Producer generates an interrupt to Consumer (asynchronous signal)
3. Consumer reads interrupt status from Producer's address space. Consumer waits for read to complete before issuing the next transaction.
4. Consumer reads data from location "X" in Coherent Memory

To ensure this behavior, an MMIO read issued to the PCI device (item 3 above) after a write that originated from this PCI device (item 1 above) must not complete out of order. The read completion must push ahead (flush) the write.

Also the MMIO read (item 3 above) should be to a location that is in the device. In the EP80579, it should not be to the PCI configuration registers but the device registers pointed to by the PCI BAR<sup>1</sup>. This ensures that IA device driver software for the EP80579 is not required to include explicit memory fence operations to enable producer-consumer synchronization for interrupt handling. Examples:

1. GigE ⇔ IA : GigE placing received data in coherent DRAM and interrupting IA, IA issuing a GigE CSR read, whose read completion must serialize the received DRAM data stream.
2. TDM ⇔ IA : TDM placing received data in coherent DRAM, then interrupting the IA, then IA gets a pointer to the data. An IA pointer dereference from the IA must see the TDM DRAM data.
3. ASU ⇔ IA : ASU placing data in coherent DRAM, then interrupting the IA, then IA gets a pointer to the data. An IA pointer dereference from the IA must see the ASU DRAM data.

---

1. The reason for this requirement is that the MCH config bus used to access the PCI configuration registers does not serialize the EP80579 internal PCI bus.

For communication using memory that is **not** coherent with the IA processor caches, or for direct communication between AIOC agents (e.g. between ASU, TDM, and GigE devices), the EP80579 may require software to insert explicit fencing operations to ensure correct producer/consumer behavior. Details are discussed in [Chapter 4.0, “Signaling”](#).

## 2.3 DMA and Peer-to-Peer Data Transfers

The EP80579 provides multiple DMA and DMA-like features that are summarized here:

- **IMCH EDMA Engine:** The four channel IMCH “Enhanced DMA” (EDMA) engine which supports DWORD aligned DMA. The EDMA engine supports memory-to-memory and memory-to-PCIe transfers. Read DMA granularity ranges from 1 byte to 4 Kilobytes. Write DMA granularity ranges from 1 to 256 bytes. The EDMA engine supports different source/target byte alignments that are important for packet processing, and is only programmable via IA PCI configuration space with completions signaled via IA interrupts. The EDMA engine can support burst data movement between “AIOC-direct memory” and IA coherent memory.
- **IICH DMA:** Supports IICH agents to/from memory, this is only used by USB and SATA.
- **LPC DMA:** Supports LPC agents. See [Chapter 20.0, “LPC DMA”](#).
- **No Peer-to-Peer Reads:** The IMCH does not support peer-to-peer reads.

[Table 2-5](#) lists the supported DMA and peer-to-peer data transfer options.

**Table 2-5. DMA and Peer-to-Peer Data Transfer Options**

| Usage Model# | Operation               | Source                       | Destination              | Initiator                    | Owner (Software)          |
|--------------|-------------------------|------------------------------|--------------------------|------------------------------|---------------------------|
| 1            | PCI DMA read            | DRAM                         | PCI Ex device            | PCI Ex Device                | IA device driver          |
| 2            | PCI DMA write           | PCI Ex Device                | DRAM                     | PCI Ex Device                | IA device driver          |
| 3            | AIOC read               | DRAM or AIOC device          | AIOC device (GE)         | Device                       | IA, ASU                   |
| 4            | AIOC write              | AIOC device                  | DRAM or AIOC device (GE) | Device                       | IA, ASU                   |
| 5            | AIOC 3rd party read     | DRAM                         | AIOC device (SSU)        | ASU                          | ASU                       |
| 6            | AIOC 3rd party write    | AIOC device (SSU)            | DRAM                     | ASU                          | ASU                       |
| 7            | Peer-to-Peer PCI Read   | Not Supported                |                          |                              |                           |
| 8            | Peer-to-Peer PCI Write  | AIOC Master or PCI Ex Device | PCI Ex Device only       | AIOC Master or PCI Ex Device | AIOC Master Device Driver |
| 9            | Mem-to-Mem              | DRAM                         | DRAM                     | EDMA Engine                  | IA                        |

§ §

## 3.0 Platform Memory and Device Configuration

---

### 3.1 Overview

This chapter presents the views of the major address spaces and device configuration structures as seen by various internal and external agents. Three related aspects are covered:

- The memory maps seen by various internal and external agents.
- The endianness seen by various agents and mechanisms the EP80579 uses to allow communication between agents with different endianness expectations.
- The PCI configuration infrastructure, which the EP80579 exposes through its memory maps.

#### 3.1.1 Configuration Objectives

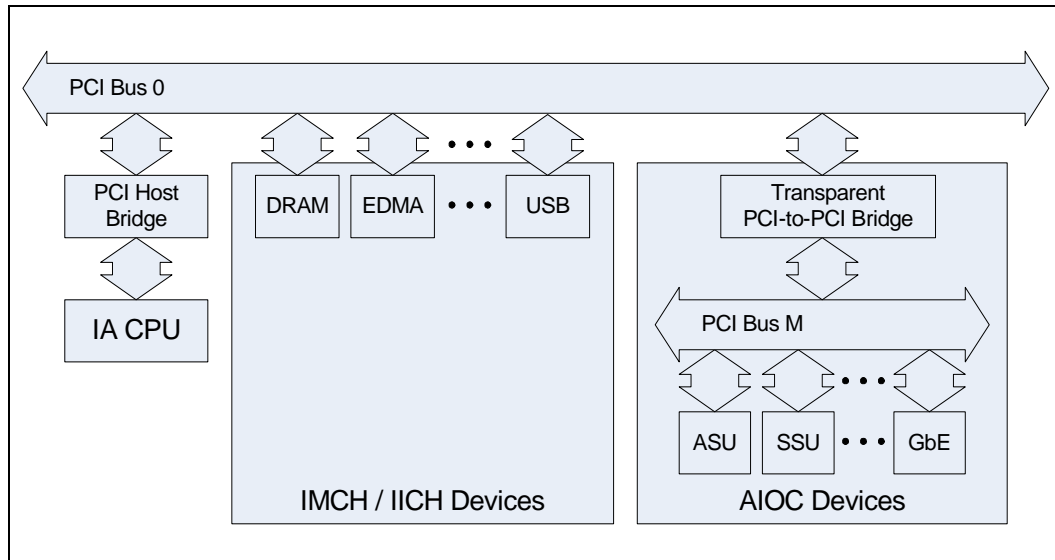

The EP80579 device and configuration model operates in a system-on-a-chip environment and blends the architectures of many disparate components into a unified whole. The major goals for the device configuration and access architecture include:

- Provide a configuration and access model that is aligned with existing IA platform algorithms.
- Support a unified address space model.

The IA-32 core is the primary agent responsible for device configuration. This is true across all supported SKUs.

To provide device configuration and operation capabilities that are aligned with the IA platform, the EP80579 uses the existing PCI infrastructure to expose on-die software-visible sub-blocks as devices on the PCI fabric. [Figure 3-1](#) presents a logical overview of this organization.

Figure 3-1. Device-Centric Logical View of EP80579 Devices

The on-die IMCH and IICH devices materialize on PCI bus 0 while the AIOC devices materialize on PCI bus “M” that is behind a transparent PCI-to-PCI bridge on PCI bus 0 (the bus that the internal IMCH and IICH devices use). For simplicity, the figure does not show external devices.

### 3.1.2 Terminology and Conventions

Throughout this chapter, we will use the generic term “device” to refer to either a PCI device or a function of a PCI device. The text will be explicit when the distinction between device and function is important.

Addresses are always in hexadecimal and broken into 16-bit segments, for example, 0\_FEED\_BEEF. When the distinction is important and not obvious, addresses are subscripted with “V”, “P”, or “S” for virtual, physical, or system address spaces, respectively.

The EP80579 addresses its DRAM in units of 8-byte quadwords. Before assigning byte addresses to the byte lanes in DRAM, we will refer to the locations as byte lane A through H as Table 3-1 illustrates.

Table 3-1. Main Memory DRAM Organization

| Address | Byte Lane H | Byte Lane G | Byte Lane F | Byte Lane E | Byte Lane D | Byte Lane C | Byte Lane B | Byte Lane A |
|---------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|-------------|
| 0       | 0H          | 0G          | 0F          | 0E          | 0D          | 0C          | 0B          | 0A          |
| 8       | 8H          | 8G          | 8F          | 8E          | 8D          | 8C          | 8B          | 8A          |
| 16      | 16H         | 16G         | 16F         | 16E         | 16D         | 16C         | 16B         | 16A         |

The byte located in address 0, lane A is referred to as 0A, the byte in address 0 lane B is 0B, etc.

## 3.2 IA Platform Infrastructure

The IMCH and IICH blocks (which, along with the IA-32 core, are collectively referred to as the VCMI) in the EP80579 provide an IA platform infrastructure with respect to endianness, address spaces and memory maps, configuration, etc.

This section focuses on the IA views and expectations around the endianness, address spaces and memory maps, and configuration for a basic IA platform. The EP80579 operates within this framework. These discussions highlight how and where the EP80579 differs from the framework. For additional detailed information on the IA infrastructure in the EP80579 specifically, see [Section 9.0, “CMI Introduction”](#), which discusses the IMCH implementation.

### 3.2.1 IA Platform View of Endianness

All memory in an EP80579 platform is little-endian to match requirements and expectations of an IA platform. The byte lanes (see [Table 3-1 on page 112](#)) are connected from the memory interface to the IMCH such that little-endian IA-32 core sees “byte 0” of a quad-word in memory in byte lane A and “byte 7” of a quad-word in memory in byte lane H.

Consider the following C code:

```
char c, *cp;           // 1 byte
short s, *sp;         // 2 bytes
long l, *lp;          // 4 bytes
long long ll, *llp;   // 8 bytes
cp = sp = lp = llp = (void *) 0x8; // QW address 1
c = *cp;
s = *sp;
l = *lp;
ll = *llp;
```

Executing this code on the IA-32 core in an EP80579 yields the following results:

```
c == 8A
s == 8B8A
l == 8D8C8B8A
ll == 8H8G8F8E8D8C8B8A
```

Where the right-hand values in these results use the notation that [Table 3-1 on page 112](#) in [Section 3.1.2](#) describes to identify the byte lanes and address.

### 3.2.2 IA Platform View of Configuration

Because the IMCH and IICH blocks in the EP80579 come from an IA heritage, the EP80579 exposes much of the functionality in these blocks through a PCI infrastructure. The EP80579 extends this PCI infrastructure to expose the functionality in the AIOC, as [Section 3.7, “PCI Configuration” on page 119](#) describes.

Before describing how the AIOC integrates with the IA-based IMCH and IICH blocks, it is helpful to consider how the PCI exposes IMCH and IICH functionality. Logically, the software-visible sub-blocks of the IMCH and IICH materialize as PCI devices and functions<sup>1</sup> on PCI bus 0 of the system through three independent address spaces:

- **Configuration Space:** Each function of each device has at least 256B of configuration space that is mapped to a fixed location by the platform (PCI Express\* devices can provide for larger configuration spaces). This space provides system software with basic information on the device and allows for device-independent configuration.
- **Memory-Mapped I/O (MMIO) and I/O Spaces:** Each function of each device can request up to six MMIO and I/O regions of device-specified sizes to be mapped into physical address space through base address registers in the configuration header. System software selects the base address of each region. These spaces support device-specific operation such as access to device-specific control registers.

Of the thirty-two possible device slots on bus 0, five slots are reserved for software-visible blocks in the EP80579 IMCH and IICH and remainder are unused.

In general, the IMCH claims configuration accesses (i.e., those accesses that target configuration space) to device numbers 0, 1, 2, and 3 of bus 0 and routes configuration accesses to the remaining devices to the IICH over an internal NSI interface using Type 0 PCI configuration transactions<sup>2</sup> (see [Section 13.2, “Platform Configuration Structure Conceptual Overview”](#) and [Section 13.3, “Routing Configuration Accesses”](#)). In the EP80579 design, transactions to bus 0 devices that are sent through NSI to the IICH and unclaimed by the IICH will master abort.

[Figure 3-2](#) presents a logical view of the EP80579 infrastructure for the software-visible blocks in the IICH and IMCH.

---

1. Except where the distinction is important, this document uses the term “device” to refer to both devices and functions in the PCI sense of these words.  
2. Configuration transactions take the Type 1 form while in transit through the PCI fabric to their destination bus; upon reaching their destination bus, they become Type 0 transactions.

Figure 3-2. Logical Overview of the CMI PCI Infrastructure

Table 3-2 summarizes the address space requirements (both in memory and I/O space) of the IMCH and IICH.

Table 3-2. Basic CMI Platform Address Space Requirements for IMCH and IICH Devices

| Unit | PCI  |     | Block                         | Mem, I/O | Size | Register  |
|------|------|-----|-------------------------------|----------|------|---|
|      | Dev. | Fn. |                               |          |      |   |
| IMCH | 0    | 0   | Northbridge                   | Mem      | 4KB  | SMRBASE (see Section 16.1.1.9, "Offset 14h: SMRBASE - System Memory RCOMP Base Address Register") |
|      |      | 1   | DRAM, Error Handling          | N/A      | N/A  |   |
|      | 1    | 0   | EDMA                          | Mem      | 4KB  | EDMALBAR (see Section 16.3.1.9, "Offset 10h: EDMALBAR - EDMA Low Base Address Register")          |
|      | 2    | 0   | PCI-Express (HSI A0) x8 or x4 | N/A      | N/A  |   |
|      | 3    | 0   | PCI-Express (HSI A1) x4       | N/A      | N/A  |   |
| IICH | 29   | 0   | USB 1.1                       | I/O      | 32B  | USBIOBAR (see Section 25.1.1.9, "USBIOBAR - Base Address Register")                               |
|      |      | 7   | USB 2.0                       | Mem      | 1KB  | MBAR (see Section 26.2.1.10, "Offset 10h: MBAR - Memory Base Address Register")                   |

**Table 3-2. Basic CMI Platform Address Space Requirements for IMCH and IICH Devices**

|  |    |   |         |     |     |  |
|--|----|---|---------|-----|-----|--|
|  |    | 0 | LPC/SPI | N/A | N/A |  |
|  | 31 | 2 | SATA    | I/O | 8B  | PCMDBA (see Section 23.1.1.8, "Offset 10h: PCMDBA – Primary Command Block Base Address Register")    |
|  |    |   |         | I/O | 4B  | PCTLBA (see Section 23.1.1.9, "Offset 14h: PCTLBA – Primary Control Block Base Address Register")    |
|  |    |   |         | I/O | 8B  | SCMDBA (see Section 23.1.1.10, "Offset 18h: SCMDBA – Secondary Command Block Base Address Register") |
|  |    |   |         | I/O | 4B  | SCTLBA   |
|  |    |   |         | I/O | 16B | LBAR (see Section 23.1.1.12, "Offset 20h: LBAR – Legacy Bus Master Base Address Register")           |
|  |    |   |         | Mem | 1KB | ABAR (see Section 23.1.1.13, "Offset 24h: ABAR – AHCI Base Address Register")                        |
|  |    | 3 | SMBUS   | N/A | N/A |  |

The IMCH and IICH devices in the EP80579 on PCI bus 0 allocate 18KB of memory space above and beyond the PCI L allocations in Figure 3-2 and 72B of I/O space through PCI BARs (this memory could be allocated in the "open" regions in Figure 3-2). This table does not include any memory regions that external devices (i.e., those attached to a IMCH PCI Express\* port) or AIOC devices might allocate.

In addition to the IMCH and IICH devices, the EP80579 includes an IA-32 core that provides MSRs and other configuration structures.

### 3.3 High-Level Views

This section presents an overview of some of the general characteristics of the agents that the various EP80579 memory maps expose.

#### 3.3.1 Characteristics of External System Memory (DRAM)

The address spaces in the EP80579 expose up to 4GB of physical system memory, in the form of DRAM, to be accessed by both on- and off-die agents.

**Table 3-3. Memory Regions**

| Region                      | Managed By                  | Accesses to System Memory by AIOC Agents Coherent with IA Caches? | Contents   |
|-----------------------------|-----------------------------|---|--|
| IA O/S                      | IA O/S                      | Y   | IA O/S and application code and data structures                              |
| IA/ASU Shared (Coherent)    | EP80579 Driver <sup>a</sup> | Y   | IA and AIOC shared data structures   |
| IA/ASU Shared (AIOC-Direct) | EP80579 Driver <sup>a</sup> | N   | AIOC data structures; IA-32 core may access a portion via the EP80579 driver |

a. The EP80579 Driver includes the EP80579-specific software stacks that run on the IA, ASU, etc.

Of the regions in [Table 3-3](#), the “IA/ASU Shared (Coherent)” and “IA/ASU Shared (AIOC-Direct)” regions are **not** managed by the IA O/S. The EP80579 software expects that the BIOS carves this memory out of the memory map early in the boot process and sets it aside for use by the Intel® EP80579 Integrated Processor with Intel® QuickAssist Technology software stack. As a result, the IA O/S does not allocate, manage, page, etc. these regions of memory.

The regions in [Table 3-3](#) fall into one of two categories with respect to IA cache coherency: one that is coherent with IA caches for **AIOC accesses** and one that is not. It is important to note that the coherent/non-coherent category of a region affects **only** how the AIOC hardware handles a **DRAM** accesses. The category, in and of itself, does **not** have any implications on how IA must always access the region.

The EP80579 expects that, in general, all agents in the system can access all memory, consistent with their addressing capabilities, in the three regions that [Table 3-3](#) lists. Exceptions to this general rule may arise due to the size of the address space that an agent supports or due to agent-specific aliasing of DRAM addresses onto other structures. The following sections on the memory maps outline any agent-specific exceptions. Finally, memory accesses that originate from the AIOC (or a device attached to the AIOC) must honor the coherency requirements in [Table 3-3](#) based on the region they target. For consistency, software is expected to configure the EP80579 such that memory that the IA-32 core cannot access is not part of regions that are expected to be coherent with IA caches.

### 3.3.2 Characteristics of Internal and External Memories

[Table 3-4](#) defines the supported operations by memory type. The table uses the following notation to indicate the behavior of the EP80579:

- “–” means the operation is not supported by the EP80579.
- “S” implies that the operation happens as a single atomic<sup>1</sup> update to memory. In other words, either the update is observable in its entirety or not at all.
- “M” implies that the operation may happen as multiple updates to memory. In other words, other agents can observe different parts of the affected memory location change values in any order but the end state of the memory location will be the desired value. This “flickering lights” effect makes such memory accesses useless for multi-agent synchronization unless a semaphore or flag variable is used to guard access to the shared location<sup>2</sup>.

This table only applies to aligned-to-size operations; that is, a 4-byte operation is aligned to a 4-byte boundary, an 8-byte operation is aligned to an 8-byte boundary, etc.)

1. In the sense that it cannot be divided into multiple smaller writes.

2. Note that in guarding the location, visibility of the new flag must imply that the “flickering” has stopped.

Table 3-5. Supported Operations by Memory Type

| Operation                          |            | IA-32 core                 |                          | AIOC Agents |                          |
|------------------------------------|------------|----------------------------|--------------------------|-------------|--------------------------|
| Type                               | Size Bytes | Coherent (IA WB Cacheable) | AIOC-Direct <sup>a</sup> | Coherent    | AIOC-Direct <sup>a</sup> |
| Read, Write                        | 1          | S                          | S                        | –           | –                        |
|                                    | 2          | S                          | S                        | –           | –                        |
|                                    | 4          | S                          | S                        | S           | M                        |
|                                    | 8          | S                          | S                        | S           | S                        |
|                                    | 16         | S                          | M                        | M           | M                        |
|                                    | 32         | –                          | –                        | M           | M                        |
|                                    | 64         | S                          | –                        | M           | M                        |
|                                    | 128        | –                          | –                        | M           | M                        |
| Atom Read-Modify-Write (Semaphore) | 1          | S                          | M                        | –           | –                        |
|                                    | 2          | S                          | M                        | –           | –                        |
|                                    | 4          | S                          | M                        | S           | S                        |
|                                    | 8          | S                          | M                        | –           | –                        |

a. AIOC-Direct is a feature of the Intel® EP80579 Integrated Processor with Intel® QuickAssist Technology SKU.

### 3.3.3 Characteristics of Device Configuration

To be able to leverage existing IA BIOS, O/S, and power management software, the EP80579’s configuration mechanisms follow existing IA platform approaches. Of the four major components of the EP80579:

- The IA-32 core can use normal IA platform configuration algorithms.
- The IMCH and IICH can use normal IA platform configuration algorithms.
- To interoperate with normal IA platform configuration algorithms, the AIOC must be configured by the IA processor.

With the EP80579, the boot and configuration process is:

4. The IA boots from a FLASH device on the IICH SPI (LPC) interface. System software discovers and configures the devices on PCI bus 0 in the IMCH/IICH.
5. System software discovers and configures the devices behind the Transparent PCI-to-PCI bridge into the AIOC. This may amount to allocating memory regions specified by the BARs<sup>1</sup>.
6. System software configures other buses on the system.

Once this process completes, the EP80579 is ready for operation.

It may be necessary for software to re-order the devices on bus 0 in the IMCH/IICH/AIOC to ensure that the AIOC can obtain the resources it needs. Since enumeration involves either a depth-first or a breadth-first traversal of the device tree from device zero (depending on the implementation of the platform PCI enumeration and discovery code), the system may not be able to honor a request for a large memory region from an AIOC device if this device is enumerated late in the process due to a large device number. This issue is not unique to the EP80579 and is handled in whatever fashion standard IA platform software handles such resource issues.

1. A 32-bit BAR can request a single memory size that is a power of 2 from 16B to 2GB according to the PCI specification.

### 3.4 Memory Map for IA-Attached Agents

There are two constraints in the EP80579 CMI and Memory Controller designs:

- The IA-32 core only supports 32-bit physical addresses.
- The Memory Controller supports at most 4GB of physical memory.

This discussion focuses on the perspective of an IA-attached agent; [Section 3.5, “Memory Map for AIOC-Attached Devices”](#) on page 119 provides similar discussion for AIOC-attached agents.

**Table 3-6. Device Exposure from an IA-attached Memory Map Perspective**

| Device to Access                         | Materializes In Region | Notes  |
|--|------------------------|--|
| PCIe GigE MACs<br>IMCH/IICH AIOC devices | PCI L                  | <ul style="list-style-type: none"> <li>• PCI BAR(s) set by IA O/S or BIOS specify address mapping(s).</li> <li>• IA-32 core configures through I/O or PCI enhanced config spaces.</li> <li>• Reads, config space access between I/O agents not supported.</li> <li>• Region is at least 128MB per definition of TOLM, see <a href="#">Section 16.1.1.30, “Offset C4h: TOLM - Top of Low Memory Register”</a>.</li> </ul> |
| DRAM                                     | DRAM AD                | <ul style="list-style-type: none"> <li>• Contains IA/ASU Shared (AIOC-Direct) region from <a href="#">Table 3-3</a>.</li> <li>• MENCBASE and MENCLIMIT registers define address range.</li> <li>• IA caches not coherent with AIOC accesses to this region.</li> <li>• Must include all DRAM that is inaccessible to the IA-32 core.</li> </ul>  |
|  | DRAM C                 | <ul style="list-style-type: none"> <li>• Contains I/A O/S, IA/ASU Shared (Coherent) regions from <a href="#">Table 3-3</a>.</li> <li>• IA caches coherent with AIOC accesses to this region.</li> <li>• Cannot include any DRAM that is inaccessible to the IA-32 core.</li> </ul>   |

### 3.5 Memory Map for AIOC-Attached Devices

AIOC-attached agents support several independent target IDs that provide independent address spaces. [Table 3-7](#) summarizes, the addressing capabilities of AIOC agents range from 25 to 32-bits.

**Table 3-7. Address Space Sizes of AIOC-attached Devices**

| Address Space Size [b] | Devices                       |
|------------------------|-------------------------------|
| 32                     | Gigabit Ethernet MACs         |
| 32                     | ASU, SSU, TDM, SSP, CAN, 1588 |

### 3.6 Endianness

The EP80579 operates in an IA platform environment that is little-endian.

### 3.7 PCI Configuration

This section presents an overview of the implementation that integrates the AIOC and memory controller with the IA PCI infrastructure for configuration.

- PCI mechanisms (configuration space, memory-mapped I/O spaces, and I/O spaces) expose state for configuration.
- The IA-32 core performs all system configuration and initialization.

- The IA-32 core configures the AIOC, IMCH and IICH using standard IA platform algorithms (i.e., PCI-based discovery, enumeration, and configuration) with modifications for the specific mix of functionality that the EP80579 CPU, IMCH, and IICH instantiations provide.
- IA software configures external PCIe devices in the EP80579 using normal PCI discovery and configuration algorithms. The device and bus numbers for external devices are assigned by the BIOS and/or O/S during boot-time enumeration as normal.
- An EP80579-specific user driver handles interaction with external non-PCI agents attached to the EP80579 through its AIOC-side I/O interfaces. That is, the EP80579 user driver, not BIOS, will “discover” and operate any devices attached to the local expansion bus, for example. Note that since these devices do not implement PCI semantics, it is expected that they will not allocate MMIO regions beyond those already allocated for the PCI view of the appropriate AIOC device.
- The O/S always allocates an aperture in the memory map for any PCI device that defines one or more BARs, even if the device is unknown to the O/S at discovery.

The PCI abstraction that the AIOC provides for its devices is primarily a **software** abstraction for the purposes of configuration; the AIOC itself does **not** contain PCI devices.

### 3.7.1 Overview

The EP80579 integrates the AIOC and memory controller into the PCI fabric as [Figure 3-3](#) describes. This figure presents a **logical** view of the system.

**Figure 3-3. Attaching the AIOC to the CMI PCI Fabric (Logical Perspective)**

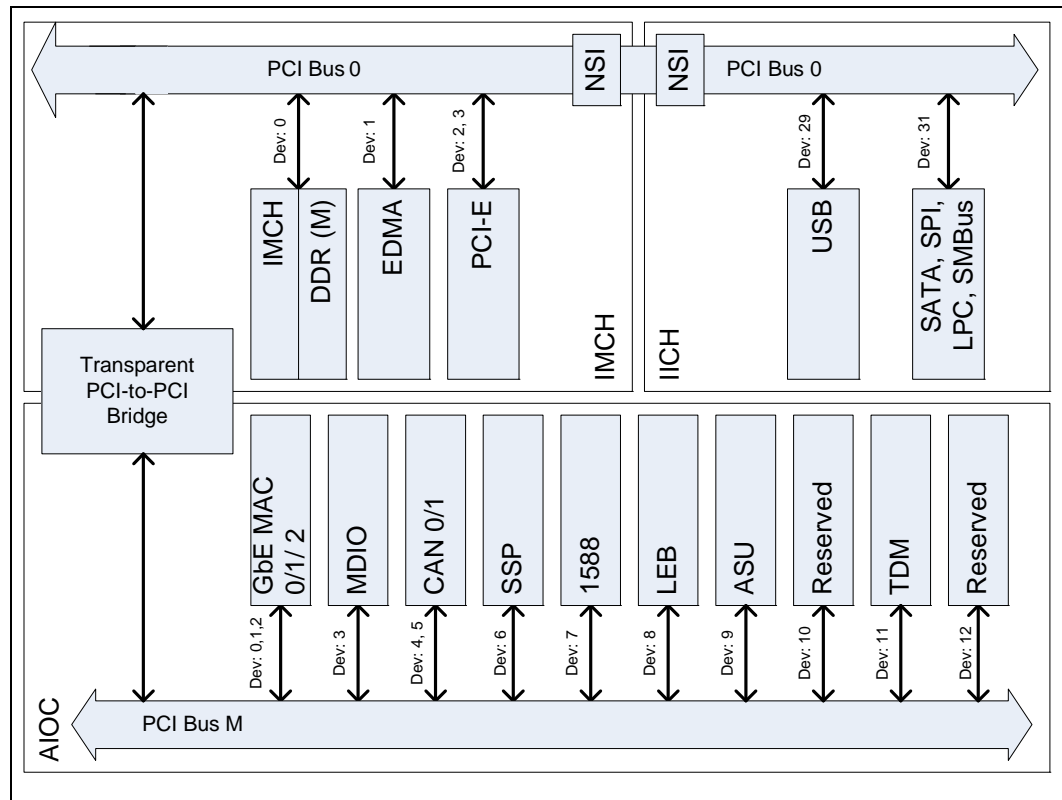

In this figure, PCI bus 0 originates in the IMCH and reaches internal IMCH PCI devices through internal paths. Bus 0 is bridged into the IICH via an NSI interconnect and into the AIOC. The memory controller materializes internally to the IMCH as device 0 of PCI bus 0. The internal transparent bridge materializes the devices for the AIOC through a bridged hierarchy as Figure 3-4 illustrates. In this hierarchy, a Transparent PCI-to-PCI bridge appear on PCI bus 0 with the remaining AIOC devices materializing behind the bridge on PCI bus M<sup>1</sup>.

### 3.7.2 Device Tree

This section describes how the devices on the EP80579 die map onto the PCI device tree. In general, the EP80579 exposes the structures and sub-blocks that Section 3.7.1 describes through PCI devices that materialize behind a transparent bridge on bus 0. Figure 3-4 presents an overview of the device tree for on-die EP80579 software-visible sub-blocks (see also Figure 13-1, “Bus 0 Device Map” on page 348).

Figure 3-4. Overview of PCI infrastructure for On-die Devices

As mentioned earlier, AIOC devices materialize on bus “M” behind a bridge on PCI bus 0 where the IA BIOS or O/S assign the secondary bus number “M” at discovery.

Devices can request space in the system memory and I/O address maps through BARs in the configuration header. In general, the EP80579 materializes most device control and status registers in memory-mapped regions allocated by a BAR. The only exception

1. The IA BIOS and/or O/S assigns the specific bus number during PCI discovery and enumeration.

lies in the standard PCI configuration, status, and capability registers that PCI requires which materialize only in PCI configuration space. The AIOC devices that lie behind the bridge allocate by either the BIOS or OS to their regions of address and I/O space within a contiguous region of address space that the bridge claims. It is assumed that system software configures the aperture for the bridge to be large enough to cover all of the address space that the devices behind the bridge request.

The remainder of this section summarizes the device tree that the EP80579 implements. This summary includes a mapping between PCI devices and the EP80579 blocks along with the value of the device ID, class code, and a summary of the resources (i.e., registers, memory, etc.) that each device requests.

Table 3-9 summarizes the PCI devices that the IMCH and IICH materialize.

**Table 3-9. IMCH and IICH PCI Device Summary**

| Device Name           | EP80579 Units | PCI                |  |  | SKU ID Number   | Resources <sup>a</sup>                           |
|-----------------------|---------------|--------------------|--|--|-----------------|--|
|                       |               | B/D/F <sup>b</sup> | BSP <sup>c</sup>   | Device ID  |                 |  |
| Memory Controller Hub | IMCH          | 0 / 0 / 0          | 060000h  | 5020h  | 1,2,3,4,5,6,7,8 | MBAR (4KB and 4KB)                               |
| Error Reporting       | IMCH          | 0 / 0 / 1          | FF0000h  | 5021h  | 1,2,3,4,5,6,7,8 |  |
| EDMA                  | EDMA          | 0 / 1 / 0          | 088000h  | 5023h  | 1,2,3,4,5,6,7,8 | MSI, MBAR (4KB)                                  |
| PCI-Ex Port 0         | PEA0          | 0 / 2 / 0          | 060400h  | 5024h  | 1,2,3,4,5,6,7,8 | PM, MSI  |
| PCI-Ex Port 1         | PEA1          | 0 / 3 / 0          | 060400h  | 5025h  | 1,2,3,4,5,6,7,8 | PM, MSI  |
| PCI-to-PCI Bridge     | IMCH          | 0 / 4 / 0          | 060400h  | 5037h  | 1,2,3,4,5,6,7,8 |  |
| USB 1.1 Controller    | USB1.1        | 0 / 29 / 0         | 0C0300h  | 5033h  | 1,2,3,4,5,6,7,8 | IOBAR (32B)                                      |
| USB 2.0 Controller    | USB2.0        | 0 / 29 / 7         | 0C0320h  | 5035h  | 1,2,3,4,5,6,7,8 | PM, MBAR (1KB)                                   |
| LPC/SPI               | LPC/SPI       | 0 / 31 / 0         | 060100h  | 5031h  | 1,2,3,4,5,6,7,8 | IOBAR (128B, 64B)                                |
| SATA                  | SATA          | 0 / 31 / 2         | 01018Ah,<br>010601h,<br>010401h,<br>010401h <sup>d</sup> | 5028h,<br>5029h,<br>502Ah,<br>502Bh <sup>e</sup> | 1,2,3,4,5,6,7,8 | PM, MSI, IOBAR (8B, 8B, 4B, 4B, 16B), MBAR (1KB) |

- a. "MBAR" is a memory space BAR, "IOBAR" is an I/O space BAR, "PM" is a power management capability, "MSI" is an MSI capability, and "ST" is an EP80579 signal target capability.  
b. PCI bus number, device number, and function number.  
c. PCI base class code, subclass code, and programming interface PCI configuration register values.  
d. These device IDs are reserved for future SKUs.  
e. The size of the region that the 0-256MB MBAR requests is a multiple of 32MB between 0MB and 256MB (inclusive) based on reset-time platform configuration.

A summary of the registers, memory-mapped, and I/O-mapped resources that [Table 3-9](#) and [Table 3-10](#) identify can be found in [Section 7.0, "Register Summary"](#). Detailed descriptions of these resources can be found in the chapters that cover the relevant block.

### 3.7.3 Materializing Device Structures

The EP80579 exposes AIOC resources through standard PCI abstractions: configuration spaces, memory-mapped I/O spaces, and I/O spaces.

Access to MMIO and I/O spaces are accessed through memory and I/O read/write instructions, respectively. The addressing of these spaces for a given device depends on the specific mapping that the PCI configuration header establishes through BARs.

PCI defines two mechanisms for accessing the 256B of each device/function configuration registers located in PCI configuration space.

- PCI Mechanism: The header is accessed using 1-, 2-, or 4-byte IN and OUT instructions that access the PCI configuration address and data I/O ports at addresses 0CF8h - 0CFBh and 0CFCh - 0CFFh, respectively, in the IA I/O space. This mechanism allows access only to the 256B PCI-compatible configuration space
- PCI Express\* Enhanced Mechanism: The header is accessed using 1-, 2-, or 4-byte memory accesses to the 256MB region starting at HECBASE (0\_E000\_0000<sub>p</sub> by default). This mechanism allows access to an expanded 4KB configuration space that PCI Express\* defines (the first 256B are, by definition, the PCI-compatible configuration space).

These mechanisms differ in the address space they use to access the header. The PCI mechanism travels through IA I/O space while the PCI Express\* Enhanced mechanism travels through IA memory space. The address format that the mechanisms use is identical to the standard IA platform format that encodes the PCI bus, device, and function numbers along with a register offset or number (see [Section 13.6.0.1, "Offset 0CF8h: CONFIG\\_ADDRESS - Configuration Address Register"](#) and [Section 13.8.4, "Enhanced Configuration FSB Address Format"](#) for details).

For either access method, the hardware in the AIOC that implements the configuration headers must be able to process accesses of the appropriate sizes.

### 3.7.4 PCI Configuration Headers

The PCI specification requires each PCI device to provide a 256B configuration space. The first 64B of this space contains a standard PCI configuration header and the remaining 192B contains any device-specific registers, capabilities records, etc. needed by the function. There are two flavors of configuration headers:

- All non-bridge devices provide a PCI type 0 configuration headers. This form of header is used to represent devices on the PCI fabric.
- All bridge devices provide a PCI type 1 configuration header. This form of header is used to represent bridge devices in the PCI fabric.

Because the AIOC devices are not PCI devices, they do not fully support all PCI configuration header fields<sup>1</sup>. The following tables describe the support in greater detail.

[Table 3-11](#) summarizes the fields in a PCI type 0 header (i.e., header for non-bridge devices) and identifies which fields the EP80579 implements for AIOC devices. The EP80579 hardware implements the appropriate PCI semantics for all supported registers and fields in this table.

---

1. Configuration headers for IMCH and IICH devices follow PCI expectations as these devices are PCI compliant.

**Table 3-11. PCI Configuration Header Support for Type 0 Headers in AIOC Devices (Sheet 1 of 2)**

| Offset           | Register and Field | Bit(s)                     | Supt. <sup>a</sup> | Acc. <sup>b</sup>  | Notes  |   |

| 3Dh       | Interrupt Pin      | 7:0      | Y                  | RO                | Supported in devices that can use INTx <sup>c</sup> .   |
|           |                    |          | N                  | RO                | Not supported in devices that do not use INTx <sup>d</sup> .  |
| 3Eh       | Min_Gnt            | 7:0      | N                  | RO                | Not supported.  |
| 3Fh       | Max_Lat            | 7:0      | N                  | RO                | Not supported.  |

- a. Supported fields provide appropriate PCI semantics. Unsupported fields always return zero on reads unless otherwise noted.
- b. RO and RW access types indicate that the register or field supports read-only access and read/write access, respectively.
- c. AIOC devices that may signal via INTx include GbE, CAN, SSP, and IEEE1588.
- d. AIOC devices that cannot signal via INTx include LEB.
- e. This behavior is a deviation from the PCI specification for only the GbE and a device that can be a bus master.

Table 3-12 summarizes the fields in a PCI type 1 header (i.e., header for bridge devices) and identifies which fields the EP80579 implements. The EP80579 hardware implements the appropriate PCI semantics for all supported registers and fields in this table.

|           |                         | Primary Discard Timeout    | 8                  | N                 | RO    | Not supported.  |
|           |                         | Fast Back-to-Back Enable   | 7                  | N                 | RO    | Not supported.  |
|           |                         | Secondary Bus Reset        | 6                  | N                 | RW    | Not supported.  |
|           |                         | Master Abort Mode          | 5                  | Y                 | RO    | Bridge delivers events that would be master aborts (primarily address decode) as SERR#. |
|           |                         | VGA Enable                 | 3                  | N                 | RW    | Not supported.  |
|           |                         | ISA Enable                 | 2                  | N                 | RW    | Not supported.  |
|           |                         | SERR# Enable               | 1                  | N                 | RW    | Not supported.  |
|           |                         | Parity Error Response      | 0                  | N                 | RW    | Not supported.  |

- Supported fields provide appropriate PCI semantics. Unsupported fields always return zero on reads unless otherwise noted and need not provide PCI semantics.
- RO and RW access types indicate that the register or field supports read-only access and read/write access, respectively.
- This is a known deviation from the PCI specification since the bridge can be a bus master.
- This is a deviation from the PCI specification since this register should be RO on bridges that do not support prefetchable regions. The registers are RW for compatibility with the base IP. Software is expected to set these fields to indicate an empty region since no secondary-side devices (i.e., bus M) request prefetchable memory.

For additional details on the headers for AIOC devices, see [Section 35.3.1, "Description of PCI Configuration Header Space"](#).

The specific portion of the 256B PCI configuration space that is active in a device depends on the needs of the specific device. In general, a device requires far less than 256B of storage to implement a typical configuration space. Regions of the 256B configuration space that are not required are reserved and need only support default behavior compliant with the PCI specification:

All PCI devices must treat Configuration Space write operations to reserved registers as no-ops; that is, the access must be completed normally on the bus and the data discarded. Read accesses to reserved or unimplemented registers must be completed normally and a data value of 0 returned.

§ §

## 4.0 Signaling

### 4.1 Overview

This chapter presents an overview of the inter-agent signaling mechanisms supported along with the implications on transaction ordering necessary to support producer/consumer software algorithms. This chapter concentrates primarily signaling for functional, not error, purposes while [Section 5.0, “Error Handling”](#) provides additional discussion on error signaling.

The EP80579 signaling model operates in a system-on-a-chip environment and must blend the signaling architectures of many disparate components into a unified whole.

- Allow signaling between IA agents (i.e., the IA-32 core, IMCH, IICH, and external PCI-Express-attached devices) and AIOC agents.
- Support producer/consumer relationships between agents in the IA or AIOC.
- Provide compatibility with existing IA signaling mechanisms for internal IMCH/IICH agents and external devices.
- Provide compatibility with IA platform signaling semantics and abstractions.

There are two tightly related parts to the signaling model:

- The *signaling mechanism* determines how takes a signal from a source agent, performs any necessary translation, and delivers it to a target agent in a form the target can understand.
- The *ordering mechanism* determines how orders a given signal from a source agent with respect to the data stream that the source agent produces to meet ordering requirements.

**Figure 4-1. Logical Overview of Signaling Architecture**

The IA complex attaches to the AIOC through a transparent PCI-to-PCI Bridge. Within the AIOC, the “Signal Bridge” block in [Figure 4-1](#) represents the hardware in the AIOC, that converts signaling between the AIOC and IA domains and presents the appropriate abstractions to agents on either side of the bridge.

### 4.1.1 Terminology and Conventions

Throughout this section, we use the following terminology:

- **Global visibility:** An operation is said to be globally visible when all side-effects of the operation are visible to every observer in the system. For example, a write to some resource (e.g., memory location, control register, etc.) R achieves global visibility when a read of R by all other agents is guaranteed to return the new value.
- **Ordering:** Ordering refers to the order in which signals and/or memory accesses to different locations must reach global visibility to ensure some behavior. Note that this excludes the “ordering” necessary to prevent data hazards which are accesses to the same location.
- **Signal:** A message sent between agents to indicate some condition of interest. A signal may be an interrupt, a memory write, etc. This section uses the term when the specific transport medium is not important.

## 4.2 Existing Signaling Capabilities

There are several agents in the EP80579 that can be both the source and the target of a “signal”: the IA-32 core and accelerators in the AIOC. In addition, there are several other agents in the EP80579 that can be the source of a signal: devices in the IMCH or IICH, the error reporting hardware, the Gigabit Ethernet MAC, the SSP interface, the CAN interfaces, the IEEE 1588 interface, externally-attached PCI-Express devices, and externally-attached local expansion bus devices (via GPIO or INTx interrupts). This section summarizes the existing signaling capabilities of each of these agents.

When discussing signaling, this section classifies all signals into one of two general categories:

- *Ordered* signals must maintain a particular relationship with the data stream. For example, a MAC signals a CPU with an ordered signal after the MAC finishes writing inbound packet data to memory.
- *Unordered* signals need not maintain a particular relationship with the data stream. For example, memory interface hardware signals a CPU with an unordered signal when the interface encounters an uncorrectable memory error.

Signals of either type may participate in producer/consumer operations between agents; however, the operation can use only ordered signals if the producer/consumer operation involves the data stream<sup>1</sup>. Finally, note that this classification refers specifically to the data stream; signals may also be ordered with respect to other events (e.g., data being available in a local device buffer).

---

1. For producer/consumer operation to work correctly, software and hardware must be able to establish ordering relationships between various events in the operation. Such a relationship cannot be established between the data stream and a signal that is unordered with respect to the data stream.

## 4.2.1 IA-32 core/Platform

The IA-32 core supports two inbound signaling mechanisms that the EP80579 can use to accept signals from other agents: a legacy interrupt (INTx) and a message-signaled interrupt (MSI). The INTx mechanism encodes an interrupt on one of four out-of-band interrupt signals that drive interrupt controllers in the IA platform. The MSI mechanism encodes an interrupt as an in-band 32-bit write to a memory-mapped location. When the platform observes a write to an MSI location, it generates an interrupt to the CPU. The operating system or system software specifies, in large part, the data value that travels with an MSI; the device has limited ability to change or modify this value in the PCI MSI model.

The IA platform also supports signaling for errors through events that the platform eventually maps onto interrupts, such as SERR or SMI. [Section 5.0, "Error Handling"](#) discusses these mechanisms in further detail. These mechanisms are not used in functional inter-agent signaling.

### 4.2.1.1 MSI and INTx Signaling

The EP80579 supports both MSI and INTx mechanisms to interoperate with IA platform system software since not all operating systems or devices support MSIs. The PCI configuration header of each device indicates the capabilities of the device (i.e., if it can generate an MSI, which pin it uses in INTx mode, etc.) and also allows system software to specify the signaling mechanism the device should use when the device is capable of both MSI and INTx signaling. Further, when signaling the IA platform, software must tolerate "warts" of the IA signaling model such as spurious interrupts, etc.

For outbound signaling from the IA-32 core to other agents, the EP80579 relies on memory writes to MMIO locations to transport signals or IA can issue an MMIO read to a device CSR.

### 4.2.1.2 GPIO Signaling

The EP80579 provides the ability to configure a subset of its GPIO pins as interrupts. GPIO pins 16-21, 23-25, 27, 28, 30, 31, 33, 34, and 40 can function in either an interrupt mode or as a GPIO. Each of these GPIO pins can be connected to a single input on the APIC when software configures the GPIO as an interrupt. These pins are then available to external devices, such as a device attached to the Local Expansion Bus, for use as signals. The EP80579 handles signals arriving through a GPIO interrupt are handled like all other interrupts connected to the APIC. For additional information, see the GPIO material in [Section 22.0, "General Purpose I/O: Bus 0, Device 31, Function 0"](#).

## 4.2.2 Other Agents

The remaining agents that are relevant to the EP80579 signaling model can only signal in the outbound direction; that is, they only generate signals from the agent into EP80579. These agents operate as follows:

- IMCH, IICH, and externally-attached PCI devices generate IA platform INTx or MSI signals based on PCI device and platform configuration. PCI mechanisms such as SERR can also support error reporting (see [Section 5.0, "Error Handling"](#)).
- Gigabit Ethernet MAC generates a side-band interrupt signal.
- CAN, SSP, and IEEE 1588 Interfaces generate side-band interrupt signals.
- Externally-attached Local Expansion Bus devices generate side-band interrupt signals. These signals are not carried on the Local Expansion bus itself but rather are presented to the IA-32 core through GPIO pins that the system configures to generate signals.

### 4.3 Inter-Agent Signaling

Signals may originate from a number of sources within the system but may only target one of the on-die agents in the EP80579: the IA-32 core or AIOC accelerator. This section considers inter-agent signaling mechanisms available in the EP80579. This material looks at signaling in isolation.

Because the EP80579 integrates devices from several different fabrics, signaling between different agents may require bridge functionality to convert signals between the various existing capabilities that Section 4.2, “Existing Signaling Capabilities” on page 132 describes. Figure 4-2 presents a logical view of the flow of signals through the EP80579.

Figure 4-2. Logical View of Signaling Flow

In this model, a signal originates from a source agent as an in- or side-band signal. Depending on the specific situation, the signal may either reach the destination directly or through a signal bridge. The signal bridge in EP80579 does not provide any mechanism to ensure that a destination agent responds to a given inbound signal. As a result, software must be able to keep up with the signaling rates if catching and processing every signal is a requirement. If software is unable to keep up with the signaling rate, one or more signals can be dropped.

Table 4-1 summarizes the cross product of the combinations of producer and consumer agents that EP80579 supports for signaling between agents. This table identifies the types of signaling allowed as well as any bridging that the EP80579 hardware must provide to support signaling between the indicated agents.

Table 4-1. Supported Inter-Agent Signaling

| Signal Bridging |                                     | On-Die Signal Consumer     |
|-----------------|-------------------------------------|----------------------------|
|                 |                                     | IA-32 core                 |
| Signal Producer | IA-32 core                          | Not Supported <sup>a</sup> |
|                 | IMCH, IICH Devices                  | PCI MSI / INTx via PCI     |
|                 | GigE MAC                            | Side band: PCI MSI / INTx  |
|                 | SSP                                 | Side band: PCI MSI / INTx  |
|                 | CAN                                 | Side band: PCI MSI / INTx  |
|                 | 1588                                | Side band: PCI MSI / INTx  |
|                 | Errors <sup>b</sup>                 | Side band: PCI MSI / INTx  |
|                 | External PCI Express* Device        | PCI MSI / INTx via PCI     |
|                 | External Local Expansion Bus Device | MSI / INTx via GPIO        |

a. Support not required since there is only one such agent in an EP80579.

b. This includes signaling for errors in the memory controller, local expansion bus, etc.

In this table, “:” and “via” indicates bridged and direct paths for the signaling (see Figure 4-2), respectively. All EP80579 hardware that inter-operates with IA platform structures for signaling, such as the signal bridge, operate in IA physical address space. This allows it to access IA platform devices, such as the LAPIC that are accessed via MMIO reads and writes in the PCI L memory region.

The next two sections cover the various signaling scenarios that are represented in the cells of Table 4-1: signaling that travels around the bridge and that is bridged from a side band signal.

### 4.3.1 Signaling that Travels Around the Signal Bridge

For signaling that does not need to travel through the signal bridge, the EP80579 does not require any specific signaling support. In these cases, the signaling occurs over an existing path. For example, an interrupt from a IICH USB controller would travel over the existing IICH INTx or MSI path based on device configuration.

### 4.3.2 Signaling that is Bridged from a Side-Band Source Signal

The majority of signaling scenarios in Table 4-1 that require bridging are conversions between side band signals and a signal that targets the IA-32 core. The EP80579 uses a centralized agent, the signal bridge to perform this conversion. One or more side-band signals arrive at the signal bridge from each AIOC device that is capable of signaling. The bridge is responsible for generating the appropriate outbound signal to either an ASU device or the IA-32 core. Figure 4-3 presents an overview of the signal bridge hardware for a subset of the EP80579 AIOC devices.

Figure 4-3. Signal Bridging

Logically, the signal bridge consists of the MSI and Signal Target capability records from the PCI configuration headers for the AIOC devices. The MSI capability record for a device includes a message address register (mar in Figure 4-3) and Message data register (mdr in Figure 4-3) that indicate the address and data for the MSI as per the PCI definition of this capability. The Signal Target capability record for a device includes a mask that determines how the bridge steers the signal, data which identifies additional signaling data, and a status that indicates which side-band signal(s) has been asserted<sup>1</sup>. The Signal Target capability is a vendor-specific capability record whose format the EP80579 defines.

In the example show in Figure 4-3, side band signals arrive from Gigabit Ethernet MAC and other AIOC agents. These agents correspond to AIOC PCI devices. Here, the GbE agent generates a signal that the signal bridge delivers as an MSI to IA based on the

1. The status is not shown in Figure 4-3.

configuration in the MSI and Signal Target capability records in the PCI configuration header. These records allow the signal bridge to determine how to handle an inbound signal from a device.

All side band signals from a given source are collected at the signal bridge. For example, a source may provide interrupt lines and error condition lines that cause the EP80579 to send a signal when any one is asserted. Sets of side band signals are then associated with each AIOC PCI device that can signal. When a given side band signal asserts, the signal bridge looks up the MSI and Signal Target capability records in the PCI configuration header that corresponds to the device. These resources tell the signal bridge how and where to deliver the outbound signal:

- If the masks in the Signal Target capability record indicate the signal should be delivered to the IA-32 core, the signal bridge sends an MSI or INTx signal to the IA-32 core.
  - If the PCI configuration header selects MSI messaging, the signal bridge generates an MSI transaction from the device that generates the signal to the IA-32 core in accordance with the MSI capability record.
  - If the PCI configuration header selects INTx messaging, the signal bridge generates an INTx transaction to the IA-32 core.

The status register in the Signal Target Capability provides the state of the side-band signals associated with a given AIOC PCI device to help software disambiguate the source of the signal.

#### 4.3.2.1 Targeting the IA-32 core with a Bridged Signal

To remain compatible with existing IA software stacks, EP80579 hardware supports the PCI MSI and legacy INTx signaling mechanisms into the CMI in response to signals targeting the IA-32 core.

- MSI enable field selects the signaling mechanism an MSI-capable device uses:
  - INTx legacy mode.
  - MSI mode.
- MSI capability record specifies how IA system software wants MSI-capable devices to signal the IA-32 core through a message address and message data register.
- Interrupt pin and line registers specify the interrupt pin and line that the hardware uses for legacy INTx mode.
- Interrupt disable bit in the command register specifies whether or not the device generates any signals.

Based on the PCI abstraction, these are *per-device* fields that are *logically* associated with a given device and that all devices that can signal the IA-32 core must implement.

Software is free to mix signal delivery mechanisms at the device level. For example, it may configure the EP80579 such that the Gigabit Ethernet MACs signal through MSIs while the remaining AIOC devices signal through INTx.

When device *X* signals the IA-32 core, it consults the PCI configuration header for device *X* to determine how to deliver the signal to IA (i.e., via MSI or INTx). For signaling via MSI, the header identifies the address and data value in the MSI transaction. Hardware builds the 32-bit data value for the MSI transaction from the contents of the PCI MSI Message Data Register,  $mdr_x$ , according to the PCI semantics. Specifically, the data value sent in the MSI to IA is:

- Bits 31:16 are zero.
- Bits 15:0 are  $mdr_x$ , the value of the PCI MSI Data Register in the PCI configuration header of the source device<sup>1</sup>.

The address is given directly by the PCI MSI Message Address Register, `mar`. Finally, the source of the MSI transaction is set to the bus/device/function number of the device that generates the signal.

For signaling via INTx, the header identifies the interrupt line and pin that the EP80579 should use. In this case, hardware generates the appropriate transactions for INTx upstream into the CMI. Since the INTx mechanism cannot transport any information beyond the fact that a signal occurred, the EP80579 needs to expose enough device state to the software stack, via device-specific control register(s), to allow software to be able to determine both the source and cause of the interrupt. Such state would be in addition to the generic interrupt state that each PCI device provides through its PCI configuration header as per the PCI specification

To integrate with the existing IMCH/IICH, the signal bridge in the EP80579 will generate four INTx signals that it tracks based on the interrupt state of the blocks from the AIOC that can generate signals. These four INTx signals are provided to interrupt hardware in the IA platform hardware where they are ORed with similar signals from other agents and converted into the appropriate signaling to the IA-32 core. This hardware will also provide a signal back to the IMCH that indicates when the local INTx state can be deasserted.

In addition to generating any transaction(s) necessary to send the signal to the IA, the AIOC must preserve the semantics of PCI interrupts and signals with respect to the state in the PCI configuration headers for the AIOC devices.

- Signaling to the IA-32 core by a device should operate in accordance with the MSI mode and configuration in the MSI capability record.
- Signaling to the IA-32 core by a device must be disabled when the interrupt disable bit in the PCI command register is set
- The interrupt status bit in the PCI status register should reflect the status of an INTx signal.

This preserves the PCI abstraction for AIOC devices.

## § §

---

1. This assumes that the device requests exactly one message in the PCI MSI capability record [PCI\_3].

## 5.0 Error Handling

---

### 5.1 Overview

This section presents an overview of the error handling mechanisms that the EP80579 provides. The intent of this discussion is to provide a broad background to error handling on the chip. Register definitions and other error handling details can be found in the discussions of the relevant units throughout this document.

### 5.2 EP80579 View of Error Reporting

This section describes the guiding principles on which the error logging and reporting registers are based for the EP80579. For the purposes of this discussion, an “error” is an exceptional condition that is beyond the control of the EP80579 hardware or software and might result in data corruption or data loss. This definition does not cover “functional” errors that are not beyond the control of the EP80579. For example, this section discusses double-bit ECC errors as they involve data corruption that occurs through no overt action of the EP80579; it does not cover an underflow error on a ring since this is a functional condition that can be managed in software to avoid data loss.

#### 5.2.1 Hardware Capabilities

With respect to their error handling capabilities, the blocks on the EP80579 can be divided into three groups: the IA blocks (including the IA-32 core, IMCH exclusive of the memory interface, IICH), the memory controller interface, and the AIOC blocks. Generally speaking,

- The IA blocks (see [Section 5.3, “Error Reporting by the IMCH” on page 141](#) and [Section 5.4, “Error Reporting by the IICH” on page 149](#)) use the FERR/NERR and PCI error reporting infrastructures.
- The memory controller block (see [Section 5.5, “Error Reporting by the System Memory Controller” on page 153](#)) uses the FERR/NERR error reporting infrastructure.
- The AIOC blocks (see [Section 5.6, “Error Reporting by AIOC Devices” on page 155](#)) use their existing error reporting infrastructures that are “bridged” into the IA-32 core to report errors to IA through PCI signals (i.e., INTx or MSI depending on device configuration). These blocks do not support other PCI error reporting capabilities such as SERR or the IMCH FERR/NERR architecture.

This organization allows an EP80579 system to use standard IA platform reporting abstractions and algorithms throughout the IA portion of the chip (including the memory controller). AIOC devices then use PCI INTx or MSI signaling to present their error handling within the IA infrastructure. Utilizing signaling in this fashion implies that the responsibility for error handling in AIOC devices resides with Intel provided AIOC device drivers in the EP80579 software stack.

The EP80579 hardware, where appropriate, supports two general capabilities for error handling. The first is support for data “poisoning” to propagate errors through the chip. The second is support for mechanisms to allow software to inspect the cause of the error.

To allow software to inspect the error, each unit in the EP80579 that is capable of detecting errors typically provides hardware support to:

- Log sufficient information for software to determine what the error was along with relevant details on the error.
- Disable error detection and reporting.
- Report if more than one error occurred. At a minimum, the unit will note that a second error occurred. Optionally, a unit may gather additional information on subsequent errors such as the type(s) of errors or other relevant details.

A given unit need not support all of these capabilities. To illustrate these capabilities, consider the EP80579 DRAM interface. DRAM on the EP80579 is protected by ECC, so, on a read with a double-bit error, the memory controller reports an error. The memory controller can poison the data return value to inform future consumers of the data that the data is bad.

For software, registers in the memory controller provide the ability to mask this error along with logging registers that captures the address that was being read when the error was encountered. On an unmasked double-bit error, the logging register captures the address and the memory controller signals the IA-32 core through the FERR/NERR infrastructure. The error address register is locked at this point, so subsequent errors will not overwrite it until software handles the error and unlocks the registers by writing a register to clear the error condition. The memory controller provides a “next error” register that can capture information on other unmasked errors that occur before software clears the double-bit error condition.

In general, the CMI will attempt to route requests based on their understanding of the address space layout of the platform (that is, the amount of installed physical DRAM, attached PCI Express\* devices, etc.). There are several tables throughout the EAS that define how various parts of the chip handle this routing task:

- [Section 10.1, “Overview”](#) and [Section 10.2, “IMCH Responses to EDMA Transactions”](#) describes how the IMCH responses to transactions from the EDMA engine.
- The memory controller does not perform bounds checking on addresses, error handling behavior is determined by the upstream agents that pass the request to the memory controller as [Section 5.5.1, “Handling Out-of-Bounds Addresses”](#) on [page 154](#) describes.

The IA portion uses the standard IA mechanisms to handle cases where this routing encounters errors (e.g., accessing an unpopulated region of memory). These cases cause aborts and are escalated through the normal error handling paths. On errors in requests arriving from the memory target, the IMCH will drop writes (i.e., not forward them into the IMCH) and poison data returns for reads through the appropriate push/pull data error signals. These error conditions are reported through IMCH error reporting registers.

## 5.2.2 Software Usage Model

The software responsibilities for error handling are split between BIOS and system/application software. The manner in which the software uses the capabilities that the hardware provides depends on the specific software stack under consideration.

In general, BIOS does not establish a usage model for error handling. Its primary responsibility is to configure the error handling registers throughout the EP80579 in a manner consistent with the needs of system and application software. The EP80579 reference BIOS provides this level of support. However, in general, a BIOS implementation may also log information on error events reported via SMI<sup>1</sup>. In this case, BIOS populates data structures in SMBIOS<sup>2</sup> that an operating system can later retrieve.

Generally speaking, the software is more interested in seeing an error rather than the specific location where it is sent. The usage model from the system or application perspective depends on the manner in which the hardware reports the event to the system along with the specific error event. There are two general types of reporting that one can consider: through a kernel-trapped signal and through a non-kernel-trapped signal. A particular error event need be reported through at least one of these mechanisms.

When the hardware reports an error event through a signal that the OS kernel handles on its own (e.g., MCERR, SERR, etc.), the operating system takes whatever corrective action it implements for the signal: bug check, panic, halt, reboot, event logging, clean up and continue, etc. In this case, the OS kernel establishes the usage model. This approach is only applicable to the IA and memory controller blocks since the AIOC devices can only report error events through INTx or MSI signals that the OS kernel passes off to the appropriate driver software rather than handle in the kernel.

When the hardware reports an error event error through a signal that the software outside of the OS kernel handles on its own (e.g., INTx, MSI, etc.), it is the responsibility of driver or other non-kernel software to take corrective action. All AIOC agents fall into this category since their hardware uses only INTx or MSI for error reporting. In this case, it is the responsibility of the driver software to establish the error handling usage model. Typically, the action the driver takes in response to an error event will match those taken by the OS kernel: panic, clean up and continue, etc.

## 5.3 Error Reporting by the IMCH

See [Section 14.2, “Exception Handling”](#) and [Section 14.3, “Error Conditions Signaled”](#) for further discussion on IMCH error handling.

### 5.3.1 Overview of the First and Next Error Architecture

The IMCH provides a “first” and “next” error architecture wherein errors accumulate locally in unit-level first/next error registers that the IMCH aggregates into global first/next error registers. Once a unit records an error event in its “first” error register, it will record all subsequent errors in its “next” error register until software clears the error condition in the first error register. The error events are then classified into “fatal” and “non-fatal” groups for reporting through the global first and next error registers. The architecture allows software to mask individual error events at the unit level. In addition, through per-unit registers, software can configure the hardware to report the error event through IA SMI, SCI, SERR, or MCERR signals.

- 
1. This approach only works for error events that the EP80579 can report through SMI. Specifically, this approach would not work for error events from AIOC agents which cannot report through SMI in the EP80579.
  2. System Management BIOS (SMBIOS) is a specification to lay out data structures and access methods in a BIOS which provides for storage and retrieval of information about the PC in question

The actions taken by the hardware in response to an error event depends on the manner in which software has configured the IMCH to report the error. For unmasked events that the IMCH signals through SMI, SCI, or SERR, the IMCH presents the error to the IA-32 core indirectly through the IICH. In these cases, the IMCH sends an error message to the IICH (via NSI) that IICH interrupt logic handles by signaling the IA-32 core through an interrupt. For unmasked events that the IMCH signals through MCERR, the IMCH directly presents the error to the IA-32 core (via FSB). In this case, the IMCH directly signals the IA-32 core through the MCERR protocol on the FSB.

After receiving the message, software will query the global IMCH error registers (see Section 5.3.2, “Global Error Events”) to determine which IMCH unit is responsible for the error. With that information, software can query the unit that generated the event to determine the specific cause.

### 5.3.2 Global Error Events

Table 5-1 summarizes the error events that the IMCH captures in its GLOBAL\_FERR and GLOBAL\_NERR error registers (see Section 16.2.1.12, “Offset 40h: GLOBAL\_FERR - Global First Error Register” and Section 16.2.1.13, “Offset 44h: GLOBAL\_NERR - Global Next Error Register”). Each of these events rolls up one or more unmasked error events from an individual IMCH unit. To determine the specific error event that causes a signal, software consults the unit-specific error registers that Table 5-1 indicates. The global registers provide summary information only; masking takes place at the unit level.

Table 5-1. Summary of IMCH Global Error Conditions

| Event                                    | Fatality <sup>a</sup> | Unit-Specific Registers       | Notes  |
|--|-----------------------|-------------------------------|--|
| DRAM Controller Fatal Error              | Fatal                 | DRAM_FERR, DRAM_NERR          | Fatal error in DRAM interface.                                 |
| FSB Fatal Error                          | Fatal                 | FSB_FERR, FSB_NERR            | Fatal error on internal CPU/IMCH FSB interface.                |
| NSI Fatal Error                          | Fatal                 | NSI_FERR, NSI_NERR            | Fatal error on internal IMCH/IICH NSI interface.               |
| DMA Fatal Error                          | Fatal                 | EDMA_FERR, EDMA_NERR          | Fatal error from DMA controller.                               |
| PCI Express* Port A1, A0 Fatal Error     | Fatal                 | PEAFERR, PEANERR <sup>b</sup> | Fatal error from PCI Express* Port A1 (PEA1) or A0 (PEA0).     |
| Buffer Unit Non-Fatal Error              | Non-Fatal             | BUF_FERR, BUF_NERR            | Non-fatal error in posted memory write buffer.                 |
| DRAM Controller Non-Fatal Error          | Non-Fatal             | DRAM_FERR, DRAM_NERR          | Non-fatal error in DRAM interface.                             |
| FSB Non-Fatal Error                      | Non-Fatal             | FSB_FERR, FSB_NERR            | Non-fatal error on internal CPU/IMCH FSB interface.            |
| NSI Non-Fatal Error                      | Non-Fatal             | NSI_FERR, NSI_NERR            | Non-fatal error on internal IMCH/IICH NSI interface.           |
| DMA Non-Fatal Error                      | Non-Fatal             | EDMA_FERR, EDMA_NERR          | Non-fatal error from DMA controller.                           |
| PCI Express* Port A1, A0 Non-Fatal Error | Non-Fatal             | PEAFERR, PEANERR <sup>b</sup> | Non-fatal error from PCI Express* Port A1 (PEA1) or A0 (PEA0). |

- a. Fatal versus non-fatal classification for reporting through GLOBAL\_FERR and GLOBAL\_NERR.
- b. Each port has its own independent PEAFERR and PEANERR registers in the PCI configuration space for the port controller device.

Section 5.3.3, Section 5.3.4, Section 5.3.5, Section 5.3.6, Section 5.3.7, and Section 5.3.8 discuss the specific per-unit events that the IMCH hardware captures and rolls up into the global conditions that Table 5-1 lists.

### 5.3.3 Unit-Level Errors from the Buffer Unit

The IMCH buffer unit captures error events from the memory system coherent Posted Memory Write Buffer (PMWB) in the BUF\_FERR and BUF\_NERR registers. The buffer unit reports an error event to the IA-32 core through SCI, SMI, SERR, or MCERR signals based on the settings in the BUF\_SCICMD, BUF\_SMICMD, BUF\_SERRCMD, and BUF\_MCERRCMD registers. Software can independently configure the specific signal that each buffer unit error event uses.

Table 5-2 summarizes the error conditions that the PMWB can generate.

**Table 5-2. Summary of IMCH Buffer Unit Error Conditions**

| Event                            | Type          | Fatality <sup>a</sup> | Reports via <sup>b</sup> | Notes  |
|----------------------------------|---------------|-----------------------|--------------------------|--|
| DRAM to PMWB Parity              | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Parity error detected on read from DRAM agent by PMWB.               |
| System Bus or I/O to PMWB Parity | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Parity error detected on write to PMWB from system bus or I/O agent. |
| PMWB to System Bus Parity        | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Parity error detected on data to the system bus.                     |
| PMWB to DRAM Parity              | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Parity error detected when PMWB is flushed to DRAM.                  |

a. Fatal versus non-fatal classification for reporting through GLOBAL\_FERR and GLOBAL\_NERR.

b. Based on BUF\_SCICMD, BUF\_SMICMD, BUF\_SERRCMD, and BUF\_MCERRCMD register values.

Table 5-3 summarizes the capabilities of the IMCH buffer unit error handling for each of the features that the unit is expected to provide.

**Table 5-3. Summary of IMCH Buffer Unit Error Reporting Capabilities**

| Feature                              | Implementation  |
|--------------------------------------|---|
| Enabling and Masking Error Reporting | The BUF_EMASK (see Section 16.2.1.29, "Offset 74h: BUF_EMASK - Memory Buffer Error Mask Register"), BUF_SCICMD, BUF_SMICMD, BUF_SERRCMD, and BUF_MCERRCMD registers enable and mask error reporting. The PCICMD register (see Section 16.2.1.3, "Offset 04h: PCICMD - PCI Command Register") also enables and masks SERR signals. |
| Logging Details                      | IMCH does not capture error logging information beyond the event flags in the BUF_FERR, BUF_NERR and PCISTS (see Section 16.2.1.4, "Offset 06h: PCISTS - PCI Status Register") registers.   |
| Reporting Multiple Errors            | The BUF_NERR register captures "next" errors. This register indicates up to one additional error (beyond the first error) of each type.   |
| Data Poisoning                       | IMCH passes along error information to poison data.   |

### 5.3.4 Unit-Level Errors from the DRAM Interface

These errors include the error events reported by the memory controller, see Section 5.5, "Error Reporting by the System Memory Controller" on page 153 for additional details.

### 5.3.5 Unit-Level Errors from the FSB Interface

The FSB interface captures error events from the FSB interface that connects the IA-32 core to the IMCH in the FSB\_FERR and FSB\_NERR registers. The FSB interface reports an error event to the IA-32 core through SCI, SMI, SERR, or MCERR signals based on the settings in the FSB\_SCICMD, FSB\_SMICMD, FSB\_SERRCMD, and FSB\_MCERRCMD registers. Software can independently configure the specific signal that each buffer unit error event uses.

Table 5-4 summarizes the error conditions that the FSB can generate.

**Table 5-4. Summary of IMCH FSB Error Conditions**

| Event                            | Type          | Fatality <sup>a</sup> | Reports via <sup>b</sup> | Notes  |
|----------------------------------|---------------|-----------------------|--------------------------|--|
| Outgoing I/O Data Parity         | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Parity error on outgoing data from I/O subsystem.                    |
| Outgoing Memory Data Parity      | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Parity error on outgoing data from memory subsystem.                 |
| FSB BINIT# Detected              | Uncorrectable | Fatal                 | N/A <sup>c</sup>         | Electrical high-to-low transition of BINIT#.                         |
| FSB MCERR# Detected              | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Electrical high-to-low transition of MCERR# when CMI is not driving. |
| Non-DRAM Lock Error              | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Lock detected to memory space that does not map to DRAM.             |
| FSB Addr. Above TOM/TOLM         | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Address detected above TOM/TOLM.                                     |
| FSB Data Parity                  | Uncorrectable | Non-Fatal             | N/A <sup>c</sup>         | Parity error on FSB detected.  |
| FSB Addr. Strobe Glitch Detected | Uncorrectable | Fatal                 | N/A <sup>c</sup>         | Glitch detected on FSB address strobe.                               |
| FSB Data Strobe Glitch Detected  | Uncorrectable | Fatal                 | N/A <sup>c</sup>         | Glitch detected on FSB data strobe.                                  |
| FSB Request/Addr Parity          | Uncorrectable | Fatal                 | N/A <sup>c</sup>         | Parity error on FSB address or request signals.                      |

- a. Fatal versus non-fatal classification for reporting through GLOBAL\_FERR and GLOBAL\_NERR.
- b. Based on FSB\_SCICMD, FSB\_SMICMD, FSB\_SERRCMD, and FSB\_MCERRCMD register values.
- c. Although the IMCH supports these errors, the EP80579 will not ever generate them since its on-die FSB implementation does not support BINIT# or parity.

Table 5-5 summarizes the capabilities of the FSB error handling for each of the features that the unit is expected to provide.

**Table 5-5. Summary of IMCH FSB Error Reporting Capabilities**

| Feature                              | Implementation  |
|--------------------------------------|---|
| Enabling and Masking Error Reporting | The FSB_EMASK FSB_SCICMD, FSB_SMICMD, FSB_SERRCMD, and FSB_MCERRCMD registers enable and mask error reporting. The PCICMD register also enables and masks SERR signals. |
| Logging Details                      | FSB does not capture error logging information beyond the event flags in the FSB_FERR, FSB_NERR and PCISTS  |
| Reporting Multiple Errors            | The FSB_NERR register captures “next” errors. This register indicates up to one additional error (beyond the first error) of each type.                                 |
| Data Poisoning                       | FSB passes along error information to poison data.  |

Although the IMCH supports all of the errors Table 5-4 lists with the features in Table 5-5, the EP80579 implementation does not take full advantage of these capabilities since its FSB implementation does not support all of the features necessary.

For additional discussion on the IMCH responses to transactions from the FSB interface, see [Section 10.1, "Overview"](#).

### 5.3.6 Unit-Level Errors from the NSI

The IMCH hardware captures error events from the NSI interface that connects the IMCH to the IICH in the NSI\_FERR and NSI\_NERR registers. The NSI interface reports an error event to the IA-32 core through IA SCI, SMI, SERR, or MCERR signals based on the settings in the NSI\_SCICMD, NSI\_SMICMD, NSI\_SERRCMD, and NSI\_MCERRCMD registers. Software can independently configure the specific signal that each buffer unit error event uses.

Table 5-6 summarizes the error conditions that the NSI can generate.

**Table 5-6. Summary of IMCH NSI Error Conditions**

| Event                            | Type          | Fatality <sup>a</sup> | Reports via <sup>b</sup> | Notes   |
|----------------------------------|---------------|-----------------------|--------------------------|---|
| Unsupported Request              | Uncorrectable | Fatal, Non-Fatal      | SCI, MCERR, SMI, or SERR | Unsupported request detected.   |
| Malformed TLP                    | Uncorrectable | Fatal, Non-Fatal      | SCI, MCERR, SMI, or SERR | Malformed TLP detected.   |
| Receiver Overflow                | Uncorrectable | Fatal                 | SCI, MCERR, SMI, or SERR | Overflow detected in posted, non-posted, or completion upstream queue.  |
| Unexpected Completion            | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Completion received that does not correspond to an outstanding request. |
| Completer Abort                  | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Completer abort detected.   |
| Completion Timeout               | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Request not completed within timeout window.                            |
| Poisoned TLP                     | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Portion of TLP data payload was corrupt.                                |
| Data Link Protocol Error         | Uncorrectable | Fatal                 | SCI, MCERR, SMI, or SERR | Error detected in data link protocol.                                   |
| Replay Timer Timeout             | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Replay timer expired.   |
| REPLAY_NUM Rollover              | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Retry buffer replay counter rolled over.                                |
| Bad DLLP CRC                     | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Calculated DLLP CRC did not equal received value.                       |
| Bad TLP CRC                      | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Calculated TLP CRC did not equal received value.                        |
| Receiver Error                   | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Packet framing error.   |
| Received Fatal Error Message     | Uncorrectable | Fatal                 | SCI, MCERR, SMI, or SERR | Fatal error message received over NSI link.                             |
| Received Non-Fatal Error Message | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Non-fatal error message received over NSI link.                         |

**Table 5-6. Summary of IMCH NSI Error Conditions**

| Event                              | Type          | Fatality <sup>a</sup> | Reports via <sup>b</sup> | Notes   |
|------------------------------------|---------------|-----------------------|--------------------------|---|
| Received Correctable Error Message | Correctable   | Non-Fatal             | SCI, MCERR, SMI, or SERR | Correctable error message received over NSI link. |
| Parity Error on Data from Core     | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Parity error detected on data received from core. |
| Link Down                          | Uncorrectable | Fatal                 | SCI, MCERR, SMI, or SERR | Link transitioned from DL_UP to DL_DOWN.          |

a. Fatal versus non-fatal classification for reporting through GLOBAL\_FERR and GLOBAL\_NERR.  
 b. Based on NSI\_SCICMD, NSI\_SMICMD, NSI\_SERRCMD, and NSI\_MCERRCMD register values.

Table 5-7 summarizes the capabilities of the NSI error handling for each of the features that the unit is expected to provide.

**Table 5-7. Summary of IMCH NSI Error Reporting Capabilities**

| Feature                              | Implementation   |
|--------------------------------------|--|
| Enabling and Masking Error Reporting | The NSI_EMASK, NSI_SCICMD, NSI_SMICMD, NSI_SERRCMD, and NSI_MCERRCMD registers enables and masks error reporting. The PCICMD register also enables and masks SERR signals.   |
| Logging Details                      | NSI captures error logging information in the following registers: <ul style="list-style-type: none"> <li>All errors: NSI_FERR, NSI_NERR, and PCISTS capture event flags.</li> <li>Poisoned TLP: PCISTS captures event flags.</li> <li>Received fatal/non-fatal/correctable error messages: NSI_ERRSID.</li> </ul> All of the logging information that the NSI captures relates to the “first” error with the exception of NSI_NERR. |
| Reporting Multiple Errors            | The NSI_NERR register captures “next” errors. This register indicates up to one additional error (beyond the first error) of each type.  |
| Data Poisoning                       | NSI passes along error information to poison data.   |

For additional discussion on the IMCH responses to transactions from the NSI interface, see Section 10.1, “Overview”.

### 5.3.7 Unit-Level Errors from the EDMA Engine

The IMCH EDMA unit captures error events from the EDMA engine in the EDMA\_FERR and EDMA\_NERR registers (The EDMA unit reports an error event to the IA-32 core through IA SCI, SMI, SERR, or MCERR signals based on the settings in the EDMA\_SCICMD, EDMA\_SMICMD, EDMA\_SERRCMD, and EDMA\_MCERRCMD registers. Software can independently configure the specific signal that each EDMA unit error event uses.

Table 5-8 summarizes the error conditions that the EDMA can generate.

**Table 5-8. Summary of IMCH EDMA Error Conditions**

| Event                 | Type          | Fatality <sup>a</sup> | Reports via <sup>b</sup> | Notes  |
|-----------------------|---------------|-----------------------|--------------------------|--|
| NDAR Addressing Error | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Descriptor pointer is of incorrect type or range for channels 0-3.         |
| NDAR Alignment Error  | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Descriptor pointer is not aligned to an 8 DW boundary for channels 0-3.    |
| Source Address Error  | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Source address does not comply with source type or range for channels 0-3. |

**Table 5-8. Summary of IMCH EDMA Error Conditions**

| Event                     | Type          | Fatality <sup>a</sup> | Reports via <sup>b</sup> | Notes  |
|---------------------------|---------------|-----------------------|--------------------------|--|
| Destination Address Error | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Destination address does not comply with destination type or range for channels 0-3. |
| Parity Error              | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Parity error during read of source data from system memory for channels 0-3.         |
| Write Error               | Uncorrectable | Non-Fatal             | SCI, MCERR, SMI, or SERR | Write to RO descriptor registers when DMA in normal mode for channels 0-3.           |

a. Fatal versus non-fatal classification for reporting through GLOBAL\_FERR and GLOBAL\_NERR.

b. Based on EDMA\_SCICMD, EDMA\_SMICMD, EDMA\_SERRCMD, and EDMA\_MCERRCMD register values.

Table 5-9 summarizes the capabilities of the EDMA error handling for each of the features that the unit is expected to provide.

**Table 5-9. Summary of IMCH EDMA Error Reporting Capabilities**

| Feature                              | Implementation  |
|--------------------------------------|---|
| Enabling and Masking Error Reporting | The EDMA_EMASK, EDMA_SCICMD, EDMA_SMICMD, EDMA_SERRCMD, and EDMA_MCERRCMD registers enables and masks error reporting. The PCICMD register also enables and masks SERR signals. |
| Logging Details                      | EDMA does not capture error logging information beyond the event flags in the EDMA_FERR, EDMA_NERR and PCISTS.  |
| Reporting Multiple Errors            | The EDMA_NERR register captures “next” errors. This register indicates up to one additional error (beyond the first error) of each type.  |
| Data Poisoning                       | EDMA passes along error information to poison data.   |

For additional discussion on the IMCH responses to transactions from the EDMA engine, see [Section 10.1, “Overview”](#) and [Section 10.2, “IMCH Responses to EDMA Transactions”](#).

### 5.3.8 Unit-Level Errors from PCI Express\* Ports A0 and A1

The IMCH PCI Express\* Port Controllers capture error events from the port A0 and A1 controllers in per-port registers. The register set provides two parallel error reporting mechanisms, one that reports standard errors defined by the PCI Express\* specification and a second that reports errors that are specific to the EP80579 PCI Express\* implementation (and thus, outside of the standard PCI Express\* errors).

The PCI Express\* controllers capture errors required by the PCI Express\* base specification in the UNCERRSTS and CORERRSTS registers. The controllers capture EP80579-specific errors in the PEAUNITERR register. The errors from both sets of errors are aggregated in the PEAFFERR and PEANERR registers. The PCI Express\* controllers report an error event to the IA-32 core through IA SCI, SMI, SERR, or MCERR signals based on the settings in the PEAERRDOCMD register.

Table 5-10 summarizes the error conditions that the PCI-Express can generate.

Table 5-10. Summary of IMCH PCI-Express Error Conditions

| Event                        | Type          | Fatality <sup>a</sup>  | Reports via <sup>b</sup> | Notes   |
|------------------------------|---------------|------------------------|--------------------------|---|
| Unsupported Request          | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR | Request type unsupported.   |
| ECRC Error                   | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR | Error in ECRC.  |
| Malformed TLP                | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR | Malformed TLP, like it says...                                    |
| Receiver Overflow            | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR | Overflow on upstream queue.                                       |
| Unexpected Completion        | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR | Received completion that does not match any outstanding requests. |
| Completer Abort              | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR | Received request violates programming model.                      |
| Completion Timeout           | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR | Timeout.  |
| Flow Control Protocol Error  | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR |   |
| Poisoned TLP                 | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR | TLP data payload corrupt.   |
| Data Link Protocol           | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR | ACK/NACK has incorrect sequence number.                           |
| Unsupported Request          | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR |   |
| Unsupported Request          | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR |   |
| Unsupported Request          | Uncorrectable | UNCERRSEV <sup>c</sup> | SCI, MCERR, SMI, or SERR |   |
| Replay Timer                 | Correctable   | Non-Fatal              | SCI, MCERR, SMI, or SERR | Replay timer expired.   |
| REPLAY_NUM Rollover          | Correctable   | Non-Fatal              | SCI, MCERR, SMI, or SERR | Retry buffer counter rolled over.                                 |
| Bad DLLP Status              | Correctable   | Non-Fatal              | SCI, MCERR, SMI, or SERR | Computed DLLP CRC does not match received value.                  |
| Bad TLP status               | Correctable   | Non-Fatal              | SCI, MCERR, SMI, or SERR | Computed TLP CRC does not match received value.                   |
| Receiver Error               | Correctable   | Non-Fatal              | SCI, MCERR, SMI, or SERR | Received 8b/10b error.  |
| LLE Protocol Error           | Uncorrectable | Non-Fatal              | SCI, MCERR, SMI, or SERR | Transaction layer detected protocol error.                        |
| Link Down Error              | Uncorrectable | Fatal                  | SCI, MCERR, SMI, or SERR | Link transitions from DL_UP to DL_DOWN.                           |
| Downstream Data Queue Parity | Uncorrectable | Non-Fatal              | SCI, MCERR, SMI, or SERR | Parity error occurred in downstream data queue.                   |
| SMB Clock Timeout            | Uncorrectable | Non-Fatal              | SCI, MCERR, SMI, or SERR | SMB CLK low greater than 25ms.                                    |
| Unexpected NAK on SMB        | Uncorrectable | Non-Fatal              | SCI, MCERR, SMI, or SERR | Unexpected NAK on SMB.  |
| SMB Arbitration              | Uncorrectable | Non-Fatal              | SCI, MCERR, SMI, or SERR | SMB lost bus arbitration.   |

- a. Fatal versus non-fatal classification for reporting through GLOBAL\_FERR and GLOBAL\_NERR.
- b. Based on PEARRDOCMD register value.
- c. Severity is set by the UNCERRSEV register.

Table 5-11 summarizes the capabilities of the PCI-Express error handling for each of the features that the unit is expected to provide.

**Table 5-11. Summary of IMCH PCI-Express Error Reporting Capabilities**

| Feature                              | Implementation   |
|--------------------------------------|--|
| Enabling and Masking Error Reporting | The UNCERRMSK, UNCEDMASK, CORERRMSK, COREDMASK, RPMERRSTS, PEAMASKERR, RPERRCMD, and PEARRDOCMD registers enables and masks error reporting. The PCICMD register also enables and masks SERR signals.  |
| Logging Details                      | PCI Express* controllers captures error logging information in the following registers: <ul style="list-style-type: none"> <li>RPMERRSTS errors: ERRSID captures requester IDs.</li> <li>Errors with Header Capture: HDRLOG0, HDRLOG1, HDRLOG2, and HDRLOG3 captures the first four 32-bit words of the headers.</li> </ul> This information is in addition to the status information in UNCERRSTS, CORERRSTS, RPMERRSTS, PEAFFERR, and PEANERR. |
| Reporting Multiple Errors            | The PEANERR and RPERRMSTS registers captures "next" errors. This register indicates up to one additional error (beyond the first error) of each type.  |
| Data Poisoning                       | PCI Express* controllers pass along error information to poison data.  |

See Section 16.4, "PCI Express\* Port A Standard and Enhanced Registers: Bus 0, Devices 2 and 3, Function 0" for additional details.

For additional discussion on the IMCH responses to transactions from the PCI Express\* ports, see Section 10.1, "Overview".

## 5.4 Error Reporting by the IICH

The EP80579 IICH devices rely on the PCI error reporting architecture to reporting errors. In this architecture, details on the errors are logged in the PCI status register from the per-device PCI configuration header. A parity or other severe system error causes the device to generate an IA SERR signal.

Errors that occur on the NSI bus between the IMCH and IICH report through the NSI\_FERR and NSI\_NERR infrastructure as Section 5.3.1, "Overview of the First and Next Error Architecture" on page 141 and Section 5.3.6, "Unit-Level Errors from the NSI" on page 145 describe.

On the IICH backbone, IICH devices must rely entirely on the SERR signal that the device generates on an error event to report the error. The IICH does not provide any other capability (such as data poisoning) that would allow a consumer of IICH data to note an error. As a result, an IICH device can return erroneous data on a request.

The remainder of this section describes the error handling capabilities of the units in the IICH.

### 5.4.1 SMBus Interface

The IICH provides a SMBus controller that can generate an interrupt or SMI on error events and can also use the PCI SERR infrastructure to report errors. The HCFG register selects either SMI or interrupt signaling; parity and system errors always signal through SERR. Table 5-12 summarizes the error conditions that the controller reports.

**Table 5-12. Summary of SMBus Interface Error Conditions**

| Event                  | Type          | Fatality <sup>a</sup> | Reports via                 | Notes                   |
|------------------------|---------------|-----------------------|-----------------------------|-------------------------|
| Device Error           | Uncorrectable | Fatal                 | Interrupt, SMI <sup>b</sup> | Device error.           |
| Bus Error              | Uncorrectable | Fatal                 | Interrupt, SMI <sup>b</sup> | Bus error.              |
| Failed Bus Transaction | Uncorrectable | Fatal                 | Interrupt, SMI <sup>b</sup> | Bus transaction failed. |
| Parity Error           | Uncorrectable | Fatal                 | SERR                        | Parity error detected.  |
| System Error           | Uncorrectable | Fatal                 | SERR                        | System error detected.  |

a. "Fatal" events result in data loss or data corruption that the unit cannot repair, "Non-Fatal" events do not.  
 b. Based on HCFG register values.

Table 5-13 summarizes the capabilities of the SMBus controller error handling for each of the features that the unit is expected to provide.

**Table 5-13. Summary of SMBus Controller Error Reporting Capabilities**

| Feature                              | Implementation  |
|--------------------------------------|---|
| Enabling and Masking Error Reporting | The CMD and USBINTR registers enables and masks error reporting.                                |
| Logging Details                      | The USB 1.1 interface captures the type of event detected in the DSR, HSTS, and AUXS registers. |
| Reporting Multiple Errors            | The SMBus interface does not capture multiple events.   |
| Data Poisoning                       | IICH backbone does not support data poisoning.  |

For additional details on error handling in the SMBus controller, see Section 24.0, "SMBus Controller Functional Description: Bus 0, Device 31, Function 3".

## 5.4.2 LPC Interface

The IICH provides a LPC interface that uses the PCI SERR infrastructure to report errors. Table 5-14 summarizes the error conditions that the controller reports.

**Table 5-14. Summary of LPC Interface Error Conditions**

| Event        | Type          | Fatality <sup>a</sup> | Reports via | Notes                  |
|--------------|---------------|-----------------------|-------------|------------------------|
| Parity Error | Uncorrectable | Fatal                 | SERR        | Parity error detected. |
| System Error | Uncorrectable | Fatal                 | SERR        | System error detected. |

a. "Fatal" events result in data loss or data corruption that the unit cannot repair, "Non-Fatal" events do not.

Table 5-15 summarizes the capabilities of the LPC interface error handling for each of the features that the unit is expected to provide.

**Table 5-15. Summary of LPC Interface Error Reporting Capabilities**

| Feature                              | Implementation  |
|--------------------------------------|---|
| Enabling and Masking Error Reporting | The CMD register supports error enabling and masking. |

**Table 5-15. Summary of LPC Interface Error Reporting Capabilities**

| Feature                   | Implementation   |
|---------------------------|--|
| Logging Details           | The LPC interface captures the type of event detected in the STS register. |
| Reporting Multiple Errors | The LPC interface does not capture multiple events.                        |
| Data Poisoning            | IICH backbone does not support data poisoning.                             |

For additional details on error handling in the LPC interface, see [Section 19.0, “LPC Interface: Bus 0, Device 31, Function 0”](#).

### 5.4.3 USB 1.1 Interface

The IICH provides a USB 1.1 controller that can generate an interrupt on error events and can also use the PCI SERR infrastructure to report errors. [Table 5-16](#) summarizes the error conditions that the controller reports.

**Table 5-16. Summary of USB 1.1 Interface Error Conditions**

| Event                         | Type          | Fatality <sup>a</sup> | Reports via | Notes   |
|-------------------------------|---------------|-----------------------|-------------|---|
| Host Controller Process Error | Uncorrectable | Fatal                 | Interrupt   | Consistency check by host controller fails while processing a TD.                   |
| Host System Error             | Uncorrectable | Fatal                 | Interrupt   | Serious error during host system access involving HC module.                        |
| USB Error                     | Uncorrectable | Fatal                 | Interrupt   | USB transaction completion ended in error.  |
| Parity Error                  | Uncorrectable | Fatal                 | SERR        | Parity error on read completion returned to host controller or UHCI register write. |

a. “Fatal” events result in data loss or data corruption that the unit cannot repair, “Non-Fatal” events do not.

[Table 5-17](#) summarizes the capabilities of the USB 1.1 controller error handling for each of the features that the unit is expected to provide.

**Table 5-17. Summary of USB 1.1 Interface Error Reporting Capabilities**

| Feature                              | Implementation   |
|--------------------------------------|--|
| Enabling and Masking Error Reporting | The CMD and USBINTR registers supports error enabling and masking.   |
| Logging Details                      | The USB 1.1 interface captures the type of event detected in the DSR and USBSTS registers.   |
| Reporting Multiple Errors            | The USB 1.1 interface does not capture multiple events, error events cause the interface to halt operation until serviced by software. |
| Data Poisoning                       | IICH backbone does not support data poisoning.   |

For additional details on error handling in the USB 1.1 controller, see [Section 25.0, “USB \(1.1\) Controller: Bus 0, Device 29, Function 0”](#).

### 5.4.4 USB 2.0 Interface

The IICH provides a USB 2.0 controller that can generate an interrupt on error events and can also use the PCI SERR infrastructure to report errors. [Table 5-18](#) summarizes the error conditions that the controller reports.

**Table 5-18. Summary of USB 2.0 Interface Error Conditions**

| Event             | Type          | Fatality <sup>a</sup> | Reports via | Notes  |
|-------------------|---------------|-----------------------|-------------|--|
| Host System Error | Uncorrectable | Fatal                 | Interrupt   | Serious error during host system access involving HC module.                                 |
| USB Error         | Uncorrectable | Fatal                 | Interrupt   | USB transaction completion ended in error.   |
| Parity Error      | Uncorrectable | Fatal                 | SERR        | Parity error on USB read completion.   |
| System Error      | Uncorrectable | Fatal                 | SERR        | Parity error on address, command, or data, or unsuccessful completion of ECH-initiated read. |

a. "Fatal" events result in data loss or data corruption that the unit cannot repair, "Non-Fatal" events do not.

Table 5-19 summarizes the capabilities of the USB 2.0 controller error handling for each of the features that the unit is expected to provide.

**Table 5-19. Summary of USB 2.0 Interface Error Reporting Capabilities**

| Feature                              | Implementation   |
|--------------------------------------|--|
| Enabling and Masking Error Reporting | The CMD and USB20INTR registers supports error enabling and masking.   |
| Logging Details                      | The USB 2.0 interface captures the type of event detected in the DSR and USB20STS registers.   |
| Reporting Multiple Errors            | The USB 2.0 interface does not capture multiple events, error events cause the interface to halt operation until serviced by software. |
| Data Poisoning                       | IICH backbone does not support data poisoning.   |

For additional details on error handling in the USB 2.0 controller, see [Section 26.0, "USB 2.0 Host Controller: Bus 0, Device 29, Function 7"](#).

### 5.4.5 SATA Interface

The IICH provides a SATA interface that can generate an interrupt on error events and can also use the PCI PERR infrastructure to report errors. Table 5-20 summarizes the error conditions that the controller reports.

**Table 5-20. Summary of SATA Interface Error Conditions**

| Event                     | Type          | Fatality <sup>a</sup> | Reports via | Notes                               |
|---------------------------|---------------|-----------------------|-------------|-------------------------------------|
| Host Bus Fatal Error      | Uncorrectable | Fatal                 | Interrupt   | Unrecoverable host bus error        |
| Host Bus Data Error       | Uncorrectable | Fatal                 | Interrupt   | Uncorrectable data error.           |
| Interface Fatal Error     | Uncorrectable | Fatal                 | Interrupt   | Fatal error on SATA interface.      |
| Interface Non-Fatal Error | Uncorrectable | Non-Fatal             | Interrupt   | Non-fatal error on SATA interface.  |
| Parity Error              | Uncorrectable | Fatal                 | SERR        | Parity error detected on interface. |

a. "Fatal" events result in data loss or data corruption that the unit cannot repair, "Non-Fatal" events do not.

Table 5-21 summarizes the capabilities of the SATA controller error handling for each of the features that the unit is expected to provide.

**Table 5-21. Summary of SATA Interface Error Reporting Capabilities**

| Feature                              | Implementation  |
|--------------------------------------|---|
| Enabling and Masking Error Reporting | The CMD and PIE[0-3] registers support error enabling and masking.                        |
| Logging Details                      | The SATA interface captures the type of event detected in the STS and PIS[0-3] registers. |
| Reporting Multiple Errors            | The SATA interface does not capture multiple events.                                      |
| Data Poisoning                       | IICH backbone does not support data poisoning.  |

For additional details on error handling in the SATA interface, see [Section 23.0, “SATA: Bus 0, Device 31, Function 2”](#).

### 5.4.6 Serial I/O Interface

The IICH provides a serial I/O interface that can generate an interrupt on error events. [Table 5-22](#) summarizes the error conditions that the serial I/O interface captures.

**Table 5-22. Summary of Serial I/O Interface Error Conditions**

| Event         | Type          | Fatality <sup>a</sup> | Reports via | Notes                                |
|---------------|---------------|-----------------------|-------------|--------------------------------------|
| Framing Error | Uncorrectable | Fatal                 | Interrupt   | Received character missing stop bit. |
| Parity Error  | Uncorrectable | Fatal                 | Interrupt   | Received character has parity error. |
| Overrun Error | Uncorrectable | Fatal                 | Interrupt   | Receive buffer over-written.         |

a. “Fatal” events result in data loss or data corruption that the unit cannot repair, “Non-Fatal” events do not.

[Table 5-23](#) summarizes the capabilities of the thermal sensor error handling for each of the features that the unit is expected to provide.

**Table 5-23. Summary of Serial I/O Interface Error Reporting Capabilities**

| Feature                              | Implementation   |
|--------------------------------------|--|
| Enabling and Masking Error Reporting | The IER and LCR registers supports error enabling and masking.                             |
| Logging Details                      | The serial I/O interface captures the type of event detected in the IIR and LSR registers. |
| Reporting Multiple Errors            | The serial I/O interface does not capture multiple events.                                 |
| Data Poisoning                       | N/A  |

For additional details on error handling in the serial I/O interface, see [Section 33.0, “Serial I/O Unit and Watchdog Timer”](#).

## 5.5 Error Reporting by the System Memory Controller

The memory controller interfaces with memory to provide data movement to and from DRAM along the AIOC-direct and coherent paths to memory. The memory controller is designed to conform to the IMCH first and next error handling architecture that [Section 5.3.1, “Overview of the First and Next Error Architecture”](#) on page 141 describes. The memory controller reports its unit-level first/next error events through the DRAM\_FERR and DRAM\_NERR registers in the memory controller (see [Section 11.5, “Error Handling”](#)). The flow of memory controller errors matches the IMCH behavior for its other errors as [Section 5.3.1](#) describes.

### 5.5.1 Handling Out-of-Bounds Addresses

The memory controller does not perform any bounds checking on system addresses that it receives from other agents. As a result, the behavior of the EP80579 in response to an access to a DRAM location that is outside the range of populated memory depends on the source of the transaction and the path it takes through the device. There are two paths of relevance to this discussion: the Coherent path through the IMCH and the AIOC-Direct path directly to the memory controller.

Accesses to locations above top of memory along the Coherent path (from either AIOC agents via the AIOC-interface, the IA-32 core, or other agents attached to the CMI through PCI Express\*, etc.) will be aborted by the IMCH. The specific manner of the abort depends on whether the transaction originates from the IA-32 core or a AIOC agent.

Access to locations above top of memory along the AIOC-Direct path (from the AIOC Memory Target) are not aborted or otherwise trapped by default. The results of such transactions are undefined and may alias onto populated memory regions. As a result, software must program the EP80579 so that it can never generate an AIOC-Direct system address above TOM. The Memory Target provides the ability to log range errors (and optionally halt the AIOC master that generated the transaction).

### 5.5.2 IMCH - Memory Controller

The memory controller can notify the IA-32 core of memory-related error events through SCI, SMI, SERR, or MCERR signals based on the settings in the DRAM\_SCICMD, DRAM\_SMICMD, DRAM\_SERRCMD, and DRAM\_MCERRCMD registers (see Section 11.0, "System Memory Controller"). Software can configure the specific signal used for each error event independently.

Table 5-24 summarizes the error conditions that the memory controller captures. Note that the memory controller always reports errors through the non-fatal classification in the error reporting registers.

Table 5-24. Summary of Memory Controller Error Conditions

| Event                             | Type          | Fatality <sup>a</sup> | Reports via <sup>b</sup> | Notes   |
|-----------------------------------|---------------|-----------------------|--------------------------|---|
| Uncorrectable Write Error         | Uncorrectable | Fatal                 | SCI, MCERR, SMI, or SERR | Write of poisoned data to DRAM.   |
| Uncorrectable Read Error          | Uncorrectable | Fatal                 | SCI, MCERR, SMI, or SERR | Error during normal demand reads.                                       |
| Uncorrectable Scrubber Data Error | Uncorrectable | Fatal                 | SCI, MCERR, SMI, or SERR | Memory scrubber encountered an uncorrectable error.                     |
| Correctable Read Error            | Correctable   | Non-Fatal             | SCI, MCERR, SMI, or SERR | Hardware will correct and report if appropriately configured            |
| Error Threshold Detect            | Status        | Non-Fatal             | SCI, MCERR, SMI, or SERR | Count of single- or double-bit errors exceeds a programmable threshold. |
| Memory Test Complete              | Status        | Non-Fatal             | SCI, MCERR, SMI, or SERR | Status event to indicate when memory test hardware completes testing.   |

a. "Fatal" events result in data loss or data corruption that the unit cannot repair, "Non-Fatal" events do not. This can differ from the fatal/non-fatal classification for reporting through GLOBAL\_FERR and GLOBAL\_NERR.  
b. Based on DRAM\_SCICMD, DRAM\_SMICMD, DRAM\_SERRCMD, and DRAM\_MCERRCMD register values.

Table 5-25 summarizes the capabilities of the memory controller error handling for each of the features that the unit is expected to provide.

Table 5-25. Summary of Memory Controller Error Reporting Capabilities

| Feature                              | Implementation   |
|--------------------------------------|--|
| Enabling and Masking Error Reporting | The DRAM_EMASK, DRAM_SCICMD, DRAM_SMICMD, DRAM_SERRCMD, and DRAM_MCERRCMD registers enable and mask error reporting.   |
| Logging Details                      | Memory Controller captures additional error logging information in the following registers: <ul style="list-style-type: none"> <li>Uncorrectable read errors: DRAM_DED_ADD.</li> <li>Uncorrectable scrubber data errors: DRAM_SCRB_ADD.</li> <li>Correctable read errors: DRAM_SECF_ADD, DRAM_SECF_SYNDROME, DRAM_SECN_ADD, DRAM_SECN_SYNDROME.</li> <li>Error threshold detect: RANKTHREX, THRESH_SEC0, THRESH_SEC1, THRESH_DED, DRAM_SEC_R0, DRAM_SEC_R1, DRAM_DED_R0, DRAM_DED_R1.</li> </ul> Additional logging information is not captured for the remaining errors in Table 5-24. With the exception of DRAM_SECN_ADD and DRAM_SECN_SYNDROME, all of the logging information that the memory controller captures relates to the "first" error. |
| Reporting Multiple Errors            | The DRAM_NERR register captures the "next" errors seen by the memory controller. This register indicates up to one additional error (beyond the first error) of each type.   |
| Data Poisoning                       | Memory Controller passes along error information to poison data both on inbound (from memory) data and outbound (to memory) data.  |

For additional details on error handling in the memory controller, see [Section 11.5, "Error Handling"](#).

## 5.6 Error Reporting by AIOC Devices

The AIOC devices continue to use the native error reporting infrastructure that each unit provides. Primarily, this infrastructure relies on one or more side-band error signals from each AIOC device that can signal an error along with parity protection on key interfaces. The AIOC native error reporting mechanisms are then bridged into the PCI framework that the EP80579 uses to expose AIOC devices to IA. Although AIOC devices present a PCI interface to IA, they do not implement PCI error reporting capabilities such as SERR. As a result, the native signals from the AIOC devices are bridged onto PCI INTx or MSI signals. This implies that the driver software provides all error handling for AIOC units<sup>1</sup>.

The following sections describe the error reporting for each of the AIOC units along with transaction responses. The per-unit presentations are organized by the PCI device in which the units materialize.

### 5.6.1 Gigabit Ethernet MAC

The Gigabit Ethernet MAC units each signal error conditions through three interrupt signals: Functional 0, Functional 1, and Error. Software uses the IMS0, IMS1, and IMS2 configuration registers in a Gigabit Ethernet MAC to map error conditions onto the Functional 0, Functional 1, and Error interrupt signals, respectively. Depending on the configuration, error and functional events may share an interrupt (e.g., software may configure the functional 1 interrupt to signal both error and functional events); typically, software will configure a MAC to deliver its error events separately through only the error interrupt.

Table 5-26 summarizes the error conditions that the Gigabit Ethernet MAC captures.

1. If PCI abstractions such as SERR were used, this would not be the case. Platform and/or O/S software would also be involved in error handling for the devices even if the involvement is limited to generating a blue screen.

**Table 5-26. Summary of Gigabit Ethernet MAC Error Conditions**

| Event                        | Type          | Fatality <sup>a</sup> | Reports via <sup>b</sup>    | Notes  |
|------------------------------|---------------|-----------------------|-----------------------------|--|
| Statistic Register ECC Error | Uncorrectable | Fatal                 | ERR, FN0, or FN1 Interrupts | Double-bit ECC error in a statistic register.                        |
| Internal Memory Error        | Uncorrectable | Fatal                 | ERR, FN0, or FN1 Interrupts | Parity or double-bit ECC error in an internal memory.                |
| DMA Packet Buffer Error      | Uncorrectable | Fatal                 | ERR, FN0, or FN1 Interrupts | Double-bit ECC error during read from DMA packet buffer on Tx or Rx. |
| DMA Tx Desc. ECC Error       | Uncorrectable | Fatal                 | ERR, FN0, or FN1 Interrupts | Double-bit ECC error during read from DMA transmit descriptor.       |
| DMA Rx Desc. ECC Error       | Uncorrectable | Fatal                 | ERR, FN0, or FN1 Interrupts | Double-bit ECC error during read from DAM receive descriptor.        |

a. "Fatal" events result in data loss or data corruption that the unit cannot repair, "Non-Fatal" events do not.  
 b. Based on settings in IMS0, IMS1, and IMS2 registers.

Table 5-27 summarizes the capabilities of the Gigabit Ethernet MAC error handling for each of the features that the unit is expected to provide.

**Table 5-27. Summary of Gigabit Ethernet MAC Error Reporting Capabilities**

| Feature                              | Implementation  |
|--------------------------------------|---|
| Enabling and Masking Error Reporting | The IMS0, IMS1, and IMS2 interrupt mask set registers and the IMC0, IMC1, and IMC2 interrupt mask clear registers support error enabling and masking. When software configures the GbE to deliver errors on their own interrupt, the SMIA and SMME registers from the signal target capability in the PCI configuration header for a GbE MAC can also support error enabling and masking. |
| Logging Details                      | The SINT register from the signal target capability in the PCI configuration header for a GbE MAC provides read-only access to the state of the interrupt signals from a GbE MAC. Additional logging information is not captured for the other errors in Table 5-26.  |
| Reporting Multiple Errors            | Individual status bits in the GbE ICR0, ICR1, and ICR2 interrupt cause registers are set as conditions occur. The unit can indicate at most one outstanding error at any time.  |
| Data Poisoning                       | GbE passes along error information to poison data.  |

See Section 37.6, "GbE Controller Register Summary" and Section 37.5.12, "Error Handling" for additional details.

### 5.6.2 CAN Interface

The CAN units signal error conditions through two interrupt signals. The CAN unit shares one interrupt between functional signaling duties (e.g., signaling that a message was received) and error reporting, while the second interrupt reports only parity errors. Status and enable registers in the CAN operate and control signaling functionality in the CAN such as error reporting.

Table 5-28 summarizes the error conditions that the CAN captures.

Table 5-28. Summary of CAN Error Conditions

| Event                 | Type          | Fatality <sup>a</sup> | Reports via          | Notes  |
|-----------------------|---------------|-----------------------|----------------------|--|
| CRC Check Error       | Uncorrectable | Fatal                 | CAN System Interrupt | Mismatch between received and computed CRC.  |
| Acknowledge Error     | Uncorrectable | Fatal                 | CAN System Interrupt | Improperly formatted ACK slot.   |
| Form Error            | Uncorrectable | Fatal                 | CAN System Interrupt | Improperly formatted fixed-form field.   |
| Bit Error             | Uncorrectable | Fatal                 | CAN System Interrupt | Mismatch between monitored and sent bit value.   |
| Stuff Error           | Uncorrectable | Fatal                 | CAN System Interrupt | Improperly formatted message from Start of Frame to CRC delimiter.   |
| CAN SRAM Parity Error | Uncorrectable | Fatal                 | CAN Parity Interrupt | Parity error in interface SRAM. Clearing the parity error requires a reset of the CAN interface. Please see section on CAN interrupts in <a href="#">Section 39.2, "Feature List"</a> on page 1569 for more details. |

a. "Fatal" events result in data loss or data corruption that the unit cannot repair, "Non-Fatal" events do not.

Table 5-29 summarizes the capabilities of the CAN error handling for each of the features that the unit is expected to provide.

Table 5-29. Summary of CAN Error Reporting Capabilities

| Feature                              | Implementation  |
|--------------------------------------|---|
| Enabling and Masking Error Reporting | The CAN interrupt enable register supports error enabling and masking. The SMIA and SMME registers from the signal target capability in the PCI configuration header for the CAN units also supports error enabling and masking. Using these registers to mask the CAN System Interrupt masks both error and functional events since the CAN units use this interrupt to signal both error and functional conditions. |
| Logging Details                      | The SINT register from the signal target capability in the PCI configuration header for a CAN unit provides read-only access to the state of the interrupt signals from a CAN unit. CAN does not log additional details on errors.  |
| Reporting Multiple Errors            | Individual status bits in CAN interrupt status register are set as conditions occur. The unit can indicate at most one outstanding error of each type at any time.  |
| Data Poisoning                       | CAN does not require support for data poisoning. Errors during transactions cause the transaction to abort and an error event to be signaled.   |

See [Section 39.6, "Register Summary"](#) and [Section 39.5.2, "Error Handling"](#) for additional details.

### 5.6.3 SSP Interface

The SSP unit signals error conditions through a single interrupt signal. The SSP block shares this interrupt between functional duties (e.g., transmit FIFO service request) and error reporting duties. Software is expected to use status registers in the SSP to determine the cause of a signal.

Table 5-30 summarizes the error condition that the SSP captures.

**Table 5-30. Summary of SSP Error Conditions**

| Event                             | Type          | Fatality <sup>a</sup> | Reports via   | Notes   |
|-----------------------------------|---------------|-----------------------|---------------|---|
| Functional Receiver Overrun (ROR) | Uncorrectable | Fatal                 | SSP Interrupt | Receive FIFO is full, any incoming data is discarded. |

a. "Fatal" events result in data loss or data corruption that the unit cannot repair, "Non-Fatal" events do not.

Table 5-31 summarizes the capabilities of the SSP error handling for each of the features that the unit is expected to provide.

**Table 5-31. Summary of SSP Error Reporting Capabilities**

| Feature                              | Implementation   |
|--------------------------------------|--|
| Enabling and Masking Error Reporting | SSP does not provide the ability to enable or mask the interrupt from an ROR error condition.<br>The SMIA and SMME registers from the signal target capability in the PCI configuration header for the SSP unit also support error enabling and masking. Using these registers to mask the SSP Interrupt masks both error and functional events since the SSP unit uses this interrupt to signal both error and functional conditions. |
| Logging Details                      | The SINT register from the signal target capability in the PCI configuration header for the SSP unit provides read-only access to the state of the interrupt signals from SSP. SSP does not log additional details on its errors.  |
| Reporting Multiple Errors            | SSP can only generate a single error. The unit can indicate at most one outstanding error at any time.   |
| Data Poisoning                       | SSP error conditions result in loss of data and system interrupt. There is no need to poison in these cases.   |

See Section 40.4, "Register Summary" and Section 40.3.2, "Error Handling" for additional details.

### 5.6.4 Local Expansion Bus

The Local Expansion Bus unit signals error conditions from the interface into the EP80579 through a single interrupt signal that is used exclusively for errors. In addition, this unit signals errors from the internal bridge through a separate interrupt.

Table 5-32 summarizes the error conditions that the local expansion bus captures.

**Table 5-32. Summary of Local Expansion Bus Error Conditions**

| Event        | Type          | Fatality <sup>a</sup> | Reports via                | Notes   |
|--------------|---------------|-----------------------|----------------------------|---|
| Parity Error | Uncorrectable | Fatal                 | LEB Parity Error Interrupt | Parity error on outbound read from the EP80579. |

a. "Fatal" events result in data loss or data corruption that the unit cannot repair, "Non-Fatal" events do not.

Table 5-33 summarizes the capabilities of the local expansion bus error handling for each of the features that the unit is expected to provide.

**Table 5-33. Summary of Local Expansion Bus Error Reporting Capabilities**

| Feature                              | Implementation   |
|--------------------------------------|--|
| Enabling and Masking Error Reporting | LEB device provides the following registers to support error enabling and masking: <ul style="list-style-type: none"> <li>• Errors from LEB: EXP_TIMING_CS[0-7].</li> </ul> The SMIA and SMME registers from the signal target capability in the PCI configuration header for the LEB also support error masking and enabling.                               |
| Logging Details                      | The SINT register from the signal target capability in the PCI configuration header for the LEB provides read-only access to the state of the interrupt signals from the LEB. LEB device captures additional error logging information in the following registers: <ul style="list-style-type: none"> <li>• LEB parity errors: EXP_PARITY_STATUS.</li> </ul> |
| Reporting Multiple Errors            | LEB device reports additional errors as follows: <ul style="list-style-type: none"> <li>• LEB errors</li> </ul>  |
| Data Poisoning                       | LEB pass along error information to poison data.   |

See [Section 42.5, “Register Summary”](#).

### 5.6.5 IEEE 1588, and GCU

The IEEE 1588 and GCU in the AIOC do not signal any non-functional error conditions.

§ §

## 6.0 Reset and Power Management

This chapter describes the Intel® EP80579 Integrated Processor reset and power management.

### 6.1 Reset and Powergood Distribution

This section discusses the detailed sequencing of how power and clocking signals must be applied to bring the EP80579 out of reset.

#### 6.1.1 Types of Reset

The EP80579 has four types of reset: Power-good (cold) reset, Hard reset, CPU-only reset, and Targeted I/O subsystem reset(s). Each of these reset subclasses have unique effects and is described in [Table 6-1](#).

**Table 6-1. Types of Reset and Wake-up from Power Saving States**

| Type                     | Mechanism                                     | Effect of Reset on following blocks |               |       |       |       |
|--------------------------|---|-------------------------------------|---------------|-------|-------|-------|
|                          |   | CPU                                 | IMCH/<br>IICH | AIOC  | PCI-E | DDR   |
| Power-good               | Input pin                                     | Reset                               | Reset         | Reset | Reset | Reset |
| Hard                     | Input pin                                     | Reset                               | Reset         | Reset | Reset | Reset |
| Software (SW) Controlled | Write to I/O port CF9                         | Reset                               | Reset         | Reset | Reset | Reset |
| CPU-only                 | Internal to the EP80579.<br>Generated by IMCH | Reset                               | -N/A          | -N/A  | -N/A  | -N/A  |
| S3 -> S0                 | Wake Event                                    | Reset                               | Reset         | Reset | Reset | -N/A  |
| S4/S5->S0                | Wake Event                                    | Reset                               | Reset         | Reset | Reset | Reset |

##### 6.1.1.1 Powergood Implementation

The initial boot from when the power supplies are energized is facilitated by the Powergood mechanism. The voltage sources from all platform power supplies are routed to a system component which tracks them as they ramp-up, asserting platform powergood (CPU\_VRD\_PWR\_GD and SYS\_PWR\_OK) after a fixed interval (nominally 99 ms) after the last voltage reference has stabilized. Powergood signals are propagated asynchronously to dedicated IICH, IMCH, and IA-32 core inputs. Generally, the devices on AIOC fabric including the AIOC reset block do not receive a powergood signal. The exception is the GbE MAC devices (see [Section 6.1.2.3.5, "GbE MAC"](#)).

[Table 6-2](#) summarizes the power wells and external voltages required by the EP80579. More detailed power supply pin information can be found in [Table 6-3](#).

Table 6-2. Power Wells and External Voltages

| Power Well | Nominal Voltage | Components   |
|------------|-----------------|--|
| Core       | 1.0-1.3 V       | IA Processor: IA-CPU   |
|            | 1.2 V           | Core Logic (IMCH, IICH, ASU, SSU, TDM, GbE MAC1, GbE MAC2), SATA pads, PCI-E pads, Local Expansion Bus |
|            | 1.8 V           | PCI-E PLL, DDR2 pads. Note: 0.9V are generated from 1.8V   |
|            | 2.5 V           | RMII/RGMII   |
|            | 3.3 V           | SATA, PCI-E  |
|            | 5.0V            | 5V tolerance reference   |
| Suspend    | 1.2 V           | IICH, USB pads, DDR2 core logic, GbE MAC0, USB core logic and pads                                     |
|            | 2.5 V           | RMII/RGMII   |
|            | 3.3 V           | USB pads, RMII/RGMII pads  |
|            | 5.0V            | 5V sustain reference   |
| RTC        | 3.3 V           | RTC  |

### 6.1.1.2 Hard Reset Implementation

A hard reset is initiated by the IICH via the PLTRST# as a result various S-state wake events or other reset signal assertions. PLTRST# is driven to the IMCH and is propagated from there to the reset block for AIOC fabric. The reset block in the AIOC fabric is responsible for resetting the individual blocks.

IMCH propagates a hard reset to the FSB and subordinate PCI Express\* subsystems. The FSB components are reset via the CPURST# (internal signal) signal, while the PCI Express\* subsystems through PCIRST#.

### 6.1.1.3 Software Controlled Reset

Software may cause a full system reset through a write to the Reset Control Register located at I/O port CF9. See also Section 6.1.1.4, "CPU Only Reset Implementation" for software controlled CPU only reset mechanisms.

### 6.1.1.4 CPU Only Reset Implementation

For power management, error conditions and other reasons, the EP80579 supports a targeted CPU only reset semantic. This mechanism eliminates system reset at large when the CPU function (such as clock gearing selection) must be updated during initialization. It only affects the IA-32 core. Other blocks such as IICH, IMCH, AIOC complex are not reset. It is controlled by IMCH.

The IA-32 core can also be reset via the assertion of its INIT# pin which may be accomplished by several conditions including a software write to the Reset Control Register in IICH. Asserting the INIT# pin on the IA-32 core invokes a response similar to that of asserting CPURST#. The major difference is that during an INIT, the internal caches, MSRs, MTRRs, and FPU state are left unchanged (although, the TLBs and BTB are invalidated as with a hardware reset). When INIT is signaled while the processor is in virtual-8086 mode, the processor leaves virtual-8086 mode and enters real-address mode. An INIT provides a method for switching from protected to real-address mode while maintaining the contents of the internal caches.

#### 6.1.1.5 S-state Wake Events

Wake events for the various ACPI sleep states cause a hard reset to the EP80579 (See [Section 27.6.3, “Exiting Sleep States”](#)). Wake on LAN, supported by the GbE MACs, leverages mechanisms provided for GPI and PME wake events.

#### 6.1.1.6 Targeted Reset Implementation

The targeted reset is provided for hot-plug events, as well as for port specific error handling under MCA or SMI software control.

A targeted reset may be requested by setting bit six (Secondary Bus Reset) of the Bridge Control register (D2, F0, offset 3Eh) in the target root port device. Setting this bit crashes the Link Training and Status State machine (LTSSM) of the target port to the reset state, where it issues at least 1024 TS1 ordered sets with the reset bit asserted. This propagates an in-band “hot” reset to the downstream device, and consequently force an equivalent reset to any devices further downstream. This reset is identical to a general hard reset from the perspective of destination PCI Express\* device.

### 6.1.2 Platform Reset and Powergood

This section describes the reset and powergood external platform interfaces.

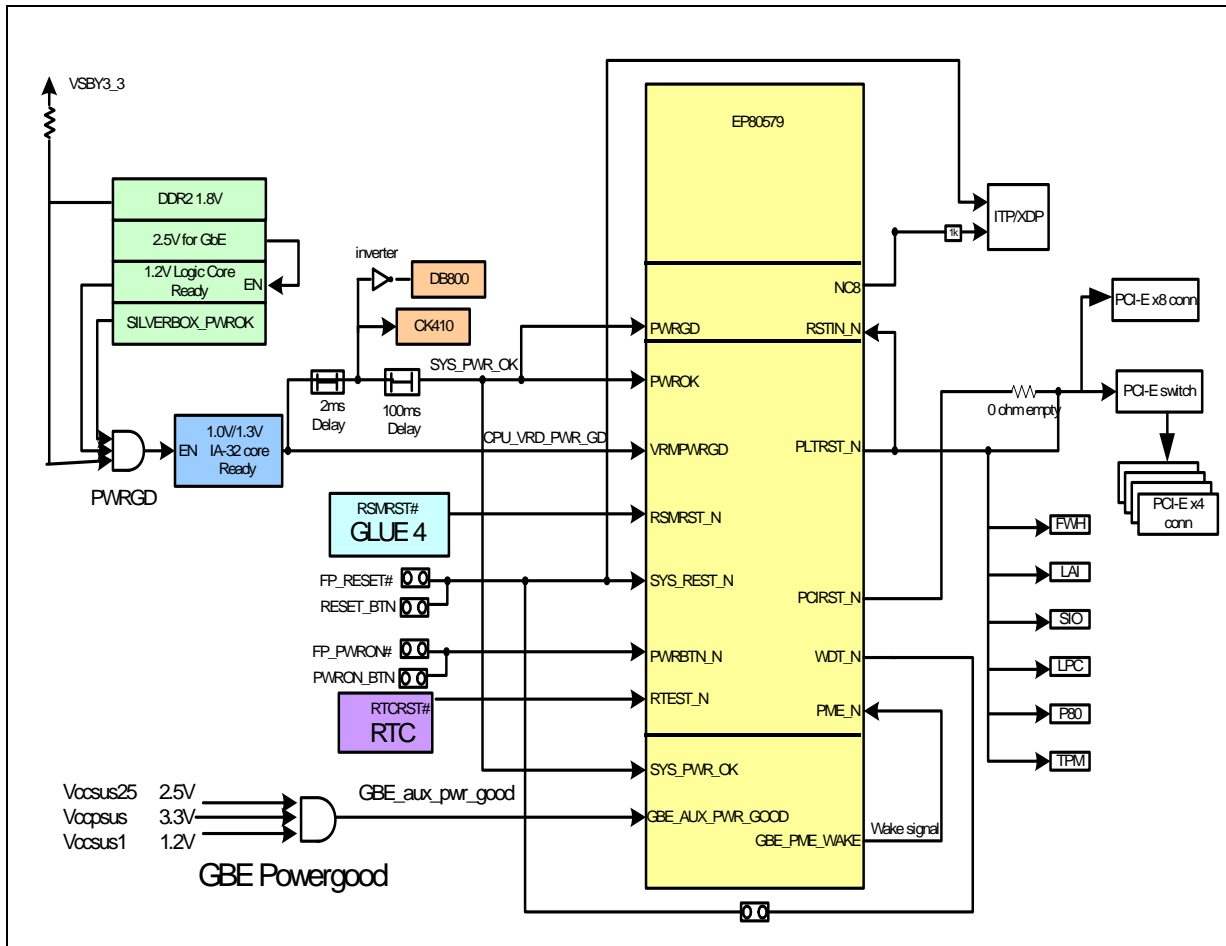

#### 6.1.2.1 Platform Powergood

The EP80579 receives two powergood signals from the platform. The first is CPU\_VRD\_PWR\_GD and the other is SYS\_PWR\_OK. SYS\_PWR\_OK is asserted after a fixed delay from the time that CPU\_VRD\_PWR\_GD goes active and indicates that power has been stable for at least 99 ms. The EP80579 inputs PWRGD, PWROK, and SYS\_PWR\_OK are connected to the SYS\_PWR\_OK platform signal. CPU\_VRD\_PWR\_GD and SYS\_PWR\_OK distribution inside the EP80579 is discussed in [Section 6.1.2.3, “Reset and Powergood Distribution”](#). Refer to [Figure 6-1](#) for the block diagram showing CPU\_VRD\_PWR\_GD and SYS\_PWR\_OK interfaces.

#### 6.1.2.2 Platform Reset

The EP80579 receives two reset signals from the platform. The first one is SYS\_RESET which includes the reset button on the platform. The second is Resume Reset which is used for resetting the IICH resume well after power is restored from a power failure. Reset distribution inside the EP80579 is discussed in [Section 6.1.2.3, “Reset and Powergood Distribution”](#). Refer to the [Figure 6-1](#), for a block diagram showing the reset interface.

Figure 6-1. Powergood and Reset Interface

### 6.1.2.3 Reset and Powergood Distribution

The EP80579 reset follows a general path through the IICH to the IMCH and out to the rest of the chip.

#### 6.1.2.3.1 IICH

IICH plays the central role in reset and powergood distribution to the whole chip. IICH receives two powergood signals from the platform (CPU\_VRD\_PWR\_GD and SYS\_PWR\_OK). The assertion of these signals starts the reset sequence for the EP80579.

IICH generates the central reset signal (known as PLTRST#) that initiates the reset of the rest of the chip. PLTRST# is received by IMCH. IICH also generates PCIRST# signal for resetting the PCI device. PCIRST# is similar to PLTRST# except that PCIRST# can be asserted using a CSR.

IICH also generates the powergood (CPUPWRGD#) signal for IA-32 core.

## IICH Signals

### Inputs

**VRMPWRGD** - Voltage Regulator PowerGood: This signal is directly connected to the platform signal, CPU\_VRD\_PWR\_GD and signifies that the voltage regulator is stable.

**PWROK** - IICH Power Okay: This signal is directly connected to the platform signal, SYS\_PWR\_OK. When asserted, PWROK is an indication to the IICH that power has been stable for at least 99 ms and that PCICLK has been stable for at least 1 mS. PWROK can be driven asynchronously. When PWROK is inactive, the IICH asserts PLTRST#.

**SYS\_RESET#** - System Reset: This signal initiates a system reset and causes PLTRST# to go active. SYS\_RESET# must be asserted for at least 100ms. System reset cannot occur again until SYS\_RESET# has been detected inactive, and the system is back to a full S0 state with PLTRST# inactive. If bit 3 of the Reset Control Register is set then the assertion of SYS\_RESET# will result in a full power cycle reset.

**RSMRST#** - Resume Well Reset: This signal resets the IICH resume power plane logic when power is reapplied after a power failure. If the AFTERG3\_EN bit in the General Power Management Configuration 3 Register (D31 F0 Offset A4) is set to 0, IICH transitions the system from G3 (mechanical off) to S0 state and causes the assertion of the PLTRST# output. If AFTERG3\_EN is 1, the system will transition to S5 state.

**RTEST#** - RTC Well Test: This signal is tied to the platform RTCRST# signal. Normally it is held high (to VccRTC), but can be driven low on the tester or motherboard to test the RTC well. RTEST# resets some bits in the RTC well that are otherwise not reset by PLTRST# or RSMRST#. An external RC circuit on the RTCRST# signal creates a time delay such that RTCRST# will go high some time after the battery voltage is valid. The RC time delay must be in the 10-20 ms range. This allows detection when a new battery has been installed. Unless entering a XOR Chain test mode, the RTEST# input must always be high when all other non-RTC power planes are on.

### Outputs

**CPUPWRGD** - CPU PowerGood: This signal is the logical AND of the IICH VRMPWRGD and PWROK input signals. This signal is connected to the processor's powergood input to indicate when the processor power is valid.

**PLTRST#** - Platform Reset: This signal is asserted by SYS\_RESET#, RSMRESET#, or software. The IICH asserts PLTRST# to reset devices on the platform (e.g., SIO, FWH, LAN, IMCH, IDE, TPM, etc.) during power-up (CPU\_PWRGD de-asserted) and when software initiates a hard reset sequence through the Reset Control register. The IICH drives PLTRST# active a minimum of 1 ms when initiated through the Reset Control register. The IICH de-asserts PLTRST# a minimum of 1 ms after CPU\_PWRGD is driven high.

**PCIRST#** - PCI Reset: This is the secondary PCI bus reset signal. This signal is asserted a small number of PCI clocks after PLTRST# or can be asserted independently by the Secondary Bus Reset bit.

### 6.1.2.3.2 IMCH

IMCH plays a crucial role in the reset sequence for IA-32 core. IMCH receives the powergood signal (SYS\_PWR\_OK) from the platform. The IICH PLTRST# drives the IMCH RSTIN# input. IMCH drives the CPURST# (internal signal) while it is in the reset. IMCH works with IICH to initialize the NSI link between IICH and IMCH. Once the central reset (PLTRST#) is de-asserted, IMCH de-asserts the CPURST# (internal signal).

IMCH can also configure some aspects of the IA-32 core at Power On. IMCH drives these configuration settings before CPURST# (internal signal) assertion based on the contents of its Power-On Configuration Register (D8, F0, offset C0h).

#### IMCH Signals

##### Inputs

**PWRGD** - IMCH PowerGood: This signal is directly connected to the platform signal, SYS\_PWR\_OK. When asserted, PWRGD is an indication to the IMCH that power has been stable for at least 99 ms. When PWRGD is inactive, the IMCH asserts its CPURST# (internal signal) outputs.

**RSTIN#** - IMCH Reset: This signal is directly connected to the IICH PLTRST# output. When RSTIN is active, the IMCH asserts its CPURST# (internal signal) output.

#### 6.1.2.3.3 IA-32 core

Early in the cold reset (powergood) sequence, the IA-32 core voltage regulator drives a default voltage to the IA-32 core to read the fuses containing the IA-32 core FSB frequency requirements. The EP80579 then drives its BSEL pin to the appropriate value which is latched by the platform when it is known to be stable. The platform uses the BSEL information to update the IA-32 core voltage regulator to the appropriate operating voltage prior to the assertion of CPU\_VRD\_PWR\_GD. The platform also uses the value of BSEL to drive the clock generator to the correct reference clock (BCLK) frequency.

Reset and configuration for IA-32 core is done by IICH and IMCH. Reset for IA-32 core starts when IMCH asserts CPURST# (internal signal) and IICH asserts CPUPWRGD. The assertion of both of these signals initiates the PLL locking process for the IA-32 core. All the flops and internal states are reset during the reset process. The processor's PLL locks before CPURST# (internal signal) is de-asserted. CPURST# (internal signal) needs to be asserted for at least 1ms and not more than 10ms (processor spec). The IA-32 core receives power-on configuration values on its address pins during CPURST# (internal signal).

#### 6.1.2.3.4 IMCH

The IMCH receives the central reset (PLTRST#) from IICH. Clocks to DIMMs are disconnected till BIOS configures the DIMMs. Memory controller core logic boots at the default frequency as driven by the BSEL pin. Based on the DDR type and frequency memory controller needs to re-lock itself at the DDR frequency once BIOS has read the DDR.

#### 6.1.2.3.5 GbE MAC

There are three GbE MAC devices. Each GbE receives the internal system reset. Each GbE also receives a power OK signal from the platform that is also used as a reset. GbE0 receives this signal via the GBE\_AUX\_PWR\_GOOD external pin. GbE1 and GbE2 receive this signal via the SYS\_PWR\_OK external pin. The SYS\_PWR\_OK pin is connected to the SYS\_PWR\_OK platform signal which is also connected to the PWROK and PWRGD pins. The GBE\_AUX\_PWR\_GOOD pin should be connected to SYS\_PWR\_OK when no auxiliary power supply is used. If an auxiliary supply is used for GbE0, then GBE\_AUX\_PWR\_GOOD should be connected to the power good signal from that power supply (this signal is subject to the timing requirements documented in [Figure 6-4, "Power Rail Sequence Timings \(Sustain Well Power Management\)"](#) on page 170).

Under all circumstances, GbE0 MUST be powered by either the system supply or the auxiliary supply. Likewise, GBE\_AUX\_PWR\_GOOD MUST be connected to the corresponding power good signal. GbE0 must be powered to enable operation of either GbE1 or GbE2.

### 6.1.3 EP80579 Power Sequencing and Reset Sequence

The following diagrams show the reset sequencing.

Figure 6-2. Reset Sequence

1. The EP80579 receives power and drives its BSEL and V\_SEL pins. CPU\_VRD\_PWR\_GD, SYS\_PWR\_OK (platform signals) are not asserted. PLTRST#, and CPURST# (internal signal) are asserted.
2. CPU\_VRD\_PWR\_GD is asserted (Platform signal). Internal signal name is VRMPWRGD.
3. External Reference Clock provided from platform is stable, and is supplied to the EP80579 internal PLLs to generate required internal clocks. Voltage regulator output is modified to correspond to BSEL and V\_SEL values.
4. The EP80579 CRU PLL locks.
5. SYS\_PWR\_OK (platform signal) == PWROK/PWRGD internal signal asserted
6. IO and Core PLLs lock on the CPU.
7. IICH de-asserts PLTRST#
8. IMCH de-asserts udrstb (internal reset unit). All EP80579 blocks except the IA-32 core come out of reset.
9. IMCH de-asserts CPURST# (internal signal) CPU executes the reset micro-code

Table 6-3. EP80579 Power Supply Pins

| Nominal Voltage                      | Voltage Tolerance | Package Pin   | Supply Types  | Description              |
|--------------------------------------|-------------------|---------------|---|--------------------------|
| <b>WELL = CORE</b>                   |                   |               |   |                          |
| 0.9 V (DDR2)                         | +/-5%             | VTTDDR        | DDR   | DDR termination voltage  |
| 1.0V@600MHz<br>1.3V@1066/<br>1200MHz | +/-2%             | VCCVC         | IA-32 core  | IA-32 core power         |
| 1.2 V                                | +/-5%             | VCCA[1]       | IA-32 core  | IA-32 core PLL1 power    |
|                                      |                   | VCCA[2]       | IA-32 core  | IA-32 core PLL2 power    |
|                                      |                   | VCC           | CRU, CRU_PAD, DDR, Expansion, Bus, GBE, IMCH_PAD, MISC IO, PCI, Express, SATA | Core power               |

| 3.3 V             | +/-5%             | VCCPSUS       | USB2, IMCH_PAD | USB and RTC IO sustain power     |
|                   |                   | VCCGBEPSUS    | GBE            | Sustain 3.3V tolerance reference |
| 5 V               | +/-5%             | VCC50_SUS     | IMCH_PAD, USB2 | 5V sustain reference             |
| <b>WELL = RTC</b> |                   |               |                |                                  |
| 3.3               | +/-5%             | VCCPRTC       | IMCH_PAD       | Real Time Clock power            |

Figure 6-3 illustrates the sequence that power rails should follow as they are brought up at Power On.

**Figure 6-3. EP80579 Rail Power On Sequence**

Figures 6-4, 6-5, 6-6, and 6-7 accompanied by Table 6-4, Table 6-5, and Table 6-6 show the relationship between the power supply rails and key reset signals upon EP80579 power-up. In Figures 6-4 and 6-5, the terms “Core” and “Suspend” refer to the power wells that Table 6-2 on page 162 describes.

Figure 6-4. Power Rail Sequence Timings (Sustain Well Power Management)

Figure 6-5. Power Rail Sequence Timing (No Sustain Well Power Management)

Table 6-4. Power Rail Sequence Signal Timings

| Sym  | Parameter  | Min | Max | Units | Notes |
|------|--|-----|-----|-------|-------|
| t200 | VCCPRTC active to RTCRST# inactive               | 18  | –   | ms    |       |
| t201 | Suspend 5 V active to Suspend 3.3 V active       | 0   | –   | ms    | 1     |
| t202 | Suspend 3.3 V active to Suspend 2.5 V active     | 0   | –   | ms    | 2     |
| t203 | Suspend 2.5 V active to Suspend 1.2 V active     | 0   | –   | ms    | 3     |
| t204 | Suspend supplies active to RSMRST# inactive      | 10  | –   | ms    |       |
| t205 | VCCPRTC supply active to Suspend supplies active | 0   | –   | ms    | 4     |
| t209 | Core 5 V active to Core 3.3 V active             | 0   | –   | ms    | 1     |

**NOTES:**

- The 5 V supply must power up before its associated 3.3 V supply within 0.3V, and must power down after the 3.3 V supply within 0.3V.
- Ensure the following: a) Suspend 3.3 V must power up before Suspend 2.5 V or after Suspend 2.5 within 0.3 V, b) Suspend 2.5 V must power down before Suspend 3.3 V or after Suspend 3.3 V within 0.3 V.
- Ensure the following: a) Suspend 2.5 V must power up before Suspend 1.2 V or after Suspend 1.2 V within 0.3 V, b) Suspend 1.2 V must power down before Suspend 2.5 V or after Suspend 2.5 V within 0.3 V.
- The VccSus supplies must never be active while the VCCPRTC supply is inactive.
- Ensure the following a) Core 3.3 V must power up before Core 2.5 V or after Core 2.5 V within 0.3 V, b) Core 2.5 V must power down before Core 3.3 V or after Core 3.3 V within 0.3 V.
- Ensure the following: a) Core 2.5 V must power up before Vcc1.2 V or after Core 1.2 V within 0.3 V, b) Core 1.2 V must power down before Core 2.5 V or after Core 2.5 V within 0.3 V.

**Table 6-4. Power Rail Sequence Signal Timings**

| Sym  | Parameter   | Min | Max | Units | Notes |
|------|---|-----|-----|-------|-------|
| t210 | Core 3.3 V active to Core 2.5 V active                          | 0   | –   | ms    | 5     |
| t211 | Core 2.5 V active to Core 1.2 V active                          | 0   | –   | ms    | 6     |
| t212 | Suspend supplies active to Core supplies active                 | 0   | –   | ms    | 4     |
| t213 | All core supplies active to SYS_PWR_OK (platform signal) active | 99  | –   | ms    |       |

**NOTES:**

1. The 5 V supply must power up before its associated 3.3 V supply within 0.3 V, and must power down after the 3.3 V supply within 0.3V.
2. Ensure the following: a) Suspend 3.3 V must power up before Suspend 2.5 V or after Suspend 2.5 within 0.3 V, b) Suspend 2.5 V must power down before Suspend 3.3 V or after Suspend 3.3 V within 0.3 V.
3. Ensure the following: a) Suspend 2.5 V must power up before Suspend 1.2 V or after Suspend 1.2 V within 0.3 V, b) Suspend 1.2 V must power down before Suspend 2.5 V or after Suspend 2.5 V within 0.3 V.
4. The VccSus supplies must never be active while the VCCPRTC supply is inactive.
5. Ensure the following a) Core 3.3 V must power up before Core 2.5 V or after Core 2.5 V within 0.3 V, b) Core 2.5 V must power down before Core 3.3 V or after Core 3.3 V within 0.3 V.
6. Ensure the following: a) Core 2.5 V must power up before Vcc1.2 V or after Core 1.2 V within 0.3 V, b) Core 1.2 V must power down before Core 2.5 V or after Core 2.5 V within 0.3 V.

**Figure 6-6. Powergood Reset Sequence**

B6548-01

**Table 6-5. Powergood Reset Timings**

| Timing          | Description   | Value  |
|-----------------|---|--|
| T <sub>ab</sub> | VRMPWRGD/ CPU_VRD_PWR_GD assertion to Reference Clock Stable  | 2 ms   |
| T <sub>ac</sub> | VRMPWRGD/ CPU_VRD_PWR_GD assertion to SYS_PWR_OK (platform signal) assertion  | 99 ms  |
| T <sub>cd</sub> | SYS_PWR_OK (platform signal) assertion to CPU_PWRGD assertion (CPU_PWRGD is logical AND of VRMPWRGD/ CPU_VRD_PWR_GD and SYS_PWR_OK) | logic delay  |
| T <sub>df</sub> | CPU_PWRGD assertion to PLTRST# de-assertion   | 1 ms   |
| T <sub>fi</sub> | RSTIN# deassertion to CPURST# (internal signal) de-assertion  | 1 ms + CPU_RST_DONE transaction delay (max 10,000 PCI-e clocks) + CPU_RST_DONE capture timer (min 2000 reference clocks) |
| T <sub>ij</sub> | CPURST# (internal signal) de-assertion to POC invalid   | 2 reference clocks   |

**Figure 6-7. Hard Reset Sequence**

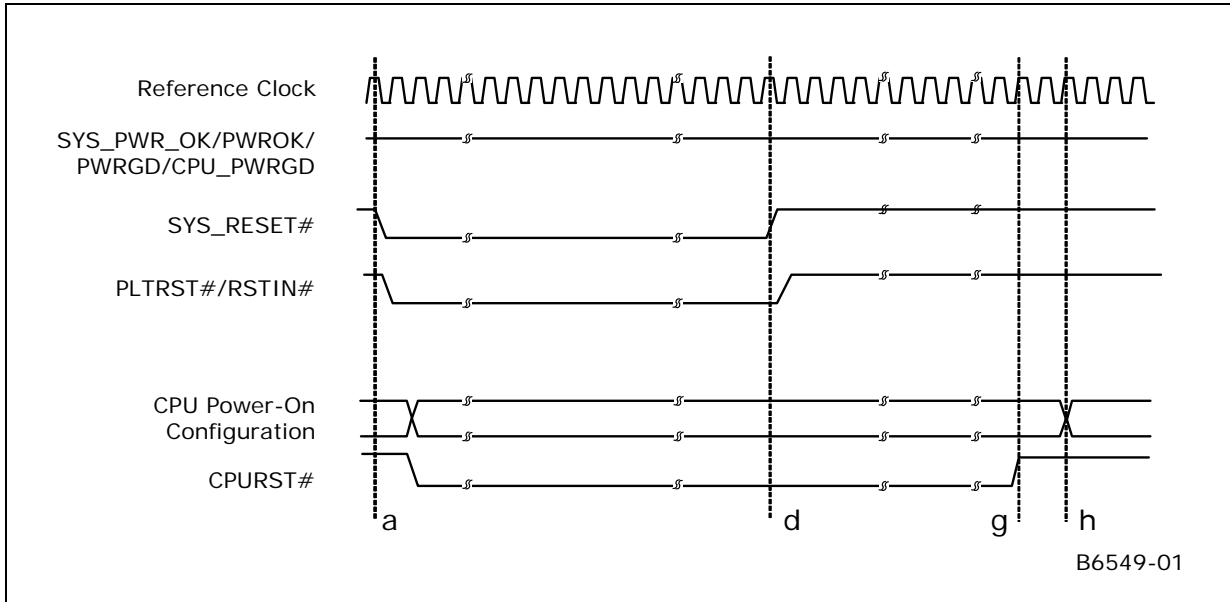

Table 6-6. Hard Reset Timings

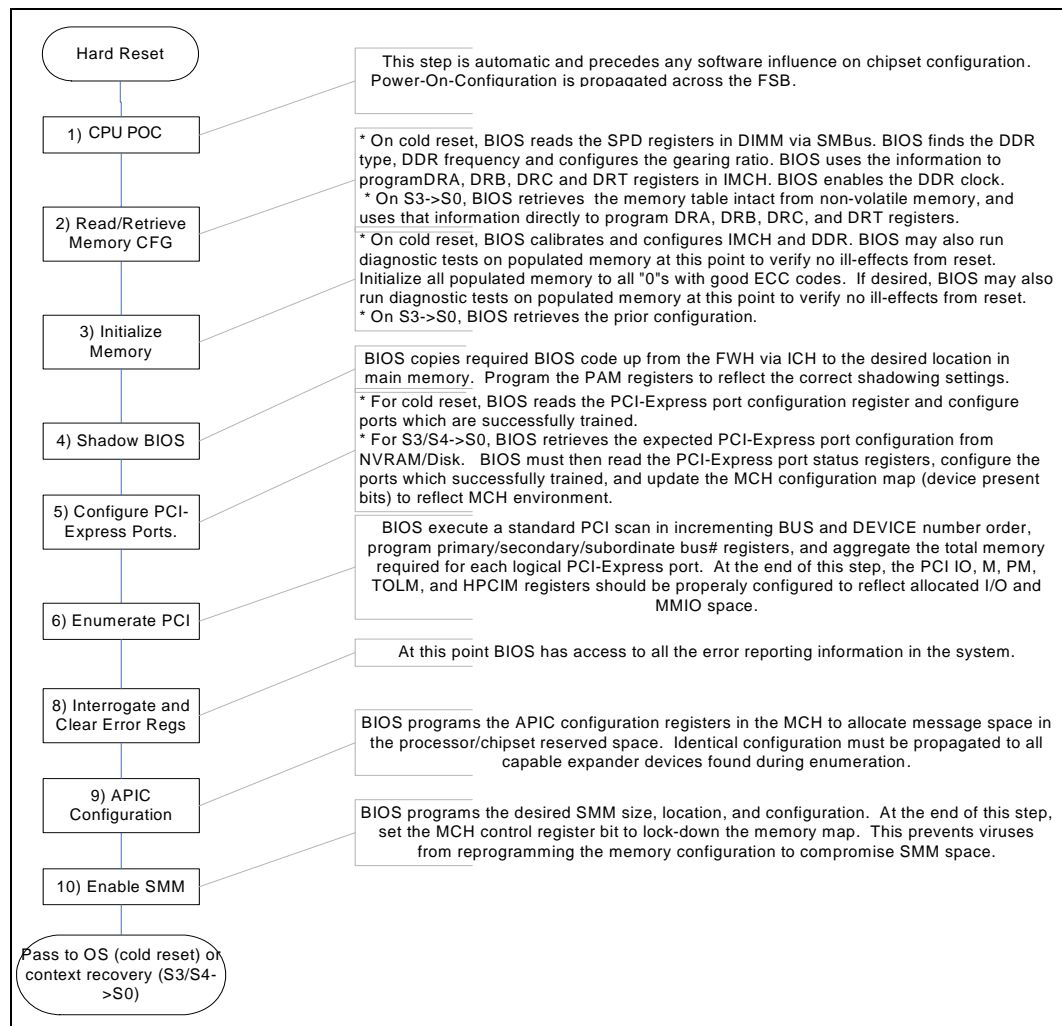

| Timing          | Description  | Value  |
|-----------------|--|--|
| T <sub>ad</sub> | Minimum SYS_RESET assertion duration                         | 100 ms   |
| T <sub>dg</sub> | RSTIN# deassertion to CPURST# (internal signal) de-assertion | 1 ms + CPU_RST_DONE transaction delay (max 10,000 PCI-e clocks) + CPU_RST_DONE capture timer (min 2000 reference clocks) |
| T <sub>gh</sub> | CPURST# (internal signal) de-assertion to POC invalid        | 2 reference clocks   |

## 6.2 BIOS Boot Flow (Initialization)

After hardware reset of the EP80579 and once IA -32 core has executed the reset micro-code, the IA 32 core reesters to reset vector (0xFFFF\_FFF0) and starts fetching from BIOS code boot rom. BIOS starts execution from the reset vector regardless of whether wake is from S3, S4, or S5. To determine that it is S3 resume, BIOS checks the SUS\_TYP field in the power management controller. If it is not S3, then normal boot occurs. If it is S3, then BIOS also checks the power failure bits (PWRBTNOR\_STS, PWR\_FLR, PWROK\_FLR). If these are set to one, then memory contents cannot be relied on and normal boot is followed. If it is an S3 resume and the power failure bits are not set, then the S3 boot path is followed. The normal boot path is that used for cold reset and for S4/S5 resume. From a BIOS perspective there is no difference between S4 and S5. The following steps describe the boot sequence after reset before handover to OS.

Figure 6-8. BIOS Boot Flow (Cold Boot, S3/S4->S0)

### 6.2.1 Memory Configuration

As described in the flow chart, one of the first actions of the BIOS is to configure main memory. This section describes the memory configuration sequence of BIOS.

At reset the memory controller disables the output clock reference drivers for all DIMM slots, which prevents them from locking at the wrong frequency, and then relocking after this step in the initialization process.

Memory controller core logic boots at a factory set default frequency as is indicated by the BSEL Pin. The BIOS must first set the DDR frequency and ratio via the DRC register because the memory controller needs to re-lock itself at the desired DDR frequency.

BIOS configures the DDR frequency by reading the FSB frequency value from a processor internal MSR and DDR2 circuitry and sets the DDR Speed bits [3:0] of the DRC register (d0, f0, offset 7Ch).

Once the correct frequencies have been selected BIOS updates CKDIS (d0, f0, offset 8Ch), such that only populated ranks of populated DIMM slots receive output clocks from the memory controller.

Using the DDR SPD data, BIOS programs the IMCH DRA and DRB registers for proper translation of physical addresses to DDR row, bank, and column addresses.

BIOS further configures the DDR configuration, timing, and impedance compensation settings to enable reliable communication between the IMCH and the DDR DIMM devices. The DRT registers (d0, f0, offsets 78h and 64h) defaults settings can be found in [Section 11.0, "System Memory Controller"](#).

BIOS further performs DDR calibration, memory initialization, and optional MemBIST.

At this stage BIOS is aware of the total amount of memory populated in the system, and may generate the starting value for the top of memory (TOM) register setting. BIOS will generally want to complete at least a rudimentary memory test sequence (next step) prior to finalizing the memory size information reported to the operating system.

For memory initialization details refer to [Section 11.0, "System Memory Controller"](#).

Wake from S3/S4/S5 are also described in the [Figure 6-8](#)

### 6.2.2 Memory Initialization

At this point in the boot sequence memory contains random data from power-on, and would therefore generate non-deterministic ECC errors on read accesses. To zero-out memory and initialize all locations with good ECC, the memory controller provides a hardware engine which will walk all populated DRAM space issuing cache-line sized writes with all zeroes as data.

### 6.2.3 Boot from Network

Booting from network on Intel platforms is supported by PXE. PXE (Preboot eXecution Environment) is an existing open industry specification for network clients to automatically download software images and configuration parameters. The PXE client software is typically implemented as a BIOS Option ROM that is executed during the preboot phase of the client system. This Option ROM (OpROM) implements a sufficient network stack to perform all of the necessary network operations to boot an operating system. This OpROM image is written assuming IA-32 architecture and instruction set. Also, each OpROM image is modified specifically for a given Network Interface Controller (NIC).

The BIOS must first establish an environment suitable for execution of the PXE OpROM. This environment must provide the following:

- System memory sufficient for C-code execution. This memory will be used to load/execute OpROM code, implement a call stack and data storage. In addition system memory must be available for loading/execution of OS.
- BIOS runtime services sufficient for OpROM execution. These services are typically provided by system BIOS and allow the PXE OpROM to be implemented for platform independence.
- The PCI sub-system is enumerated with allocation of system memory space, IO space and interrupts completed. This will establish the address location of resources accessed by the OpROM code during execution.

After OpROM initialization, the code remains in memory and waits until the BIOS reaches the point at which the OS-boot process begins. When a GbE is selected for boot, code in the OpROM will be used to initiate communication with a server to supply the images required for boot. After these images are loaded execution control passes from the BIOS to the images loaded in memory. This transition concludes the Preboot phase and enters in to the OS-boot phase.

## 6.3 Power Management

### 6.3.1 Power Management States

Figure 6-9. Global System Power States and Transitions

From a user-visible level, the system can be thought of as being in one of the states shown in Figure 6-9. In general use, computers alternate between the Working and Sleeping states. In the Working state, the computer is used to do work. User-mode application threads are dispatched and running. Individual devices can be in low-power (Dx) states and processors can be in low-power (Cx) states if they are not being used.

Any device the system turns off because it is not actively in use can be turned on with short latency. (What “short” means depends on the device. An LCD display needs to come on in sub-second times, while it is generally acceptable to wait a few seconds for a printer to wake.)

Precise definitions for Gx, Dx, Sx and Cx states are given in [Table 6-7](#), [Table 6-8](#), [Table 6-9](#), and [Table 6-10](#).

**Table 6-7. Global Power States**

| Global Power State | Description  |
|--------------------|--|
| G3 Mechanical Off  | A computer state that is entered and left by a mechanical means (for example, turning off the system's power through the movement of a large red switch). Various government agencies and countries require this operating mode. It is implied by the entry of this off state through a mechanical means that no electrical current is running through the circuitry and that it can be worked on without damaging the hardware or endangering service personnel. The OS must be restarted to return to the Working state. No hardware context is retained. Except for the real-time clock, power consumption is zero. |
| G2/S5 Soft Off     | A computer state where the computer consumes a minimal amount of power. No user mode or system mode code is run. This state requires a large latency in order to return to the Working state. The system's context will not be preserved by the hardware. The system must be restarted to return to the Working state. It is not safe to disassemble the machine in this state.  |
| G1 Sleeping        | A computer state where the computer consumes a small amount of power, user mode threads are not being executed, and the system “appears” to be off (from an end user's perspective, the display is off, and so on). Latency for returning to the Working state varies on the wake environment selected prior to entry of this state (for example, whether the system should answer phone calls). Work can be resumed without rebooting the OS because large elements of system context are saved by the hardware and the rest by system software. It is not safe to disassemble the machine in this state.             |
| G0 Working         | A computer state where the system dispatches user mode (application) threads and they execute. In this state, peripheral devices (peripherals) are having their power state changed dynamically. The user can select, through some UI, various performance/power characteristics of the system to have the software optimize for performance or battery life. The system responds to external events in real time. It is not safe to disassemble the machine in this state.  |

**Table 6-8. Device States**

| Device State | Description  |
|--------------|--|
| D3 Off       | Power has been fully removed from the device. The device context is lost when this state is entered, so the OS software will reinitialize the device when powering it back on. Since device context and power are lost, devices in this state do not decode their address lines. Devices in this state have the longest restore times. All classes of devices define this state. |
| D2           | The meaning of the D2 Device State is defined by each device class. Many device classes may not define D2. In general, D2 is expected to save more power and preserve less device context than D1 or D0. Buses in D2 may cause the device to lose some context (for example, by reducing power on the bus, thus forcing the device to turn off some of its functions).           |
| D1           | The meaning of the D1 Device State is defined by each device class. Many device classes may not define D1. In general, D1 is expected to save less power and preserve more device context than D2.   |
| D0 Fully-On  | This state is assumed to be the highest level of power consumption. The device is completely active and responsive, and is expected to remember all relevant context continuously.   |

Table 6-9. Sleeping States

| Sleeping State | Description  |
|----------------|--|
| S0             | Fully Active   |
| S1             | The S1 sleeping state is a low wake latency sleeping state. In this state, no system context is lost (CPU or chip set) and hardware maintains all system context.  |
| S2             | The S2 sleeping state is a low wake latency sleeping state. This state is similar to the S1 sleeping state except that the CPU and system cache context is lost (the OS is responsible for maintaining the caches and CPU context). Control starts from the processor's reset vector after the wake event.   |
| S3             | The S3 sleeping state is a low wake latency sleeping state where all system context is lost except system memory. CPU, cache, and chip set context are lost in this state. Hardware maintains memory context and restores some CPU and L2 configuration context. Control starts from the processor's reset vector after the wake event.  |
| S4             | The S4 sleeping state is the lowest power, longest wake latency sleeping state supported by ACPI. In order to reduce power to a minimum, it is assumed that the hardware platform has powered off all devices. Platform context is maintained.   |
| S5 Soft Off    | The S5 state is similar to the S4 state except that the OS does not save any context. The system is in the "soft" off state and requires a complete boot when it wakes. Software uses a different state value to distinguish between the S5 state and the S4 state to allow for initial boot operations within the BIOS to distinguish whether or not the boot is going to wake from a saved memory image. |

Table 6-10. CPU States

| Processor Power State | Description  |
|-----------------------|--|
| C0 - Full On          | Processor core is active. All clocks are running. Processor can maintain cache coherency via snoops. Processor responds to interrupt.  |
| C1 - Auto Halt        | Processor Core is not active after executing an Auto-Halt instruction. Processor Core clock is internally gated. Processor can maintain cache coherency via snoops. Processor responds to interrupts. Aside from putting the processor in a non-executing power state, this state has no other software-visible effects.   |
| C2 - Stop Grant       | Processor Core is not active after its STPCLK# input is asserted. Processor Core clock is internally gated. Processor can maintain cache coherency via snoops. Processor responds to interrupts. Aside from putting the processor in a non-executing power state, this state has no other software-visible effects.  |
| C3 - Deep Sleep       | Processor Core is not active after its SLP# input is asserted. Processor Core clock is gated and PLLs are disabled. Processor does not respond to snoops or interrupts. While in the C3 state, the processor's caches maintain state but ignore any snoops. The operating software is responsible for ensuring that the caches maintain coherency. The EP80579 does not support C3 while functioning in S0 state, however, while in S1 state, The EP80579 will put the processor in Deep Sleep state through the assertion on the SLP# signal. |

### 6.3.2 Power Management Support

As a system on a chip with embedded I/O devices and many SKUs, the EP80579 power management needs to perform multiple functions (typically under ACPI and/or BIOS system software control):

- Minimize power consumption of software-disabled interfaces/units.
- Transition between defined ACPI states as defined in [Table 6-11](#).
- Support system wake-up from GPIO, PCI Express\* devices and GbE MAC ports (Wake-on-LAN).

- Support cold and warm reset for the whole chip.

**Table 6-11. ACPI States**

| ACPI State                  | IICH                               | IMCH   | IA-32 core    | AIOC  |
|-----------------------------|------------------------------------|--|---------------|---|
| S0                          | Full On                            | Full On  | C0, C1, C2    | Full On   |
| S1                          | Full On                            | Full On  | Deep Sleep    | Full On   |
| S2                          | Not Supported                      | Not Supported                                  | Not Supported | Not Supported   |
| S3-hot                      | Not Supported                      | Not Supported                                  | Not Supported | Not Supported   |

| RTC        | VCCPRTC                  | On | On | On      | On | On |

- VTTDR, can optionally be powered off during S3, but typically is derived from and tracks DDR IO voltage, VCC18, to avoid the complexity involved in timing the VTTDDR power up with the exit of S3.
- VCCTMP18 and VCCAPEOPLL18 can optionally be powered off in S3 state. They are feed areas that consume very little power and are grouped with VCC18, which must be on in S3, to avoid requiring an additional power supply to support them.

### 6.3.2.1 Transitioning Between Power States

The EP80579 uses a cooperative power-down that is driven by software. To transition from S0 into the S3 or S4 state under ACPI/BIOS/OS/device driver control, system software is required to:

- Suspend acceleration and security service application-level threads.
- Place ASU and SSU devices into quiescent idle state, by completing all outstanding work requests, saving internal state to memory, then disabling ASU/SSU interrupts.
- Quiesce I/O interfaces by disabling Rx of new traffic, finalizing outstanding Tx operations, disabling interrupts, and saving snap-shot of internal state to memory.
- Save internal IMCH and IICH state to memory.
- If transitioning to S4, move DRAM image to disk.
- Drain all outstanding IMCH updates to DRAM.
- Signal IICH to power-down the IA-32 core, the AIOC, the IMCH and the IICH. In case of S3, the memory interface is placed into self-refresh mode. In S3/S4 state, the GbE MAC, GPIO and LPC interfaces remain powered to process wake events.

An external wake event from GPIO, GbE MAC (received Wake-on-LAN packet) or PCI Express\* signals the IICH to initiate a complete reset sequence that transitions the EP80579 back into the S0 state as follows:

- All internal states outside of the IICH Resume Well are fully reset.
- On resume from S3, BIOS does not reinitialize memory. Please refer to [Section 6.2, "BIOS Boot Flow \(Initialization\)"](#) for details.
- On resume from S3 or S4, all EP80579 device drivers (including ASU and SSU drivers) are expected to restore internal device state from their memory resident save area.
- On resume from S3 or S4, resume acceleration and security service application-level threads.

**Note:** There is no support for wake from USB when in S3/S4/S5.

### 6.3.2.2 Power State Transition Timing Diagrams

For power state transition timing details, refer to [Section 49.5.1.2, "Power Management AC Characteristics"](#).

### 6.3.3 Thermal Sensor

The EP80579 has an on-die thermal sensor. It helps to control the silicon temperature by monitoring the silicon thermal status and activating the thermal control sequence when the silicon reaches its maximum operating temperature. See [Chapter 50.0, "Thermal Specifications and Design Considerations"](#) for details.

### 6.3.4 ACPI Implementation

The PCI device tree for the EP80579 is shown in [Figure 3-4, "Overview of PCI infrastructure for On-die Devices"](#) on page 121. The EP80579 follows the ACPI specification (<http://www.acpi.info/DOWNLOADS/ACPIspec30a.pdf>) which implies that all the PCI devices implement the standard PCI/ACPI registers:

1. PCI Power Management Block
2. Capability ID
3. Next Item Pointer
4. Power Management Capabilities (PMC)
5. Power Management Control and Status Register (PMCSR)

§ §

## 7.0 Register Summary

---

### 7.1 Overview of Register Descriptions and Summaries

This chapter presents summary tables for the registers and MMIO spaces that the components of the EP80579 define. In addition, this chapter describes how to read the standard register description that is used throughout this document to describe the functionality of individual registers.

The register summaries in this document follow a general formatting structure that includes, for each register, its name, default value, offsets, and a cross-reference to its detailed register description. Locations that are not associated with a register in the summary table should be assumed to be reserved.

The summaries in this chapter are organized by functional unit and describe the EP80579 registers that are visible from the IA platform perspective (e.g., PCI registers, PCI memory-mapped I/O registers, fixed IA I/O space registers, etc.).

#### 7.1.1 Register Description Tables

In addition to the summaries in this chapter, this document uses a standard tabular format to describe the operation of each register in the device. These descriptions are cross-referenced from summary tables and cover the specific content and functionality of a register. The information in a register description table can be broken down into three major areas:

- Materialization information that establishes how the register appears to software.
- Global information that lists the size, default, value, power well, etc. for the register.
- Field definitions that list the name, description, default value, and attributes of all the fields in the register.

The register definition can describe a unique register entity in the design or serve as a template that describes several register entities are instantiated in the design. The materialization information in the register description table can handle common scenarios with minimal duplication of content:

- A single physical register that materializes at multiple “addresses” in the system (i.e., a double- or triple-mapped register).
- Multiple physical registers that share the same definition but materialize within different “device” instances.
- Multiple physical registers that share the same definition but materialize repeatedly within a single “device”.

The register description table format handles the first two scenarios through “views” that make up the bulk of the materialization information in a register description table and handles the final scenario through a set of “repeated register” conventions.

The materialization information in a table includes specification of one or more “views”. Each view consists of a view “type” along with several type-specific fields that serve to specify the “address” of the register in the system from a particular perspective. For example, a PCI “view” includes, in part, the PCI bus number as a parameter since this information is necessary to specify the location of the register. In a register description table, each view specification occupies one row of the table. A register description table includes one or more views depending on how the register materializes to software.

There are a number of different views that this document uses to describe how EP80579 registers materialize to software. Table 7-1 defines the views that this document uses along with the type-specific fields that each view includes.

**Table 7-1. Definition of the Views Used in Register Description Tables**

| View Type | Describes Registers in   | Type-Specific Fields |   |
|-----------|--|----------------------|---|
|           |  | Name                 | Description   |
| PCI       | PCI configuration space or memory/IO spaces that are mapped via PCI BARs | B:D:F                | PCI Bus, Device, and Function number that the register is associated with through PCI configuration, memory-mapped, or I/O-mapped spaces (see BAR).   |
|           |  | BAR                  | PCI base address register in B:D:F that the register is referenced from. This field is “Configuration” for registers that materialize in PCI configuration space. Otherwise, the field is the name of the BAR register in B:D:F that provides the base address.<br>The register materializes in memory space unless the BAR field contains “(IO)”; i.e., views with a BAR of “FOOBAR” and “FOOBAR (IO)” materialize in memory and I/O spaces, respectively. |
|           |  | Offset Start         | Starting offset from BAR. The offset is in bytes unless the field contains “(2B)”, “(4B)”, and “(8B)” to indicate a single-, double-, or quad-word offset, respectively <sup>a</sup> .  |
|           |  | Offset End           | Ending offset of register from BAR. The offset is in bytes unless the field contains “(2B)”, “(4B)”, and “(8B)” to indicate a single-, double-, or quad-word offset, respectively <sup>a</sup> .  |
| IA F      | General “fixed” location in IA memory or I/O spaces                      | Base Address         | Base address. Typically, this field contains a number or register name. It may contain a comma-separated list if the register can materialize at one of several possible bases (for example, “100h, 200h based on FOOREG”).<br>The register materializes in memory space unless the base address field contains “(IO)”; i.e., views with a base address of “0000h” and “0000h (IO)” are in memory and I/O space, respectively.                              |
|           |  | Offset Start         | Starting address or offset from base address field. The offset is in bytes unless the field contains “(2B)”, “(4B)”, and “(8B)” to indicate a single-, double-, or quad-word offset, respectively <sup>a</sup> .  |
|           |  | Offset End           | Ending address or offset from base address field. The offset is in bytes unless the field contains “(2B)”, “(4B)”, and “(8B)” to indicate a single-, double-, or quad-word offset, respectively <sup>a</sup> .  |

**Table 7-1. Definition of the Views Used in Register Description Tables**

| View Type | Describes Registers in                                    | Type-Specific Fields |   |
|-----------|---|----------------------|---|
|           |   | Name                 | Description   |
| IA I      | Indirect location accessed via index/window register pair | Win:Idx              | Name of the window and index registers that expose the indirect register(s).<br>For example, W:I of "FOO:BAR" indicates that accesses to FOO indirectly access the register that is located at the index (i.e., offset) in BAR.           |
|           |   | Offset Start         | Starting offset to put in the index register to access the indirect register. The index is in bytes unless the field contains "(2B)", "(4B)", and "(8B)" to indicate a single-, double-, or quad-word offset, respectively <sup>a</sup> . |
|           |   | Offset End           | Ending address or offset from base address field. The offset is in bytes unless the field contains "(2B)", "(4B)", and "(8B)" to indicate a single-, double-, or quad-word offset, respectively <sup>a</sup> .                            |

a. In this usage, words, double words, and quad words are 16-, 32-, and 64-bits, respectively.

The register description tables adopt the convention that [Table 7-2](#) and [Table 7-3](#) describe for view and register name information to distinguish the three scenarios mentioned above (single physical register, multiple physical registers in the same device, and multiple physical registers in different devices). [Table 7-2](#) describes how to interpret the combination of register views and name. This table elides the type-specific fields and simply lists the types of views for brevity.

**Table 7-2. View Convention to Describe Single Versus Multiple Physical Registers**

| Scenario | Register Name | Example Views from Register Table | Interpretation   |
|----------|---------------|-----------------------------------|--|
| Single   | FOO           | PCI<br>PCI<br>IA F<br>IA F        | This example shows a single physical register FOO. FOO materializes in two different PCI devices and at two different "fixed" memory locations that the PCI and IA M views describe. |

**Table 7-2. View Convention to Describe Single Versus Multiple Physical Registers**

| Scenario                                   | Register Name | Example Views from Register Table                     | Interpretation   |
|--|---------------|---|--|
| Multiple<br>(Different Devices, Same name) | BAZ           | PCI 1<br>PCI 2<br>IA F 1<br>IA F 2                    | All views for the register include a numeric suffix that corresponds to the physical instance of the register. Views with the same suffix address the same physical register.<br><br>This example shows two physical registers matching the description of BAZ. The first instance of BAZ materializes in the PCI device and at the memory location that the PCI 1 and IA F 1 views describe, while the second instance of BAZ materializes in PCI 2 and at IA F 2.  |
| Multiple<br>(Different Devices and Names)  | BAZ{2:0}      | PCI 0<br>PCI 1<br>PCI 2<br>IA F 0<br>IA F 1<br>IA F 2 | Like the Multiple scenario above, the views also include a numeric suffix that, in this case, maps to different register names. The {m:n} notation in the register name indicates that each physical instance of the register has a different name that includes the instance number. An instance number <i>i</i> is an integer such that $n \leq i \leq m$ . This implies that there are $m - n + 1$ distinct instances of the register.<br><br>This example shows three physical registers matching the description of BAZ: BAZ0, BAZ1, and BAZ2. BAZ0 materializes in the PCI device and at the memory location that the PCI 0 and IA F 0 views describe, BAZ1 materializes in PCI 1 and at IA F 1, and BAZ2 materializes in PCI 2 and at IA F 2. |
| Multiple<br>(Same Device)                  | BLEH[1-3]     | PCI<br>PCI<br>IA F<br>IA F                            | The register name has a suffix indicating the number of physical instances of the register. The format of the suffix is “[m-n]” where <i>m</i> and <i>n</i> are integers and implies that there are $n - m + 1$ distinct instances of the register.<br><br>This example shows three physical registers matching the description of BLEH: BLEH[1], BLEH[2], and BLEH[3]. Each register materializes in two different PCI devices and at two different “fixed” memory locations that the PCI and IA M views describe.  |

When describing multiple physical registers of the same “format” that materialize in the same device, the tables use the convention that [Table 7-3](#) describes to denote the offsets<sup>1</sup>.

**Table 7-3. Offset Convention to Describe Multiple Physical Registers in the Same Device**

| Register Name | Offset in View(s) (Start or End) | Interpretation  |
|---------------|----------------------------------|---|
| BLEH[1-3]     | 10h, 38h, 70h                    | Three BLEH registers whose offsets match the elements of the comma-separated list. The offsets are BLEH[1] = 10h, BLEH[2] = 38h, BLEH[3] = 70h. |
| BAZ[1-2]      | 103h at 2h                       | Two BAZ registers whose offsets stride by 2h starting from 103h. The offsets are BAZ[1] = 103h, BAZ[2] = 105h.                                  |

The remainder of this section presents several examples that illustrates how to read register definition tables. These examples are intended to illustrate how to interpret a register definition table, *not* describe actual registers in the EP80579. As a result, some of the examples may be contrived from the perspective of an implementation.

1. In this scenario, it is the offset that distinguishes the different materialization points of the registers; the remaining view fields should be the same since this scenario applies to registers in the same “device”.

Given the conventions outlined above, [Table 7-4](#) presents an example definition for the register EG\_SINGLE which corresponds to a single physical register. This register materializes at offset E0h in the configuration space for PCI device 4, at *double-word* (i.e., 32-bit) offset 100h in the memory region defined by FOOBAR of PCI device 12, and at the fixed offset 0A0h in IA I/O space<sup>1</sup>.

**Table 7-4. EG\_SINGLE: Example Single Register with Different Views**

|   |                                 |  |  |                        |                   |
|---|---------------------------------|--|--|------------------------|-------------------|
| <b>Description:</b> A single physical register that materializes at multiple locations. |                                 |  |  |                        |                   |
| <b>View:</b> PCI  | <b>BAR:</b> Configuration       | <b>Bus:Device:Function:</b> 0:4:0                              | <b>Offset Start:</b> E0h<br><b>Offset End:</b> E1h             |                        |                   |
| <b>View:</b> PCI  | <b>BAR:</b> FOOBAR              | <b>Bus:Device:Function:</b> 0:12:0                             | <b>Offset Start:</b> 100h (4B)<br><b>Offset End:</b> 101h (4B) |                        |                   |
| <b>View:</b> IA F   | <b>Base Address:</b> 0000h (IO) |  | <b>Offset Start:</b> A0h<br><b>Offset End:</b> A1h             |                        |                   |
| <b>Size:</b> 16 bit   | <b>Default:</b> 8086h           |  | <b>Power Well:</b> Core  |                        |                   |
| <b>Bit Range</b>  | <b>Bit Acronym</b>              | <b>Bit Description</b>   | <b>Sticky</b>  | <b>Bit Reset Value</b> | <b>Bit Access</b> |
| 15 : 00   | MAGIC                           | <b>Magic Stuff:</b> This field contains a magic number, 8086h. |  | 8086h                  | RO                |

In the table, the materialization information includes the rows starting with “View” and the title; the field definitions includes all rows below the row starting with “Bit Range”, and the rows beginning “Description” and “Size” encompass the global information.

[Table 7-5](#) presents an example definition for the register EG\_MULTI\_DIFF which corresponds to two physical registers that materialize in different “devices”. The first instance materializes at offset D0h in the configuration space for PCI device 20 and at the fixed offset FFEF01B0h in IA memory space. The second instance materializes at offset D0h in the configuration space for PCI device 21 and at the fixed offset FFEF11C0h in IA memory space. Both registers have the same name, EG\_MULTI\_DIFF.

**Table 7-5. EG\_MULTI\_DIFF: Example Multiple Registers in Different Devices with Different Views**

|  |                                |   |  |                        |                   |
|--|--------------------------------|---|--|------------------------|-------------------|
| <b>Description:</b> A set of two physical registers that materialize in different devices. |                                |   |  |                        |                   |
| <b>View:</b> PCI 1   | <b>BAR:</b> Configuration      | <b>Bus:Device:Function:</b> 0:20:0                            | <b>Offset Start:</b> D0h<br><b>Offset End:</b> D3h             |                        |                   |
| <b>View:</b> PCI 2   | <b>BAR:</b> Configuration      | <b>Bus:Device:Function:</b> 0:21:0                            | <b>Offset Start:</b> D0h<br><b>Offset End:</b> D3h             |                        |                   |
| <b>View:</b> IA F 1  | <b>Base Address:</b> 00000000h |   | <b>Offset Start:</b> FFEF01B0h<br><b>Offset End:</b> FFEF01B3h |                        |                   |
| <b>View:</b> IA F 2  | <b>Base Address:</b> 00000000h |   | <b>Offset Start:</b> FFEF11C0h<br><b>Offset End:</b> FFEF11C3h |                        |                   |
| <b>Size:</b> 32 bit  | <b>Default:</b> DEADBEEFh      |   | <b>Power Well:</b> Core, Reset                                 |                        |                   |
| <b>Bit Range</b>   | <b>Bit Acronym</b>             | <b>Bit Description</b>  | <b>Sticky</b>  | <b>Bit Reset Value</b> | <b>Bit Access</b> |
| 31 : 00  | BMAGIC                         | <b>Black Magic Stuff:</b> This field contains a magic number. |  | DEADBEEFh              | RO                |

1. Recall that offsets are in bytes unless otherwise specified with “(2B)”, “(4B)”, or “(8B)”.

This table illustrates how the global information can be tied to a particular register in multiple register cases. In this table, the first and second instances of EG\_MULT\_DIFF are in the “Core” and “Reset” power wells, respectively. Typically, this notation is only be used for the power well.

It is also possible to incorporate the instance number in the name as Table 7-2 describes. Using the name EG\_MULTI{2:1}\_DIFF in Table 7-5 would identify two physical registers with different names. The first, EG\_MULTI2\_DIFF, materializes according to the PCI 2 and IA F 2 views, while the second, EG\_MULTI1\_DIFF, materializes according to the PCI 1 and IA F 1 views.

Table 7-6 presents an example definition for the register EG\_MULTI\_SAME which corresponds to two physical registers that materialize in the same “device”. The instance EG\_MULTI\_SAME[1] materializes at offset ACE0h in the I/O region defined by BLAHBAR of PCI device 16 and at the fixed offset 100h in IA I/O space. The instance EG\_MULTI\_SAME[2] materializes at offset ACE4h in the I/O region defined by BLAHBAR of PCI device 16 and at the fixed offset 120h in IA I/O space.

**Table 7-6. EG\_MULTI\_SAME[1-2]: Example Multiple Registers in Same Device with Different Views**

|  |                                 |   |                                    |  |                   |
|--|---------------------------------|---|------------------------------------|--|-------------------|
| <b>Description:</b> A set of two physical registers that materialize in the same device. |                                 |   |                                    |  |                   |
| <b>View:</b> PCI   | <b>BAR:</b> BLAHBAR (IO)        |   | <b>Bus:Device:Function:</b> 0:16:0 | <b>Offset Start:</b> ACE0h at 4h<br><b>Offset End:</b> ACE3h at 4h |                   |
| <b>View:</b> IA F  | <b>Base Address:</b> 0000h (IO) |   |                                    | <b>Offset Start:</b> 100h, 120h<br><b>Offset End:</b> 103h, 123h   |                   |
| <b>Size:</b> 32 bit  | <b>Default:</b> DEAD8086h       |   |                                    | <b>Power Well:</b> Core  |                   |
| <b>Bit Range</b>   | <b>Bit Acronym</b>              | <b>Bit Description</b>  | <b>Sticky</b>                      | <b>Bit Reset Value</b>   | <b>Bit Access</b> |
| 31 : 00  | BRMAGIC                         | <b>Blacker Magic Stuff:</b> This field contains a magic number. |                                    | DEAD8086h  | RO                |

Note that in this example, the strides do not need to be the same across the different views.

Finally, Table 7-7 presents an example definition for the register EG\_INDEX which corresponds to a physical registers that materialize indirectly. To access the EG\_INDEX register, the starting offset 0100h (in double words of 32-bits) is written to the APIC\_IDX index register to select EG\_INDEX which is then accessed through the APIC\_WND window registers.

**Table 7-7. EG\_INDEX: Example Single Indexed Register**

|  |                                  |   |               |  |                   |
|--|----------------------------------|---|---------------|--|-------------------|
| <b>Description:</b> A single indexed register. |                                  |   |               |  |                   |
| <b>View:</b> IA I                              | <b>Win:Idx</b> APIC_WND:APIC_IDX |   |               | <b>Offset Start:</b> 0100h (4B)<br><b>Offset End:</b> 0100h (4B) |                   |
| <b>Size:</b> 32 bit                            | <b>Default:</b> OACEFACEh        |   |               | <b>Power Well:</b> Core  |                   |
| <b>Bit Range</b>                               | <b>Bit Acronym</b>               | <b>Bit Description</b>                                  | <b>Sticky</b> | <b>Bit Reset Value</b>   | <b>Bit Access</b> |
| 31 : 00  | MAGIC                            | <b>Magic Stuff:</b> This field contains a magic number. |               | OACEFACEh  | RO                |

The offsets should always fit within the index register.

## 7.1.2 Register Field Access Attributes

Table 7-8 describes the register field access attribute acronyms that this document uses in its summaries and descriptions.

**Table 7-8. Register Field Access Attributes**

| Attribute | Description   |
|-----------|---|
| RV        | Reserved – A reserved field.  |
| RO        | Read-Only – Software/BIOS can only read this bit. Contents are either hardwired or set by hardware.   |
| WO        | Write-Only – Not supported as a bit. The write causes a hardware event to take place.   |
| WRC       | Write/Read to Clear – Writes and reads clear. See bit descriptions.   |
| RC        | Read to Clear – Cleared automatically when read.  |
| RW        | Read/Write – Software/BIOS can read and write this bit.   |
| RWC       | Read/Write-Clear – Software/BIOS can read this bit and must write to a 1 to clear this bit.   |
| RCWC      | Read-Clear/Write-Clear – Cleared when read or Write one to clear.   |
| RWOC      | Read/Write zero to Clear – Software/BIOS can read this bit, and must write to a 0 to clear this bit.  |
| RO/W      | Read zero/Write – This register will only read 0. Must read register description for write actions.   |
| RO/RWC    | Read only/Read-Write-Clear – Attribute dependent on configuration. See bit description  |
| RS/W1C    | Read-Set/Write-Clear – Read to set, write 1 to clear  |
| RWS       | Read/Write-Set – Software/BIOS can read this bit and write it to a 1. Hardware clears this bit.   |
| RWL       | Read/Write-Lock – Software/BIOS can read and write this bit. Hardware or another configuration bit can lock this bit and prevent it from being updated.   |
| RWO       | Read/Write-Once – Software/BIOS can read this bit, but can only write this bit once. It is a special form of RWL. Once any byte within a register with RWO bits has been written, the RWO bits are locked and only a reset can clear its contents. Any exceptions are clearly documented. |

In some cases, the access attribute for a field may depend on a setting of a fuse or a value in another register. In this case, the access types for the field will be of the form “X or Y”. Readers should consult the description of the field for additional information on the conditions that enable the various access types. For example, a field FOO that is either RO or RW based on the setting of a fuse bit would have an access type of “RO or RW”.

## 7.1.3 Register Nomenclature and Values

The summary and description tables also include register and field values. In general, a number is given by a string of digits followed by a single-character that identifies the base as decimal, “d”, hexadecimal, “h”, or binary, “b”. Both the digits and base pieces of a number are always case-insensitive<sup>1</sup>. That is, beefh and BEEFH represent the same hexadecimal number. A value of 0 (zero) does not require a base character. If a value is non-zero, the default base is assumed to be binary unless stated otherwise. All hexadecimal and decimal numbers must always have a base character.

In addition to the legal digits for the base, the digit string can contain “x” to denote undefined values. Typically, Xh is equivalent to XXXXb, XXh is equivalent to XXXXXXXb. However, a 5-bit wide field that is undefined can be represented as both XXh and XXXXXb; that is, a nibble in a hex representation must be “x” if any of its bits are “x”.

1. The “suggested” convention is that digits are always upper case while the base is always lower case.

There are three special values that can be used in place of numbers to indicate cases where the value of a register or field is not fixed at design time and depends on other parameters:

- **Fuse:** The setting of one or more fuses determines the value of the register or field.
- **Strap:** The setting of a strap pin determines the value of the register or field.
- **Variable:** The setting of other on-die state determines the value of the register or field.

In these cases, the description of the register or field that is not fixed should contain additional information that describes how the EP80579 arrives at the value.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

#### 7.1.4 “Sticky” Register Fields

For each field in a register, the description tables include an indication of whether or not the bits that make up the field are “sticky” or not. Sticky bits in registers will retain their value across a hard reset. Resetting field in a register that is designated as “sticky” to its default/reset value requires a cold reset. Unless explicitly noted, all register fields are assumed to not be sticky.

## 7.2 IA-32 core Registers

The IA-32 core registers are described in the related documentation for the Intel® Pentium® M Processor .

## 7.3 IMCH and IICH Registers

This section summarizes the registers found in the IMCH and the IICH.

### 7.3.1 IMCH Registers: Bus 0, Device 0, Function 0

The IMCH includes the registers listed in Table 7-9 through Table 7-11. These registers materialize in PCI configuration and memory (via PCI BAR) spaces. See Section 16.1, “IMCH Registers: Bus 0, Device 0, Function 0”, and Section 16.7, “Memory Mapped I/O for NSI Registers” for detailed discussion of these registers.

**Table 7-9. Bus 0, Device 0, Function 0: Summary of IMCH PCI Configuration Registers (Sheet 1 of 2)**

| Offset Start | Offset End | Register ID - Description   | Default Value |
|--------------|------------|---|---------------|
| 00h          | 01h        | “Offset 00h: VID – Vendor Identification Register” on page 391                        | 8086h         |
| 02h          | 03h        | “Offset 02h: DID – Device Identification Register” on page 391                        | 5020h         |
| 04h          | 05h        | “Offset 04h: PCICMD: PCI Command Register” on page 392                                | 0006h         |
| 06h          | 07h        | “Offset 06h: PCISTS: PCI Status Register” on page 393                                 | 0010h         |
| 08h          | 08h        | “Offset 08h: RID - Revision Identification Register” on page 394                      | Variable      |
| 0Ah          | 0Ah        | “Offset 0Ah: SUBC - Sub-Class Code Register” on page 394                              | 00h           |
| 0Bh          | 0Bh        | “Offset 0Bh: BCC – Base Class Code Register” on page 394                              | 06h           |
| 0Eh          | 0Eh        | “Offset 0Eh: HDR - Header Type Register” on page 395                                  | 80h           |

### 7.3.2 IMCH Error Reporting Registers: Bus 0, Device 0, Function 1

The IMCH includes the registers listed in Table 7-12. These registers materialize in PCI configuration space. See Section 16.2, “DRAM Controller Error Reporting Registers: Bus 0, Device 0, Function 1” for detailed discussion of these registers.

**Table 7-12. Bus 0, Device 0, Function 1: Summary of IMCH Error Reporting PCI Configuration Registers (Sheet 1 of 2)**

| Offset Start | Offset End | Register ID - Description   | Default Value |
|--------------|------------|---|---------------|
| 00h          | 01h        | “Offset 00h: VID - Vendor Identification Register” on page 447              | 8086h         |
| 02h          | 03h        | “Offset 02h: DID - Device Identification Register” on page 447              | 5021h         |

### 7.3.3 EDMA Engine Registers: Bus 0, Device 1, Function 0

The EDMA engine includes the registers listed in Table 7-13 and Table 7-14. These registers materialize in PCI configuration and memory (via PCI BAR) spaces. See Section 16.3, “EDMA Registers: Bus 0, Device 1, Function 0” and Section 16.6, “Memory Mapped I/O for EDMA Registers” for detailed discussion of these registers.

**Table 7-13. Bus 0, Device 1, Function 0: Summary of EDMA PCI Configuration Registers**

| Offset Start | Offset End | Register ID - Description   | Default Value |
|--------------|------------|---|---------------|
| 00h          | 01h        | “Offset 00h: VID - Vendor Identification Register” on page 502            | 8086h         |

### 7.3.4 PCI Express\* Port A Registers: Bus 0, Device 2, Function 0

The PCI Express\* Port A includes the registers listed in Table 7-15. These registers materialize in PCI configuration spaces. See Section 16.4, “PCI Express\* Port A Standard and Enhanced Registers: Bus 0, Devices 2 and 3, Function 0” for detailed discussion of these registers.

**Table 7-15. Bus 0, Device 2, Function 0: Summary of PCI Express Port A Standard and Enhanced PCI Configuration Registers (Sheet 1 of 3)**

### 7.3.5 PCI Express\* Port A1 Registers: Bus 0, Device 3, Function 0

The PCI Express\* Port A1 includes the registers listed in Table 7-16. These registers materialize in PCI configuration space. See Section 16.4, “PCI Express\* Port A Standard and Enhanced Registers: Bus 0, Devices 2 and 3, Function 0” for detailed discussion of these registers.

**Table 7-16. Bus 0, Device 3, Function 0: Summary of PCI Express Port A1 Standard and Enhanced PCI Configuration Registers (Sheet 1 of 3)**

| Offset Start | Offset End | Register ID - Description  | Default Value |

### 7.3.6 USB (1.1) Controller: Bus 0, Device 29, Functions 0

The USB 1.1 controller includes the registers listed in Table 7-17 and Table 7-18. These registers materialize in PCI configuration and I/O spaces (via PCI I/O BAR), respectively. See Chapter 25.0, “USB (1.1) Controller: Bus 0, Device 29, Function 0” for detailed discussion of these registers.

**Table 7-17. Bus 0, Device 29, Functions 0, Summary of USB (1.1) Controller PCI Configuration Registers**

### 7.3.7 USB (2.0) Controller: Bus 0, Device 29, Function 7

The USB 2.0 controller includes the registers listed in Table 7-19 and Table 7-20. These registers materialize in PCI configuration and I/O spaces (via PCI I/O BAR), respectively. See Chapter 26.0, “USB 2.0 PCI Configuration Registers” for detailed discussion of these registers.

**Table 7-19. Bus 0, Device 29, Function 7: Summary of USB (2.0) Controller PCI Configuration Registers**

| Offset Start | Offset End | Register ID - Description   | Default Value |

### 7.3.8 Root Complex: Bus 0, Device 31, Function 0

The Root Complex includes the registers listed in Table 7-21. These registers materialize in memory space (via PCI memory BAR), respectively. See Chapter 17.0, “Bridging and Configuration” for detailed discussion of these registers.

**Table 7-21. Bus 0, Device 31, Function 0: Summary of Root Complex Configuration Registers Mapped Through RCBA Memory BAR**

| Offset Start | Offset End | Register ID - Description  | Default Value     |
|--------------|------------|--|-------------------|
| 0000h        | 0003h      | “Offset 0000h: VCH - Virtual Channel Capability Header Register” on page 691               | 10010002h         |

### 7.3.9 LPC Interface: Bus 0, Device 31, Function 0

The LPC interface includes the registers listed in Table 7-22 through Table 7-26. These registers materialize in PCI configuration and I/O spaces (via PCI I/O BAR). See Chapter 19.0, “LPC Interface: Bus 0, Device 31, Function 0”, Chapter 27.0, “Power Management”, Chapter 18.0, “System Management”, and Chapter 22.0, “General Purpose I/O: Bus 0, Device 31, Function 0” for detailed discussion of these registers.

**Table 7-22. Bus 0, Device 31, Function 0: Summary of LPC Interface PCI Configuration Registers**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|
| 00h          | 03h        | “Offset 00h: ID: Vendor Identification Register” on page 734       | 50318086h     |

### 7.3.10 SATA Controller: Bus 0, Device 31, Function 2

The SATA controller includes the registers listed in [Table 7-27](#), [Table 7-28](#), and [Table 7-29](#). These registers materialize in PCI configuration, I/O, and memory spaces (via PCI I/O and memory BARs). See [Chapter 23.0, "SATA: Bus 0, Device 31, Function 2"](#) for detailed discussion of these registers.

**Table 7-27. Bus 0, Device 31, Function 2: Summary of SATA Controller PCI Configuration Registers (Sheet 1 of 2)**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|

### 7.3.11 SMBus Controller: Bus 0, Device 31, Function 3

The SMBus controller includes the registers listed in Table 7-30 and Table 7-31. These registers materialize in PCI configuration and I/O spaces (via PCI I/O BAR), respectively. See Chapter 24.0, “SMBus Controller Functional Description: Bus 0, Device 31, Function 3” for detailed discussion of these registers.

**Table 7-30. Bus 0, Device 31, Function 3: Summary of SMBus Controller PCI Configuration Registers**

| Offset Start | Offset End | Register ID - Description  | Default Value |

### 7.3.13 IMCH PCI Configuration

The PCI configuration interface includes the registers listed in [Table 7-33](#). These registers materialize at fixed locations in I/O space.

**Table 7-33. Summary of IMCH PCI Configuration Registers Mapped in I/O Space**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|
| 0CF8h        | 0CF8h      | "Offset 0CF8h: CONFIG_ADDRESS: Configuration Address Register" on page 354 | 00000000h     |
| 0CFCh        | 0CFCh      | "Offset 0CFCh: CONFIG_DATA: Configuration Data Register" on page 355       | 00000000h     |

### 7.3.14 APIC

The APIC includes the registers listed in [Table 7-34](#) and [Table 7-35](#). These registers materialize at fixed locations in memory space and are indexed, respectively. See [Chapter 30.0](#) for detailed discussion of these registers.

**Table 7-34. Summary of APIC Registers Mapped in Memory Space"**

| Offset Start | Offset End | Register ID - Description                | Default Value |
|--------------|------------|--|---------------|
| 0000h (4B)   | 0000h (4B) | "APIC_IDX - Index Register" on page 1135 | 00h           |
| 0010h (4B)   | 0010h (4B) | "APIC_DAT – Data Register" on page 1136  | 00h           |
| 0040h (4B)   | 0040h (4B) | "APIC_EOI - EOI Register" on page 1136   | 00h           |

Table 7-35. Summary of APIC Indexed Registers

| Offset Start    | Offset End      | Register ID - Description                               | Default Value          |
|-----------------|-----------------|---|------------------------|
| 00h (4B)        | 00h (4B)        | "APIC_ID – Identification Register" on page 1138        | 0000h                  |
| 01h (4B)        | 01h (4B)        | "APIC_VS - Version Register" on page 1138               | 00170020h              |

### 7.3.15 8259 Interrupt Controller (PIC)

The 8259 Interrupt Controller includes the registers listed in Table 7-36. These registers materialize at fixed locations in I/O space. See Chapter 30.0, “Interrupts” for detailed discussion of these registers.

**Table 7-36. Summary of 8259 Interrupt Controller (PIC) Registers Mapped in I/O Space**

| Offset Start | Offset End | Register ID - Description   | Default Value |
|--------------|------------|---|---------------|
| 020h, 0A0h   | 020h, 0A0h | “ICW1[0-1] - Initialization Command Word 1 Register” on page 1119               | 0001X0XXb     |
| 021h, 0A1h   | 021h, 0A1h | “ICW2[0-1] - Initialization Command Word 2 Register” on page 1120               | XXh           |
| 21h          | 21h        | “MICW3 - Master Initialization Command Word 3 Register” on page 1121            | 04h           |

| 21h, 0A1h    | 21h, 0A1h  | “ICW4[0-1] - Initialization Command Word 4 Register” on page 1122               | 01h           |
| 021h, 0A1h   | 021h, 0A1h | “OCW1[0-1] - Operational Control Word 1 (Interrupt Mask) Register” on page 1122 | 00h           |
| 020h, 0A0h   | 020h, 0A0h | “OCW2[0-1] - Operational Control Word 2 Register” on page 1123                  | 001XXXXXb     |
| 020h, 0A0h   | 020h, 0A0h | “OCW3[0-1] - Operational Control Word 3 Register” on page 1124                  | 001XX10b      |
| 4D0h         | 4D0h       | “ELCR1 - Master Edge/Level Control Register” on page 1125                       | 00h           |
| 4D1h         | 4D1h       | “ELCR2 - Slave Edge/Level Control Register” on page 1126                        | 00            |

### 7.3.16 APM Power Management

The APM power management includes the registers listed in Table 7-37. These registers materialize at fixed locations in I/O space. See Chapter 27.0, “Power Management” for detailed discussion of these registers.

**Table 7-37. Summary of APM Registers Mapped in I/O Space**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|
| B2h          | B2h        | “Offset B2h: APM_CNT - Advanced Power Management Control Port Register” on page 1054 | 00h           |
| B3h          | B3h        | “Offset B3h: APM_STS - Advanced Power Management Status Port Register” on page 1054  | 00h           |

### 7.3.17 LPC DMA

The LPC DMA interface includes the registers listed in Table 7-38 through Table 7-40. These registers materialize at fixed locations in I/O space. See Chapter 20.0, “LPC DMA” for detailed discussion of these registers.

**Table 7-38. Summary of LPC DMA Registers Mapped in I/O Space**

| Offset Start       | Offset End         | Register ID - Description  | Default Value |
|--------------------|--------------------|--|---------------|
| 00h at 02h         | 10h at 02h         | “Offset 00h: DMA_BCA[0-3] - DMA Base and Current Address Registers for Channels 0-3” on page 766 | XXXX          |

### 7.3.20 Watchdog Timer and Serial I/O

The Watchdog Timers and Serial I/O units includes the registers listed in [Table 7-43](#) and [Table 7-44](#). These registers materialize at fixed locations in I/O space. See [Chapter 33.0, “Serial I/O Unit and Watchdog Timer”](#) for detailed discussion of these registers.

**Table 7-43. Summary of UART Timer registers in I/O space**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|

### 7.3.21 Real Time Clock

The Real Time Clock include the registers listed in Table 7-45. These registers materialize at indexed locations. See Chapter 29.0, "Real Time Clock" for detailed discussion of these registers.

Table 7-45. Summary of Real Time Clock Indexed Registers

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|

## 7.4 AIOC Registers

This section summarizes the registers in the AIOC. The registers are presented as they materialize from a PCI perspective.

### 7.4.1 PCI-to-PCI Bridge: Bus 0, Device 4, Function 0

The PCI-to-PCI Bridge includes the registers listed in Table 7-46. These registers materialize in PCI configuration space. See Chapter 34.0, “PCI-to-PCI Bridge Detailed Register Descriptions” for detailed discussion of these registers along with alternative materializations.

**Table 7-46. Bus 0, Device 4, Function 0: Summary of PCI-to-PCI Bridge PCI Configuration Registers (Sheet 1 of 2)**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|
| 0h           | 1h         | “Offset 0h: VID: Vendor Identification Register” on page 1217                          | 8086h         |

### 7.4.2 Gigabit Ethernet MAC: Bus M, Devices 0, 1, and 2, Function 0

The Gigabit Ethernet MAC includes the registers listed in Table 7-47 through Table 7-44. These registers materialize in PCI configuration, I/O (via PCI BAR), and memory (via PCI BAR) spaces. See Section 35.6, “Gigabit Ethernet MAC Configuration Spaces: Bus M, Device 0-2, Function 0”, Section 35.7, “Gigabit Ethernet MAC I/O Spaces: Bus M, Device 0-2, Function 0”, and Section 37.6, “GbE Controller Register Summary” for detailed discussion of these registers along with alternative materializations.

**Table 7-47. Bus M, Device 0, Function 0: Summary of Gigabit Ethernet MAC Interface PCI Configuration Registers (Sheet 1 of 2)**

### 7.4.3 GCU: Bus M, Device 3, Function 0

The GCU includes the registers listed in [Table 7-56](#) and [Table 7-57](#). These registers materialize in PCI configuration and memory (via PCI BAR) spaces. See [Section 35.8](#), “GCU Configuration Space: Bus M, Device 3, Function 0” and [Chapter 38.0](#), “Register Summary” for detailed discussion of these registers along with alternative materializations.

**Table 7-56. Bus M, Device 3, Function 0: Summary of GCU PCI Configuration Registers**

| Offset Start | Offset End | Register ID - Description   | Default Value |

### 7.4.4 CAN Interface: Bus M, Device 4 and 5, Function 0

The CAN interface includes the registers listed in Table 7-58 through Table 7-61. These registers materialize in PCI configuration and memory (via PCI BAR) spaces. See Section 35.9, “CAN Controller Configuration Spaces: Bus M, Device 4-5, Function 0” and Chapter 39.0, “Detailed Register Descriptions” for detailed discussion of these registers along with alternative materializations.

**Table 7-58. Bus M, Device 4, Function 0: Summary of CAN Interface PCI Configuration Registers**

| Offset Start | Offset End | Register ID - Description  | Default Value |

### 7.4.5 SSP Interface: Bus M, Device 6, Function 0

The SSP interface includes the registers listed in [Table 7-62](#) and [Table 7-63](#). These registers materialize in PCI configuration and memory (via PCI BAR) spaces. See [Section 35.10, "SSP Controller Configuration Space: Bus M, Device 6, Function 0"](#) and [Table 40.4, "Register Summary"](#) on page 1606 for detailed discussion of these registers along with alternative materializations.

**Table 7-62. Bus M, Device 6, Function 0: Summary of SSP Controller PCI Configuration Registers (Sheet 1 of 2)**

| Offset Start | Offset End | Register ID - Description                                      | Default Value |

## 7.4.6 IEEE 1588 Timestamp Unit: Bus M, Device 7, Function 0

The IEEE 1588 Timestamp Unit includes the registers listed in [Table 7-64](#) and [Table 7-65](#). These registers materialize in PCI configuration and memory (via PCI BAR) spaces. See [Section 35.11](#), “IEEE 1588 Hardware Assist Unit Configuration Space: Bus M, Device 7, Function 0” and [Chapter 41.0](#), “Register Summary” for detailed discussion of these registers along with alternative materializations.

**Table 7-64. Bus M, Device 7, Function 0: Summary of IEEE 1588 Timestamp Unit PCI Configuration Registers**

#### 7.4.7 Local Expansion Bus Interface: Bus M, Device 8, Function 0:

The Local Expansion Bus interface includes the registers listed in [Table 7-66](#) and [Table 7-67](#). These registers materialize in PCI configuration and memory (via PCI BAR) spaces. See [Section 35.12, "Expansion Bus Configuration Space: Bus M, Device 8, Function 0"](#), and [Table 42.5, "Register Summary" on page 1696](#) for detailed discussion of these registers along with alternative materializations.

**Table 7-66. Bus M, Device 8, Function 0: Summary of Local Expansion Bus PCI Configuration Registers (Sheet 1 of 2)**

# IA-32 Core and Integrated Memory Controller Hub, Volume 2 of 6

---

## 8.0 IA-32 Core

---

### 8.1 Overview

The EP80579 system-on-a-chip (SoC) uses an IA-32 core, which is based on the Intel® Pentium® M processor (90 nm). Major features include:

- 600 MHz, 1066 MHz and 1200 MHz operating frequencies
- FSB frequency of 400 MHz and 533 MHz.
- Uni-directional FSB interface (on-chip) for SoC applications
- 32 KByte L1 split instruction and data caches
- 256 KByte 2-way L2 cache with 64B lines
- Soft error protection on L2 cache data and tags (via ECC), soft error protection on L1 cache data and tags (via parity)
- New CPU identifier (CPUID)

Note the differences between the IA-32 core and the Intel® Pentium® M processor (90 nm) are:

- Core and FSB operating frequencies
- Uni-directional FSB instead of bi-directional
- Different CPU identifier (CPUID)
- Reduced L2 cache size and ways
- De-featured Intel SpeedStep® Technology (no VRM specification required)

### 8.2 Theory of Operation

This section discusses several operational areas of IA-32 core.

#### 8.2.1 L2 Cache Size

The IA-32 core reduces the size and associativity of the L2 cache on the Pentium M processor (90 nm) from 2MB 8-way to 256KB 2-way.

#### 8.2.2 Platform and JTAG Identifiers

The Platform ID is a project-specific value. It is used solely for selecting a microcode update (i.e., patch) and is tightly-coupled to a specific CPUID number. BIOS and OS software are aware of the Platform ID convention and automatically pick up the appropriate patch. There are two views to the Platform ID: the MSR view and the Patch view: The MSR view is a 3-bit value read out of the processor's FUSE\_MSR[52:50]. This value is determined by three fuses and is unique per CPUID SKU. The Patch view is the binary value which represents two raised to the power of the MSR view value. A microcode update is considered applicable to a specific processor if, and only if, the following condition is true:

```
((Patch.header.cpuid == Processor's CPUID) &&
((Patch.header.platformID & 2^FUSE_MSR[52:50]) != 0))
```

The MSR view of the EP80579 Platform ID is 100b. Table 8-1 summarizes the format of the processor version identification signature (CPUID).

**Table 8-1. Processor Version Identification Signature (CPUID)**

|                 |    |    |   |                |    |    |      |        |    |    |    |              |   |             |   |   |   |   |   |   |   |   |   |
|-----------------|----|----|---|----------------|----|----|------|--------|----|----|----|--------------|---|-------------|---|---|---|---|---|---|---|---|---|
| 31              | 28 | 27 |   | 20             | 19 | 16 | 15   | 14     | 13 | 12 | 11 | 8            | 7 | 4           | 3 | 0 |   |   |   |   |   |   |   |
| Extended Family |    |    |   | Extended Model |    |    | Type | Family |    |    |    | Model Number |   | Stepping ID |   |   |   |   |   |   |   |   |   |
| 0               | 0  | 0  | 0 | 0              | 0  | 0  | 0    | 0      | 0  | 0  | 0  | 0            | 1 | 1           | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 |

### 8.2.3 FSB Physical Interface

The IA-32 core replaces the standard bi-directional, tri-state FSB interface found on the Pentium M processor (90nm) with a uni-directional interface. This uni-directional interface is better suited for SoC applications that use a single core. This modification replaces a single bi-directional wire with two uni-directional wires.

### 8.2.4 IA-32 Core and FSB Frequency

The EP80579 is targeted to operate with IA-32 core frequencies of 600 MHz, 1066 MHz and 1200 MHz and FSB frequencies of 400 MHz (600 MHz SKU) and 533 MHz (1066 MHz and 1200 MHz SKUs).

§ §

## 9.0 CMI Introduction

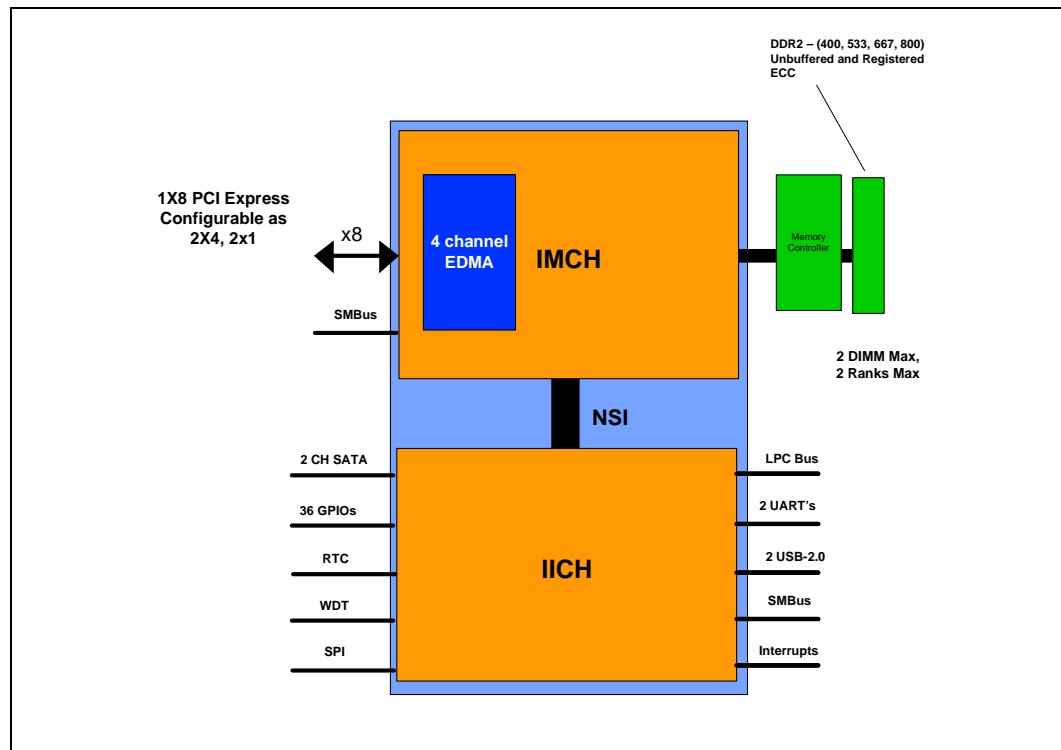

This section details the system architecture supported by the Memory Controller Hub and I/O Controller Hub complex. The Memory Controller Hub and I/O Controller Hub are referred to collectively as the CMI (IMCH and ICH).

Subsequent chapters cover the following aspects of the MCH and the ICH:

- Description of the CMI architecture.
- Descriptions of internal registers.
- Descriptions of all external interfaces.

The EP80579 is a single chip that integrates the functionality of an IA-32 core, Memory Controller Hub, and an I/O Controller Hub (see [Figure 9-1](#)). In this document the Memory Controller Hub and I/O Controller Hub in CMI are referred to as IMCH (Integrated Memory Controller Hub) and IICH (Integrated I/O Controller Hub) respectively. The IMCH and IICH units are connected internally through the NSI (North South Interface). The NSI is an internal bus that is not externally accessible.

Figure 9-1. CMI Block Diagram

## 9.1 System Architecture

CMI implements numerous RASUM (Reliability, Availability, Serviceability, Usability and Manageability) features on multiple interfaces.

The IMCH and IICH consist of:

- A Memory Controller.
- A four-channel, descriptor-chain-based Enhanced DMA (EDMA) controller.
- Several I/O devices such as USB, SATA, etc.
- One x8 PCI Express\* interface, which may be split into a pair of independent x4 or x1 PCI Express\* interfaces.

Desired I/O Controller Hub (IICH) functions are integrated eliminating the requirement for a legacy I/O bridge.

CMI also supports:

- Two USB 2.0/1.1 ports
- Two SATA ports Gen1/Gen2
- One LPC bus
- One SPI port
- Two UART port
- Two SMBus ports

For additional information see [Section 11.3, "Configurations" on page 291](#).

## 9.2 PCI Express\*

CMI provides one configurable x8 PCI Express interface with a maximum theoretical bandwidth of 4 GByte/s (aggregate). The x8 PCI Express interface may alternatively be configured as two independent x4 or x1 PCI Express interfaces.

CMI is a root-class component as defined in the *PCI Express\* Interface Specification, Rev 1.0a*. The PCI Express interfaces support connection of CMI to a variety of other bridges compliant with the same revision of the *PCI Express\* Interface Specification, Rev 1.0a*. For example, the Intel® 82571EB Gigabit Ethernet adaptor and the Intel PCI Express I/O processor are directly supported on any of these PCI Express ports. Other compatible PCI Express devices implement functionality such as graphics, hardware RAID controllers and TCP/IP off-load engines. These devices are available from Intel and/or third-party vendors.

As required by the interface specification, CMI will automatically negotiate for and train a single lane (x1) link if an attached device on any logical port fails to establish a viable x4 or x8 connection. This does not imply a capability for CMI to support more than two independent PCI Express ports of any width simultaneously on the x8 port, nor does it imply that the remaining three lanes of a potential x4 port are useful once the associated link has been established for x1 operation. Similarly, CMI will automatically negotiate for and train a single lane (x1) link if an attached device on any logical port fails to establish a viable x4 connection.

External bridge devices such as PCI or PCI-X Gigabit Ethernet or RAID storage devices are directly supported on the PCI Express ports. This does not preclude connection of the IMCH to other bridges compliant with the same revision of the *PCI Express Interface Specification*.

## 9.2.1 Supported PCI Express Configurations

CMI PCI Express ports are setup using a configuration register. This register is “DEVPRES” BDF 000, Offset 9Ch, Bits 2 and 3 which control Device 2 and Device 3 present.

Table 9-1 shows all of the valid combinations of this register.

**Table 9-1. Supported PCI Express Configurations**

|       |                | DEVPRES                                 |                      |                      |                       |
|-------|----------------|---|----------------------|----------------------|-----------------------|
|       |                | DEV2 En,<br>DEV3 En                     | DEV2 En,<br>DEV3 Dis | DEV2 Dis,<br>DEV3 En | DEV2 Dis,<br>DEV3 Dis |
| Strap | AUTO Negotiate | 1x8,<br>2x4,<br>lower 1x4,<br>upper 1x4 | 1x8,<br>lower 1x4    | Not supported        | All Disabled          |
|       | 2x4            | 2x4                                     | lower 1x4            | upper 1x4            | All Disabled          |
|       | 1x8            | 1x8                                     | 1x8                  | Not supported        | All Disabled          |

### 9.2.1.1 Low power SKU with PCI Express ports removed

To enable low power SKU for configurations that do not utilize the PCI Express ports, the user can disable PCI Express ports and configuration bits for power savings.

## 9.3 Supported Debug and Management Interfaces

The IMCH supports a target SMBus interface for access and control of the IMCH through its configuration registers. A Test Access Port (TAP) interface is also supported for IMCH system debug purposes. The TAP is capable of full read/write access to the entire internal IMCH register space.

Platforms based on CMI may also make use of the Inter-Chassis Management Bus (ICMB) architecture to extend SMBus based management throughout a desegregate multi-chassis platform solution.

## 9.4 Supported IMCH Integrated Features

This section provides a brief overview of internal IMCH features. The subsections are intended for use as an introduction and a quick reference. See [Section 9.5](#) for more detailed descriptions of these features.

### 9.4.1 EDMA Controller

The IMCH includes an integrated four-channel Enhanced Direct Memory Access (EDMA) controller to perform background data transfers between locations in main memory, or from main memory to a memory-mapped I/O destination. These transfers may be

individually designated to be coherent (snooped on the FSB) or non-coherent (not snooped on the FSB), providing improvements in system performance and utilization when cache coherence is managed by software rather than hardware.

Each of the four channels implements an independent set of configuration and status registers, and is capable of fully independent operation. Each channel may operate in a single block transfer mode, or a hardware traversed linked-list scatter/gather mode.

The internal EDMA controller only supports transfers between main memory locations, and transfers from a main memory source to an I/O subsystem destination. The internal EDMA controller supports neither transfers between I/O interfaces, nor transfers from an I/O interface source to a main memory destination.

### 9.4.2 Integrated Memory Init/Test Engine

The IMCH provides hardware-managed ECC memory auto-initialization and testing of all populated DRAM space under software control. Once internal configuration has been updated to reflect the type and size of populated DIMM, the IMCH can traverse the populated address space issuing line-sized writes of all zero data, thereby initializing all locations with good ECC memory. This greatly speeds up the mandatory memory initialization step and frees the CPU to pursue other machine initialization and configuration tasks.

Additional features have been added to the initialization engine to support high-speed population and verification of a programmable memory range with one of eight known data patterns, random data, a walking data pattern, or an explicitly specified cache line (data plus ECC). This function facilitates a limited high-speed memory test and provides BIOS-accessible memory testing capability for potential use by management code or by the operating system.

For additional information see [Section 11.2, “Memory Controller Feature List” on page 289](#).

### 9.4.3 Coherent Memory Write Buffer

The IMCH includes an integrated coherent write buffer sized for 16 64-byte cache lines (a total of 1 Kbyte of storage). This feature enables the IMCH to optimize memory read latency, allowing reads to pass less critical writes en-route to the main memory store. The write buffer includes a CAM structure to enforce ordering among conflicting accesses to the same cache line, as well as to provide for read service from the write cache. In the latter case, the access to the main memory store never occurs, which both improves latency and conserves bandwidth on the memory interface.

The write buffer is capable of servicing processor read requests directly via a “hit” to the internal location containing the data without initiation of any DDR subsystem accesses. Inbound read requests such as PCI Express, i.e. not processor, which “hit” the write buffer result in a flush of the target data, followed by retrieval via an external read request.

Processor writes to shared non-coherent address space with the ASU result in a flush of the current cacheline to main memory. ASU atomics will result in a DW write to the ASU out of the write cache.

### 9.4.4 RASUM Features

The IMCH is designed to bring enterprise-level reliability, availability, serviceability, usability, and manageability to the embedded platform. All internal SRAM memory arrays are covered by parity. CMI’s PCI Express interface supports detection and automatic recovery for all transient signaling errors. All IMCH internal configuration

register space is accessible from the system management bus (SMBus) to facilitate system management. The IMCH supports ACPI power management, PCI Express native hot-plug, and wake-from-LAN to maximize platform stand-by flexibility.

#### 9.4.4.1 SEC-DED ECC

The IMCH supports a standard (72-bit, non-interleaved) single error correction (SEC) and double error detection (DED) ECC mechanism for the DDR memory.

The IMCH supports both ECC and non-ECC DIMMs.

For additional information see [Section 11.2, “Memory Controller Feature List” on page 289](#).

#### 9.4.4.2 Integrated Memory Scrub Engine

The IMCH includes an integrated engine to walk the populated memory space proactively seeking out soft errors in the memory subsystem. This hardware detects, logs, and corrects any single-bit ECC errors it encounters, and logs any uncorrectable errors it encounters. Both types of errors may be reported via multiple alternate mechanisms under configuration control. The scrub hardware will also execute “demand scrub” writes when correctable errors are encountered during normal operation (on demand reads, rather than scrub-initiated reads). This functionality provides incremental protection against time-based deterioration of soft memory errors from correctable to uncorrectable.

An uncorrectable error encountered by the memory scrub engine is a “speculative error.” This designation is applied because no system agent has specifically requested use of the corrupt data, and no real error condition exists in the system until that occurs. It is possible that the error resides in an unmodified page of memory that is simply dropped on a swap back to disk. If that were to occur, the speculative error would simply “vanish” from the system without any adverse consequences.

### 9.5 IMCH Feature List

This section provides an overview of the major IMCH architectural features. Detailed usage information and operational flows, internal register bit information and other specific details of the implementation are provided later in this document.

#### 9.5.1 Memory Interface

For additional information see [Section 11.2, “Memory Controller Feature List” on page 289](#).

#### 9.5.2 PCI Express Interface in IMCH

- Support for one x8 PCI Express dual-simplex, high-speed serial I/O interface with eight striped differential pairs in each direction (outbound and inbound)
  - The interface may be unpopulated; connected to PCI, Ethernet, I/O Processor, Infiniband\* bridge devices, External bridge devices (PCI or PCI-X Gigabit Ethernet or RAID storage devices); or connected to any other device compliant with the same revision of the *PCI Express Specification* as CMI.
  - The x8 interface is capable of bifurcation into two logically independent x4 interfaces with full specification compliance at half the bandwidth capability
- This interface is referred to throughout this document as the PCI Express Port A (PEA). When configured as x8, the reference is PEA. When in x4 mode there are two available x4 ports referred to as PEA0 and PEA1.

- Raw bit-rate on the data pins of 2.5 Gbit/s.
  - Maximum theoretical realized bandwidth on the x8 PCI Express interface of 2 GByte/s in each direction simultaneously, for an aggregate of 4 GByte/s.
  - Maximum theoretical realized bandwidth on the x4 PCI Express interface of 1 GByte/s in each direction simultaneously, for an aggregate of 2 GByte/s per port.
  - x8 sustainable data bandwidth is approximately 1.6 GByte/s in each direction simultaneously
- Plesiochronous operation with automatic clock extraction and phase correction at the receiver.
- Hierarchical PCI-compliant configuration mechanism for downstream devices
  - Support for PCI Express memory-mapped enhanced configuration mechanism, up to 4 Kbyte per device.
- 64 bit addressing support.
  - 64 bit upstream addressing (full DAC support), limited to 32 bits internally to/from system memory (external DDR).
  - 32 bit downstream addressing support.
  - Full 36 bit support for peer segment accesses.

*Note:* Only 32-bit addresses can be snooped. Addresses larger than 32 bits will be truncated. e.g. If a 36-bit address is snooped the upper 4 bits are ignored.

- Full-speed interface self-test and diagnostic (IBIST) functionality.
- Automatic discovery, negotiation, and training of PCI Express ports out of reset.
  - Automatic detection of widest operational link; x8, x4 or x1.
- No support for Hot-plug via an external SMBus connected device.
- Run-time detection and recovery for loss of link synchronization.
- 32 bit CRC (cyclic redundancy checking) on all transaction layer packets with link-level retry on error (recovery from transient errors without software-visible system failure).
- 16 bit CRC on all link message information
- No support for the optional extended CRC (ECRC) mechanism
- Aggressive transceiver design to facilitate flexible system topologies
- Target BER of  $10^{-12}$  for physical signaling interface
- Support for peer segment destination write traffic (no peer-to-peer read traffic)
- Support for coherent and non-coherent transactions through EDMA to PEA to external agent
- Support for both coherent and non-coherent traffic to memory within VC#0
  - Non-coherent implies a combination of Snoop-Not-Required and Relaxed-Ordering attributes
  - Coherent traffic implies a combination of Snoop-Required and Strong-Ordering attributes.
- Support for lane reversal at all native widths, and for reversed x4 training on any x8 port
- Support for peer segment PCI interrupt forwarding to the IICH for boot from I/O
  - Legacy mode support for level-sensitive interrupt emulation without IOxAPIC support

- APIC and MSI interrupt messaging support DMA internal score-boarding to translate messages into level-sensitive IICH pin semantics
  - XTPR-based interrupt redirection for APIC messages with lowest priority tie breaking
- Support for up to 256B read completion combining
- Support for link messaging to facilitate active link and device power state management
- Support for ASPM L0s entry, no support for optional L1 ASPM support
- No support for inbound configuration or I/O traffic
- No support for inbound special cycles or writes requiring completions
- No support for downstream special cycle messages requiring completions

### 9.5.3 EDMA Controller

- Four Independent Channels
  - Dedicated data transfer queue per channel
  - Full register set for descriptor and transfer handling per channel
- Support for transfer between main memory locations, and from memory to the I/O subsystem
- Supports PCI Express traffic class to allow external prioritization of traffic
- Supports transfers only between two Physical Addresses
  - 32 bit (4 GB) addressing range on the Local System Memory Interface
  - 32 bit addressing range on the Memory Mapped I/O Subsystem Interface
- Maximum transfer of 16 Mbyte transfers per block
- Fully programmable by the host CPU
  - Configuration space mapping for DMA engine capability and control
  - Memory-mapped space for DMA channel-specific register sets
- Chain mode DMA transfer with automatic data chaining for scattering/gathering of data blocks
  - DMA chaining continued until a “null” Descriptor Pointer is encountered
  - Support for appending a block to the end of current DMA chain
  - Automated descriptor retrieval from DDR during chaining – single read
- Programmable independent alignment between source and destination
  - Byte aligned transfer on the DDR Memory Interface
  - Byte aligned transfer on the I/O Subsystem Interface
- Support for non-coherent transfers both to and from system memory on a per descriptor basis
  - Independent control of coherency for source and destination
- Programmable support for interrupt generation on block-by-block basis
  - Selectable MSI or legacy level-sensitive interrupt function
  - End of current block transfer
  - End of current chain
  - For any error causing a transfer to abort

- Increment of the source and destination address for standard transfers
- Increment of the destination and decrement of the source address to enable byte stream reversal.
- Constant address mode for the destination address based on the transfer granularity to enable targeting of memory mapped I/O FIFO devices
- Buffer/Memory Initialization Mode

#### 9.5.4 Coherent Memory Write Buffer

- Support for 16 64-byte cache-lines of write data
- Fully associative conflict detection for accesses targeting memory
- Read around write support (non-conflicting) for all traffic to memory
- Read-hit support for CPU traffic to memory
  - Direct data service from buffer without generation of memory traffic
- Write-hit support for memory traffic with address conflicts
  - Hardware-based merging to collapse down to a single memory write
- Opportunistic and demand (buffer full) mode processing of pending writes
  - Configurable “watermark” mechanism for hardware-based prioritization
  - Flush on demand via software configuration mechanism
- Parity protection on all data
- Data poisoning capability in the main store for data received with errors
- Processor writes to shared non-coherent address space with the ASU result in a flush of the current cacheline to main memory
- ASU atomics will result in a DW write to the ASU out of the write cache

#### 9.5.5 Integrated Memory Scrub Engine

For additional information see [Section 11.2, “Memory Controller Feature List” on page 289](#).

- Periodic (programmable) read-modify-write algorithm
- Support for the SEC-DED mode of operation
- Automatic correction of encountered SEC errors
- Logging of detected errors with granularity to isolate DRAM device
  - Support for logging of both first and next subsequent error
  - Count of errors beyond the first two which are logged
- Support for on-demand hardware scrub of SEC errors detected during normal operation
- Programming interface permits software suspend/resume of scrub in progress

#### 9.5.6 Hardware Memory Initialization Engine

- Available via BIOS for hardware memory initialization and/or test
- Provides fast WHQL initialization of all populated DRAM space to “0” with good ECC
- Target region may be a single location, an entire rank, or all populated ranks
- Algorithm optimized for speed, runs at DDR channel saturation rate

- Test extensions permit high-speed population of a target range with a known pattern
  - Selectable hardware-generated fixed patterns: 0, 3, 5, 6, 9, A, C, F
  - Hardware generated random pattern capability
  - Explicitly stipulated data pattern including ECC
- High speed verification capability
  - Selectable write-only, verify-only, or write-read-verify per location
  - Logs error location, optional stop and escalate on error detection
- May be made available to the operating system via BIOS for security “clear to 0” function

### 9.5.7 System Management Functions

- Full SMBus target support
- Support for remote chassis management via the ICMB architecture
- Serial presence detect of memory devices via standard I<sup>2</sup>C protocol (accessed via IICH)
- ACPI and PCI-PM compatible power management
  - Includes PME support comprehending PCI Express extensions
- MSI interrupt messaging and redirection support
- Hardware relay of PCI Express legacy mode PCI interrupt messages to IICH
  - Supports boot from I/O when IOxAPIC functions are unavailable

### 9.5.8 RASUM

- SEC/DED ECC protection of external memory DRAM data
- Parity protection on internal data propagated through the IMCH
- CRC on data packets and hardware link-level retry on NSI to the IICH
- 32-bit CRC on data packets and hardware link-level retry on PCI Express ports
- Hardware memory initialization
  - True “clear-to-zero” via hardware writes to all populated devices
  - Support for hardware-based fast initialization of memory with selectable patterns
  - Support for hardware-based fast verification of memory via accelerated scrub
- Hardware periodic memory scrubbing, including demand scrub support
- Flexible extended error reporting capabilities
- Configurable error containment at I/O interfaces (poison/propagate or stop/escalate)
- Partial access to internal configuration registers via the TAP port
- Full access to internal configuration registers via SMBus port

## 9.6 IICH Feature List

This section provides a listing of architectural functionality for the major features of the IICH. Detailed usage information and operational flows, internal register bit information, and other specific details of the implementation are provided later in this document.

### 9.6.1 Low-Pin count (LPC) Interface and Firmware Hub (FWH) Interface

- Allows connection of devices such as Super I/O, micro controllers, customer ASICs.
- Supports two master/DMA devices.
- Memory size up to 8 Mbit.

### 9.6.2 Serial Peripheral Interface (SPI)

*Note:* Intel recommends using the SPI as your boot interface.

- Supports multiple SPI Flash vendors.
- Simplified Hardware.
- Equivalent to LPC-based Firmware Hubs.

### 9.6.3 Integrated Serial ATA Host Controllers

- Independent DMA operation on two ports.
  - Two ports in SATA 1.0a and AHCI mode.
  - Two ports in AHCI mode only.
- Data transfer rates up to 300 Mbyte/s.
- Support Gen2m electrical spec (cable not exceeding 2m).

### 9.6.4 USB

- One EHCI USB 2.0 Host Controller with a total of two ports (shared with the UHCI ports).
- One UHCI Host Controller for a total of two ports (shared with the EHCI ports).
- Supports a Debug Port at USB 2.0 transfer rates.

### 9.6.5 Interrupt Controller

- Supports up to 8 PCI interrupt pins.
- Two cascaded 82C59 with 15 interrupts.
- Integrated I/O APIC supports a total of 40 interrupts (24 interrupts only, when ETR3.GPIO\_IRQ\_STRAP\_STS is 0).
- Serial Interrupt input for ISA legacy-compatible and PCI interrupts.
- Supports PCI scheme for delivering interrupts as write cycles (rather than via PIRQ[A-H]#).
- Front-Side Message Interrupt Delivery.
- Supports EOI message.

### 9.6.6 Power Management Logic

Power management logic for various environments require updates.

- ACPI 2.0 Compliant.
- Support for APM-based legacy power management for non-ACPI implementations.
- Supports ACPI defined power states S0, S1, S3 cold, S4 and S5 (SOFF).
- ACPI Power Management Timer.
- SMI# Generation.
- PCI PME#.

### 9.6.7 DMA Controller

- Two cascaded 8237 DMA Controllers.
- Supports LPC DMA.

### 9.6.8 Timers Based on 82C54

- System Timer, Refresh Request, Speaker Tone Output.

### 9.6.9 High Precision Event Timers (HPET)

- Three timer comparators provided.
- One-shot and periodic interrupts supported.

### 9.6.10 Real-Time Clock with 256-byte Battery-backed CMOS RAM

- Integrated components for the oscillator to reduce problems with incorrect external selections.
- Lower Power DC/DC Converter implementation.

### 9.6.11 System TCO Reduction Circuits

- Timers to detect improper CPU reset and to generate SMI# and Reset upon detection of stuck CPU.
- Interrupt capability to OS-specific manageability extension and OS capability to call TCO BIOS.
- Supports CPU BIST.
- Ability to disable external devices.

### 9.6.12 SMBus

- Host interface allows CPU to communicate via SMBus.
- Compatible with most 2-wire components that are also I<sup>2</sup>C compatible.
- Slave interface allows internal or external microcontroller to access system resources.
- SMBus 2.0 Compliant.
- No ASF support.

### 9.6.13 Watchdog Timer

- Selectable Prescaler:
  - Approximately 1 MHz (1  $\mu$ s to 1 s).
  - Approximately 1 KHz (1 ms to 10 min.)
- 33 MHz Clock (30 ns Clock Ticks).
- Multiple Modes (WDT and Free-Running).
- Free-Running Mode:
  - One Stage Timer.
  - Toggles WDT\_TOUT# after programmable time.
- WDT Mode:
  - Two Stage Timer (First Stage generates Interrupt, Second Stage drives WDT\_TOUT# low).
  - First Stage generates an SERIRQ, NMI or SMI interrupt after Programmable time.
  - Second Stage drives WDT\_OUT# low or inverts the previous value.
  - Used only after first timeout occurs.
  - Status bit preserved in RTC well for possible error detection and correction.
  - Drives WDT\_TOUT# if OUTPUT is enabled.
- Timer can be disabled (default state) or Locked (Hard Reset required to disable WDT).
- WDT Automatic Reload of Preload value when WDT Reload Sequence is performed.

### 9.6.14 Serial Port

- Two Full Function 16550 Compatible Serial Ports.
- Configurable I/O addresses and interrupts.
- 16-Byte FIFOs.
- Supports up to 115 Kbps.
- Programmable Baud Rate Generator.
- Modem Control Circuitry.
- 14.7456 MHz and 48 MHz supported for UART baud clock input.

### 9.6.15 GPIO

- General Purpose I/Os .
- There are 36 GPIO pins of which 5 have alternate power on functions.

## 10.0 System Address Map

### 10.1 Overview

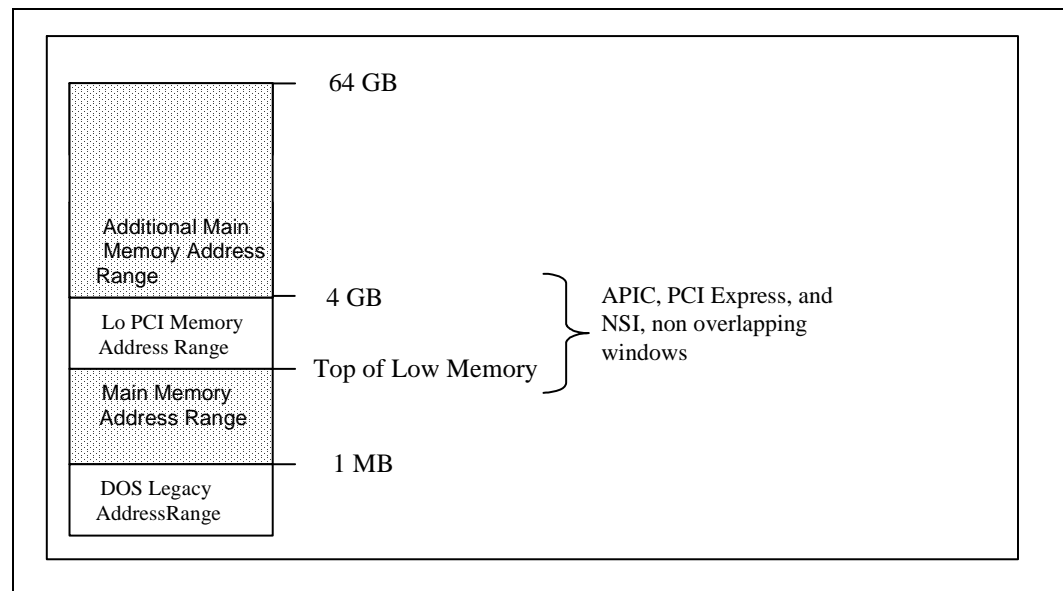

The IA-32 core addressable memory map is 32 bits or up to 4 GBytes and has 64 KBytes+3 of addressable I/O space. The I/O and memory spaces are divided by system configuration software into non-overlapping regions. The memory ranges are useful either as system memory or as specialized memory, while the I/O regions are used solely to control the operation of devices in the system.

There are five basic regions of memory in the system. The regions are shown in Table 10-1. Figure 10-1 illustrates the basic memory regions.

Table 10-1. Regions of Memory Ranges

| Range                                    | Description                  |
|--|------------------------------|
| Between top of main memory and 64 GBytes | High PCI Memory Range        |
| Between 4 GBytes and top of main memory  |                              |
| Between TOLM Register and 4 GBytes       | Low PCI Memory Address Range |
| Between 1 MByte and the TOLM Register    | Main Memory Address Range    |
| Below 1 MByte                            | DOS Legacy Address Range     |

Figure 10-1. Basic Memory Regions

## 10.1.1 System Memory Spaces

Table 10-2. System Memory Space

|         | From        | To          |
|---------|-------------|-------------|
| DOSMEM  | 0_0000_0000 | 0_0009_FFFF |
| MEM1_15 | 0_0010_0000 | 0_00EF_FFFF |
| MAINMEM | 0_0100_0000 | TOLM        |
| HIGHMEM | 1_0000_0000 | 7_FFFF_FFFF |

Table 10-2's address ranges are always mapped to system memory, regardless of the system configuration. The Top of Low Memory (TOLM) register (see [Section 16.1.1.30, "Offset C4h: TOLM - Top of Low Memory Register"](#)) provides a mechanism to carve memory out of the MAINMEM segment for use by System Management Mode (SMM) hardware and software, PCI add-in devices, and other functions. The address of the highest 128 MByte quantity of populated DRAM memory in the system is placed into the DRB3 register, which will match the value in the Top of Memory (TOM) register (see [Section 16.1.1.34, "Offset CCh: TOM - Top Of Memory Register"](#)).

## 10.1.2 VGA and MDA Memory Spaces

Table 10-3 lists the VGA and MDA Memory spaces. [Figure 10-2](#) illustrates the DOS legacy Region.

Table 10-3. IMCH VGA and MDA Memory Spaces

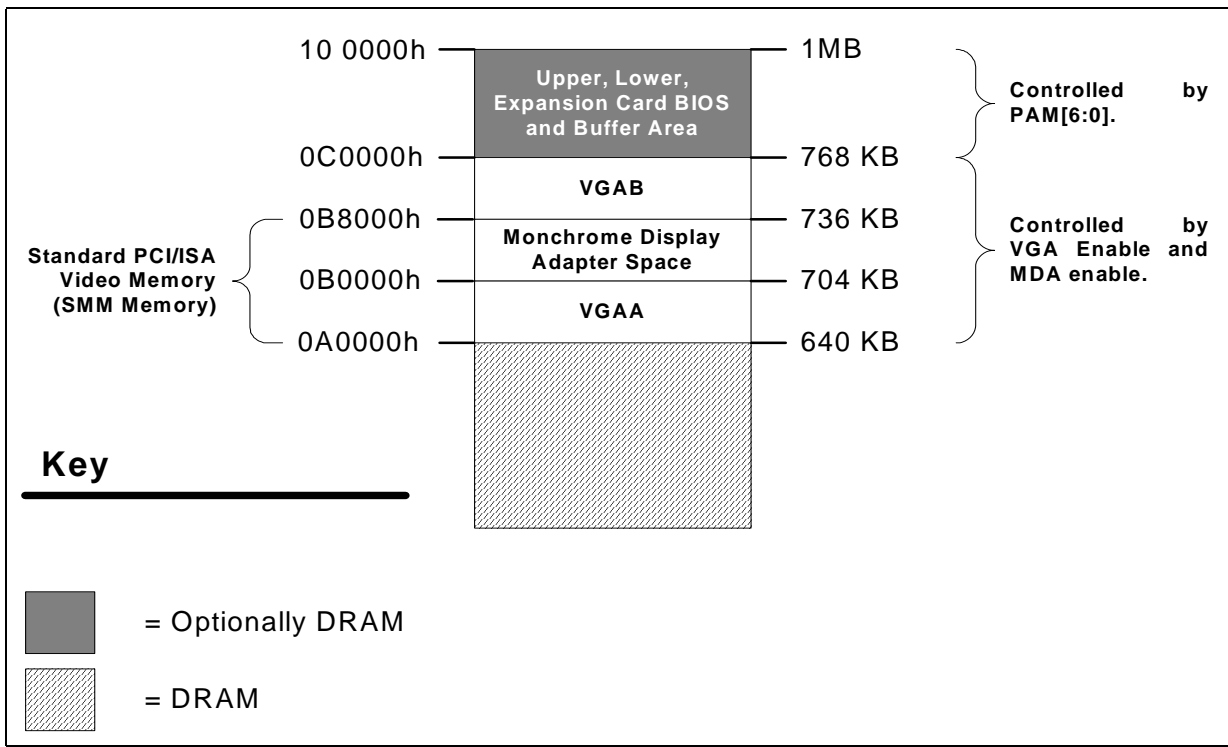

|      | From        | To          |
|------|-------------|-------------|
| VGAA | 0_000A_0000 | 0_000A_FFFF |
| MDA  | 0_000B_0000 | 0_000B_7FFF |
| VGAB | 0_000B_8000 | 0_000B_FFFF |

These legacy address ranges are used on behalf of video cards to map a frame buffer or a character-based video buffer into a dedicated location. By default, accesses to these ranges are forwarded to the NSI. However, if the VGAEN bit is set in one of the BCTRL configuration registers (see [Section 16.4.1.26, "Offset 3Eh: BCTRL - Bridge Control Register"](#)), then transactions within the VGA and MDA spaces are sent to one of the PCI Express interfaces in IMCH.

*Note:* The VGAEN bit may be set in *one and only one* of the BCTRL registers. Software *must not* set more than one VGAEN bit.

Figure 10-2. DOS Legacy Region

If the configuration bit EXSMRC.MDAP (see [Section 16.1.1.25, "Offset 9Dh: EXSMRC - Extended System Management RAM Control Register"](#)) is set, then accesses that fall within the MDA range are sent to NSI without regard for the VGAEN bits. Legacy support requires the ability to have a second graphics controller (monochrome display adapter) in the system. In a CMI system with PCI graphics installed via a PCIe to PCI bridge like PXH, accesses in the standard VGA range may be forwarded to any of the logical PCI Express ports (depending on configuration bits). Since the monochrome adapter may be on the NSI (or logical ISA) bus, the IMCH must decode cycles in the MDA range and forward them to NSI. This capability is controlled via the MDAP configuration bit. In addition to the memory range B0000h to B7FFFh, the IMCH decodes I/O cycles at 3B4h, 3B5h, 3B8h, 3B9h, 3BAh and 3BFh and forwards them to NSI.

An optimization allows the system to reclaim the memory displaced by these regions. If SMM memory space is enabled by EXSMRC.G\_SMRAME and either the SMRAM.D\_OPEN bit (see [Section 16.1.1.25, "Offset 9Dh: EXSMRC - Extended System Management RAM Control Register"](#) and [Section 16.1.1.26, "Offset 9Eh: SMRAM - System Management RAM Control Register"](#)) is set or the processor bus receives an SMM-encoded request for code (not data), then the transaction is steered to system memory rather than NSI. Under these conditions, both the VGAEN bits and the MDAP bit are overridden.

If any VGAEN bit is set, then all ISAEN bits (see [Section 16.4.1.26, "Offset 3Eh: BCTRL - Bridge Control Register"](#)) must be set. The *PCI Specification* defines VGAEN to be 10-bit decode. Therefore the other peer bridges must also be 10-bit decodes (ISAEN), so that two or more devices don't claim same access. (Bridge C doesn't know bridge B has its VGAEN bit set.)

The MDA bit may only be set when one of the VGAEN bits is set. If no VGAEN bit is set, then MDA must not be set either. When the VGA range is already mapped onto the NSI interface, the MDA range is included as a subset, and the MDA enable is meaningless.

### 10.1.3 PAM Memory Spaces

The Address range for the PAM memory space is defined in Table 10-4.

Table 10-4. IMCH PAM Memory Address Ranges

|       | From        | To          | Access Region                |
|-------|-------------|-------------|------------------------------|
| PAMC0 | 0_000C_0000 | 0_000C_3FFF | ISA Expansion<br>(16KB/each) |
| PAMC4 | 0_000C_4000 | 0_000C_7FFF |                              |
| PAMC8 | 0_000C_8000 | 0_000C_BFFF |                              |
| PAMCC | 0_000C_C000 | 0_000C_FFFF |                              |
| PAMD0 | 0_000D_0000 | 0_000D_3FFF |                              |
| PAMD4 | 0_000D_4000 | 0_000D_7FFF |                              |
| PAMD8 | 0_000D_8000 | 0_000D_BFFF |                              |
| PAMDC | 0_000D_C000 | 0_000D_FFFF |                              |
| PAME0 | 0_000E_0000 | 0_000E_3FFF | Extended BIOS<br>(16KB/each) |
| PAME4 | 0_000E_4000 | 0_000E_7FFF |                              |
| PAME8 | 0_000E_8000 | 0_000E_BFFF |                              |
| PAMEC | 0_000E_C000 | 0_000E_FFFF |                              |
| PAMFO | 0_000F_0000 | 0_000F_FFFF | System BIOS<br>(64KB)        |

The 256 Kbyte Programmable Access Memory (PAM) region is divided into three parts:

- ISA expansion region, a 128 Kbyte area between 0\_000C\_0000h – 0\_000D\_FFFFh.
- Extended BIOS region, a 64 Kbyte area between 0\_000E\_0000h – 0\_000E\_FFFFh.
- System BIOS region, a 64 Kbyte area between 0\_000F\_0000h – 0\_000F\_FFFFh.

Specialized programmable hardware in the IMCH supports routing of read and write accesses within the PAM region independently to memory or to NSI.

Non-snooped transactions are treated accordingly:

- Non-snoop Reads: Memory address 0h. The result is an unsupported request (UR) completion.
- Non-snoop Writes: Memory address 0h with byte enables deasserted.

The ISA expansion region is divided into eight 16 Kbyte segments. Each segment can be assigned one of four Read/Write memory states: read-only, write-only, read/write, or disabled. These segments are typically set to disabled for memory access, which leaves them routed to NSI for ISA space.

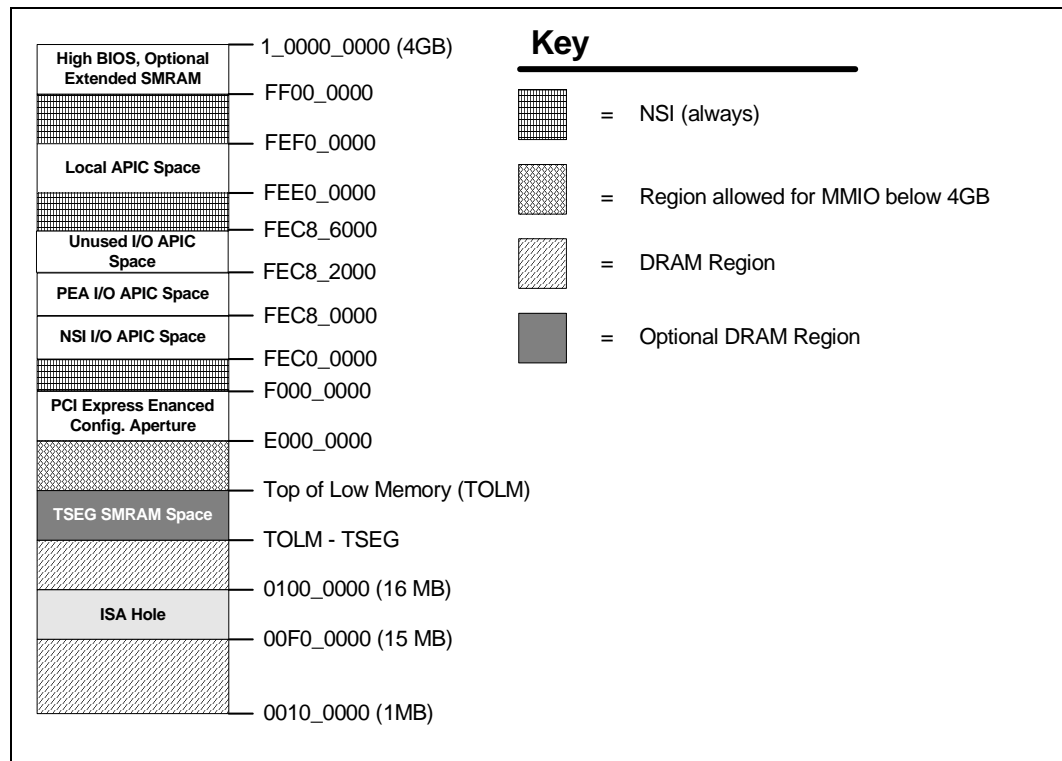

The extended System BIOS region is divided into four 16 Kbyte segments. Each segment can be assigned independent read and write attributes so it can be mapped either to main DRAM or to NSI. Typically, this area is used for RAM or ROM.

The system BIOS region is a single 64 Kbyte segment. This segment can be assigned independent memory read and write attributes. It is by default (after reset) Read/Write disabled and cycles are forwarded to NSI. By manipulating the Read/Write attributes, the IMCH can “shadow” BIOS into the main DRAM. The term “shadow” is used to describe the condition where ROM memory has been duplicated into main memory; such that reads are serviced from memory, while writes are directed back to the original ROM device. Such a configuration allows low-latency reads of BIOS information from the ROM while preventing malicious or inadvertent alteration of the BIOS information in use.

*Note:* The PAM regions are generally inaccessible from the logical PCI Express ports. All inbound writes from any port that hit the PAM regions are sent to NSI, which prevents corruption of non-volatile data shadowed in main memory. All inbound reads from any port that hit the PAM regions are harmlessly terminated internally; data is returned, but not necessarily from the requested address. Transaction routing is not hardware enforced based on the settings in the PAM configuration registers.

*Note:* The PAM regions are inaccessible from the logical AIOC port. All inbound reads/writes from any port that hit the PAM regions are master aborted by the AIOC preventing them from ever pushed into the IMCH.

**Figure 10-3. Memory Region from 1 MByte through 4 GBytes**

The IMCH allows programmable memory attributes on 13 legacy memory segments of various sizes in the 768 Kbyte to 1 Mbyte (C0000h – FFFFFh) and 640 Kbytes to 1 Mbyte address range. Seven Programmable Attribute Map (PAM) registers are used to support these features. Not all seven of these registers are identical. PAM0 controls only one segment (high), while PAM[1:6] each control two segments (high and low). Cache ability of these areas is controlled via the MTRR registers in the processor. The following two bits apply to both host accesses and PCI initiator accesses to the PAM areas and are used to specify the memory attributes for each memory segment: These bits apply to both host accesses and PCI initiator accesses to the PAM areas

- RE Read Enable. When RE = 1, the IA-32 core read accesses to the corresponding memory segment are claimed by the IMCH and directed to main memory. Conversely, when RE = 0, the host read accesses are directed to the IICH's PCI bus.
- WE Write Enable. When WE = 1, the host write accesses to the corresponding memory segment are claimed by the IMCH and directed to main memory. Conversely, when WE = 0, the host write accesses are directed to the IICH's PCI bus.

Together, these two bits specify memory attributes (Read-Only, Write Only, Read/Write and Disabled) for each memory segment. These bits only apply to host-initiated access to the PAM areas. The IMCH forwards to main memory any PCI Express initiated accesses to the PAM areas. At the time such PCI Express accesses to the PAM region may occur, the targeted PAM segment must be programmed to Read/Write. It is illegal to issue a PCI Express initiated transaction to a PAM region with the associated PAM register not set to Read/Write.

As an example, consider a BIOS that is implemented on the expansion bus. During the initialization process, BIOS can be shadowed to main memory to increase system performance. When BIOS is shadowed to main memory it must be copied to the same address location. To shadow the BIOS, the attributes for that address range must be set to Write-Only. The BIOS is shadowed by first doing a read of that address, which is forwarded to the expansion bus. The host then writes the same address, which is directed to main memory. After BIOS is completely shadowed, the attributes for that memory area are changed to Read-Only so that all writes are forwarded to the expansion bus. [Figure 10-4](#) and [Table 10-5](#) show the PAM registers and the associated attribute bits.

Figure 10-4. PAM Associated Attribute Bits

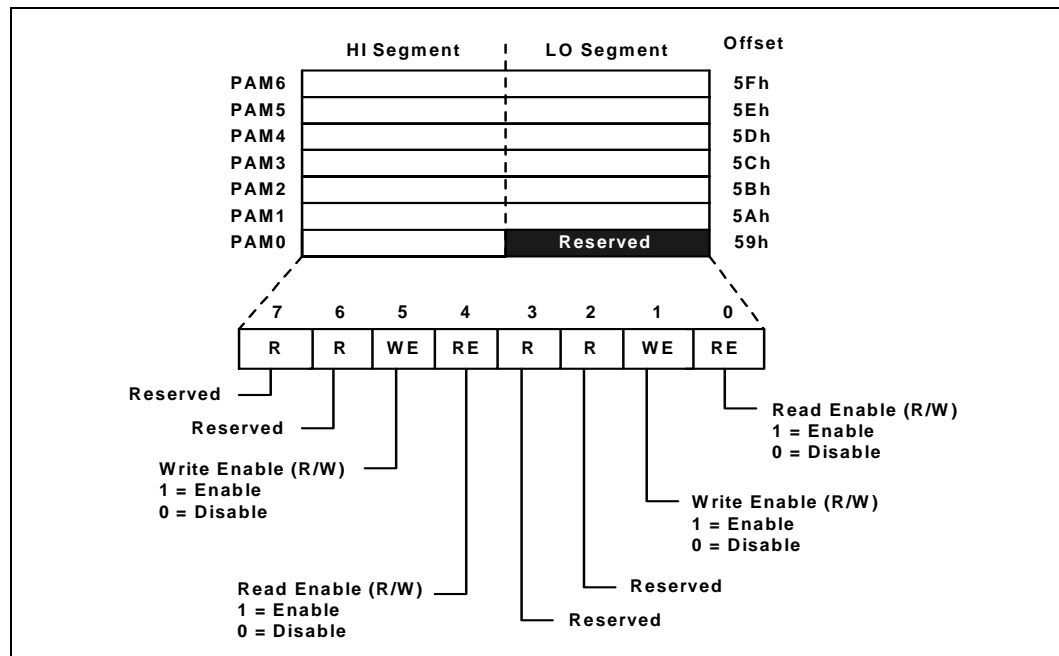

Table 10-5. PAM Associated Attribute Bits

| PAM Reg           | Attribute Bits |    | Memory Segment   | Comments       | DO:F0 Offset |
|-------------------|----------------|----|------------------|----------------|--------------|
| PAM0 03:00, 07:06 | Reserved       |    | —                | Reserved       | 59h          |
| PAM0 05:04        | WE             | RE | 0F0000h–0FFFFFFh | BIOS Area      | 59h          |
| PAM1 03:02, 07:06 | Reserved       |    | —                | Reserved       | 5Ah          |
| PAM1 01:00        | WE             | RE | 0C0000h–0C3FFFh  | BIOS Area      | 5Ah          |
| PAM1 05:04        | WE             | RE | 0C4000h–0C7FFFh  | BIOS Area      | 5Ah          |
| PAM2 03:02, 07:06 | Reserved       |    | —                | Reserved       | 5Bh          |
| PAM2 01:00        | WE             | RE | 0C8000h–0CBFFFh  | BIOS Area      | 5Bh          |
| PAM2 05:04        | WE             | RE | 0CC000h–0CFFFFh  | BIOS Area      | 5Bh          |

See Section 16.1.1.17, “Offset 59h: PAMO - Programmable Attribute Map 0 Register” through Section 16.1.1.23, “Offset 5Fh: PAM6 - Programmable Attribute Map 6 Register” for more register information on PAM memory space registers.

### 10.1.4 TSEG SMM Memory Space

Table 10-6. TSEG SMM Memory Space

|         | From        | To   |
|---------|-------------|------|
| TSEGSMM | TOLM - TSEG | TOLM |

The TSEG SMM space allows system management software to partition a region of main memory just below the top of low memory (TOLM) that is accessible only by system management software.

- Size** 128kB, 256kB, 512kB, or 1 MByte in size, depending upon the EXSMRC.TSEG\_SZ field (see Section 16.1.1.25). This space must be below 4 GBytes, so it is specified relative to TOLM and not relative to the top of physical memory.
- Enabling** SMM memory is globally enabled by EXSMRC.G\_SMFRAME (see Section 16.1.1.25). Requests may access SMM system memory when either SMM space is open (see SMRAM.D\_OPEN in Section 16.1.1.26) or the IMCH receives an SMM code request on its processor bus.
- Access** In order to access the TSEG SMM space, the TSEG must be enabled by EXSMRC.T\_EN (Section 16.1.1.25). When all of these conditions are met, then a processor bus access to the TSEG space (between TOLM-TSEG and TOLM) is sent to system memory. If the high SMRAM is not enabled or if the TSEG is not enabled, then all memory requests from all interfaces are forwarded to system memory. If the TSEG SMM space is enabled, and an agent attempts a non-SMM access to TSEG space, then the transaction is specially terminated.

Inbound accesses from NSI or PCI Express ports are not allowed to access SMM space.

### 10.1.5 PCI Express Enhanced Configuration Aperture

Table 10-7. PCI Express Enhanced Configuration Aperture

|           | From        | To          |
|-----------|-------------|-------------|
| HECREGION | 0_E000_0000 | 0_EFFF_FFFF |

PCI Express defines a memory-mapped aperture mechanism through which to access 4 Kbyte of PCI configuration register space for each possible bus, device, and function number. This 4 Kbyte space includes the compatible 256 B of register offsets that are traditionally accessed via the legacy CF8/CFC configuration aperture mechanism in I/O address space, making the enhanced configuration mechanism a full superset of the legacy mechanism. The enhanced mechanism has the advantage that full destination and type of access is specified in a single memory-mapped uncacheable transaction on the FSB, which is both faster and more robust than the historical I/O-mapped address and data register access pair.

CMI places the enhanced configuration aperture at E000\_0000h by default, as this is the first contiguous 256 MByte location below the 4 GByte boundary available for such usage.

CMI provides for relocation of this aperture via the HECBASE register (see [Section 16.1.1.35, "Offset CEh: HECBASE - PCI Express Port A \(PEA\) Enhanced Configuration Base Address Register"](#), although validation of moving the region is minimal.

## 10.1.6 IOAPIC Memory Space

**Table 10-8. IOAPIC Memory Space**

|                       | From        | To          |
|-----------------------|-------------|-------------|
| <b>IOAPIC0 (NSI)</b>  | 0_FEC0_0000 | 0_FEC7_FFFF |
| <b>IOAPIC2 (PEA0)</b> | 0_FEC8_0000 | 0_FEC8_OFFF |
| <b>IOAPIC3 (PEA1)</b> | 0_FEC8_1000 | 0_FEC8_1FFF |

The IOAPIC spaces are used to communicate with IOAPIC interrupt controllers that may be populated on NSI through PCI-Express port A (PEA). Since it is difficult to relocate an interrupt controller using plug-and-play software, fixed address decode regions have been allocated for them. Processor accesses to the IOAPIC0 region are always sent to NSI. Processor accesses to the IOAPIC2 region are always sent to PEA. These regions are subject to the APIC disable, which are cleared by BIOS after the allocated regions have been reflected down to the base registers of APIC controllers discovered during standard enumeration. Until this step of the initialization sequence has been performed, accesses to these regions are treated as subtractive decode and routed to NSI.

The IMCH does not support an IOAPIC range for the EDMA controller or the AIOC, since there is no IOxAPIC device or corresponding register set integrated into the EDMA controller or the AIOC.

## 10.1.7 FSB Interrupt Memory Space

**Table 10-9. FSB Interrupt Memory Space**

|                | From        | To          |
|----------------|-------------|-------------|
| <b>FSBINTR</b> | 0_FEE0_0000 | 0_FEEF_FFFF |

The FSB Interrupt space is the address range used to deliver interrupts to the FSB. Any device below AIOC, NSI or a PCI Express port may issue a Memory Write to OFEEx\_xxxxh. The IMCH will forward this Memory Write along with its associated data to the FSB as a Message Signaled Interrupt (MSI) transaction. The IMCH terminates the FSB transaction by asserting TRDY# and providing the response. This Memory Write cycle does not go to DRAM.

Reads to this address range are aborted by the IMCH.

## 10.1.8 High SMM Memory Space

Table 10-10. High SMM Memory Space

|         | From        | To          |
|---------|-------------|-------------|
| HIGHSMM | 0_FEDA_0000 | 0_FEDB_FFFF |

The HIGHSMM space allows cacheable access to the compatible SMM space by remapping valid SMM accesses between 0\_FEDA\_0000 and 0\_FEDB\_FFFF to physical accesses between 0\_000A\_0000 and 0\_000B\_FFFF. The accesses are remapped when SMRAM space is enabled, an appropriate access is detected on the processor bus, and when EXSMRC.H\_SMROME (Section 16.1.1.25) allows access to high SMRAM space. Inbound SMM memory accesses from any port are specially terminated; reads are provided with data retrieved from address 0, while writes are ignored entirely (all byte enables deasserted).

## 10.1.9 PCI Device Memory (MMIO)

The IMCH provides two distinct regions of memory that may be mapped to populated PCI devices. The first is the traditional (non-prefetchable) MMIO range, which must lie below the 4 GByte boundary. The registers associated with non-prefetchable MMIO (MBASE/MLIMIT, see Section 16.4.1.17, “Offset 20h: MBASE - Memory Base Address Register”/Section 16.4.1.18, “Offset 22h: MLIMIT - Memory Limit Address Register”) are unchanged from historical 32-bit architecture IMCH implementations. The second is the prefetchable MMIO range, which has been extended in CMI such that it may lie on either side of the 4 GByte boundary. The registers associated with prefetchable MMIO (PMBASE/PMLIMIT, see Section 16.4.1.19, “Offset 24h: PMBASE - Prefetchable Memory Base Address Register”/Section 16.4.1.20, “Offset 26h: PMLIMIT - Prefetchable Memory Limit Address Register”) have been augmented by the PCI defined upper 32-bit base/limit register pair (PMBASU/PMLMTU, see Section 16.4.1.21, “Offset 28h: PMBASU - Prefetchable Memory Base Upper Address Register”/Section 16.4.1.22, “Offset 2Ch: PMLMTU - Prefetchable Memory Limit Upper Address Register”), although only the first nibble of each register is implemented in the IMCH.

The MBASE/MLIMIT pair must be programmed to lie between TOLM and 4 GBytes. The PMBASE/PMLIMIT and PMBASU/PMLMTU registers must be programmed to lie between TOLM and 4 GBytes.

Because these registers define a PCI memory space, they are subject to the memory access enable (MAE) control bit in the standard PCI command register (see Section 16.4.1.4, “Offset 04h: PCICMD - PCI Command Register”).

*Note:* Using the same address space as both cacheable and non cacheable is discouraged. Also, assigning and writing the same host address space to two independent downstream devices is also discouraged. Although not illegal, both of the above conditions are very difficult to setup intelligently and validate. If 2 devices decide to use the same memory space, and they both send write cycles to it (both either cacheable or uncacheable), there are no guarantees that device 1 data (being older) will get there before device 2 data (being newer) if they do not use a flagging mechanism.

### 10.1.9.1 Device 2 Memory and Prefetchable Memory

**Table 10-11. Device 2 Memory and Prefetchable Memory**

|            | From            | To               |
|------------|-----------------|------------------|
| <b>M2</b>  | MBASE2          | MLIMIT2          |
| <b>PM2</b> | PMBASE2/PMBASU2 | PMLIMIT2/PMLMTU2 |

Plug-and-play software configures the PEA a memory window in order to provide enough memory space for the devices behind this virtual PCI-to-PCI bridge. Accesses whose addresses fall within these windows are decoded and forwarded to PEA0 for completion. Note that neither region should overlap with any other fixed or relocate-able area of memory. Also note that PCICMD2 refers to PCICMD for device 2.

### 10.1.9.2 Device 3 Memory and Prefetchable Memory

**Table 10-12. Device 3 Memory and Prefetchable Memory**

|            | From            | To               |
|------------|-----------------|------------------|
| <b>M3</b>  | MBASE3          | MLIMIT3          |
| <b>PM3</b> | PMBASE3/PMBASU3 | PMLIMIT3/PMLMTU3 |

Plug-and-play software configures the PEA1 memory window in order to provide enough memory space for the devices behind this virtual PCI-to-PCI bridge. Accesses whose addresses fall within this window are decoded and forwarded to PEA1 for completion. Note that neither region should overlap with any other fixed or relocate-able area of memory. Also note that PCICMD3 refers to PCICMD for device 3.

*Note:* If PCI Express Port A0 is configured to operate in x8 mode, all functional space for PEA1 disappears; effectively collapsing M3/PM3 to match the limit addresses of M2/PM2.

### 10.1.9.3 Device 4 Memory and Prefetchable Memory

**Table 10-13. Device 4 Memory and Prefetchable Memory**

|            | From            | To               |
|------------|-----------------|------------------|
| <b>M4</b>  | MBASE4          | MLIMIT4          |
| <b>PM4</b> | PMBASE4/PMBASU4 | PMLIMIT4/PMLMTU4 |

Plug-and-play software configures the PCI memory window in order to provide enough memory space for the devices behind this virtual PCI-to-PCI bridge. Accesses whose addresses fall within this window are decoded and forwarded to PCI for completion. Note that neither region should overlap with any other fixed or relocate-able area of memory. Also note that PCICMD4 refers to PCICMD for device 4.

## 10.2 IMCH Responses to EDMA Transactions

In the following tables, the term “Abort” implies that the EDMA engine will immediately stop the transfer in progress. The offending access will not be forwarded to the inbound/outbound arbiter at all, an error bit will be set accordingly, and the error will be escalated as specified by the configuration bits controlling interrupts and errors.

*Note:* This behavior is quite different from the and PCI Express inbound ports, as in the latter cases the transaction in question was requested by some other initiator elsewhere in the platform. The EDMA engine is a source of traffic all by itself, which makes error containment much simpler in the case of EDMA traffic.

### 10.2.1 Fixed Address Spaces (EDMA)

Table 10-14 summarizes IMCH responses to EDMA accesses to the various fixed address spaces.

Table 10-14. EDMA Accesses to Fixed Address Spaces

| Address Space                            | Conditions  | Destination | IMCH Response  |
|--|---|-------------|--|
| DOSMEM                                   | -   | MainMem     | Transaction is sent to memory system   |
| VGAA<br>VGAB<br>MDA<br>PAMCO...<br>PAMFO | -   | Abort       | Programmer's responsibility not to target EDMA accesses in the legacy region between 640KB and 1 MByte |
| MEM1_15                                  | -   | MainMem     | Transaction is sent to memory system   |
| ISA15                                    | FDHC.HEN = 0  | MainMem     | Hole Disabled: Transaction is sent to memory system  |
|  | FDHC.HEN = 1  | Abort       | Hole Enabled: EDMA will abort on accesses directed to the ISA hole when enabled                        |
| MAINMEM                                  | -   | MainMem     | Transaction is sent to memory system (unless address hits an enabled TSEG SMM range. See TSEGSMM)      |
| TSEGSMM                                  | -   | Variable    | Refer to <a href="#">Table 10-16, “Supported SMM Ranges”</a> .   |
| IOAPIC[0,2-3]                            | -   | Abort       | Programmer's responsibility to avoid the APIC ranges   |
| FSBINTR                                  | -   | Abort       | Programmer's responsibility to avoid the FSB interrupt messaging range                                 |
| HIGHSMM                                  | -   | Variable    | Refer to <a href="#">Table 10-16, “Supported SMM Ranges”</a> .   |
| HIGHMEM                                  | Address is below the top of memory space defined by TOM and the REMAP registers | MainMem     | Transaction is sent to memory system.  |
|  | Address is above the top of memory  | Abort       | Hardware will detect an attempt to access above the populated DRAM space, and will abort.              |

### 10.2.2 Relocatable Address Spaces (EDMA)

Table 10-15 summarizes IMCH responses to EDMA accesses to the various relocatable address spaces.

**Note:** EDMA access is not permitted to the port, thus any address mapping to the legacy interface will cause an abort.

**Table 10-15. EDMA Accesses to Relocatable Address Spaces**

| Address Space           | Conditions       | Destination | IMCH Response                                  |
|-------------------------|------------------|-------------|--|
| NSI: M<br>NSI: PM       | -                | Abort       | No support for EDMA destination on NSI         |
| PEA: M[n]<br>PEA: PM[n] | Write, MAE = 1   | PEA[n]      | Transaction forwarded to destination PEA port. |
|                         | Write, MAE = 0   | Abort       | Abort. Memory access disabled.                 |
|                         | Read Transaction | Abort       | Abort. No support for peer segment reads.      |
| NSI_SUB                 | -                | Abort       | No support for EDMA destination on NSI         |
| PEA:<br>PM[n]           | Write, MAE = 1   | PEA[n]      | Transaction forwarded to destination PEA port. |
|                         | Write, MAE = 0   | Abort       | Abort. Memory access disabled.                 |
|                         | Read Transaction | Abort       | Abort. No support for peer segment reads.      |

## 10.3 I/O Address Space

The IMCH generates outbound transactions on behalf of all IA-32 core I/O accesses. The IMCH contains two internal registers in the IA-32 core I/O space dedicated to the configuration access mechanism; the Configuration Address Register (CONFIG\_ADDRESS) and the Configuration Data Register (CONFIG\_DATA). The behavior of the IMCH in response to accesses to these registers is described in [Chapter 13.0, "Platform Configuration."](#)

The IA-32 core allows 64 K+3 bytes to be addressed within the I/O space. The IMCH propagates the IA-32 core I/O address without any translation to the targeted destination bus. Note that the upper three locations can be accessed only during I/O address wrap-around; when signal A16# is asserted on the processor bus. A16# is asserted on the processor bus whenever a Dword I/O access is made from address 0FFFDh, 0FFFEh, or 0FFFFh. In addition, A16# is asserted when software attempts a two-byte I/O access from address 0FFFFh.

All I/O accesses (read or write) which do not map to internal IMCH registers will receive a DEFER response on the FSB, and be forwarded to the appropriate outbound port. The IMCH never posts an I/O write.

The IMCH never responds to inbound transactions to I/O or configuration space initiated on any port. Inbound I/O or configuration transactions requiring a completion are terminated with "master abort" completion packets on the originating port interface. Inbound I/O or configuration write transactions not requiring completion are dropped.

### 10.3.1 Configuration Window

The I/O addresses 0CF8h and 0CFCh are treated specially, as they define the compatible configuration window. Dword accesses to 0CF8h address the internal IMCH configuration address register. Accesses from 1 to 4 bytes in size to the region from 0CFC-0CFFh are treated as configuration data accesses if configuration space is enabled (bit31 of the configuration address register is set). Refer to [Chapter 13.0, "Platform Configuration."](#) for further details.

### 10.3.2 VGA and MDA Regions

Along with the memory space address regions described in [Section 10.1.2, “VGA and MDA Memory Spaces”](#), there are fixed I/O locations associated with both the VGA and the MDA regions. Accesses to these addresses are routed to NSI by default, but this behavior may be modified via the VGAEN, MDAP and MAE configuration settings. Refer to the prior sections for the rules associated with the configuration settings of VGAEN, MDAP and MAE.

The MDA region includes I/O space addresses 3B4h, 3B5h, 3B8h, 3B9h, 3BAh and 3BFh. The VGA region includes I/O space ranges 3B0-3BBh, and 3C0-3DFh. The *PCI Specification* defines both MDA and VGA to be 10-bit address decode, thus all accesses with A[9:0] matching any of these addresses are subject to the associated routing rules. Address bits A[15:10] are ignored when the check against these fixed addresses are applied.

The order of precedence for the routing checks is as follows:

- MAE = 0, MDA addresses will route to NSI if MDAP is set, overriding any VGAEN.
- MAE = 1, MDA addresses will route to the Peer device if MDAP is set, overriding any VGAEN.
- MAE = 0, VGA addresses will route to the NSI.
- MAE = 1, VGA addresses will route to the PCI Express port with its VGAEN set, if any.
- MAE = 0, MDA addresses which fall within VGA regions will route to the NSI if MDAP is clear.
- MAE = 1, MDA addresses which fall within VGA regions will follow VGAEN if MDAP is clear.
- Both VGA and MDA addresses default to NSI if MDAP and all VGAEN bits are clear.

*Note:* Setting of MDAP or any of the VGAEN bits implies that the ISAEN bit is also set in all virtual P2P bridges, because of the 10-bit decode requirement.

*Note:* AIOC access to this space is not supported. Upstream attempted accesses to this space are programming errors and will result in a master abort.

## 10.4 Main Memory Addressing

The “High Memory” and “Extended Memory” address regions are together called “Main Memory.” Main memory is composed of address segments that refer to DDR SDRAM system memory. Main memory addresses are mapped to DDR SDRAM channels, devices, banks, rows, and columns in different ways depending upon the type of memory being used and upon the density or organization of the memory. The process for determining the device and channel IDs for addressed devices is as follows:

- The requested address is compared against the values of all eight DRB registers. The number of the register whose programmed value is greater than the address and whose previous register is less than the address is the output of the comparison.
- The value of the DRB register “below” is subtracted from the address in order to determine the offset into the group.
- The offset determines the manner in which the row, column, and bank address bits are extracted from the address.

## 10.5 System Management Mode (SMM) Space

CMI supports the use of main memory as System Management RAM (SMM RAM) enabling the use of System Management Mode. The IMCH supports three SMM options:

- Compatible SMRAM (C\_SMRAM)
- High Segment (HSEG)
- Top of Memory Segment (TSEG)

System Management RAM space provides an access protected memory area that is available for SMI handler code and data storage. This memory resource is normally hidden from the Operating System so that the processor has immediate access to this memory space upon entry to SMM (cannot be swapped-out).

### 10.5.1 SMM Addressing Ranges

IMCH provides three SMRAM options:

- Below 1 MByte option that supports compatible SMI handlers.
- Above 1 MByte option that allows new SMI handlers to execute with write-back cacheable SMRAM.
- Optional larger write-back cacheable T\_SEG area from 128 Kbyte to 1 MByte in size. The above 1 MByte solutions require changes to compatible SMRAM handler code to properly execute above 1 MByte.

*Note:* The first two options both map legal accesses to the same physical range of memory, while the third defines an independent region of addresses.

#### 10.5.1.1 SMM Space Restrictions

If any of the following conditions are violated, the results of SMM accesses are unpredictable and may cause the system to hang:

- The Compatible SMM space must not be set-up as cacheable.
- Both D\_OPEN and D\_CLOSE must not be set to 1 at the same time.
- When TSEG SMM space is enabled, the TSEG space must not be reported to the OS as available DRAM. This is a BIOS responsibility.

BIOS and SMM code must cooperate to properly configure the IMCH in order to ensure reliable operation of the SMM function.

### 10.5.1.2 SMM Space Definition

SMM space is defined by both its addressed SMM space and its DRAM SMM space. The addressed SMM space is defined as the range of FSB addresses used by the IA-32 core to access SMM space. DRAM SMM space is defined as the range of physical DRAM memory locations containing SMM information.

The SMM space can be accessed at one of three transaction address ranges:

- Compatible
- High
- TSEG

The Compatible and TSEG SMM space is not remapped and therefore the addressed and DRAM SMM physical addresses are identical. The High SMM space is remapped; thus the addressed and DRAM SMM locations are different. Note that the High DRAM space is the same as the Compatible Transaction Address space.

Table 10-16 describes all three unique addressing combinations:

- Compatible Transaction Address
- High Transaction Address
- TSEG Transaction Address

Table 10-16. Supported SMM Ranges

| SMM Space Enabled | Transaction Address Space (Adr) | DRAM Space (DRAM)      |
|-------------------|---------------------------------|------------------------|
| Compatible (C)    | A0000h to BFFFFh                | A0000h to BFFFFh       |
| High (H)          | 0FEDA0000h to 0FEDBFFFFh        | A0000h to BFFFFh       |
| TSEG (T)          | (TOLM-TSEG_SZ) to TOLM          | (TOLM-TSEG_SZ) to TOLM |

**Notes:**

1. High SMM: This implementation is consistent with the Intel E7500 and Intel E7501 designs. In prior MCH designs the High segment was the 384 Kbyte region from A\_0000h to F\_FFFFh. However C\_0000h to F\_FFFFh was not useful, so it has been deleted in the IMCH design.
2. TSEG SMM: This implementation is consistent with the Intel E7500 and Intel E7501 designs. In prior MCH designs the TSEG address space was offset by 256 MBytes to allow for simpler decoding and the TSEG was remapped to just under the TOLM. In the IMCH the TSEG region is not offset by 256 MBytes and it is not remapped.
3. In Cases where DRAM TOLM is less than TOM TSEG cannot be used for SMM. For this case MENC memory spans consecutive space from above TOLM to below TOLM and will conflict with TSEG space

## 10.6 Memory Reclaim Background

The following Memory Mapped I/O devices and ranges are typically located below 4 GBytes:

- High BIOS
- H-Seg
- XAPIC
- Local APIC
- FSB Interrupts
- PEA0 through PEA1 M, PM and BAR regions

In previous generation MCH architectures, the physical DRAM memory overlapped by the logical address space allocated to these Memory Mapped I/O devices was unusable. In server systems the memory allocated to memory mapped I/O devices could easily exceed 1 GByte. This creates the possibility of a large amount of physical memory populated in the system becoming unusable.

The IMCH provides the capability to reclaim the physical memory overlapped by the Memory Mapped I/O logical address space via remapping physical memory from the Top of Low Memory (TOLM) boundary up the 4 GBytes boundary (or TOM if less than 4 GBytes) to an equivalent sized logical address range located just above the top of physical memory

### 10.6.1 Memory Remapping Algorithm

*Note:* The IA-32 core is not capable of using the remap capability and care must be taken to ensure that no addresses sent to the IA-32 core are greater than TOLM in that it will cause aliasing. The remap capability can be utilized by the AIOC, IICH and PCIe ports.

Terminology clarification:

|                  |  |
|------------------|--|
| Physical Address | The address presented to the IMCH is traditionally called a "physical address," because Intel architecture processors contain both segmentation and paging hardware, and all compatible software differentiates between logical addresses, virtual addresses, and physical addresses. The algorithm for remapping addresses presented to the IMCH to reclaim DRAM address space must be implemented such that the mechanism is invisible to compatible software. |
| System Address   | The system address applies to the internal IMCH interface to physical DRAM memory, and is not directly visible to software, other than through certain internal logging registers used to store decoded DRAM address information for error isolation.  |

An incoming address (referred to as a physical address) is checked to see if it falls in the memory remap window. The bottom of the remap window is defined by the value in the REMAPBASE register (see [Section 16.1.1.31, "Offset C6h: REMAPBASE - Remap Base Address Register"](#)). The top of the remap window is defined by the value in the REMAPLIMIT register ([Section 16.1.1.32, "Offset C8h: REMAPLIMIT - Remap Limit Address Register"](#)). An address that falls within this window is remapped to the physical memory starting at the address defined by the TOLM register.

## 10.7 IICH Register and Memory Mappings

This section covers CMI's IICH various address decoding ranges.

This section is for background purposes, and must not to be considered by implementers and validators as part of the behavioral definition of CMI. Each decode range is described elsewhere in the section associated with the corresponding function.

### 10.7.1 I/O Map

The I/O map is divided into separate types. Fixed ranges cannot be moved, but in some cases can be disabled. Variable ranges can be moved and can also be disabled.

#### 10.7.1.1 Fixed I/O Address Ranges

Table 10-17 shows the Fixed I/O decode ranges from the IA-32 core perspective. Note that for each I/O range, there may be separate behavior for reads and writes. Cycles that go to target ranges that are marked as Reserved will not be decoded, and are passed to PCI to PCI Bridge where they are dropped.

Address ranges that are not listed or marked reserved are NOT positively decoded by the IICH (unless assigned to one of the variable ranges). In subtractive mode, I/O ranges that are not otherwise decoded are forwarded to PCI to PCI Bridge where they are dropped.

**Table 10-17. Fixed I/O Ranges Decoded by IICH (Sheet 1 of 3)**

| I/O Address | Read Target          | Write Target         | Internal Unit    | Separate Enable/Disable |
|-------------|----------------------|----------------------|------------------|-------------------------|
| 00h – 08h   | DMA Controller       | DMA Controller       | DMA              | None                    |
| 09h – 0Eh   | RESERVED             | DMA Controller       | DMA              | None                    |
| 0Fh         | DMA Controller       | DMA Controller       | DMA              | None                    |
| 10h – 18h   | DMA Controller       | DMA Controller       | DMA              | None                    |
| 19h – 1Eh   | RESERVED             | DMA Controller       | DMA              | None                    |
| 1Fh         | DMA Controller       | DMA Controller       | DMA              | None                    |
| 20h – 21h   | Interrupt Controller | Interrupt Controller | Interrupt        | None                    |
| 24h – 25h   | Interrupt Controller | Interrupt Controller | Interrupt        | None                    |
| 28h – 29h   | Interrupt Controller | Interrupt Controller | Interrupt        | None                    |
| 2Ch – 2Dh   | Interrupt Controller | Interrupt Controller | Interrupt        | None                    |
| 2E – 2F     | LPC SIO              | LPC SIO              | Forwarded to LPC | Yes                     |
| 30h – 31h   | Interrupt Controller | Interrupt Controller | Interrupt        | None                    |
| 34h – 35h   | Interrupt Controller | Interrupt Controller | Interrupt        | None                    |
| 38h – 39h   | Interrupt Controller | Interrupt Controller | Interrupt        | None                    |
| 3Ch – 3Dh   | Interrupt Controller | Interrupt Controller | Interrupt        | None                    |
| 40h – 42h   | Timer/Counter        | Timer/Counter        | PIT (8254)       | None                    |
| 43h         | RESERVED             | Timer/Counter        | PIT              | None                    |
| 4E – 4F     | LPC SIO              | LPC SIO              | Forwarded to LPC | Yes                     |
| 50h – 52h   | Timer/Counter        | Timer/Counter        | PIT              | None                    |
| 53h         | RESERVED             | Timer/Counter        | PIT              | None                    |

| 208 – 20Fh  | Gameport High        | Gameport High        | Forwarded to LPC     | Yes                     |
| 376h        | SATA                 | SATA                 | SATA                 | Yes                     |
| 3F6h        | SATA                 | SATA                 | SATA                 | Yes                     |
| 4D0h – 4D1h | Interrupt Controller | Interrupt Controller | Interrupt            | None                    |
| CF9h        | Reset Generator      | Reset Generator      | IA-32 core Interface | None                    |

**Notes:**

1. Only if the Port 61 Alias Enable bit (GCS.P61AE) bit is set. Otherwise, the target is dropped.
- 2.

**10.7.1.2 Variable I/O Decode Ranges**

Table 10-18 shows the Variable I/O Decode Ranges. They are set using Base Address Registers (BARs) or other configuration bits in the various configuration spaces. The PnP software (PCI or ACPI) can use their configuration mechanisms to set and adjust these values.

**Warning:** The Variable I/O Ranges must not be set to conflict with the Fixed I/O Ranges. If the configuration software allows conflicts to occur, it may produce unpredictable results. There are no checks for conflicts.

**Table 10-18. Variable I/O Decode Ranges**

| Range Name             | Mappable                                  | Size (Bytes)   | Target                        |
|------------------------|---|----------------|-------------------------------|
| ACPI                   | Anywhere in 64K I/O Space                 | 64             | Power Management              |
| USB #1                 | Anywhere in 64K I/O Space<br>(See Note 1) | 32             | USB1 Host Controller 1        |
| SMBus                  | Anywhere in 64K I/O Space                 | 32             | SMB Unit                      |
| TCO                    | 96 bytes above ACPI base                  | 32             | TCO Unit                      |
| GPIO                   | Anywhere in 64K I/O space                 | 64             | GPIO Unit                     |
| Parallel Port          | 3 ranges in 64K I/O Space                 | 8 <sup>2</sup> | LPC Peripheral                |
| Serial Port 1          | 8 Ranges in 64K I/O Space                 | 8              | LPC Peripheral                |
| Serial Port 2          | 8 Ranges in 64K I/O Space                 | 8              | LPC Peripheral                |
| Floppy Disk Controller | 2 Ranges in 64K I/O Space                 | 8              | LPC Peripheral                |
| LPC Generic 1          | Anywhere in 64K I/O Space                 | 128            | LPC Peripheral                |
| LPC Generic 2          | Anywhere in 64K I/O Space                 | 16             | LPC Peripheral                |
| I/O Trapping Ranges    | Anywhere in 64K I/O Space                 | 1 to 256 Bytes | Trap on Internal I/O Data Bus |

**Notes:**

1. These ranges are decoded directly.
2. There is also an alias 400h above the parallel port range that is used for ECP parallel ports.

## 10.7.2 Memory Map

Table 10-19 shows (from the IA-32 core perspective) the memory ranges that are decoded. Cycles that arrive that are not directed to any of the internal memory targets that decode (see Table 10-19) are dropped.

Software must not attempt locks to the IICH's memory-mapped I/O ranges for USB 2.0, and HPET (High Precision Event Timer). If attempted, the lock is not honored which means potential deadlock conditions may occur.

**Table 10-19. IICH Memory Decode Ranges (from IA-32 core Perspective)**

| Memory Range                                   | Target                  | Dependency/Comments  |
|--|-------------------------|--|
| 000E0000 - 000EFFFF                            | FWH                     | Bit 6 in FWH Decode Enable Register is set.  |
| 000F0000 - 000FFFFF                            | FWH                     | Bit 7 in FWH Decode Enable Register is set   |
| FEC00000 - FEC0 0040                           | I/O(x)APIC inside IICH  |  |
| FFC0 0000 - FFC7 FFFF<br>FF80 0000 - FF87 FFFF | FWH                     | Bit 8 in FWH Decode Enable Register  |
| FFC8 0000 – FFCF FFFF<br>FF88 0000 - FF8F FFFF | FWH                     | Bit 9 in FWH Decode Enable Register  |
| FFD0 0000 - FFD7 FFFF<br>FF90 0000 - FF97 FFFF | FWH                     | Bit 10 in FWH Decode Enable Register is set  |

### 10.7.3 Boot-Block Update Scheme

The IICH supports a “Top-Block Swap” mode that swaps the top block in the FWH (the boot block) with another location. This allows for safe update of the Boot Block (even if a power failure occurs). When the “top-swap” enable bit is set, inverts A16 for cycles going to the upper two 64 Kbyte blocks in the FWH. Specifically, in this mode, accesses to FFFF\_0000h-FFFF\_FFFFh are directed to FFFE\_0000h-FFFE\_FFFFh and vice versa. When the Top Swap Enable bit is 0, the IICH will not invert A16. This bit is automatically set to 0 by RTEST#, but not by PLTRST#.

The scheme is based on the concept that the top block is reserved as the “boot” block, and the block immediately below the top block is reserved for doing boot-block updates.

The algorithm is:

1. Software copies the top block to the block immediately below the top.
2. Software checks that the copied block is correct. This could be done by performing a checksum calculation.
3. Software sets the “Top-Block Swap” bit. This will invert A16 for cycles going to the FWH.
4. Software erases the top block.
5. Software writes the new top block.
6. Software checks the new top block.
7. Software clears the top-block swap bit.
8. Software sets the Top\_Swap Lock-Down bit.

If a power failure occurs at any point after step 3, the system is able to boot from the copy of the boot block that is stored in the block below the top. This is because the top-swap bit is backed in the RTC well.

*Note:* The top-block swap mode may be forced by an external strapping option (see [Chapter 16.0, “IMCH Registers.”](#)). When top-block swap mode is forced in this manner, the TOP\_SWAP bit cannot be cleared by software. A reboot with the strap removed will be required to exit a forced top-block swap mode.

*Note:* Top-block swap mode only affects accesses to the Firmware Hub space, not feature space.

*Note:* The top-block swap mode has no effect on accesses below FFFE\_0000h.

## 11.0 System Memory Controller

---

### 11.1 Overview

The memory controller is responsible for controlling the off-chip DRAM devices. The unit scheduler, control and protocol state machines access DRAM devices over a wide range of speed bins using DDR2 DRAM technology. The EP80579 supports one memory channel.

### 11.2 Memory Controller Feature List

The memory controller supports the following features

- Supports 1 DIMM
  - DDR2
  - 64 and 32-bit mode.
  - Single rank (64 or 32-bit mode) or Dual rank (64 bit mode) device.
  - DDR2-400, DDR2-533, DDR2-667, DDR2-800.
  - See to [“Rules for Populating DIMM Slots”](#) for more details.
- Supports dual DIMMs
  - DDR2 and 64 bit mode only
  - Registered Dual DIMM support with 1T command/address timing. Unbuffered Dual DIMM support with 2T command/address timing. Please refer to [“2T Timing Mode”](#) for details.
  - 32-bit mode dual DIMM is not supported
  - Restrictions on speed, number of ranks and modes in 2 DIMM mode, refer to [“Rules for Populating DIMM Slots”](#) for details.
  - DDR2-400 is supported.
  - DDR2-533 and DDR2-667 are also supported with special design guidelines. Refer to [Table 11-5](#) for more details.
- Supports 32-bit mode
  - 32-bit mode is for memory-down configuration, thus the following modes are not supported: dual DIMM, dual rank, registered
- Supports 256 Mb, 512 Mb, 1 Gb and 2 Gb density parts in the x8 configuration. [Table 11-1](#) shows the various DDR2 device densities and widths supported. [Table 11-2](#) and [Table 11-3](#) shows the various memory capacity configurations supported using these parts in the 64 bit and 32-bit modes.
  - Memory Controller does not support 4 Gb density
  - See [Section 11.3, “Configurations”](#) for more details.
- Supports 4-bank devices
  - 256 Mb and 512 Mb DDR2 parts

- Supports 8-bank devices.
  - 1 Gb and 2 Gb DDR2 parts
- Supports unbuffered and registered DIMMs
- Supports discrete memory components soldered on the board
  - supports 2 DQ loads similar to the double sided DIMM configuration.
- One 72b wide DRAM interface, 64b data + 8b ECC.
  - The 64b data interface can optionally configured to be a 32b interface with 8b ECC. The 32b option provides half the total bandwidth compared to the 64b interface, and meets the requirements for systems that are cost sensitive and want to populate small memory footprint soldered on the mother board.
- Supports burst-of-4 mode with a minimum access size of 32B for the 64b interface.
  - On the 64b interface accesses longer than 32B are serviced as multiple burst-of-4 transactions without closing the page.
  - On the 32b interface, the controller supports burst-of-8 for a minimum access size that is still 32B.
- Optional error protection using ECC bits and error code that supports SEC/DED (single bit error correction/double bit error detection). Please see [“Offset 7Ch: DRC – DRAM Controller Mode Register”](#) for details.
  - On a single bit error, the memory controller corrects the error bit and writes back the correct data value to DRAM, if enabled by software selection.
  - Does not support DED (double-bit error detect) retries.
- Supports maximum of 4 GB DRAM capacity as shown in [Table 11-2](#).
  - One memory channel
- Support for demand scrub in hardware
  - Refer to [Section 16.1.1.45, “Offset 88h: SDRS – DDR SDRAM Secondary Control Register”](#) on page 439 for details.
- Support for background scrubbing in hardware.
  - Programmable hardware scrub engine that allows background scrub at a wide range of rates, including, but not limited to: up to 4 GB every hour, day, week, or very fast rates, mainly used for validation purposes.

The memory controller supports the following transactions

- Simple read transactions.
  - Supported lengths - 1-7B, 8B, 16B, 24B, 32B, 64B
  - Read transactions smaller than 32B will result in a full 32B read on the interface
- Simple write transactions.
  - Supported lengths - 8B, 16B, 24B, 32B, 64B
  - Writes of lengths 8B, 16B and 24B will take the same time on the interface as a 32B write, the actual bytes that are written are specified by the DQ masks
  - Writes of length 40B, 48B, 56B will be treated as a 32B write followed by an 8B, 16B or 24B write
  - Writes that are smaller than 8B (i.e 1-7B) require a read-modify-write operation and these will be supported upstream in the pipeline in other units. The memory controller will not support read-modify-write operation.
- CSR reads and writes

- The memory controller does not support any atomic operations. Other units upstream support atomic operations.
- All memory controller operations are aligned on a 64B boundary
- The memory controller interleaves the memory across banks on a 64B boundary
  - Any transaction that crosses a 64B alignment boundary or is larger than 64B must be split by the upstream agent.
- Supports external DIMMs or SO-DIMMs.

### 11.3 Configurations

Table 11-1 shows the various DDR2 device densities and widths supported by the memory controller.

**Table 11-1. Supported DDR2 Device Densities and Width**

| Density (Mb) | DDR2x8        |
|--------------|---------------|
| 256          | Supported     |
| 512          | Supported     |
| 1024         | Supported     |
| 2048         | Supported     |
| 4096         | Not Supported |

Table 11-2 shows the various capacity configurations supported in 64b mode. The first column shows the total DRAM capacity on the channel. The rest of the columns indicate the DRAM devices features, densities and the number of devices required to achieve the given capacity. A single sided DIMM is indicated by no parts populated on side B. Double sided DIMM has parts populated on both sides.

For each configuration, an additional DRAM part per side is required to support ECC bits. A x8 part provides all the bits required for ECC. Note that memory system can be built without ECC enabled.

In the 64b configuration, the minimum capacity supported is 256 MB and the maximum capacity supported is 4 GB.

**Table 11-2. Supported DRAM Capacity for 64b Mode**

| Total DRAM Capacity | DRAM Density | DRAM Part Width | Total # of parts on side A (w/o ECC) | Total # of parts on side B (w/o ECC) |
|---------------------|--------------|-----------------|--------------------------------------|--------------------------------------|
| 256 MB              | 256 Mb       | x8              | 8                                    | 0                                    |
| 512 MB              | 256 Mb       | x8              | 8                                    | 8                                    |
|                     | 512 Mb       | x8              | 8                                    | 0                                    |
| 1 GB                | 512 Mb       | x8              | 8                                    | 8                                    |
|                     | 1 Gb         | x8              | 8                                    | 0                                    |
| 2 GB                | 1 Gb         | x8              | 8                                    | 8                                    |
|                     | 2 Gb         | x8              | 8                                    | 0                                    |
| 4 GB                | 2 Gb         | x8              | 8                                    | 8                                    |

Table 11-3 shows the various configurations supported in the 32b mode. In the 32-bit mode only single rank DDR2 devices are supported. In this mode, the minimum capacity supported is 128 MB and the maximum capacity supported is 1 GB.

**Table 11-3. Supported DRAM Capacity for 32b Mode**

| Total DRAM Capacity | DRAM Density | DRAM Part Width | Total # of parts on side A (w/o ECC) | Total # of parts on side B (w/o ECC) |
|---------------------|--------------|-----------------|--------------------------------------|--------------------------------------|
| 128 MB              | 256 Mb       | x8              | 4                                    | 0                                    |
| 256M B              | 512 Mb       | x8              | 4                                    | 0                                    |
| 512 MB              | 1 Gb         | x8              | 4                                    | 0                                    |
| 1 GB                | 2 Gb         | x8              | 4                                    | 0                                    |

*Note:* The EP80579 supports only single ranks in 32-bit mode.

Table 11-4 shows the supported DIMM raw cards in the registered and unbuffered formats.

**Table 11-4. Raw Cards Supported by the EP80579**

| Raw Card | Number of DDR2 SDRAMs | SDRAM Organization     | Number of Ranks |       |
|----------|-----------------------|------------------------|-----------------|-------|
| A        | 9                     | x8, planar, single row | 1               | RDIMM |
| F        | 9                     |                        | 1               |       |
| B        | 18                    |                        | 2               |       |
| G        | 18                    |                        | 2               |       |
| D        | 8                     |                        | 1               | UDIMM |
| F        | 9                     |                        | 1               |       |
| E        | 16                    |                        | 2               |       |
| G        | 18                    |                        | 2               |       |

Table 11-5 shows the supported DDR2 device speed grades for single and Dual DIMMs. Dual DIMM support uses 2N or 2T command/address timing.

**Table 11-5. Supported DDR2 Data Speeds**

| DDR Speed   | 1 DIMM 1 rank     | 1 DIMM 2 ranks    | 2 DIMMs 1 rank each |
|---|-------------------|-------------------|---------------------|
| DDR2-400  | R = 1T<br>UB = 1T | R = 1T<br>UB = 1T | R = 1T<br>UB = 2T   |
| DDR2-533  | R = 1T<br>UB = 1T | R = 1T<br>UB = 1T | R = 1T<br>UB = 2T   |
| DDR2-667  | R = 1T<br>UB = 1T | R = 1T<br>UB = 1T | R = 1T<br>UB = 2T   |
| DDR2-800  | R = 1T<br>UB = 2T | R = 1T<br>UB = 2T | Not supported       |
| R = Registered<br>UB = Unbuffered<br>1T = 1T Address/Command Timing<br>2T = 2T Address/Command Timing |                   |                   |                     |

### 11.3.1 Rules for Populating DIMM Slots

1. In all configurations, the speed and timing will be the lowest among the 2 DIMMs, as determined by the SPD registers on the DIMMs
2. Dual DIMM mode supports a subset of the DDR2 data speeds as shown in [Table 11-5](#).
3. [Table 11-6](#) shows the supported DIMM population of the 2 ranks. All of configurations not shown in [Table 11-6](#) are not supported. The rank configurations supported are one or two ranks on a single DIMM or one rank on each of the 2 DIMMs. Two ranks in each of the 2 DIMMs (i.e., 4 ranks) is not supported.

**Table 11-6. Supported DIMM Populations**

|                 | DIMM 1              |        | DIMM 0              |                     |
|-----------------|---------------------|--------|---------------------|---------------------|
|                 | Rank 0              | Rank 1 | Rank 0              | Rank 1              |
| 1 - Single Rank | Empty               | Empty  | DRB0<br>CS0<br>ODT0 | Empty               |
| 1 - Dual Rank   | Empty               | Empty  | DRB0<br>CS0<br>ODT0 | DRB2<br>CS1<br>ODT1 |
| 2 - Single Rank | DRB2<br>CS1<br>ODT1 | Empty  | DRB0<br>CS0<br>ODT0 | Empty               |

TABLE KEY:  
 ODT0/ODT1: ODT pins. Please refer to [Section 11.4.2](#) for more information.  
 CS0/CS1: Chip Selects  
 DRB: Dram Row Boundary Register

4. [Table 11-7](#) shows the supported rank configurations when using 2 ranks for the single and dual DIMM.

**Table 11-7. Supported Rank Configurations in Single and Dual DIMM mode**

| Single DIMM<br>(DDR2)<br>(64 bits - rank 0 & rank 1)<br>(32 bits - rank 0 only) |        | Dual DIMM<br>(DDR2, 64 bit only) |                               |
|---|--------|----------------------------------|-------------------------------|
| Rank 0  | Rank 1 | Rank 0, DIMM 0                   | Rank 0, DIMM 1                |
| 128 MB<br>(32 bit only)   | NA     | NA                               | NA                            |
| 256 MB  | 256 MB | 256 MB                           | 256 MB, 512 MB, 1 GB,<br>2 GB |
| 512 MB  | 512 MB | 512 MB                           | 256 MB, 512 MB, 1 GB,<br>2 GB |
| 1 GB  | 1 GB   | 1 GB                             | 256 MB, 512 MB, 1 GB,<br>2 GB |
| 2 GB  | 2 GB   | 2 GB                             | 256 MB, 512 MB, 1 GB,<br>2 GB |

- 5. There are additional restrictions when 2 ranks are used. Both the ranks need to be:
  - Either registered or unbuffered. No mixing of registered and unbuffered ranks.
  - 64 bit mode only. 32-bit mode is not supported in dual rank.
- 6. For 32-bit mode, only discrete components of single rank are supported. Two ranks in 32-bit mode is not supported. [Table 11-3](#) shows the supported configurations in the 32-bit mode.

### 11.3.2 DRAM Addressing

[Table 11-8](#), [Table 11-9](#), [Table 11-10](#) and [Table 11-11](#) show the DRAM device addressing for the various DDR2 device densities supported by the memory controller.

Note that:

- x4 and x 16 devices are not supported.
- 4Gb and higher device density parts are not supported.
- See [Table 11-7](#) for the supported device densities and widths.

**Table 11-8. 256Mb Addressing**

| Configuration  | DDR2<br>32 Mb x 8 |
|----------------|-------------------|
| # of Banks     | 4                 |
| Bank Address   | BA0, BA1          |
| Auto Precharge | A10               |
| Row Address    | A0-A12            |
| Column Address | A0-A9             |
| Page Size      | 1KB               |

**Table 11-9. 512Mb Addressing**

| Configuration  | DDR2<br>64 Mb x 8 |
|----------------|-------------------|
| # of Banks     | 4                 |
| Bank Address   | BA0, BA1          |
| Auto Precharge | A10               |
| Row Address    | A0-A13            |
| Column Address | A0-A9             |
| Page Size      | 1KB               |

**Table 11-10. 1Gb Addressing**

### 11.3.3 Memory Address Translation Tables

Section 11.3.3.1 shows the address bit translation from the system address to the DRAM row/column/bank address for the different DDR2 configurations supported by the memory controller.

256 Mb, 512 Mb, 1024 Mb and 2048 Mb DRAM device densities are shown but please refer to Table 11-1 for supported DDR2 device densities and widths. The memory capacity that can be achieved for each device density in the single and dual rank mode is also shown in the address mapping tables.

#### 11.3.3.1 DDR2 Address Translation Tables

Figure 11-1 shows the translation tables for 64 bit, burst size 4 devices in x8 width. Note: only burst 4 is supported for a DDR2 64 data bit interface.

Figure 11-2 shows the translation tables for 32 bit, burst size 8 devices in x8 width. Note: only burst 8 is supported for a DDR2 32 data bit interface.

For a list of memory controller supported DDR2 device types and widths see Table 11-1.

Figure 11-1. Memory Address Tables for 64 Bit, Burst Size 4 and x8 DDR2 Devices

| Total Cap (MB) | Device Density (Mb) | Device Width (h) | Device Bus Width (th) | R/C/B addr lines | R/C/B |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |    |

### 11.3.4 DRAM Timings

The EP80579 is highly configurable in its DRAM timing configuration, but only a limited subset of the setting combinations possible are verified by Intel. The approved and expected settings for the various flavors of supported memory are listed in Table 11-12. For more information on the DRT register see “Offset 78h: DRT0 - DRAM Timing Register 0” and “Offset 64h: DRT1 – DRAM Timing Register 1”.

Table 11-12. Supported DRAM Timings

| Memory Speed          | CL (CAS latency) | tRCD (RAS-CAS delay) | tRP (RAS Precharge) |
|-----------------------|------------------|----------------------|---------------------|
| DDR2-400 <sup>a</sup> | 3                | 3                    | 3                   |
| DDR2-400 <sup>b</sup> | 4                | 4                    | 4                   |
| DDR2-533              | 4                | 4                    | 4                   |
| DDR2-667              | 5                | 5                    | 5                   |
| DDR2-800              | 5                | 5                    | 5                   |
|                       | 6                | 6                    | 6                   |

a: 3-3-3 is not supported for systems which require ODT  
b: May be accomplished by programming 3-3-3 parts to 4-4-4

### 11.3.4.1 2T Timing Mode

The address and command group (Bank Address BA[2:0], Address MA[14:0], Command pins RAS\_L, CAS\_L and WE\_L) of pins to the DRAM devices can be clocked either by 1T or 2T timing as shown in Figure 11-3. The control group of pins (CKE, CS, ODT) are not impacted by the 2T timing mode.

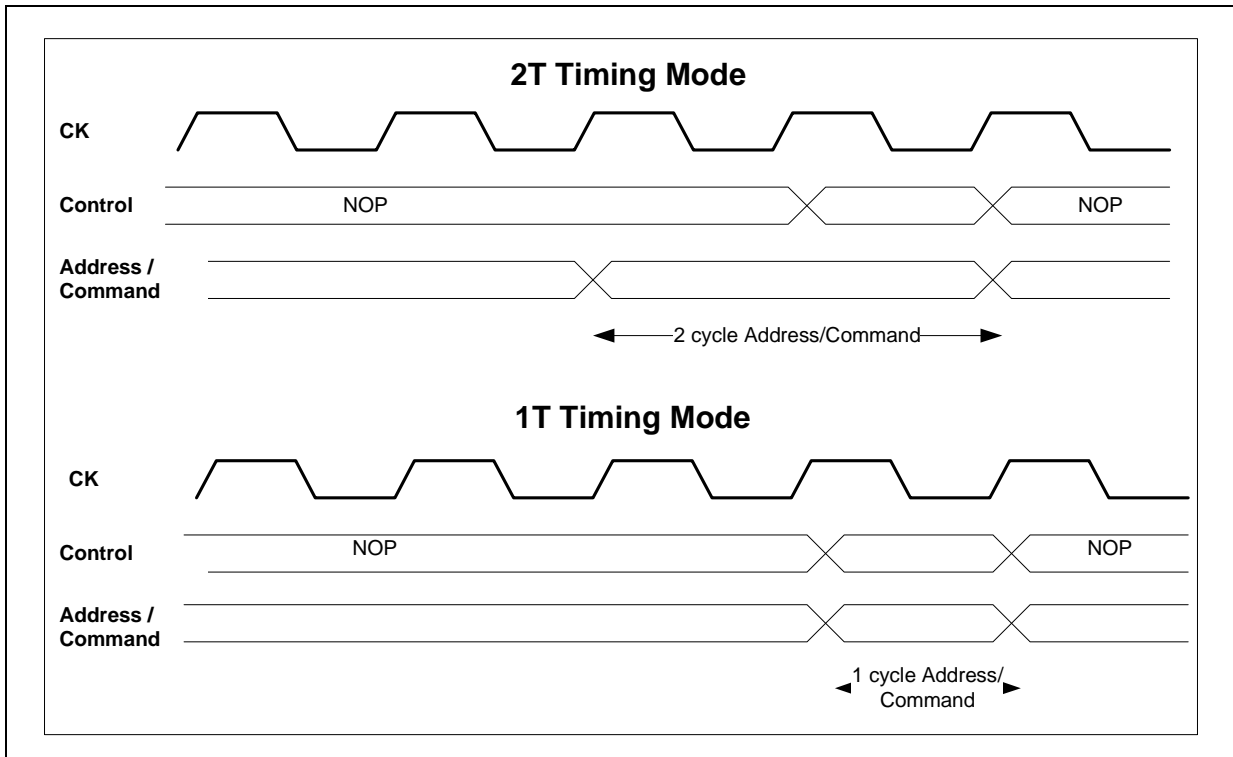

When in 1T timing mode, a new command can be issued to the DRAM devices every DRAM clock cycle. In 2T timing mode, a new command can be issued to the DRAM devices every other DRAM clock cycle i.e., the address and command bus needs to be held valid for 2 cycles.

2T timing reduces the efficiency of the command bus by half but it doubles the setup and hold time for the command and address bus. The timing for the DRAM data bus and all other signals to the DRAM devices remain the same between 1T and 2T timing modes.

On the EP80579, unbuffered dual DIMM configurations are supported in 2T timing mode. Single DIMM configurations are supported in 1T timing mode. Please refer to Table 11-5 for details. The 2T timing mode can be selected by setting the 2T or 1T bit in “Offset 64h: DRT1 – DRAM Timing Register 1”.

*Note:* 1T/2T timing is also referred to as 1N/2N timing.

Figure 11-3. 2T and 1T Timing Mode

### 11.3.5 DQ/DQS Mapping

The data signal (DQ) to data strobe (DQS) relationship is controlled by the setting in the DRAM Row Attribute (DRA) registers (see [Section 16.1.1.40, “Offset 70h: DRA\[0-1\] – DRAM Row \[0:1\] Attribute Register”](#) for details). Bits 7:6 and 3:2 of these registers respectively define the device width for the odd and even rows, which is also used in the mapping of DQS signals to DQ signals.

**Table 11-13. DRA Mapping for DQS**

| Bits | Definition | DQS per DQ                 |
|------|------------|----------------------------|
| 00   | Reserved   | NA                         |
| 01   | x8 DDR     | 1 DQS strobe per data byte |
| 10   | Reserved   | NA                         |
| 11   | Reserved   | NA                         |

Table 11-13 shows the mapping of DQS to DQ in general terms. Table 11-14 gives the exact relationship.

**Table 11-14. DQS to DQ Mapping for x8 Devices**

|         | x8 devices |
|---------|------------|
| DQ Byte | DQS bit    |
| 0       | 0          |
| 1       | 1          |
| 2       | 2          |
| 3       | 3          |
| 4       | 4          |
| 5       | 5          |
| 6       | 6          |
| 7       | 7          |
| 8       | 8          |

### 11.3.6 32-Bit Mode

DQ[31:0] and the associated DQS[3:0] are connected to the DIMMs in 32-bit mode. Operation in 32-bit mode is invisible to software and on-chip memory controller interfaces.

## 11.4 DDR2 Features

The DDR2 generation of technology introduces some new features beyond standard DDR. This section highlights those supported.

### 11.4.1 Interface Signalling Voltage

The memory controller supports 1.8 V signaling for DDR2-400, DDR2-533, DDR2-667 and DDR2-800 DIMMs.

## 11.4.2 On-DIMM Die Termination (ODT)

The JEDEC DDR2 DRAM Specification requires that DDR2 DIMM devices provide selectable on-DieDIMM Termination (ODT) as an alternative to traditional discrete termination on the motherboard. The On-DIMM termination ODT feature is enabled via the DDR extended memory register select (EMRS) command ODTENA and supports both 75 and 150 terminations activated dynamically via dedicated On-DIMM termination ODT interface signals on the DIMM.

The EP80579 implements two ODT pins to control the behavior of the termination on the two ranks of DRAM devices. The mapping of the CS & ODT pins for the various DIMM configurations is shown in [Table 11-6](#). The behavior of these ODT signals can be controlled by setting the appropriate bits in the [Section 16.1.1.49, "Offset B0h: DDR2ODTC - DDR2 ODT Control Register"](#).

The EP80579 controls operation of DDR2 devices with or without on-DIMM Die termination enabled, but is verified by Intel only in On-Die (ODT) enabled mode of operation. ODT can be disabled by setting the appropriate bits in DRAMODT bit in [Section 16.1.1.43, "Offset 7Ch: DRC – DRAM Controller Mode Register"](#).

[Table 11-15](#) shows the ODT related timing parameters.

The EP80579 supports operation of DDR2 devices with or without on-DIMM Die termination enabled, but is verified by Intel only in the On-Die (ODT) enabled mode of operation. ODT can be disabled by setting the DRAMODT bit in [Section 16.1.1.43, "Offset 7Ch: DRC – DRAM Controller Mode Register"](#).

**Table 11-15. ODT Timing Parameters**

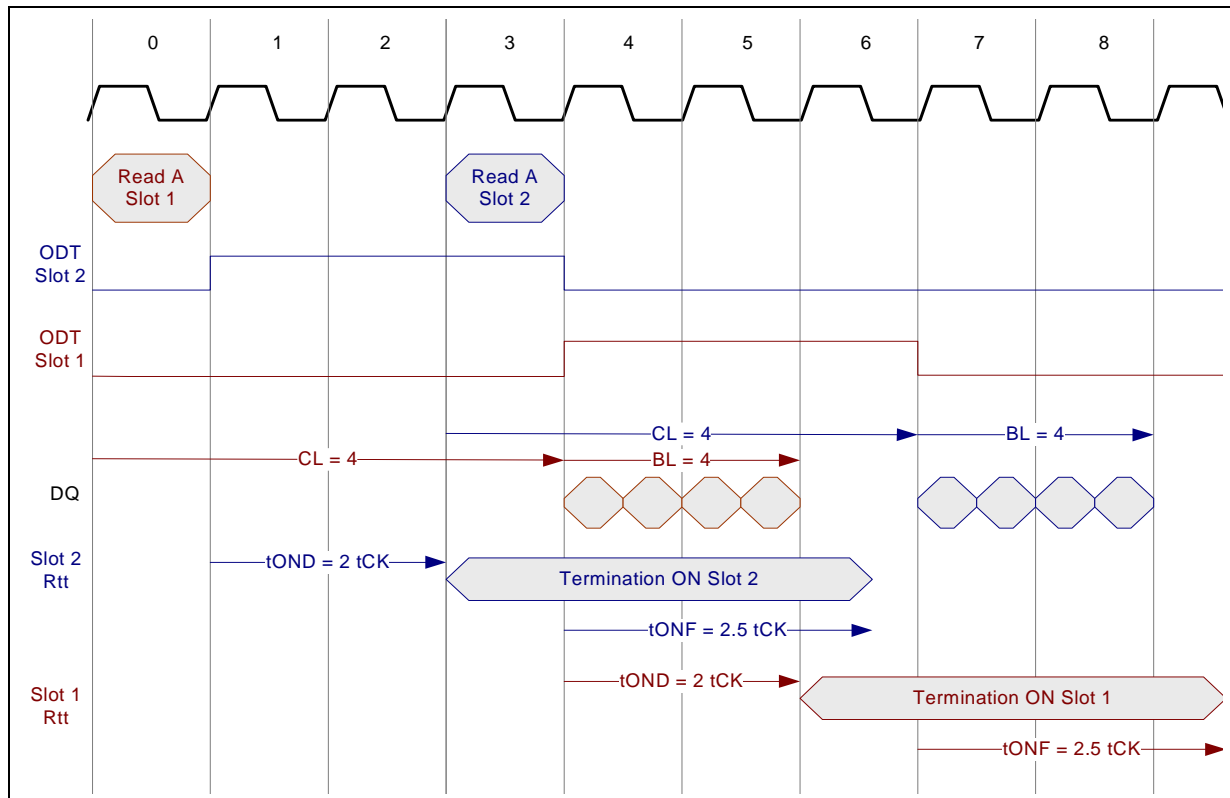

| Parameter   | Description   | Value  |
|---|---|--|
| tCK   | Clock Period  | 5, 3.75, 3, 2.5ns  |
| tOND  | ODT turn on delay                                   | 2 tCK  |
| tOFD  | ODT turn off delay                                  | 2.5 tCK  |
| CL  | CAS Latency   | 3, 4, 5, 6   |
| RL  | Read Latency  | CL   |
| WL  | Write Latency (RL - 1)                              | CL - 1   |
| BL  | Burst Length  | 4, 8   |
| ODT_RD_on   | Assertion of ODT pin to inactive slot during reads  | = RL - tOND - 1<br>= RL - 3  |
| ODT_RD_ontime   | Time for which the ODT pin is asserted              | = tOND + 1 + BL/2 + 0.5 - tONF<br>= 2 + 1 + BL/2 + 0.5 - 2.5<br>= BL/2 + 1 |
| ODT_WR_on   | Assertion of ODT pin to inactive slot during writes | = WL - tOND - 1<br>= WL - 3  |
| ODT_WR_ontime   | Time for which the ODT pin is asserted              | = tOND + 1 + BL/2 + 0.5 - tONF<br>= 2 + 1 + BL/2 + 0.5 - 2.5<br>= BL/2 + 1 |
| <ul style="list-style-type: none"> <li>For WL = 2 (CL = 3), the ODT_WR_on = -1. This requires the controller to enable ODT 1 tCK before the Write command is issued. EP80579 memory controller will not support asserting the ODT pin before it issues the write command. The result is that for CL=3, the termination in the inactive slot will be turned on at the same time the DQ bus is being driven by the memory controller.</li> <li>The ODT turn on and off timings will be calculated by the hardware based on the DRAM configuration parameters: CL and BL.</li> </ul> |   |  |

### 11.4.2.1 ODT Control of Reads

During a read command in a 2 slot configuration as shown in Figure 11-4, the memory controller will enable ODT on the inactive slot. The ODT pin will be asserted by the controller such that the termination in the inactive slot will be enabled 1 tCK before the active slot starts driving the DQ bus. The termination will be turned-off by the controller ½ tCK after the last DQ is driven by the active slot as show in Figure 11-4.

There is no assertion of the ODT signal to the DRAM device in a 1 slot configuration. Please refer the Section 16.1.1.49, "Offset BOh: DDR2ODTC - DDR2 ODT Control Register" for more details on the CSR that needs to be programmed by BIOS so that the memory controller drives the proper ODT control signals.

Figure 11-4. ODT Timing on Back-to-Back Reads to Different Slots

### 11.4.2.2 ODT Control of Writes

During a write command in a 2 slot configuration as shown in Figure 11-5, the EP80579 memory controller will enable ODT on the inactive slot. The ODT pin will be asserted by the controller such that the termination in the inactive slot will be enabled 1 tCK before the controller starts driving the DQ bus (except for configurations where CL = 3). The termination will be turned-off by the controller ½ tCK after the last DQ is driven by the controller to the active slot as shown in Figure 11-5.

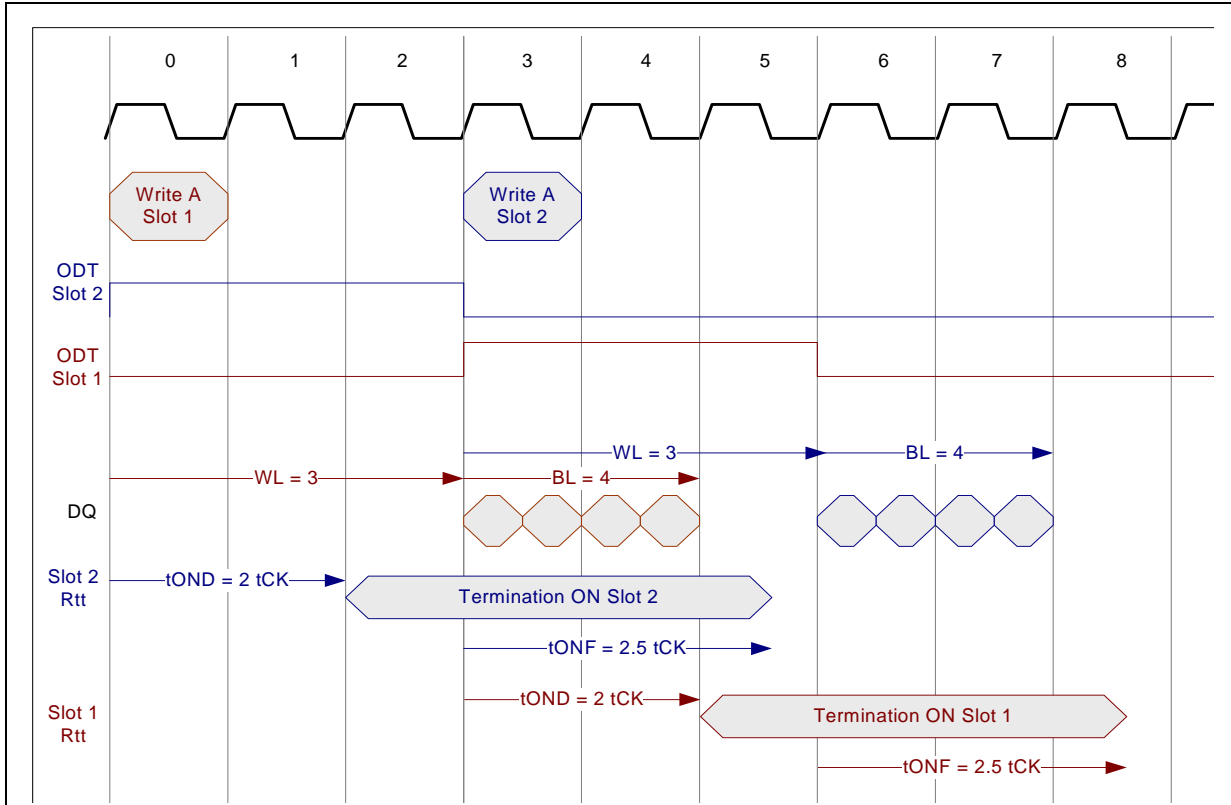

During a write command in a one slot configuration, the memory controller will enable ODT to the active slot such that the termination is enabled 1 tCK before the controller starts driving the DQ bus (except for configurations where CL = 3, see note below).

Please refer the [Section 16.1.1.49, "Offset B0h: DDR2ODTC - DDR2 ODT Control Register"](#) for more details on the CSR that needs to be programmed by BIOS so that the memory controller drives the proper ODT control signals.

**Note:** The memory controller will not enable ODT before the write command is issued on the DRAM interface (See [Table 11-15](#) for more details). For configurations with CL=3, WL=2 the controller will assert the ODT pin along with the write command. This will result in the termination in the inactive slot to be enabled at the same time the controller starts driving the DQ data bus.

**Figure 11-5. ODT Timing on Back-to-Back Writes to Different Slots**

### 11.4.3 On-Die Termination (ODTZ) on the EP80579

The EP80579 supports ODT (referred to as ODTZ to differentiate it from the On-DIMMDie Termination, ODT that is implementation on the DRAM devices) on the DQ/DQS buffers to improve signal integrity on the inbound path (read data from DRAM).

ODTZ will be enabled on read accesses to the DRAM devices and can be in one of the 3 states - 60ohms, 120ohms or off. ODTZ will be automatically disabled when the EP80579 DQ/DQS buffers are enabled for a write access to the DRAM device. There are no timing parameters implemented to control this functionality and the DDRIO pads are responsible for ensuring that ODTZ is in the disabled state when issuing writes to the DRAM devices.

The termination value for ODTZ can be set by programming the ODTZENA bit in [Section 16.1.1.45, "Offset 88h: SDRC – DDR SDRAM Secondary Control Register"](#).

#### 11.4.4 Refresh

The EP80579 supports generation of the refresh commands (REF) that are necessary for the DRAM devices to retain its data. When the refresh cycle is launched by memory controller an address counter, internal to the DRAM device, supplies the bank address during the refresh cycle. No control of the address bus is required for a refresh cycle. When the refresh cycle has completed, all banks of the DDR2 device will be in the precharged (idle) state. A delay between the Refresh command and the next activate command or subsequent Refresh command must be greater than or equal to the Refresh cycle time (tRFC). There are 3 mechanisms through which the EP80579 memory controller will generate the refresh commands:

1. **Programmable counter:** The refresh engine can be programmed to generate refresh commands at programmable time intervals. The choice of intervals are meant to cover DDR2 device tREFI specifications. Please refer to [Section 16.5.1.3, "Offset 40h: DCALCSR – DDR Calibration Control and Status Register"](#) details on programming the refresh engine.
2. **Programmable OPCODE generation:** A single refresh command can be generated under software control using the available opcodes in [Section 16.5.1.3, "Offset 40h: DCALCSR – DDR Calibration Control and Status Register"](#).
3. **Self-Refresh exit state machine:** The self-refresh exit engine will issue one refresh command to each rank after it brings them out of self refresh.

*Note:* The EP80579 does not support posted refresh cycles.

#### 11.4.5 Self-Refresh

The EP80579 supports the generation of self-refresh commands that can be used to retain data in the DRAM devices without any support from the memory controller. The DRAM device has built-in counters timers to accommodate the self-refresh operation.

There are 2 mechanisms to enter and exit the self-refresh mode:

1. Self-Refresh Entry
  - a. **S3:** The memory controller will issue a self-refresh entry command at the end of the S3 sequence.
  - b. **Programmable OPCODE generation:** A self-refresh entry command can be generated under software control using the available opcodes [Section 16.5.1.3, "Offset 40h: DCALCSR – DDR Calibration Control and Status Register"](#).
2. Self-Refresh Exit
  - a. **Power up after S3 event:** The memory controller implements a self-refresh exit engine which under software control can bring the DRAM devices out of self-refresh. Refer to [Table 16-226, "Rules about issuing Self-Refresh and Refresh commands using DCALCSR.OPCODE" on page 604](#) for details on the rules that software should follow when using this mechanism.
  - b. **Writing to DRC.CKE[1:0] register bits:** By writing to the DRC.CKE[1:0] registers, software can assert the CKE pins to the DRAM devices bringing them out of self-refresh. Please refer to [Section 16.5.1.59, "Offset 1F4h: MB\\_ERR\\_DATA32 - Memory Test Error Data 3"](#) for more details.

The de-emphasis feature on the command/clock pins should be disabled before entering self-refresh. Please see the DEMCA bit in [Section 16.5.1.63, "Offset 264h: DDRIOMC1 - DDR IO Mode Control Register 1"](#) for more details.

### 11.4.6 RCOMP

The EP80579 supports RCOMP for the DDR pads. RCOMP control is implemented for 2 groups of DDR pads. The RCOMP used for the 2 groups can either be static or dynamic based on DDRIOMC2.LEGOVERRIDE[5:4]. For more details on how to control the RCOMP for the 2 groups of DDR pads please see [Section 16.5.1.64, “Offset 268h: DDRIOMC2 - DDR IO Mode Control Register 2”](#). The final values that are used for Group 1 and Group 2 drivers can be viewed using the bits in [Section 16.5.1.29, “Offset F0h: DIOMON - DDR I/O Monitor Register”](#).

- Group1: Data, data mask and data strobes:
  - DDRIOMC2.LEGOVERRIDE[4:0] bits can be used in dynamic mode to achieve the target impedance on the group 1 DDR pads. In dynamic RCOMP mode, these CSR bits control several pull-up devices that are binary sized. The pull-up devices are tuned using an external resistor (Rext). In Static mode, DDRIOMC2.LEGOVERRIDE[3:0] determines the RCOMP value used by the Group 1 DDRIO pads.
- Group2: Command, Address and Clock:
  - In dynamic RCOMP mode the digital control for these group of DDR pads is derived by multiplying the group 1 digital control by a factor determined by DDRIOMC2.LEGOVERRIDE[6:9]. In static RCOMP mode, DDRIOMC2.LEGOVERRIDE[6:9] directly controls the RCOMP value used by the Group 2 DDRIO pads.

### 11.4.7 DDR2 MR and EMR settings

[Table 11-16](#) shows the supported settings of DDR2 mode register (MR) and extended mode register (EMR). Note that only the architecturally relevant settings of the MR and EMR are listed in this table. These registers can be updated using the MRS and EMRS commands. Please see [Section 16.5.1.3, “Offset 40h: DCALCSR – DDR Calibration Control and Status Register”](#) and [Section 16.5.1.4, “Offset 44h: DCALADDR - DDR Calibration Address Register”](#) for more details on generation of MRS and EMRS commands.

**Table 11-16. Supported DDR2 MR and EMR settings**

| MR/EMR Feature                    | EP80579 Support   |
|-----------------------------------|---|
| Burst Type                        | Sequential only   |
| Burst Length                      | 4 (64-bit mode) and 8 (32-bit mode)   |
| Write Recovery for Auto-precharge | Supported. Settings based on speed bins. Please see <a href="#">Section 16.0, “IMCH Registers”</a> for details.                                     |
| CAS Latency                       | 3, 4, 5 and 6 depending upon Speed bin. Please see <a href="#">Table 11-12</a> and <a href="#">Section 16.0, “IMCH Registers”</a> for more details. |
| ODT (EMR)                         | Supported.<br>Please see <a href="#">Section 11.4.2</a> for more details.   |
| OCD Calibration (EMR)             | Not Supported.  |
| Additive Latency (EMR)            | Not Supported.  |

## 11.4.8 Scrubbing Support

The memory controller will support both demand scrubbing and background scrubbing in hardware. This section provide details of the scrubbing mechanism.

### 11.4.8.1 Demand Scrubbing

When the controller detects a single bit error on a DRAM read, the ECC logic fixes the single bit error and returns the corrected data to the requester. The controller also writes the corrected data back into DRAM using the demand scrub operation.

### 11.4.8.2 Background Scrubbing

The controller supports a simple state machine that periodically injects read transactions into the stream. The scrub rate meets a general requirement for scrubbing a 4GB memory capacity every 24 hours. It can also be programmed to scrub the entire DDR at faster rates, if that is desired. Rates available extend from an entire scrub every few days, to every day, every hour, every minute, and even very fast rates, mainly used for validation purposes. Data for a background scrub read operation is discarded if no error is detected on the read. When a single bit error is detected on a background scrub read transaction, the mechanism specified in [Figure 11.4.8.1](#) is used to correct the single bit error in DRAM. The read data is dropped. When a double bit error is detected on a background scrub read transaction, the controller log the error and interrupts the IA-32 core.

## 11.5 Error Handling

The memory controller accesses may encounter data with ECC violations and/or parity errors.

- For writes with bad parity, as indicated on bits in the command from either AIOC memory target (MT) or IMCH, the memory controller will execute the write, poisoning the data as it writes it to DDR. Please see [Table 11-17](#) for the granularity of poisoned data. Poisoning is accomplished by inverting each bit of ECC calculated for that particular write, based on the bad write data sent to the memory controller from AIOC or IMCH.
- For reads from DDR with single bit parity errors, the memory controller will correct all correctable errors, and return the data, to either requestor, corrected, and without a bad parity indication. Status logging, as discussed above, will be done.
- For reads from DDR with multiple bit, uncorrectable ECC violations, the memory controller will return the data to either requestor, however, a bad parity indication will be driven back with the data. Please see [Table 11-17](#) for the granularity of poisoned data. AIOC memory target (MT) or IMCH should poison the data when seeing the bad parity bit set, along with the read data returned.

Table 11-17. Poisoning Granularity

| Command   | Error Source                                  | Command Source | Memory Controller Action  |
|---|---|----------------|---|
| Read from DRAM  | DRAM (DED)                                    | IMCH           | Poison parity bits on 32B granularity and return read data to IMCH.                   |
| Read from DRAM  | DRAM (DED)                                    | AIOC MT        | Poison parity bits on 8B granularity and return read data to AIOC memory target (MT). |
| Write to DRAM   | IA or IO Device including AIOC (Parity Error) | IMCH           | Poison ECC bits on 16B granularity and write to DRAM.                                 |
| Write to DRAM   | AIOC (Parity Error)                           | AIOC MT        | Poison ECC bits on 8B granularity and write to DRAM.                                  |
| <ul style="list-style-type: none"> <li>ECC can be enabled by setting the DDIM bit in <a href="#">Section 16.1.1.43, "Offset 7Ch: DRC – DRAM Controller Mode Register"</a>.</li> <li>Poisoning of write data to DRAM can be enabled using the MEMPEN bit in <a href="#">Section 16.1.1.44, "Offset 84h: ECCDIAG – ECC Detection/Correction Diagnostic Register"</a>.</li> <li>Poisoning of read data from DRAM to IMCH or AIOC MT can be enabled by using ENDP bit in <a href="#">Section 16.1.1.43, "Offset 7Ch: DRC – DRAM Controller Mode Register"</a>.</li> </ul> |   |                |   |

For compatibility with accepted IA platform algorithms and mechanisms, the memory controller will follow general IA error logging and reporting mechanisms as closely as possible with the following exception:

- The memory controller does not implement uncorrectable retries (DED retries). Therefore all registers and bit definitions that support uncorrectable retries are not implemented in the memory controller.

## 12.0 Enhanced Direct Memory Access Controller (EDMA)

---

The IMCH includes an integrated four-channel Enhanced Direct Memory Access (EDMA) controller to facilitate “push model” block transfers without IA-32 core intervention for higher overall system performance. This section details the operating modes, setup, interfaces, register set, and high-level implementation of the EDMA controller.

### 12.1 Overview

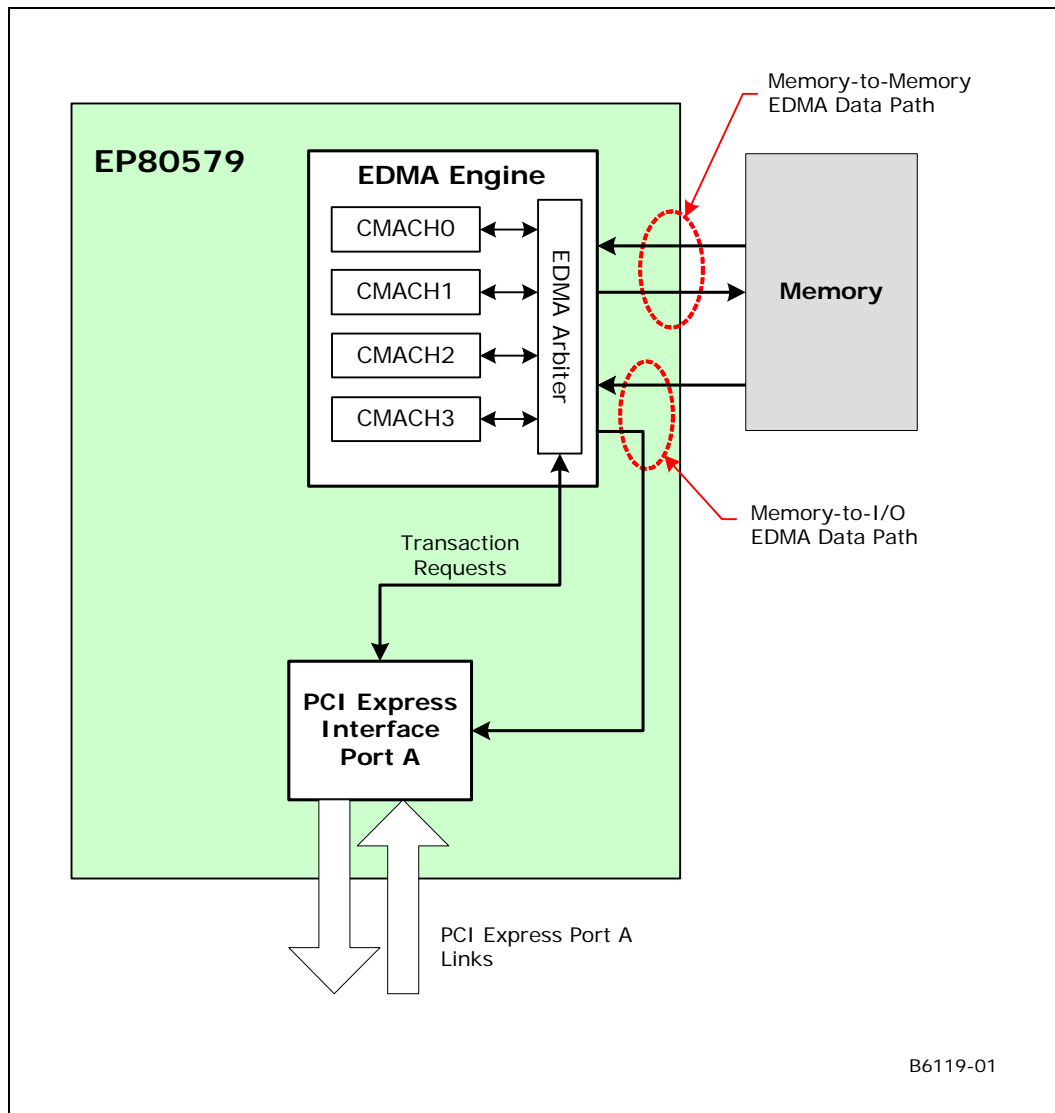

The EDMA engine provides a highly efficient means to move data within local system memory or from the local system memory to the I/O subsystem. Each EDMA channel provides low-latency, high-throughput data transfer capability with minimal IA-32 core intervention. For the IA-32 core, it is a “fire and forget” type of memory transfer, with a doorbell starting mechanism and interrupt capability for signaling completion.

Each channel optimizes block transfers of data through a linked-list descriptor chaining mechanism that supports scatter/gather operations. Each channel is responsible for providing the EDMA programming interface, executing the data transfers, and handling any errors encountered during operation.

Each channel initiates traffic on both the local system memory and outbound traffic arbiter interfaces, and is designed such that each independent channel is capable of generating at least 1 GB/s of traffic during data hauls. In the absence of competition from other traffic sources, multiple channels could theoretically saturate the local memory interface. See [Figure 12-1](#).

Each channel is independently enabled by setting the Start bit in the Control Configuration Register. The Start bit is cleared after power-up or reset and consequently the EDMA controller is disabled until software explicitly turns each one on.

Figure 12-1. Concept Diagram of EDMA Data Path

### 12.1.1 Features

The following features are supported by the EDMA controller:

- Four independent channels (see Figure 12-2)
  - Dedicated data transfer queue per channel
  - Full register set for descriptor and transfer handling per channel
- Support for transfer between main memory locations, and from memory to the I/O subsystem
- PCI Express\* support of traffic class to provide external prioritization of traffic
- Supports transfers only between two physical addresses
  - 32-bit (4 GB) addressing range on the local system memory interface

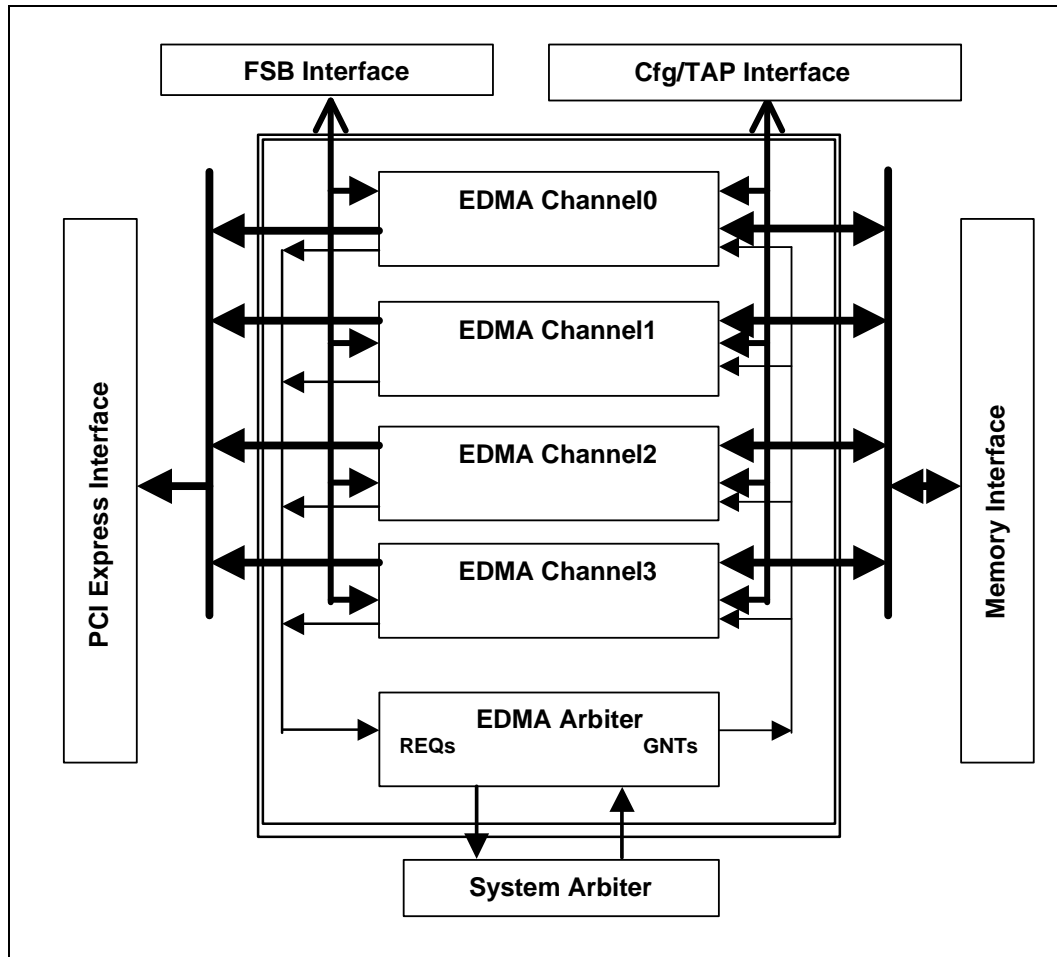

- 32-bit addressing range on the Memory Mapped I/O Subsystem Interface (no NSI access)
- Maximum transfer of 16 MB transfers per descriptor
- Fully programmable by the IA-32 core
  - Configuration space mapping for EDMA engine capability and control
  - Memory-mapped space for EDMA channel-specific register sets
- Chain Mode EDMA transfer with automatic data chaining for scattering/gathering of data blocks
  - EDMA chaining continued until a “null” descriptor pointer is encountered
  - Support for appending a block to the end of current EDMA chain
  - Automated descriptor retrieval from local memory during chaining – single read
- Programmable independent alignment between source and destination
  - Byte aligned transfer on the local system memory interface
  - Byte aligned transfer on the I/O subsystem interface
- Support for non-coherent transfers both to and from system memory on a per descriptor basis
  - Independent control of coherency for source and destination
- Programmable support for interrupt generation on block-by-block basis
  - Selectable MSI or legacy level-sensitive interrupt function
  - End of current block transfer
  - End of current chain
  - For any error causing a transfer to abort
- Increment of the source and destination address for standard transfers
- Increment of the destination and decrement of the source address to enable byte stream reversal
- Constant address mode for the destination address based on the transfer granularity to enable targeting of memory mapped I/O FIFO devices
- Buffer/memory initialization mode

## 12.1.2 Logical Block Diagram

Figure 12-2 shows the conceptual interface of the EDMA channels to different I interfaces.

Figure 12-2. Conceptual Diagram of Four Channel EDMA Engine

## 12.2 Channel Programming Interface

The EDMA channel programming interface is accessible from the IA-32 core via a combination of chain descriptors (shown in [Figure 12-3](#)) written to main memory and a memory-mapped internal register set. The EDMA controller provides four channels, each of which can be independently used to transfer data within the local system memory or from the local system memory to the I/O subsystem. Each channel has its own set of 12 registers. Refer to [“Memory Mapped I/O for EDMA Registers” on page 651](#) for a description of the channel register set.

The channel programming interface is accessible from the IA-32 core via a combination of descriptors written to main memory and a memory-mapped internal register set. Each channel is programmed independently.

Each channel supports full chaining capability. The chain descriptors can be cascaded together in system memory to form a linked list. Each chain descriptor contains all the information necessary for transferring a block of data, as well as a pointer to the next chain descriptor in the list. The next descriptor pointer of the last chain descriptor in a linked list will be a null pointer (address zero), indicating the end of that chain.

Throughout this document, all register references are made using the name of the lower 32-bit register, irrespective of whether the target is a 32-bit or 64-bit register with lower and upper halves.

## 12.3 Chaining Operation

An EDMA access transfers a block of data from one address to another. The desired transfer is specified by setting up a linked list of chain descriptors in the local system memory, and initiated by programming the first chain descriptor start address into the Next Descriptor Address Registers (NDAR/NDUAR) of the EDMA channel and setting the Start bit of the Channel Control Register (CCR). Each block of the transfer is defined by a descriptor in main memory containing the source address, destination address, transfer length and control values. Setting the Start bit of the Channel Control Register (CCR) causes the channel to fetch the current chain descriptor information and place it into its corresponding register set. Once all the register information has been fetched, the actual data transfer starts.

*Note:* The Start bit will be ignored unless the Channel Status Register (CSR) is in an appropriate state. Software must ensure that the status bits for end of chain, stopped, aborted, and active are all clear prior to attempting to initiate a new transfer with the start function.

### 12.3.1 Chain Descriptor Definition

All EDMA transfers are controlled by chain descriptors in the local system memory. A single block transfer will specify only a single chain descriptor. Chain descriptors can be linked together to form a linked list, providing a capability for complex EDMA scatter/gather operations.

Figure 12-3 shows the format of a chain descriptor. Each chain descriptor consists of eight contiguous DWords (32-bits) in the local system memory, and must be naturally aligned to an eight Dword boundary. All eight DWords must be defined and are required for the proper operation of the EDMA engine.

Figure 12-3. Chain Descriptor in Memory

| <i>Chain Descriptor in Memory</i>            | <i>Description</i>                                     |
|--|--|
| <b>Source Address (SAR)</b>                  | Lower 32-bit Source Memory Address Register            |
| <b>Source Upper Address (SUAR)</b>           | Upper 32-bit Source Memory Address Register            |
| <b>Destination Address (DAR)</b>             | Lower 32-bit Destination Memory Address Register       |
| <b>Destination Upper Address (DUAR)</b>      | Upper 32-bit Address of Next Chain Descriptor Register |
| <b>Next Descriptor Address (NDAR)</b>        | Lower 32-bit Address of Next Chain Descriptor Register |
| <b>Next Descriptor Upper Address (NDAUR)</b> | Upper 32-bit Address of Next Chain Descriptor Register |
| <b>Transfer Count (TCR)</b>                  | Number of Bytes to Transfer Register                   |
| <b>Descriptor Control (DCR)</b>              | Descriptor Control Register                            |

B4483-01

### 12.3.2 DMA Chain Descriptor in Memory

Each chain descriptor is composed of eight Dwords. Each Dword in the chain descriptor in the local memory is analogous to the corresponding EDMA channel register value. The bit definitions in the chain descriptor in memory are identical to those of the corresponding channel register. Refer to the EDMA channel-specific register definitions in [“Memory Mapped I/O for EDMA Registers”](#) on page 651 for descriptions of the fields defined by a chain descriptor.

After a transfer has been requested, the EDMA channel reads the specified chain descriptor from local system memory and updates its own corresponding channel registers automatically.

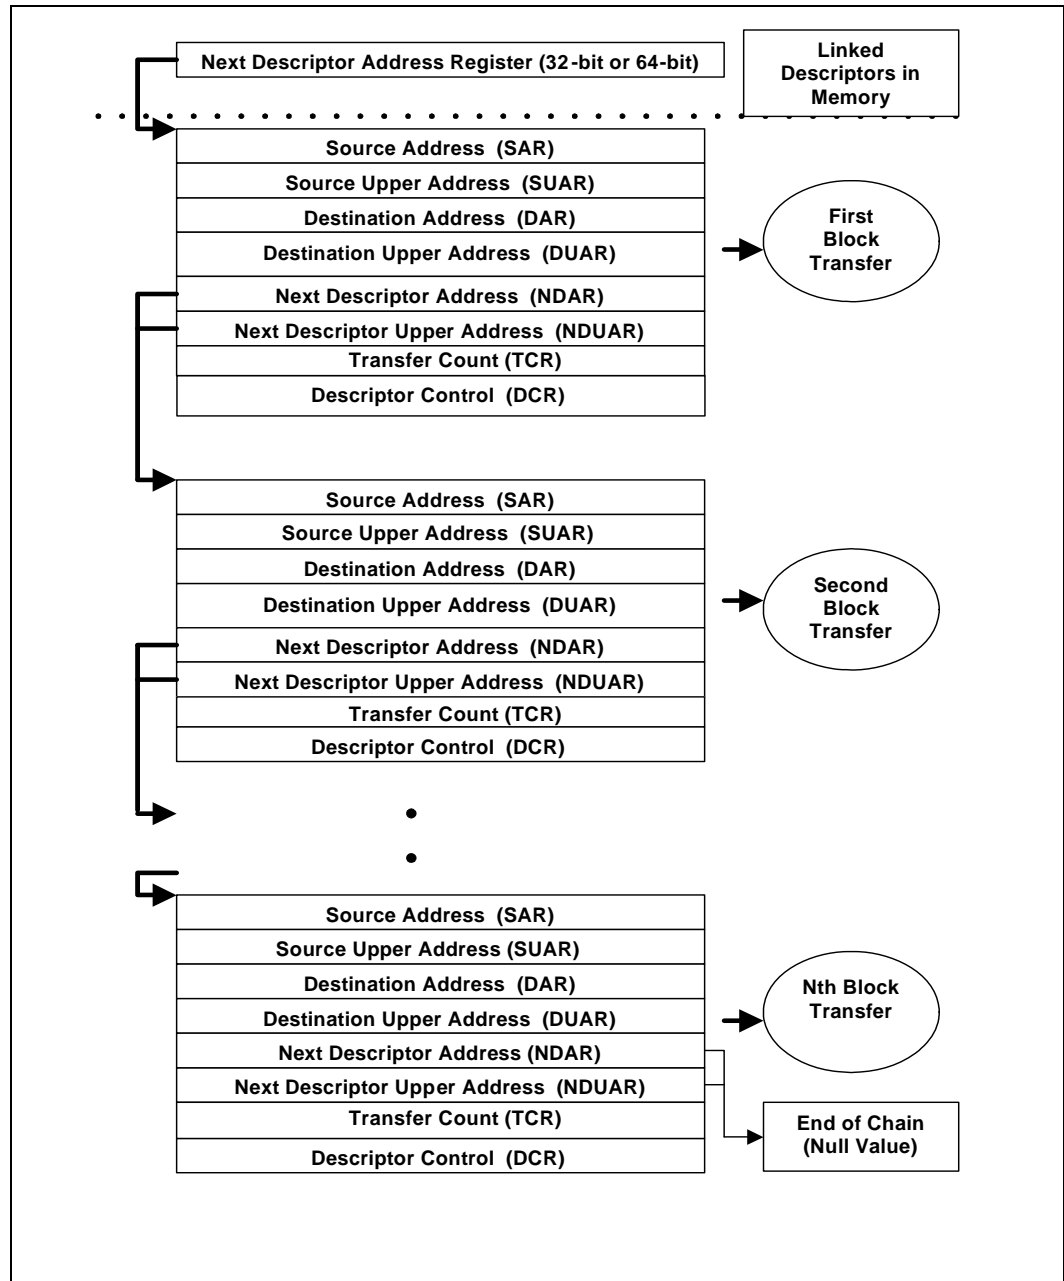

### 12.3.3 Chain Descriptor Usage

A linked list of chain descriptors may be built in the local system memory to transfer data within the local system memory or from local system memory to I/O subsystem memory. An application may build multiple chain descriptors to transfer many blocks with differing source addresses, destination addresses, data transfer counts, alignments, and coherence attributes. The application may connect these chain descriptors using the Next Descriptor Address in a sequence of chain descriptors, creating a linked list of EDMA transfers, all of which may complete without any processor intervention. [Figure 12-4](#) shows a linked list of transfers built in local system memory and illustrates how they are “chained” together.

It is possible but unexpected that the source and destination address ranges defined by chain descriptors may overlap in physical memory. While there are scenarios where this may produce no errors in the resulting memory image, the software must ensure that no failure results from such usage. Hardware checks are not built into the EDMA mechanism to ensure that source and destination physical address ranges do not overlap. Similarly, there are no hardware interlocks to ensure that independent channels are not programmed to modify the same address range simultaneously. If software were to create such a situation, the resultant memory image would be indeterminate, since there are no guarantees as to the relative access ordering among simultaneously active channels.

Figure 12-4. Chaining Mechanism

### 12.3.4 Scatter/Gather Transfer

The EDMA descriptors in memory may be defined such that they cause the channel to perform typical scatter/gather data transfers. To “gather” data, software may create a linked list of descriptors that will move non-contiguous source blocks of data into a contiguous set of destination blocks. To “scatter” data, software may create a linked list of descriptors that will move contiguous blocks of source data to non-contiguous destination blocks. It is even possible to program the EDMA transfer descriptors in such a way that some blocks of source data within a single chain are moved to new memory locations, while other blocks are moved out to the I/O subsystem.

There is no hardware restriction limiting the nature of source and destination address ranges, other than that the source and destination types (memory or I/O subsystem) must match the descriptor address mappings. The IMCH aborts the EDMA operation and reports a programming error if this requirement is not met.

### 12.3.5 Appending to a Descriptor Chain

After an EDMA channel has started processing a linked list of descriptors, the application software may need to append a chain descriptor to the end of the current chain without tearing down the transfer in progress. Such an operation requires a mechanism to guarantee that a descriptor is never in the process of modification by the IA-32 core *while being retrieved* by the EDMA channel (This would result in a hybrid descriptor loaded into the corresponding EDMA channel register set, and spurious operation). The suspend function of the EDMA controller is defined to facilitate this type of usage.

The preferred mechanism for appending to a linked list currently being processed is to suspend the current transfer, modify the terminal chain descriptor to update its Next Descriptor Address field(s), and then allow the transfer to resume. This is accomplished by first setting the Suspend bit in the Channel Control Register (CCR) followed by a read of the Channel Status Register (CSR) to verify that the suspend has taken effect. The Next Descriptor Address fields of the terminal chain descriptor in the current linked list are updated with the address of the first descriptor to be appended. After this update has occurred, software then clears the Suspend bit, sets the Channel Resume bit and allows execution to proceed.

*Note:* A single write to the CCR may update both bits simultaneously.

This append algorithm covers the following cases:

- The EDMA channel has completed execution of the terminal descriptor in the original chain, and is idle. The EDMA channel examines the Channel Resume bit when the Channel Control Register (CCR) is written. If the bit is set, the EDMA channel will automatically clear the bit and re-read the last chain descriptor (as indicated by CDAR/CDUAR), which updates NDAR with the appended chain descriptor address. A non-null value in NDAR will result in a fetch of the target chain descriptor, and resumed execution. (If the resulting NDAR/NDUAR pair remains null, the EDMA channel will remain idle.)
- The EDMA channel is executing a descriptor prior to the terminal chain descriptor in the linked list. Regardless of whether the channel completes execution of its current descriptor prior to the CCR write to clear Suspend and set Channel Resume, the channel will re-read the current chain descriptor in response to the Channel Resume bit. The next chain descriptor in the chain will be fetched from the address indicated by NDAR/NDUAR, and the channel will continue execution. The appended chain descriptor (or descriptors) will be executed after the channel reaches the end of the original chain.
- The channel is executing the terminal chain descriptor at the time of the suspend command. The channel will complete the final chain descriptor of the original linked

list and examine the state of the Channel Resume bit when the Suspend bit is cleared. As in the prior case, the channel will re-read the current chain descriptor to update NDAR/NDUAR, load the first appended chain descriptor, and resume execution. The only difference in this case is that the re-read operation on the current chain descriptor was required for proper execution (in the prior case it was wasted effort, but did not result in erroneous behavior). If the channel had completed execution of the terminal chain descriptor and set the “end of chain” status bit, this bit is automatically cleared when the channel resumes operation.

- If the current transfer had a non-fatal error, it follows one of the above cases. If the error is fatal, the channel will abort, and the software must take proper action and restart the EDMA transfer. Note that the channel will ignore the state of the Channel Resume bit if the abort status has not been cleared from the CSR. This simplifies the case of linked list append, as software need not take extra steps to verify that no errors exist prior to setting the Channel Resume bit. The normal polling or interrupt mechanism may handle the error without interacting with the append routine.

*Note:* Software is at liberty to modify the Next Descriptor Address fields of the terminal chain descriptor at any time after setting the Suspend bit in the CCR – there is no requirement that software verify that the channel has gone idle prior to modifying the memory image. Also, software does not need to verify that the channel has completed execution of the current chain descriptor and acknowledged Suspend EDMA prior to issuing the final update to CSR that sets the Channel Resume bit. The hardware interlock will cover the case where the end of the chain descriptor is reached during the append sequence, but proper operation is guaranteed regardless of whether the interlock is exercised.

A further simplification to the linked list append sequence is possible in the case of chain descriptors located strictly below the 4 GB boundary in memory; that is, in the case where NDUAR of the terminal descriptor is zero and only NDAR contains asserted bits. Under these conditions, it is safe to issue the NDAR write cycle without first suspending operation, because there is no risk of a hybrid NDAR/NDUAR pair retrieved by the channel. If desired, software could take the simplified approach of issuing the descriptor update followed by a CCR write to set the Channel Resume bit. In all cases, this will result in successful execution of the appended chain irrespective of current execution status.

### 12.3.6 Splicing a Descriptor Chain into a Linked List

Software may utilize a slight modification of the algorithm described in [“Appending to a Descriptor Chain” on page 314](#) to splice a new descriptor or chain of descriptors into the chain already executing. Such an operation would be useful to provide service to a higher priority EDMA transfer without aborting work already in progress.

The steps required to splice into a chain are as follows:

1. Write to the CCR to set the Suspend EDMA bit.
2. Read the CDAR/CDUAR pair to determine which chain descriptor the EDMA channel is currently executing.
3. Read the Next Descriptor Address field of the current chain descriptor, and write the retrieved address into the Next Descriptor Address field of the terminal chain descriptor in the linked list to be spliced-in.
4. Write the address of the descriptor (or lead descriptor of the chain) to be spliced-in into the Next Descriptor Address field of the current descriptor (in memory).
5. Write to the CCR to clear the Suspend bit and set the Channel Resume bit.

The hardware interlock of the suspend function will guarantee that the channel will not proceed beyond the current chain descriptor until the Suspend bit has been cleared in the CCR, and the Channel Resume function will guarantee that the current chain descriptor will be re-read to retrieve the modified NDAR/NDUAR value pointing to the spliced chain descriptor. The channel will resume execution with the head of the spliced linked list, and will traverse that linked list back to its original list of chain descriptors.

*Note:* The channel must refrain from updating CDAR/CDUAR from NDAR/NDUAR in addition to dropping the returned data. Were the channel to update its CDAR/CDUAR values, it would “skip” the entire spliced chain in response to Channel Resume, because software would have spliced in the new descriptor chain at a position “behind” the new value for CDAR/CDUAR in the original chain.

## 12.4 Transfer Types

The EDMA controller is optimized to perform high throughput data transfers between local memory locations, and from local memory to I/O subsystem memory. Supported transfer types are summarized in the following subsections.

### 12.4.1 Local Memory to Local Memory

The local memory to local memory transfer will move blocks of data specified by descriptors from one region in main memory to another. The channel control hardware will issue read cycles to the local memory interface using an incrementing or decrementing source address, and place the retrieved data into a channel buffer. It will then issue write cycles back to the memory interface using an incrementing or constant destination address. Each EDMA channel supports pipelining making it possible for a single channel to have multiple read and write cycles active at the same time.

All read requests to memory are a full cache-line in length (64 B), so the EDMA channel must discard data as needed to realign the initial read in a transfer to the alignment specified by the source address. The number of cache-line reads issued by the controller in any given internal arbitration cycle is dependent upon the number of available cache-line spaces in the data queue, and upon the configuration of the inbound/outbound arbiter, but is limited to a maximum of two cache-line requests.

All write requests to memory are also a full cache-line in length, although not all bytes must be enabled for every write. The EDMA channel is responsible for translating the alignment specified by the destination address registers and the destination alignment bit in DCR into a corresponding set of byte enables for the initial write in a transfer. Once the initial alignment has been enforced, the rest of the transfer on behalf of any given descriptor is contiguous.

### 12.4.2 Local Memory to I/O Subsystem Memory

The local memory to I/O memory transfer will move blocks of data specified by chain descriptors from a source region in main memory to a destination region in the I/O subsystem. The channel control hardware will issue read cycles to the local memory interface using an incrementing or decrementing source address, and place the retrieved data into a channel buffer. It will then issue write cycles to the I/O subsystem using an incrementing or constant destination address. Each EDMA channel supports pipelining for this transfer type as well, thus multiple read and write requests may be outstanding from the same EDMA channel at any given time during a block transfer.

All read and write requests are full cache-line size (64 B), irrespective of alignment and length specified in the descriptors; it is up to the EDMA channel to discard read data and calculate write byte enables to enforce the descriptor alignment specified.

The number of reads issued by each EDMA channel in any given internal arbitration cycle is dependent upon the number of available cache-line spaces in the data queue, and upon the configuration of the inbound/outbound arbiter, but is limited to a maximum of two cache-line requests. The number of writes issued in any given arbitration cycle is dependent upon the number of cache-lines waiting in the data queue, and upon the CCR configuration, but is limited to a maximum of two cache-line requests. The EDMA controller never speculatively issues a write in anticipation of data returning from the memory subsystem.

### 12.4.3 I/O Memory to Local Memory

The I/O memory to local memory transfer is not supported.

### 12.4.4 I/O Memory to I/O Memory

The I/O memory to I/O memory transfer is not supported.

## 12.5 Addressing

Each EDMA is capable of 36-bit addressing on both source and destination interfaces.

Alignment specification is independent for source and destination. Transfers may be specified to be aligned to any byte boundary except in destination constant address modes where the granularity is greater than 1-byte.

Each EDMA channel uses direct addressing for both the source and destination interfaces. There is no internal support for any virtual address translation.

Each EDMA channel will attempt to compensate for misalignment between source and destination. At a minimum, misalignment will result in decreased performance at either end of the transfer, where a second read is required prior to the first write, or vice-versa.

### 12.5.1 Address Coherence

Each EDMA channel provides support for non-coherent access specification to improve bandwidth and provide more consistent average latency, as well as to free the FSB for simultaneous IA-32 core traffic. The source and destination addresses for each DMA channel may be independently specified on a chain descriptor granularity via bit settings in the DCR to be either coherent or non-coherent. For non-coherent accesses, no FSB snoop cycle is issued on behalf of EDMA memory accesses to snoop processor caches. The software must verify that snoops of IA-32 core caches are not required for proper system operation prior to setting either of the non-coherent bits in any given descriptor. Non-coherent accesses are used for un-cacheable memory regions, or for cacheable regions where software can guarantee no modified state in any IA-32 core cache by some other means.

The non-coherent attribute further implies relaxed posted write ordering as defined by PCI/PCI-X. A non-coherent write may pass coherent posted writes en route to memory. Software should verify that snoops of IA-32 core caches are not required for proper system operation prior to setting either of the non-coherent bits in the DCR field of any given descriptor. Software need not take special steps to accommodate the relaxed ordering behavior, because each channel will only generate a single stream of output per descriptor, and no ordering is defined between competing I/O subsystem traffic sources. Non-coherent access may be used for uncacheable memory regions, or for cacheable regions where software can guarantee the IA-32 core cache state has not been modified by other means.

An example usage model for non-coherent accesses is management of data block areas reserved for use by an EDMA-capable peripheral device, such as a network interface controllers (NIC). The NIC writes data directly into a buffer in memory allocated for the exclusive use of that device. Each EDMA channel would then execute a block transfer from that buffer to an area allocated for IA-32 core use. Both integrity verification and security functions executed by the IA-32 core could follow such a model. As long as software ensures that the IA-32 core never traverses the device-allocated memory, the block transfer could be accomplished using non-coherent source address reads followed by coherent destination address writes.

*Note:* I/O subsystem destination addresses are always treated as non-coherent or coherent based on the bit setting in the DCR. Setting the destination coherency bit will result in the PCI-Express snoop not required attribute bit being clear, snoop required.

Example: Setting BDF 010 Offset 2C DCRx register bit 7

Destination non-coherent = 0 => Snoop not required attribute bit = 1

Destination coherent = 1 => Snoop not required attribute bit = 0

## 12.5.2 Addressing Modes

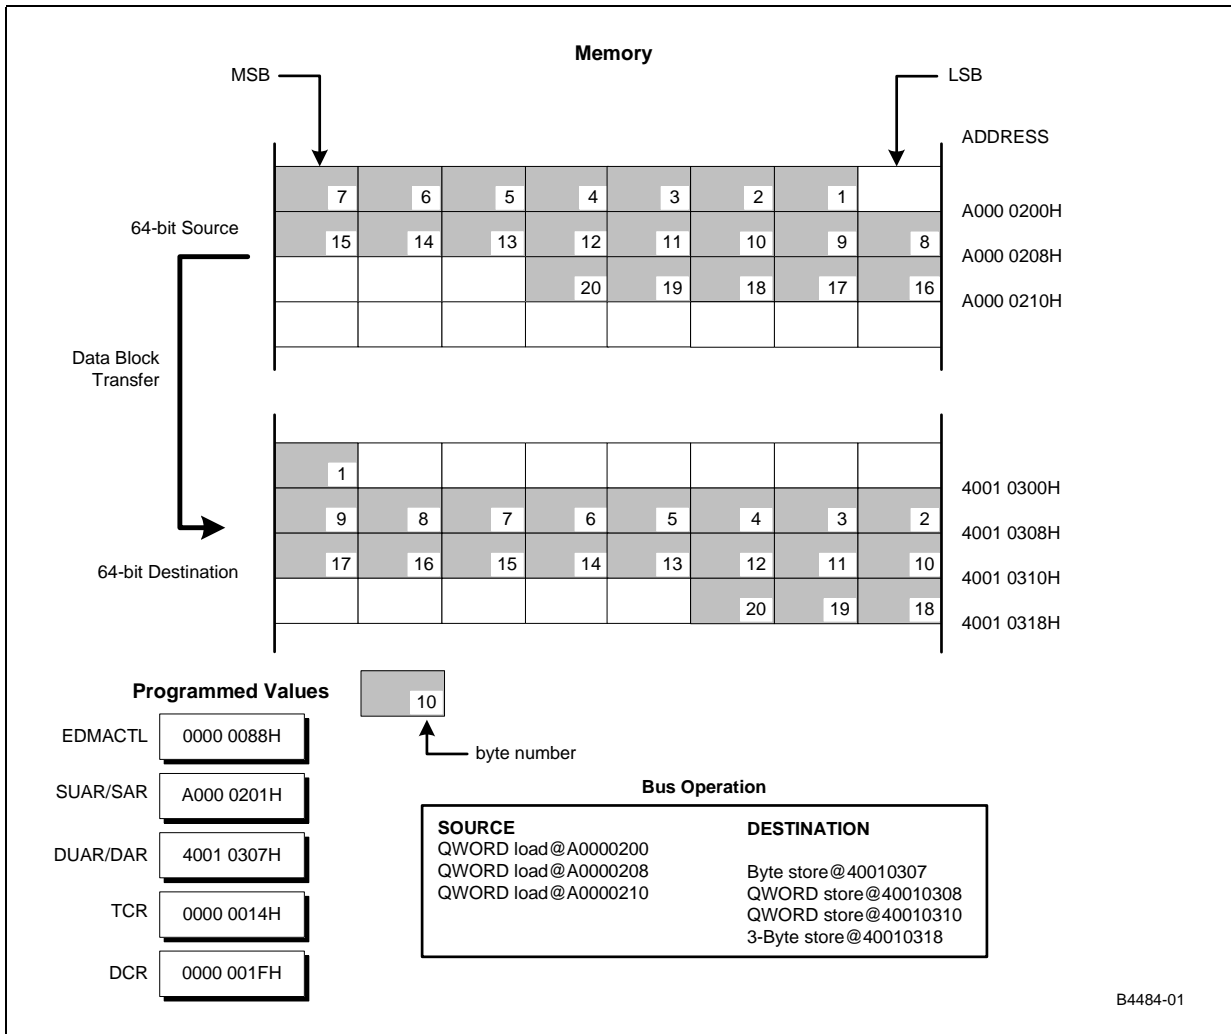

Many different addressing modes are available, including standard byte movement mode, byte reversal mode, constant address mode, and memory and buffer initialization modes. In the examples shown for each of the following modes, a 64-bit interface is used for simplicity. The interface could be the memory interface or an external device on an expansion bus. Internally, the EDMA data path is significantly wider.

### 12.5.2.1 Standard Byte Movement Mode

Standard byte movement mode is the most common method in which data is transferred within the memory sub-system. In this mode, the source and destination are specified down to the byte address. The source address is incremented as data is read and the destination address is incremented as data is written. Transfers can be memory to memory or memory to memory mapped I/O. [Figure 12-5](#) illustrates a memory to memory data transfer between unaligned 64-bit, source and destination addresses.

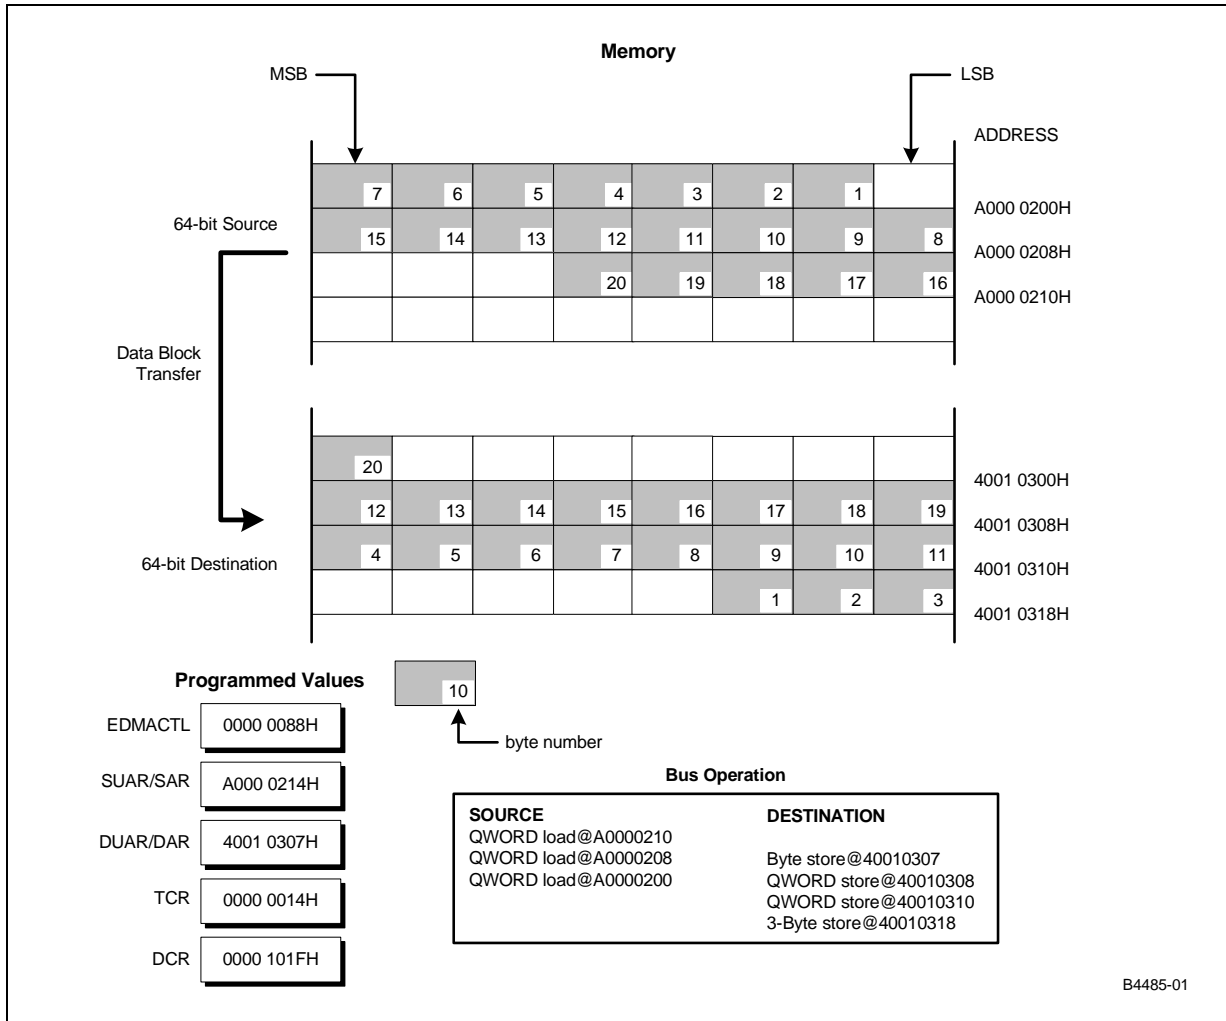

Figure 12-5. Source and Destination in Increment Mode Transfer

### 12.5.2.2 Decrement/Byte Reversal Mode

Decrement/byte reversal mode is useful when an entire data stream needs to be reversed at the byte level. This must not be confused with endian swapping, as this implies a specific word size. In this mode, the source and destination are specified down to the byte address. The source data is read in reverse order and written to the destination in increasing order. Transfers can be memory to memory or memory to memory mapped I/O. Figure 12-6 illustrates a memory to memory data transfer between unaligned 64-bit, source and destination addresses when the source is in decrement mode and the destination is in increment mode.

**Figure 12-6. Source in Decrement and Destination in Increment Mode Transfer (Byte Reversal)**

### 12.5.2.3 Constant Address Modes

In constant address mode, there is built-in support for “mailbox” destinations in the memory mapped I/O subsystem. A mailbox is a single or limited set of addresses used to collect information for dispersal later to their actual destination addresses by the receiving device. In constant address mode, one, two, or four bytes will be sent repeatedly until the byte count is satisfied.

The source address can be byte aligned; however, unlike other transfer modes, in constant address Mode the destination address must be aligned to the granularity size. No errors will be flagged if the destination address is not matched to the granularity, but the required lower address bits will be ignored. Additionally, software must ensure that the transfer byte count is an integer multiple of the granularity size. No error will be flagged if the transfer byte count is not an integer multiple and the remaining bytes in the requested granularity will be padded and transferred.

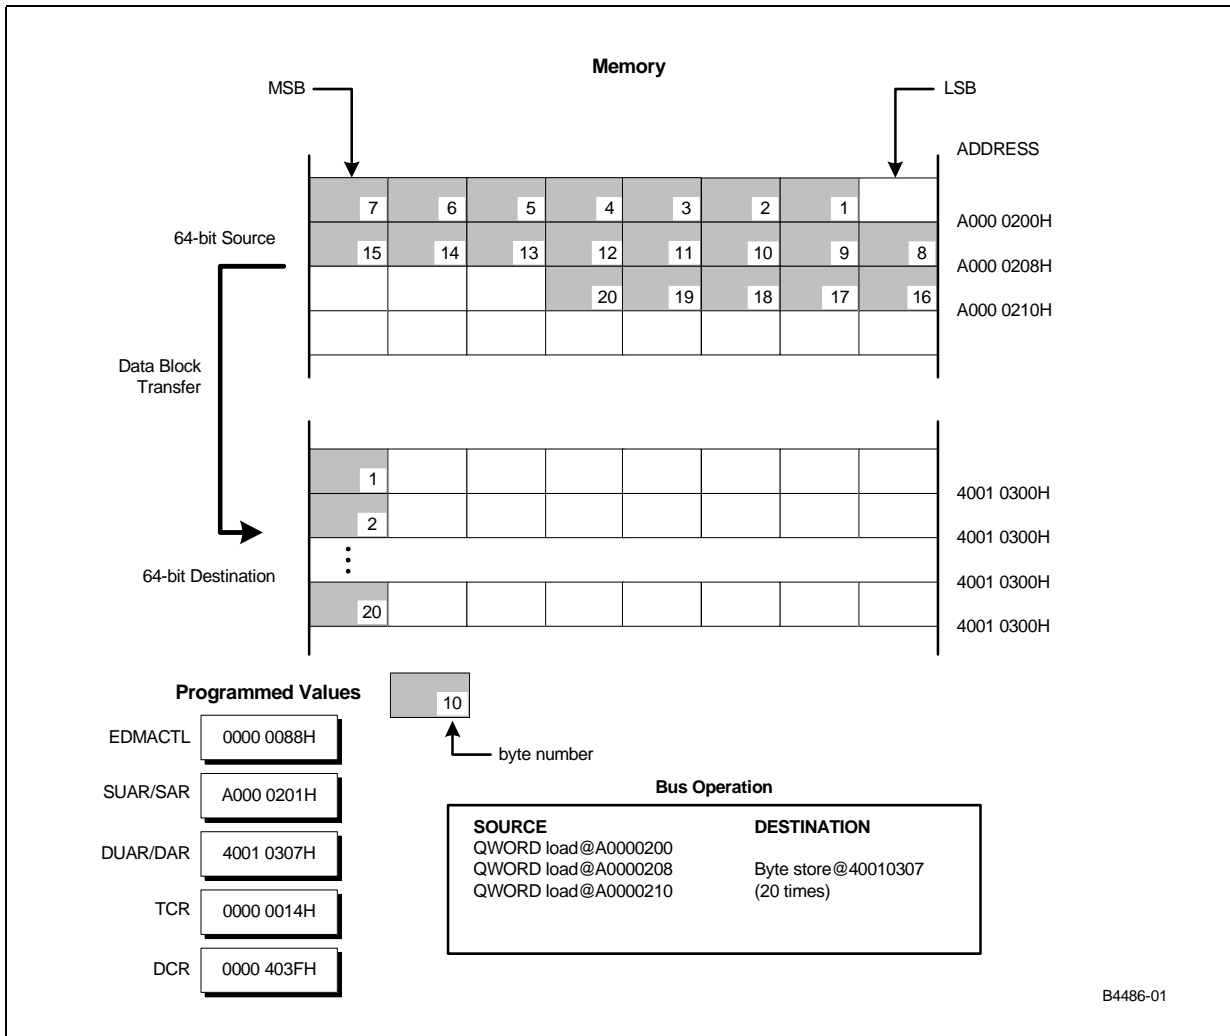

In this mode, the EDMA will write to the address that is placed in the DAR/DUAR pair with the transfer size specified in the granularity field. The transfers will continue until the byte count register is satisfied. Logically, transfers will only be memory to memory mapped I/O.

Constant address mode can be used with an increasing or decreasing source address to present data to the external device in either order.

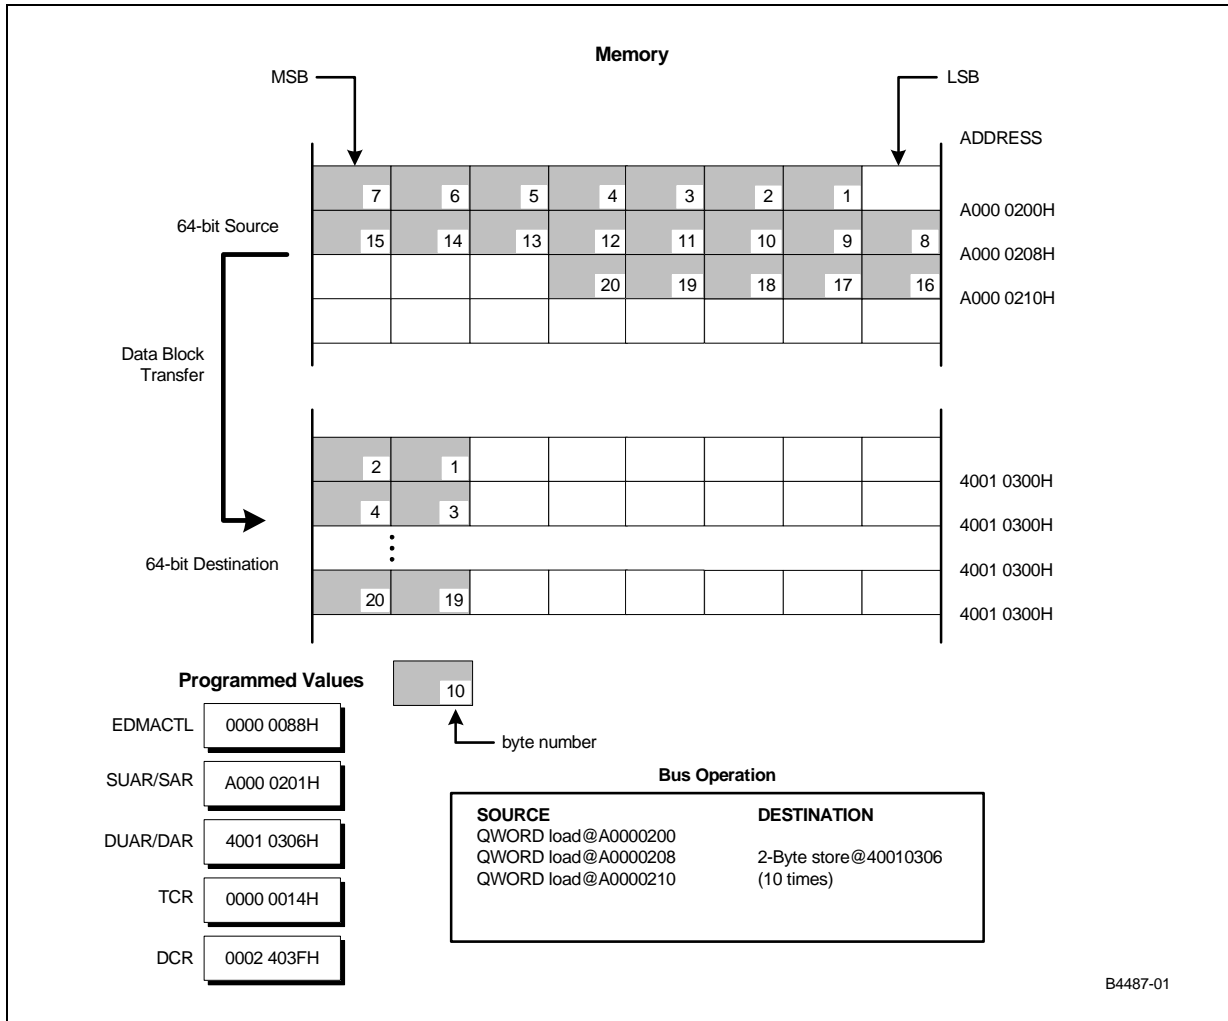

Figure 12-7 through Figure 12-9 illustrate data transfers between an unaligned 64-bit, source and a constant destination addresses when the source is in increment mode.

**Figure 12-7. Source in Increment and Destination in 1-Byte Granularity Constant Mode Transfer**

**Figure 12-8. Source in Increment and Destination in 2-Byte Granularity Constant Mode Transfer**

B4487-01

Figure 12-9. Source in Increment and Destination in 4-Byte Granularity Constant Mode Transfer

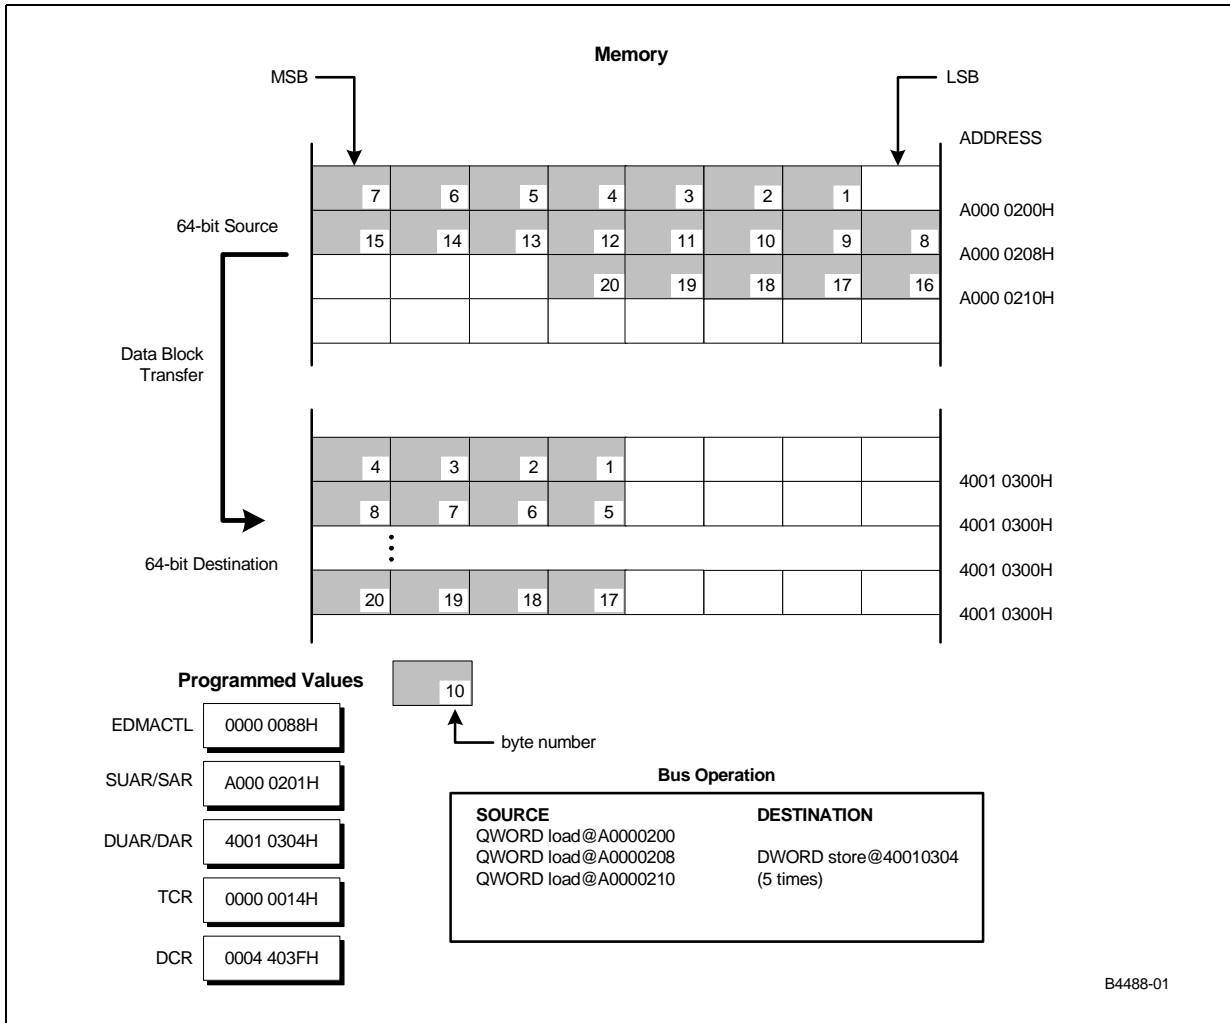

Figure 12-10. Source in Decrement and Destination in 1-Byte Granularity Constant Mode Transfer

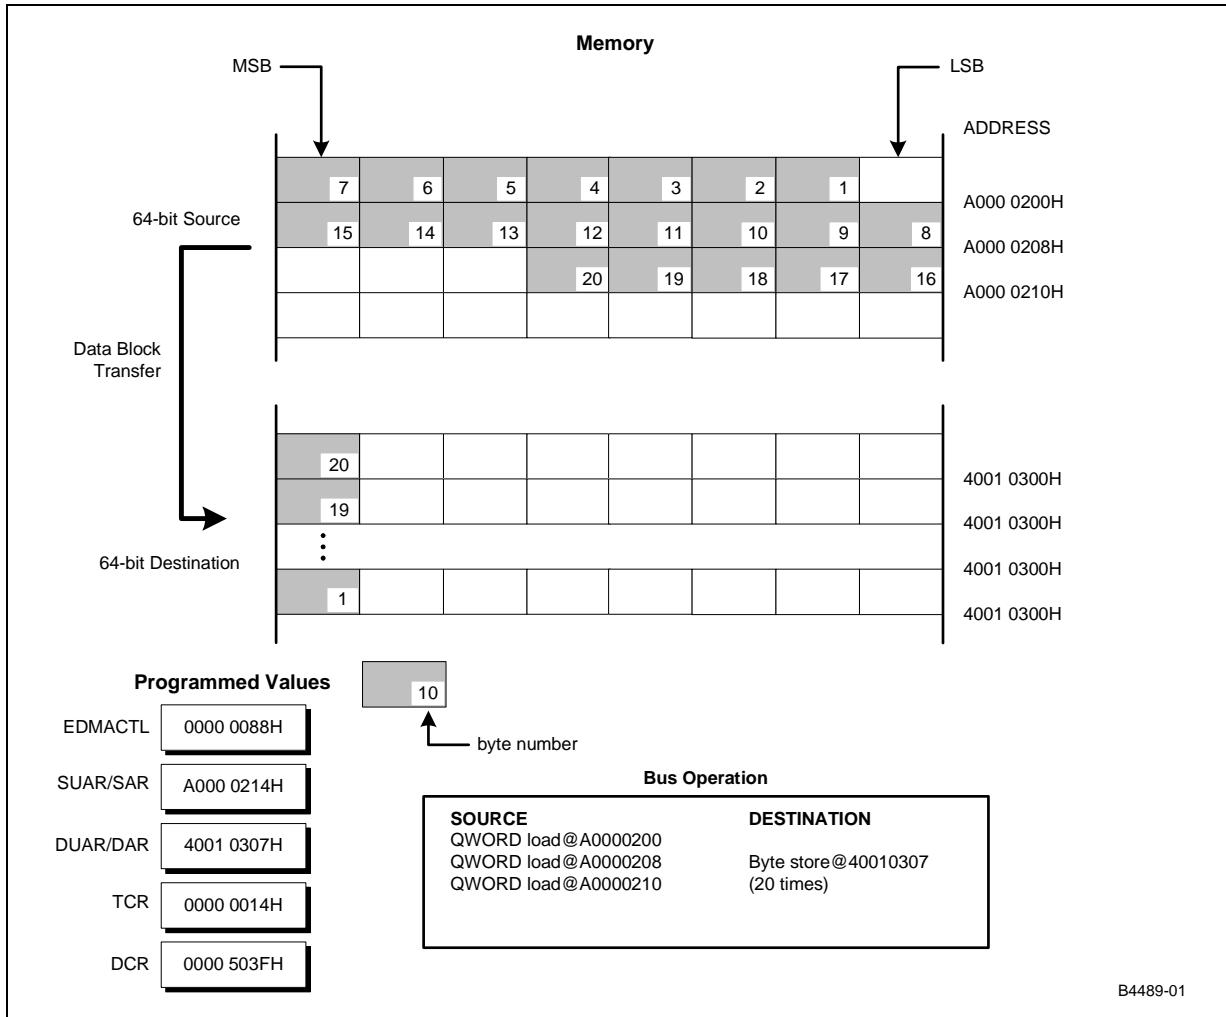

Figure 12-11. Source in Decrement and Destination in 2-Byte Granularity Constant Mode Transfer

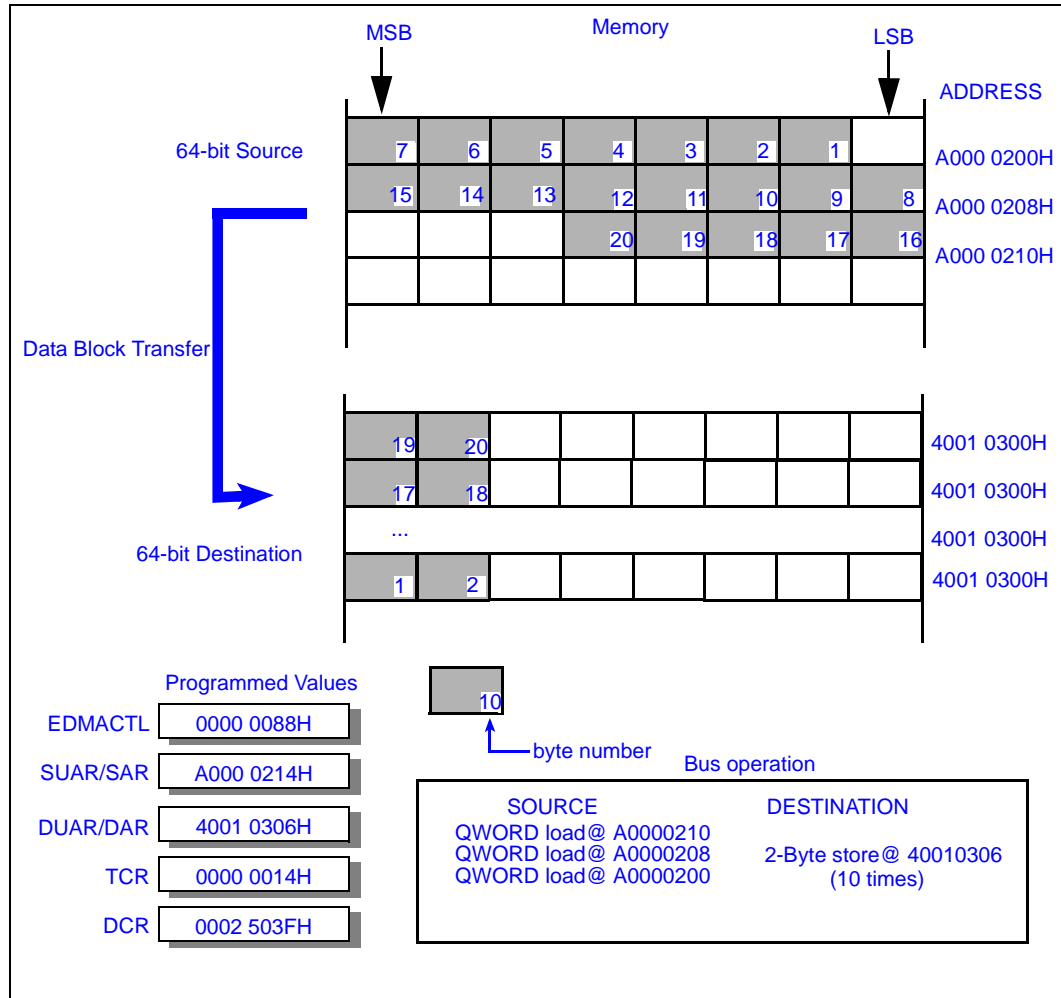

Figure 12-12. Source in Decrement and Destination in 4-Byte Granularity Constant Mode Transfer

### 12.5.2.4 Buffer and Memory Initialization Modes

The EDMA can be used to write a constant value to local memory or to memory mapped I/O. As with normal transfers, descriptors are used to specify the memory blocks to which the data contained in the Source Address Register is written.

When buffer or memory initialization modes are selected, the data in the SAR is sent to the destination address. No data is fetched. Data is transferred in 32-bit replicated chunks to the destination. The transfers will continue until the byte count register is satisfied.

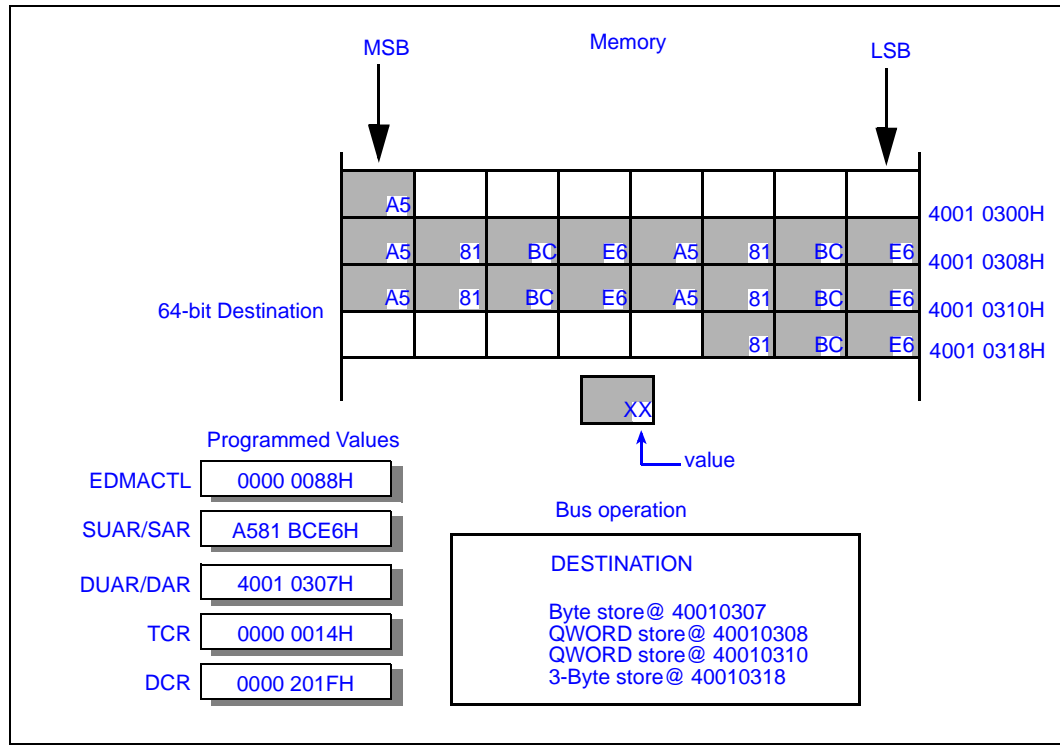

#### 12.5.2.4.1 Memory Initialization Mode

Memory initialization mode transfers can be to memory or to memory mapped I/O. In this mode, the destination can be specified down to the byte address.

Figure 12-13 illustrates memory initialization to an arbitrary destination address.

Figure 12-13. Source in Memory Initialization and Destination in Increment Mode Transfer

#### 12.5.2.4.2 Buffer Initialization Mode

Buffer initialization mode transfers will logically only be to memory mapped I/O and will utilize the constant destination mode and granularity fields of the DCR. The address granularity is dictated by the granularity field in the DCR. No errors will be flagged if the destination address is not matched to the granularity, but the required lower address bits will be ignored.

Figure 12-14 through Figure 12-16 illustrate buffer initialization mode to an arbitrary destination address.

Figure 12-14. Source in Buffer Initialization and Destination in 1-Byte Granularity Constant Mode Transfer

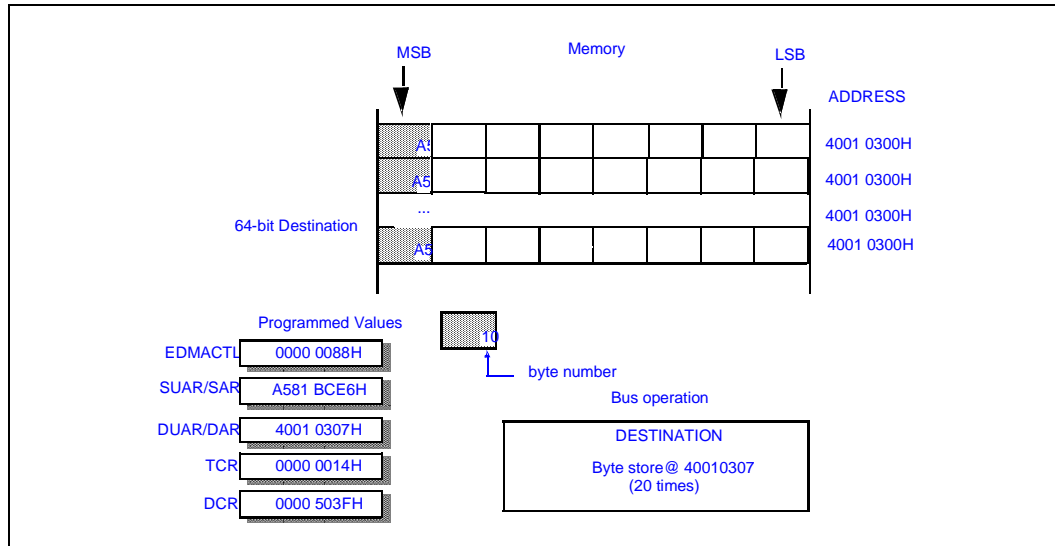

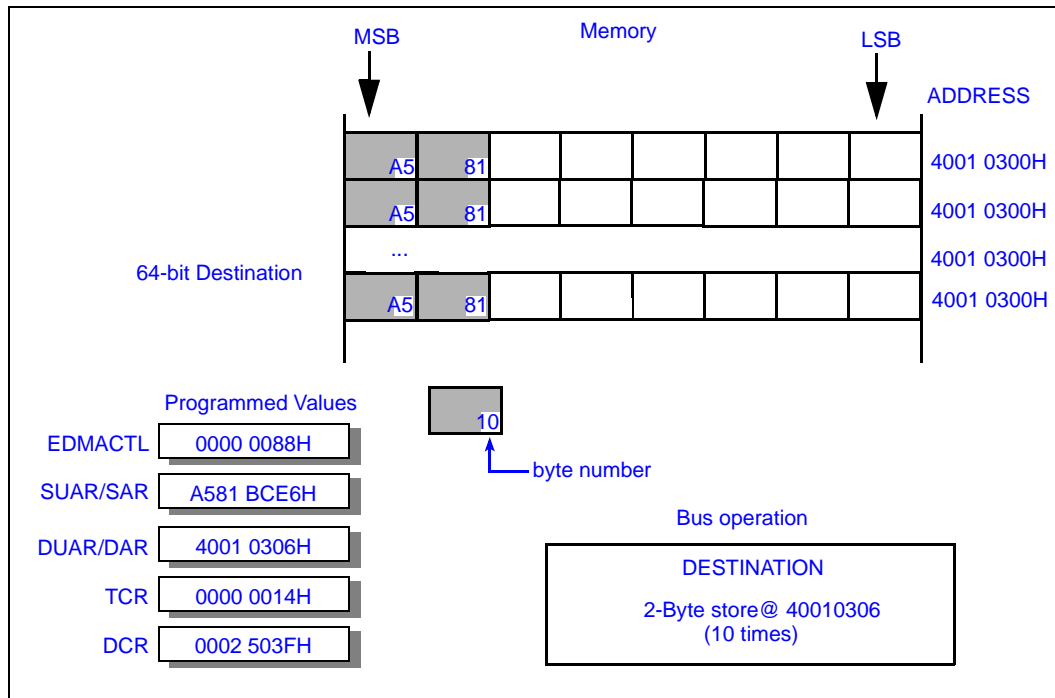

Figure 12-15. Source in Buffer Initialization and Destination in 2-Byte Granularity Constant Mode Transfer

**Figure 12-16. Source in Buffer Initialization and Destination in 4-Byte Granularity Constant Mode Transfer**

### 12.5.3 PCI Express Traffic Class

To provide traffic shaping and quality of service within the system fabric, the EDMA contains the traffic class field within the DCR. Traffic class is provided to the external switches, bridges, and other fabric devices to allow one transaction to pass another based on a software generated priority map. The three bit field in the DCR is directly copied to the transaction traffic class field in the PCI-Express header as write transactions are generated to PCI-Express. This field is ignored for all other destinations.

### 12.6 Channel Data Queuing

Each channel contains a data buffer that is four cache-lines in size (256 bytes). The data buffer holds data temporarily to facilitate pipelining and hide latency, improving the throughput of data transfers between the source and destination.

### 12.7 Error Conditions

Any of several possible error conditions may arise during a transfer depending on which interfaces the transfer utilizes. The interfaces covered are the EDMA controller interface, the memory interface, and the I/O subsystem destination port interface. All error conditions are reported by setting the corresponding error bits in the Channel Status Register (CSR).

The subsections below describe all possible errors at each interface that the EDMA controller must detect and report. For those errors resulting in a channel abort, the response to the error is highly configurable. The controller may be configured to

generate a IA-32 core interrupt upon detection of an error. Beyond this mechanism, errors detected and logged in the CSR may be escalated as described in the chapter on RASUM and exception handling.

Refer to the EDMA access disposition tables in [Chapter 10.0, "System Address Map,"](#) for an overview of defined ranges in the memory map and associated EDMA access treatment.

### 12.7.1 Controller Interface Error

The following errors may be reported for any EDMA initiated access, regardless of target interface:

- Illegal NDAR address
  - The descriptor pointer in NDAR is not naturally eight Dword aligned
  - The value in NDAR does not point to a valid memory location
- Illegal source address
  - Address does not comply with the Source Type bit in the DCR
  - Address out of range
- Illegal destination address
  - Address does not comply with the Destination Type bit in the DCR
  - Address out of range
  - Accesses to any IICH address region via the NSI
- Data parity error (corrupt data) returned by memory read retrieving descriptor information

All controller interface errors are fatal to the transfer in process and will result in channel abort.

*Note:* This includes data parity errors, since an error in reading a descriptor implies a corrupt descriptor in main memory, and in this case, it is impossible for the channel to determine precisely what part of the descriptor is damaged. The automatic abort upon detection of a corrupt descriptor is necessary to prevent any further data corruption as a result of its execution.

### 12.7.2 Memory Interface Error

The following errors may be reported for a EDMA initiated access (read or write) on the local memory interface:

- Addressing error (source or destination)
  - Physical EDMA address above REMAPLIMIT (see [Section 10.6.1](#))
  - Physical address not allocated to memory (including PAM destination mapping)
  - Physical address specified an illegal memory destination (e.g., protected SMM range)
- Data parity error in reading data from the EDMA Data Queue
- Data parity error (poisoned data) returned by memory read for payload data

There is no time-out mechanism associated with transfers. The EDMA channel assumes that all reads to memory will eventually return, although they may return corrupt data, and will wait indefinitely for an outstanding read.

Addressing errors are fatal and will result in a EDMA channel abort, logged in CSR bit 4. The channel response to data errors is configurable; the channel may be programmed to abort, or to propagate the bad data to its destination.

### 12.7.3 I/O Interface Error

The following errors may be reported for a EDMA initiated access (write) on an I/O interface:

- Address crossed into a memory destination range (checked on each write access)
- Address crossed to a new destination port during a transfer (checked at 4 KB boundaries)

The latter error will result if poorly formed destination descriptor information specifies a length plus address combination that crosses the addressing boundary between independent outbound ports on the I/O subsystem. Any transfer with a destination range crossing an aligned 4 KB boundary in address space may encounter this error.

Addressing errors are fatal and will result in a channel abort. Channel response to data errors is configurable; each channel may be programmed to abort, or to propagate the corrupt data to its destination.

## 12.8 Channel Arbitration

Arbitration among the four independent channels occurs in two stages. Each channel has an independent bus request/grant pair to the arbiter internal to the controller. The controller in turn has a single request/grant pair to the main arbiter. The arbiter within the controller handles the fairness among channels, while the inbound/outbound arbiter handles fairness between the EDMA channels and other competing traffic sources.

The internal arbiter uses a strict round-robin policy, with the added modification of an optional "high priority" designation for one channel at any given time. Thus a set of competing channels will achieve balanced bandwidth performance during normal operation.

The inbound/outbound arbiter provides a programmable single or double "grant duration" for the EDMA controller. Thus the channel that "wins" internal arbitration may be allowed to issue one or two access requests back-to-back in a single arbitration cycle. The second request is accepted if the inbound/outbound arbiter is programmed to a grant count of 2 the requesting channel has two consecutive requests of the same type targeting the same destination ready to send, and there are sufficient command and data resources available for the second request.

### 12.8.1 Normal Arbitration Scheme

A fully connected round-robin arbiter provides a distinctive balanced service among competing requestors. Each of the actively competing channels will receive an equal fraction of the bandwidth service provided by the inbound/outbound arbiter on behalf of each EDMA channel. In the absence of any competition from the IA-32 core, PCI Express ports, or other I/O, each EDMA channel will be allowed to saturate the memory interface. For example, given a memory interface "saturation point" of 4 GB/s, the round-robin scheme would be equally distributed between the competing EDMA channels.

### 12.8.2 Prioritized Arbitration Scheme

The high priority option in the arbitration scheme provides for a single “high priority” channel to receive favorable latency and bandwidth service in the face of multiple competing “normal priority” channels. This is accomplished by designating the high priority channel using a priority enable bit and a two-bit field (to select one of four channels) in the EDMA control register.

The internal EDMA controller arbiter modifies its arbitration algorithm to provide a grant to the priority channel between the grants for each of the other channels, which retain their round-robin prioritization relative to each other. For example, given a hypothetical memory interface bandwidth of 4 GB/s, the priority-modified scheme would result in 2 GB/s (half the available bandwidth) for the designated priority channel, and the remaining 2 GB/s split equally among the other competing channels.

The limitation that a single channel at a time be designated as the priority channel is an acknowledgement that quality of service differences, given multiple “priority” channels, would be slight in this implementation with two-level arbitration and only four competing channels. It is anticipated that software will be able to determine when an application is particularly sensitive to service level, has been allocated a channel, and will manage the assignment of priority accordingly. If more than one such “sensitive” application is in flight at the same time, it is perceived to be more efficacious to allow fair competition between those sources, and let the kernel or device driver software attempt to manage competition for resources at the system level to prevent service level problems.

Each EDMA channel supports dynamic modification to the priority channel settings (while one or more channels are active). A write to the control register that changes the priority channel configuration takes affect at the next arbitration decision point after the write has completed. There is no direct interlock between the arbiter configuration and any of the active channels. Such an event is effectively an environment change, orthogonal to work in progress on any given channel.

## 12.9 Configuration

The EDMA controller uses memory-mapped configuration registers for the majority of its per channel register sets. The controller is software compatible with standard PCI device configuration and implements a standard PCI header in its configuration-mapped register set as shown in Figure 12-1. The memory-mapped register space associated with the controller is identified by a 32-bit memory Base Address Register (BAR). Table 12-1 provides an overview of the memory-mapped register set for a representative channel of the controller.

Table 12-1. Channel 0 Memory-mapped Register Set

| Memory Mapped I/O for EDMA Channel 0       | Memory offset | Access  | Size    | Default    | Sticky |
|--|---------------|---------|---------|------------|--------|
| Channel Control Register (CCR0)            | 00-3h         | RW      | 32 bits | 0000_0000h | No     |
| Channel Status Register (CSR0)             | 04-07h        | RWC, RO | 32 bits | 0000_0000h | No     |
| Current Descriptor Addr Reg (CDAR0)        | 08-0Bh        | RO      | 32 bits | 0000_0000h | No     |
| Current Descriptor Upper Addr Reg (CDUAR0) | 0C-0Fh        | RO      | 32 bits | 0000_0000h | No     |
| Source Address Register (SAR0)             | 10-13h        | RO      | 32 bits | 0000_0000h | No     |
| Source Upper Address Register (SUAR0)      | 14-17h        | RO      | 32 bits | 0000_0000h | No     |
| Destination Address Register (DAR0)        | 18-1Bh        | RO      | 32 bits | 0000_0000h | No     |
| Destination Upper Address Register (DUAR0) | 1C-1Fh        | RO      | 32 bits | 0000_0000h | No     |

**Table 12-1. Channel 0 Memory-mapped Register Set**

|   |        |     |         |            |    |
|---|--------|-----|---------|------------|----|
| Next Descriptor Address Register (NDAR0)        | 20-23h | RWL | 32 bits | 0000_0000h | No |
| Next Descriptor Upper Address Register (NDUAR0) | 24-27h | RWL | 32 bits | 0000_0000h | No |
| Transfer Count Register (TCR0)                  | 28-2Bh | RO  | 32 bits | 0000_0000h | No |
| Descriptor Control Register (DCR0)              | 2C-2Fh | RO  | 32 bits | 0000_0000h | No |

All internal registers are accessible through host-initiated configuration space accesses or SMBus interface accesses. Internal registers are not accessible from the I/O subsystem interfaces.

### 12.9.1 Power Up/Default Status

Upon power-up or hardware reset, the channel registers are initialized to their default values. All reserved and unimplemented registers and bits in the device return zero on reads and are unaffected by writes.

### 12.9.2 Channel-Specific Register Definitions

Each channel has twelve 32-bit memory-mapped registers for its independent operation. Eight of these registers (refer to the descriptions below) are loaded automatically from their corresponding fields in the chain descriptor when a new descriptor is fetched from local memory during normal operation. The format of the corresponding descriptor fields in memory is identical to the format defined for the channel-specific registers. Refer to [“Memory Mapped I/O for EDMA Registers” on page 651](#) for bit definitions.

Read/write access is available only to the following:

- Channel Control Register (CCR)
- Channel Status Register (CSR)
- Next Descriptor Address Register (NDAR)
- Next Descriptor Upper Address Register (NDUAR)

The remaining registers are read-only and are automatically loaded with new values defined by the chain descriptor whenever the channel reads a chain descriptor from local system memory.

*Note:* Automatic loading of the channel-specific registers occurs after the memory read completion returns the descriptor data (32 B), and verification has taken place. Verification includes checking parity on the data returned and checking that the channel is properly configured to receive new descriptor data. (If a suspend is in progress, the descriptor data will be dropped in honor of the suspend.)

#### 12.9.2.1 Channel Control Register – CCR

The Channel Control Register (CCR) specifies the overall operating environment for the channel. This is a read/write register, and is cleared to zero on power-on or system reset (contains no sticky bits). Application software initializes this register only after initializing the chain descriptors in system memory and updating the Next Address Registers with the location of the first chain descriptor in memory. The CCR may be written when the channel is active to modify channel operation (stop, suspend, etc.) while the channel is active.

The following bits are defined in the CCR:

- Start: initiate a new transfer (requires that the CSR be appropriately cleared)
- Stop: abort the current transfer (immediately)
- Suspend: suspend the current transfer (upon completion of the current descriptor)
- Channel Resume: resume a suspended transfer (retrieve the descriptor indicated by NDAR/NDUAR from local memory, and proceed with execution per the value returned). Requires that the stopped and abort status bits in the CSR be clear to take effect and will automatically clear end of chain and end of transfer flags.

Refer to “Offset 00h: CCR0 - Channel 0 Channel Control Register” on page 653 for the format of the CCR.

### 12.9.2.2 Channel Status Register – CSR

Channel Status Register (CSR) contains flags to indicate the channel status. The register is read by application software to get the current channel status and to determine the source of interrupts. CSR is cleared to zero on power-on or system reset. This is a read/write register.

The following bits are defined in CSR:

- Channel Active: transfer in progress
- Aborted: transfer encountered an error
- Stopped: transfer stopped via software request (Stop bit detected)
- Suspended: transfer suspended via software request (Suspend bit detected)
- End of Transfer: channel has completed execution of (at least one) descriptor
- End of Chain: channel has completed execution of the terminal descriptor (null NDAR/NDUAR)

Refer to “Offset 04h: CSR0 - Channel 0 Channel Status Register” on page 656 for the format of CSR.

### 12.9.2.3 Current Descriptor Address Register – CDAR

The Current Descriptor Address Register (CDAR) contains the lower 32-bits of the address for the current chain descriptor in local system memory. The CDAR is cleared to zero on power-on or system reset, and is loaded automatically with the value from the Next Descriptor Address Register (NDAR) when a new block transfer is initiated. This register is read-only, and may be polled by software to monitor the progress of the channel as it traverses the descriptor chain.<sup>1</sup>

### 12.9.2.4 Current Descriptor Upper Address Register – CDUAR

The upper address will not be used in the EP80579, which is limited to 32-bit addressing.

The Current Descriptor Upper Address Register (CDUAR) contains the upper 32-bits of the address of the current chain descriptor in local system memory. The CDUAR is cleared to zero on power-on or system reset and is loaded automatically with the value from the Next Descriptor Upper Address Register (NDUAR) when a new block transfer is initiated. This register is read-only.<sup>1</sup>

---

1. Note that the IMCH does not provide an interlock to guarantee that consecutive reads to the CDAR/CDUAR pair return portions of the same descriptor in the event of a collision between the read accesses and a descriptor load operation. If software requires knowledge of the current descriptor, the “Suspend” function must be invoked prior to polling these registers.

### 12.9.2.5 Source Address Register – SAR

The Source Address Register (SAR) contains the lower 32-bits of the source address for the current transfer. The SAR is cleared to zero on power-on or system reset and is loaded automatically with the Source Address field of the chain descriptor (first DWord) when a new chain descriptor is read from memory. The address can be aligned to any byte boundary. The system destination for reads to this address range must match the Source Type setting of the DCR or the transfer will abort.

### 12.9.2.6 Source Upper Address Register – SUAR

The upper address will not be used in the EP80579, which is limited to 32-bit addressing.

The Source Upper Address Register (SUAR) contains the upper 32-bits of the source address for the current transfer. The SUAR is cleared to zero on power-on or system reset and is loaded automatically with the Source Upper Address field of the chain descriptor (second DWord) when a new chain descriptor is read from memory.

### 12.9.2.7 Destination Address Register – DAR

The Destination Address Register (DAR) contains the lower 32-bits of the destination address for the current transfer. The DAR is cleared to zero on power-on or system reset and is loaded automatically with the Destination Address field of the chain descriptor (third DWord) when a new chain descriptor is read from memory. The address can be aligned to any byte boundary. The system destination for writes to this address range must match the Destination Type setting of the DCR or the transfer will abort.

### 12.9.2.8 Destination Upper Address Register – DUAR

The upper address will not be used in the EP80579, which is limited to 32-bit addressing.

The Destination Upper Address Register (DUAR) contains the upper 32-bits of the destination address for the current transfer. The DUAR is cleared to zero on power-on or system reset and is loaded automatically with the Destination Upper Address field of the chain descriptor (fourth DWord) when a new chain descriptor is read from memory.

### 12.9.2.9 Next Descriptor Address Register – NDAR

The Next Descriptor Address Register (NDAR) contains the lower 32-bit address of the next descriptor chain in the local system memory. The NDAR is cleared to zero on power-on or system reset and is loaded automatically with the Next Descriptor Address field of the chain descriptor (fifth DWord) when a new chain descriptor is read from memory. This address must be aligned to an 8-DWord address boundary. A value of zero implies the end of chain if the value of Next Descriptor Upper Address (loaded into the NDUAR) is also zero. Application software writes this register with the address of the first chain descriptor in memory prior to initiating a transfer.

*Note:* The application software must make sure that the Start bit in the CCR and the Channel Active bit in the CSR are clear prior to writing to the NDAR. The IMCH protects this register from being written when these bits are not clear. If the NDAR and NDUAR are zero when the Start bit is set, no transfer will be initiated.

### 12.9.2.10 Next Descriptor Upper Address Register – NDUAR

The upper address will not be used in the EP80579, which is limited to 32-bit addressing.

The Next Descriptor Upper Address Register (NDUAR) contains the upper 32-bit address of the next descriptor chain in the local system memory. All address bits above bit 35 must be zero or the transfer will abort and an error will be reported. A value of zero implies the end of chain if the value of Next Descriptor Address (loaded into the NDAR) is also zero. NDUAR is cleared to zero on power-on or system reset and is loaded automatically with the Next Descriptor Upper Address field of the chain descriptor (sixth DWord) when a new chain descriptor is read from memory. Application software (likely the device driver) writes this register with the address of the first chain descriptor in the memory prior to initiating a transfer.

*Note:* The application software must make sure that the Start bit in the CCR and the Channel Active bit in the CSR are clear prior to writing to the NDUAR. The IMCH protects this register from being written when these bits are not clear. If the NDAR and NDUAR are zero when the Start bit is set, no transfer will be initiated.

### 12.9.2.11 Transfer Count Register – TCR

The Transfer Count Register (TCR) contains the length of the current transfer in bytes. The TCR is cleared to zero on power-on or system reset and is loaded automatically with the Transfer Count field of the chain descriptor (seventh DWord) when a new chain descriptor is read from memory. The TCR allows for a maximum transfer of 16 MB, commensurate with current operating system capabilities. A value of zero is valid and results in no data being transferred and no cycles generated on the source or destination buses. It also results in completion bits being set after successful completion “same as if it were a no zero length transfer”.

### 12.9.2.12 Descriptor Control Register – DCR

The Descriptor Control Register (DCR) contains control values for the transfer on a per descriptor basis. The DCR is cleared to zero on power-on or system reset and is loaded automatically with the Descriptor Control field of the chain descriptor (eighth DWord) when a new chain descriptor is read from memory. The values in the DCR may vary for different descriptors within a single chain.

*Note:* The descriptor control register value stipulates coherence attributes for both the source and destination addresses defined by this chain descriptor. Independent bits are also defined to specify whether the source and destination address ranges are to be treated as “coherent” or “non-coherent” by the IMCH. When the DCR value stipulates that one or both of the source and destination are to be treated as “non-coherent” space, the IMCH will rely on software to maintain system memory coherency and will not issue FSB cycles during the block transfer to snoop processor caches on behalf of the corresponding address range(s).

The following bits are defined in the CCR:

- Destination Address Mode: two bits specify destination address as increment or constant
- Granularity of the transfer in destination constant address mode: two bits (1B, 2B, or 4B)
- PCI-Express Destination Traffic Class: three bits define this traffic class
- Source Address Mode: two bits specify source address as increment, decrement, or buffer/memory initialization
- Buffer/Memory Initialization Mode: Specifies a write to fill an area of memory

- Destination Coherency: specifies whether destination addresses should be snooped on the FSB
- Source Coherency: specifies whether source addresses should be snooped on the FSB
- Destination Type: specifies whether the destination is local memory or the I/O subsystem
- Source Type: specifies whether the source is local memory or the I/O subsystem (defined only for symmetry, I/O subsystem source addresses are not supported)
- Abort Interrupt Enable: specifies whether to generate an interrupt on abort
- Stop Interrupt Enable: specifies whether to generate an interrupt on stop
- Suspend Interrupt Enable: specifies whether to generate an interrupt on suspend
- End of Transfer Interrupt Enable: specifies whether to generate an interrupt on EOT
- End of Chain Interrupt Enable: specifies whether to generate an interrupt on EOC

Refer to [Chapter](#), “Offset 2Ch: DCR0 - Channel 0 Descriptor Control Register,” for the format of the DCR.

## 12.10 Interrupts

Each EDMA channel can be configured to generate interrupts to the processor interface. The interrupt enable bits for end of transfer and end of chain in the Descriptor Control Register (DCR) determine if the channel generates an interrupt upon successful error-free completion of a transfer. The Abort Interrupt Enable bit in the DCR determines if the channel generates an interrupt upon encountering an error. Refer to “[Error Conditions](#)” on [page 329](#) for details on errors on both the source and destination interface. [Table 12-2](#) summarizes the status flags, and the conditions under which interrupts will be generated.

Each chain descriptor can independently set or clear the various interrupt enable bits in the Descriptor Control Register. This level of control for interrupt generation permits flexibility in synchronization between application software and transfers in progress. If interrupts are not enabled, synchronization can be achieved by polling the status bits in the Channel Status Register (CSR).

*Note:* “-” In the table below equates to a non valid combination

Table 12-2. Interrupt Summary

| Interrupt Conditions       | Channel Status Register (CSR) Flags |                |                |                 |              |                         | DCR Bit Settings (INTR Enable Bits) |                     |                 |                 |                   |
|----------------------------|-------------------------------------|----------------|----------------|-----------------|--------------|-------------------------|-------------------------------------|---------------------|-----------------|-----------------|-------------------|
|                            | Channel Active                      | Stopped        | Suspended      | End of Transfer | End of Chain | Channel Aborted (Error) | Stop INTR Enable                    | Suspend INTR Enable | EOT INTR Enable | EOC INTR Enable | Abort INTR Enable |
| Stopped                    | 0                                   | 1              | 0 <sup>2</sup> | -               | -            | -                       | 1 <sup>4</sup>                      | -                   | -               | -               | -                 |
| Suspended                  | 0                                   | 0 <sup>2</sup> | 1              | 1 <sup>3</sup>  | -            | -                       | -                                   | 1                   | -               | -               | -                 |
| End of Transfer            | 1                                   | -              | -              | 1               | -            | -                       | -                                   | -                   | 1               | -               | -                 |
| End of Chain               | 0                                   | -              | -              | 1               | 1            | -                       | -                                   | -                   | -               | 1               | -                 |
| Channel Abort <sup>1</sup> | 0                                   | -              | -              | 0               | 0            | 1                       | -                                   | -                   | -               | -               | 1                 |

**Notes:**

1. The IMCH ensures that any aborted transfer will be reported via the Channel Abort status bit and that this bit will never be accompanied by an End of Transfer or End of Chain indication. This ensures that software never mistakes an aborted transfer for a successfully completed transfer – even if the error is not detected until the final write to the final destination address of the terminal chain descriptor.
2. The Stop and Suspend functions are mutually exclusive, and only one of the two status bits will ever be asserted by the IMCH. In the event that software asserts both controls in the CCR, the Stop function will take precedence.
3. The EDMA Suspend function causes the channel to suspend operation at the completion of the current descriptor. The EOT status bit will always accompany the suspended status bit. Note that even if interrupts are enabled for both EOT and suspend, only a single interrupt event will result.
4. The Stop function causes the channel to abort the transfer in progress immediately. It is recommended that software read back the channel status register to verify that a stop command has taken effect, since this will be much faster than setting the interrupt enable for stop and waiting for the interrupt to occur.

### 12.10.1 Interrupt Routing Mechanisms

Two different mechanisms are available to route interrupts generated by channels to the IA-32 core. Note that the interrupt mechanism itself is not channel-specific; all channels generating interrupts share the same interrupt vector and handler. This is in line with the expectation that a single device driver controls each EDMA channel at large, rather than independent drivers per channel.

The first interrupt mechanism uses the integrated IOxAPIC and 8259 emulation hardware. All interrupts from the channels are logically OR'ed and routed to the interface controller for propagation via the in-band Assert\_Intx and Deassert\_Intx special cycles, emulating a level-sensitive interrupt output. The IMCH tracks these special cycles, and forwards the signaled interrupt to the IA-32 core. If the APIC enable bit is set, an interrupt will result in an APIC message. If the APIC enable bit is clear (unanticipated but possible), an interrupt will result in a legacy mode 8259-style level sensitive interrupt directly to the IA-32 core socket.

The second interrupt mechanism uses Message Signaled Interrupt (MSI) generation functionality integrated into the EDMA. Internal interrupt messaging utilizes the PCI message capability structure and does not support external interrupt input routing.

(That is, the limited MSI functionality described here is dedicated to the EDMA channel.) This second mechanism is preferred for interrupt signaling, but is only available in platforms running an MSI-capable operating system.

Selection between these two mechanisms is automatic in the IMCH. If MSI messaging is enabled, as indicated by the enable bit in the MSI control register, then the MSI interrupt mechanism is used. If MSI message generation is disabled, any initiated interrupt will use the dedicated pin legacy mechanism.

For both interrupt mechanisms, the interrupt service routine (ISR) must service all interrupts for all channels. The memory-mapped EDMA Controller Global Status Register must be statused before returning from the ISR to ensure no additional interrupts have occurred. Failure to address interrupts in all channels will result in potential system starvation.

### 12.10.2 Message Signaled Interrupt (MSI)

The EDMA controller is capable of generating upstream interrupt messages (MSI) directly to the IA-32 core. An MSI is signaled via a Memory Write to address OFEEx\_xxxxh.

Three 32-bit registers are required in the controller to support this mechanism. The default values of these registers are compatible with the default value of the IOxAPIC specification. The three registers are the MSI Control Register (MSICR), MSI Address Register (MSIAR), and MSI Data Register (MSIDR). Software must program these registers to appropriate values prior to enabling internal MSI functionality.

*Note:* It is unsafe to enable the integrated MSI APIC function of the controller in environments under control of a non MSI-capable operating system.

The MSI mechanism supports differentiation between interrupts generated during normal operation (EOT, EOC, stop, and suspend) and interrupts due to errors (abort). This extra level of granularity is unavailable via the legacy interrupt mechanism.

To facilitate use of a single device driver for the entire EDMA function, a single MSI register set services all channels. The support for two different messages on behalf of the controller is included in the MSI register set. Refer to [“EDMA Registers: Bus 0, Device 1, Function 0” on page 501](#) for the format of these registers.

*Note:* The integrated APIC functionality will not support level-sensitive interrupt emulation requiring the use of broadcast EOI cycles from the FSB. No path is provided to handle such traffic from IA-32 core to EDMA control engine. Thus the only supported MSI type is the edge-triggered variety.

The following subsections describe the register set for MSI support.

#### 12.10.2.1 MSI Control Register – MSICR

The MSI Control Register (MSICR) contains control information for MSI interrupt capability. The multiple-message enable field and MSI enable are contained in this register.

#### 12.10.2.2 MSI Address Register – MSIAR

The MSI Address Register (MSIAR) contains address information specifying the message destination address for MSI interrupts.

### 12.10.2.3 MSI Data Register – MSIDR

The MSI Data Register (MSIDR) contains routing and priority data for generation of MSI interrupts.

### 12.10.3 Interrupt Ordering

To support MSI signaling as transfers complete, the IMCH must take special steps in hardware to ensure that IA-32 core accesses to memory in response to MSI do not experience producer/consumer ordering failures. Specifically, the chip must internally guarantee functionality equivalent to a logical “FENCE” operation between the MSI and subsequent IA-32 core traffic from the FSB.

#### 12.10.3.1 Interrupt Ordering for Memory Destination

The failure to be prevented for interrupts signaled at the end of transfers to memory destinations is as follows:

- Each EDMA channel is programmed to move a single cache-line of data and issue an MSI upon completion. This is a special case, for illustrative purposes; a similar scenario arises for the last few writes of a multi-line transfer.
- As soon as the write data is posted into the inbound/outbound arbiter headed for the memory interface, the MSI is issued directly to the FSB. Note that the transfer to memory may be issued without an accompanying FSB snoop cycle (non-coherent), thus the data and interrupt message are logically traversing independent traffic paths.
- In response to the MSI, the IA-32 core issues a memory read to retrieve the data from memory. In the absence of an internal interlock, this read may proceed to the memory controller before the posted write data is accepted into the memory controller from the inbound/outbound arbiter. This is where the error occurs, because the memory controller will not have any information regarding the relative issue order of the write and the read – if the read gets there first, it will retrieve stale data.

To prevent such a failure, the inbound/outbound arbiter includes specialized hardware to guarantee that all posted write data received ahead of an MSI are forwarded out of the arbiter before the MSI message will be forwarded to the FSB.

A similar interlock in the inbound/outbound arbiter prevents failures in the non-interrupt case. When software is polling the Channel Status Register (CSR) to detect transfer completion, specialized hardware guarantees that the read completion stalls until all prior posted write data is forwarded out of the arbiter.

#### 12.10.3.2 Interrupt Ordering for Outbound Destination

The failure to be prevented for interrupts signaled at the end of transfers to outbound port destinations is as follows:

- Each EDMA channel is programmed for a single block transfer to an I/O device, with interrupt notification enabled at the completion of that transfer. For this example, MSI generation is disabled.
- When the final write of the transfer is posted into the inbound/outbound arbiter, a level-sensitive interrupt is signaled directly to the interrupt output pin, bypassing all internal queue structures.
- If the integrated IOxAPIC is enabled, the response to the interrupt pin will be an APIC message received. If the APIC is disabled, a sideband interrupt is signaled directly to the IA-32 core via a level sensitive output.

- For either case, the likely software response to the interrupt will be a posted write “door-bell” access to a memory mapped control register in the EDMA destination device to communicate completion of the transfer. (Semantic: EDMA transfer completed without errors, you have all the data, GO.)
- In the absence of internal interlocks as described above, multiple failures are possible. The APIC message could bypass EDMA data pending within the inbound/outbound arbiter, and the IA-32 core doorbell write could do the same. This would result in stale data “executed” in response to the doorbell.

The internal IMCH hardware interlock prevents APIC messages from being forwarded to the FSB while posted data remains pending in the inbound/outbound arbiter. This prevents most of the problematic behavior in this case. If the APIC is disabled, the IA-32 core must retrieve the interrupt vector from the 8259 emulator, and the read completion interlock will then guarantee that all posted write data has cleared the arbiter.

Another potential issue is relaxed write ordering within a system agent en route to the EDMA destination device. If the hardware were to issue EDMA outbound posted writes and IA-32 core posted writes with differing stream ID codes, an intermediary component may allow the IA-32 core doorbell access to move around posted EDMA data. This would again result in stale data “executed” by the destination device.

The IMCH could solve this problem by issuing an explicit FENCE between the final EDMA write and the interrupt, preventing subsequent IA-32 core accesses from reordering en route to the destination. A simpler (but more limited) solution is to utilize the same stream ID for all outbound traffic regardless of source. This makes transactions initiated by each EDMA channel indistinguishable from those initiated by any of the IA-32 core threads. With no stream ID information to determine reordering legality, an intermediary device must necessarily enforce strong ordering for all accesses outbound.

The single initiator ID in concert with the internal interlock for APIC messages and read completions is sufficient to guarantee proper behavior. The implementation guarantees that any flag write or data read to the destination port will necessarily push the EDMA transfer data ahead of it, ensuring correct producer/consumer operation.

## 12.11 Initiating an EDMA Transfer

The following subsections detail the steps the software must take in programming a channel to initiate a transfer (or chain of transfers). The steps covered include channel initialization, transfer start, and suspend or stop. Each channel is designed to have independent control of interrupt enabling and generation, and independent transfer attribute controls; this provides the greatest flexibility to the application program.

### 12.11.1 Setup and Initiation

Initializing a channel begins with constructing one or more chain descriptors in local system memory. Each chain descriptor takes the form described in [Section 12.3.1, “Chain Descriptor Definition” on page 311](#). Once the descriptors are defined, the following steps are required to initiate a transfer:

1. Ensure the EDMA channel is enabled and in Normal Mode by setting the EDMA Enable and Mode bits of the EDMA Control Register.
2. The channel must be inactive/idle prior to starting a transfer. This may be verified by reading the Channel Active bit in the Channel Status Register (CSR), which is clear when the channel is inactive/idle.
3. Update the Next Descriptor Address Register (NDAR/NDUAR) with the address of the first chain descriptor in local system memory.

4. Clear the Channel Status Register (CSR) of any asserted error or status bits. Each EDMA channel will not initiate a new transfer when an error condition remains in the CSR.
5. Clear the Suspend bit and set the Start bit in the Channel Control Register (CCR). Since this is the start of a new transfer and not the resumption of a previous transfer, the Channel Resume bit in the CCR must be clear. (Resume overrides start.)
6. The channel starts the transfer by fetching the chain descriptor at the address contained in the Next Descriptor Address Register (NDAR/NDUAR). The channel moves the NDAR/NDUAR values into the CDAR/CDUAR, and loads the chain descriptor values into their corresponding internal registers. If the load completes without any error, the actual data transfer begins. The Current Descriptor Address Register (CDAR/CDUAR) now contains the address of the chain descriptor just fetched and the Next Descriptor Address Register (NDAR/NDUAR) now contains the descriptor address of the next descriptor in the chain, if any.
7. When the current EDMA transfer has completed without any errors, the channel fetches the next chain descriptor from the address contained in the Next Descriptor Address Register (NDAR/NDUAR) automatically without any software intervention, and proceeds with the next block transfer (provided the value in the NDAR/NDUAR pair is non-zero).

The last descriptor in the chain list has a null value in the Next Descriptor Address field, specifying the end of the chain. The null value in the Next Descriptor Address Register (NDAR/NDUAR) notifies the channel not to read additional chain descriptors from local system memory, and the channel goes idle.

### 12.11.2 Suspend Function

Software may temporarily suspend execution of a descriptor chain by setting the Suspend bit in the Channel Control Register (CCR). The target channel will complete execution of the current descriptor and suspend operation without losing current status. Software may later cause the channel to resume execution of the descriptor chain by writing to the CCR to clear the Suspend bit and set the Resume bit. In response, the channel will initiate a descriptor fetch from the NDAR/NDUAR, and resume the suspended operation.

Software does not need to re-program the channel configuration after a suspend sequence.

### 12.11.3 Stop Function

Software may intentionally abort a transfer by setting the Stop bit in the Channel Control Register (CCR). Once aborted, the transfer cannot be resumed. In response to the Stop bit, the target channel will immediately cease fetching source data, drain any buffered destination data, and go idle. Usage of this mechanism will result in assertion of the Stopped status bit in the CSR, and will generate an interrupt if so enabled. (Note that the stop function is sufficiently fast in the IMCH that reading back the channel status register is preferred over utilizing the interrupt on stop function.)

Usage of the Stop mechanism will not result in assertion of the Abort status bit, nor will it generate an "interrupt on abort" indication if so enabled. The channel differentiates an abort on error from an abort on software command, and will ensure that all error status bits remain clear.

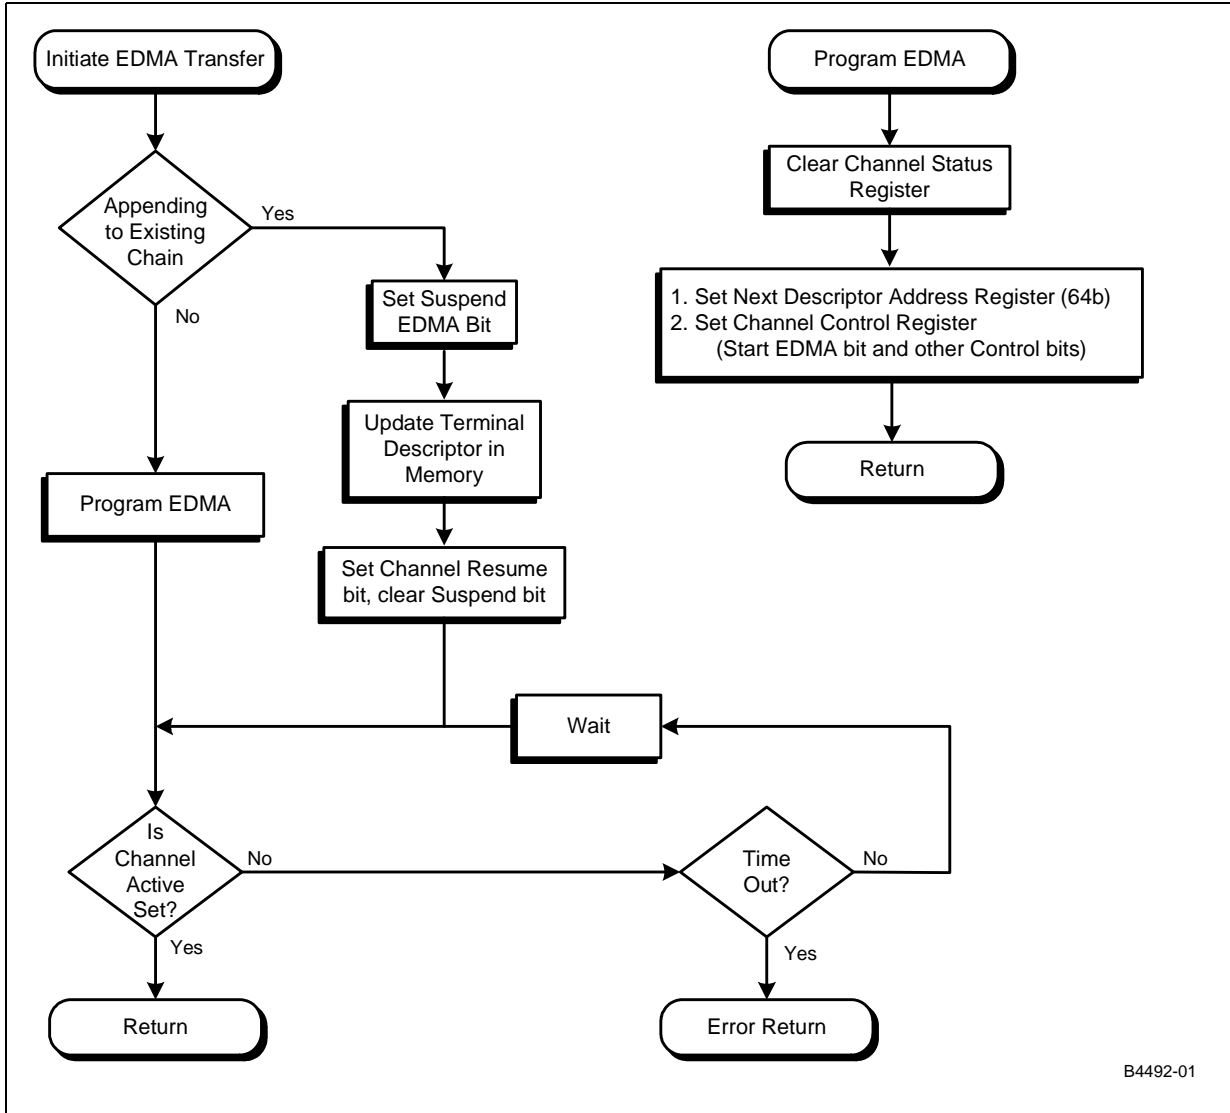

If the MSI mechanism is in use for interrupt generation, and independent messages are defined for abort on error and normal run-time interrupts, the latter message type will be utilized on behalf of the stop function.

### 12.11.4 EDMA Process Flow

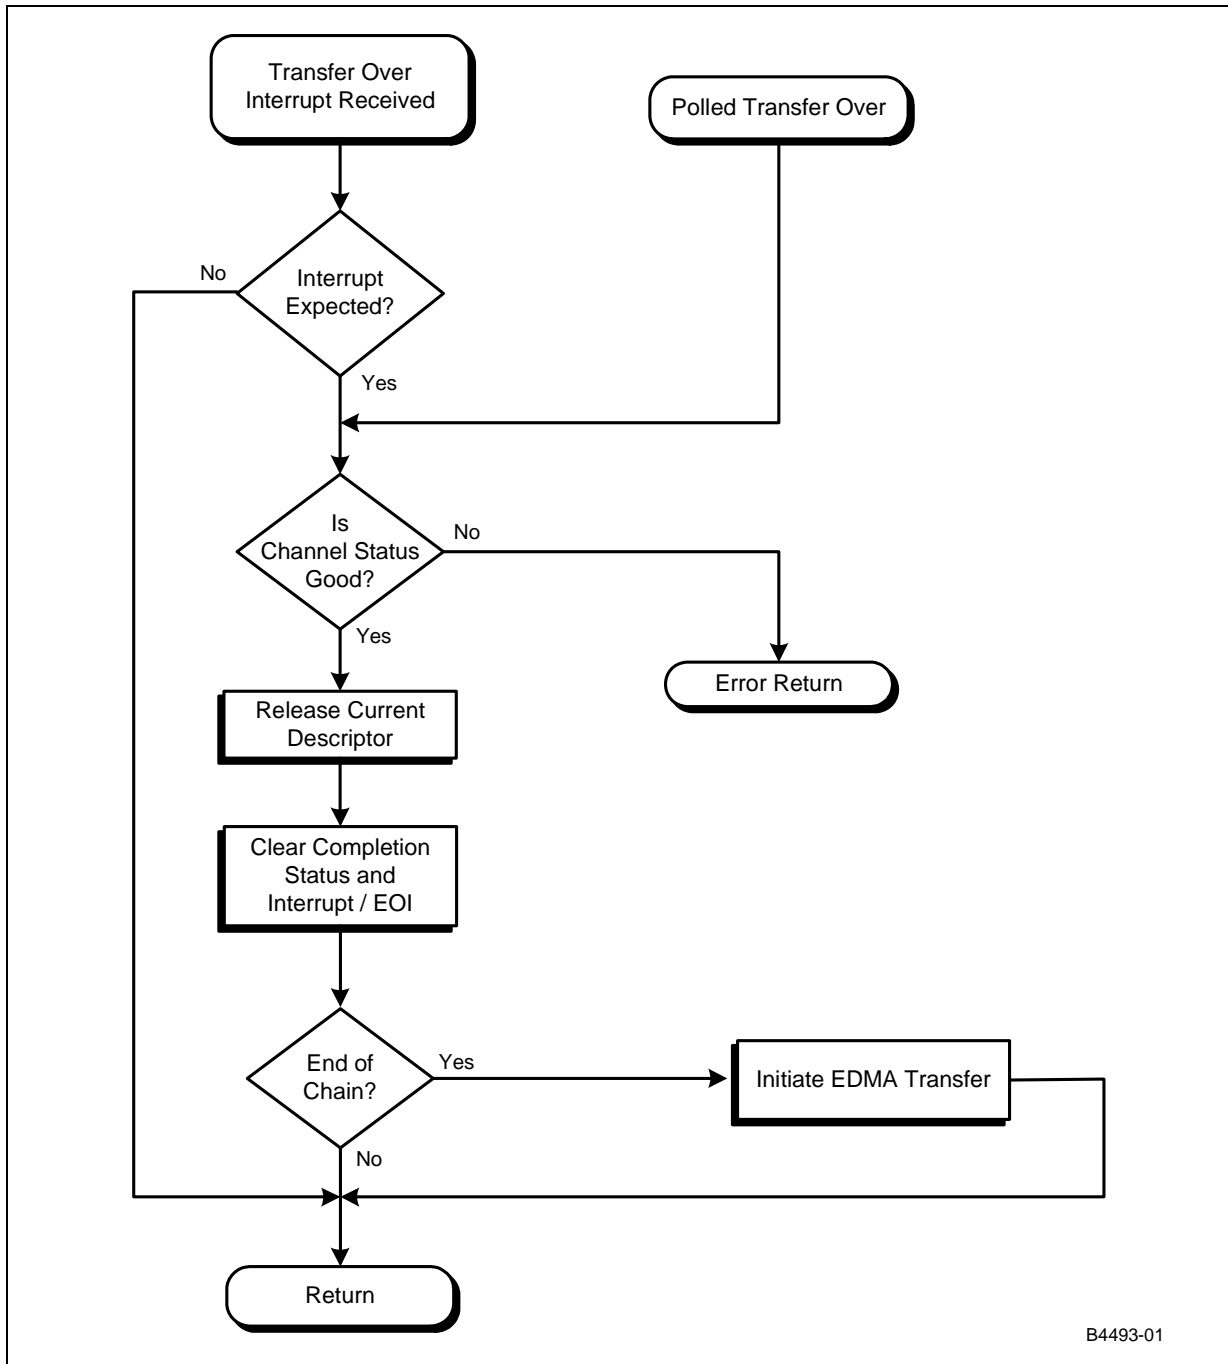

Figure 12-17 provides a high-level flow chart of the EDMA initialization sequence. Figure 12-18 provides a similar view of the EDMA completion sequence.

§ §

## 13.0 Platform Configuration

---

### 13.1 RASUM Features - SMBus Access

Configuration registers are accessible from either the IA-32 core or from the SMBus. The IA-32 core will be able to access all configuration registers through host configuration cycles. Access via SMBus is read/write to the IMCH configuration registers. The SMBus cannot use the IMCH's SM-port target interface to access any register in the IICH or outside of CMI. Each device must have its own SMBus target port.

CMI does not shadow the RASUM registers for the SMBus. To clear these registers, a write access will need to be performed. The IMCH SMBus has full read/write access to the IMCH PCI legacy registers.

The IMCH global RASUM register set and those registers applicable to logical bus#0 and memory are implemented in Function 1 of Device 0. RASUM registers specific to other internal devices appear in the register map for the associated device. The IMCH error control registers are in Function 1, and are read/write accessible by the processor and through the SMBus. The IMCH error logging registers are also available to the processor and SMB master in Function 1. The IMCH RASUM control register and the "CMD" registers (SERRCMD, SMICMD, etc.) which control generation of SERR#, SMI#, and SCI# are read/write accessible by the processor and through the SMBus.

FSB-initiated accesses to configuration space registers are serviced through configuration ring. It is perfectly legal for an SMBus access to be requested while an FSB-initiated access is already in progress. In other words, SMBus configuration accesses and processor configuration cycles may occur at the same time. The IMCH supports "wait your turn" arbitration to resolve all collisions and overlaps, such that the access that reaches the configuration ring arbiter first is serviced first while the conflicting access is held off. An absolute tie at the arbiter is resolved in favor of the FSB.

### 13.2 Platform Configuration Structure Conceptual Overview

The IMCH and IICH are physically connected by an internal interface called NSI (North South Interface). From a configuration standpoint, NSI is logically PCI bus #0. As a result, all devices internal to the IMCH and IICH, except host switch devices appear to be on PCI bus #0. The system's primary PCI expansion bus is physically attached to the IICH and, from a configuration perspective, appears to be a hierarchical PCI bus behind a PCI-to-PCI bridge and therefore has a programmable Bus number. The PCI Express ports appear to system software to be real PCI buses behind PCI-to-PCI bridges that reside as devices on PCI bus #0.

CMI decodes multiple PCI Device numbers. The configuration registers for the devices are mapped as devices residing on PCI bus #0 except for host switch devices. Each Device Number may contain multiple functions. See [Table 13-1, "PCI Devices and Functions on Bus 0"](#) for device and function assignments.

Table 13-1. PCI Devices and Functions on Bus 0

| Device | Function | Function Description                   |
|--------|----------|--|
| 0      | 0        | IMCH                                   |
| 0      | 1        | IMCH, error status                     |
| 1      | 0        | IMCH EDMA engine                       |
| 2      | 0        | IMCH PCI Express Port A0 X8 or X4 unit |
| 8      | 0        | IMCH Test and Device 0 Overflow        |
| 31     | 0        | IICH LPC Interface                     |
| 31     | 2        | IICH SATA Controller                   |
| 31     | 3        | IICH SMBus Controller                  |
| 31     | 5        | Reserved                               |
| 31     | 6        | Reserved                               |
| 29     | 0        | IICH USB Controller #1                 |
| 29     | 7        | IICH USB 2.0 Controller                |

### 13.2.1 IMCH PCI Devices

The PCI predefined header has five fields that deal with device identification. All devices are required to implement these fields. Generic configuration software is able to easily determine the device available for use. These registers are read only. The five fields are vendor ID, device ID, revision ID, header type, and class code:

- The 16-bit vendor ID is assigned by PCI SIG and has a value of 8086h for Intel.
- The 16-bit device ID is assigned by the vendor.
- The 8-bit revision ID is chosen by the vendor to indicate the different steppings of a device. The value 00h designates an A0 stepping. The value 01h designates an B0 stepping.
- The header type specifies the structure of the second half of the header, and also whether or not the device has multiple functions. The value 80h indicates a multi-function device.
- The class-code field identifies the generic function of the device. The class-code is further broken into three sub-fields, base class, sub-class, and programming interface. CMI proper has a base class code of 06h indicating a bridge device. The sub-class value of 00h indicates a host bridge.

A disabled or non-existent IMCH device's configuration register space is hidden, returning all 1's for reads and dropping writes just as if the cycle terminated with a Master Abort on PCI.

If one or more IICH devices or some of their functions are not supported on the platform, each can be disabled individually. When a device or function is disabled, it does not appear at all to the software: No responses to any register reads and no responses to any register writes. This is intended to prevent software from thinking that a device or function is present (and reporting it to the end-user).

When a PCI Express interface is unpopulated or fails to train, the associated configuration register space is hidden, returning all ones for all registers just as if the cycle terminated with a Master Abort on PCI. Also, if PCI Express port PEA0 is configured for x8 operation rather than x4, the corresponding PCI Express port PEA1 configuration space will be hidden.

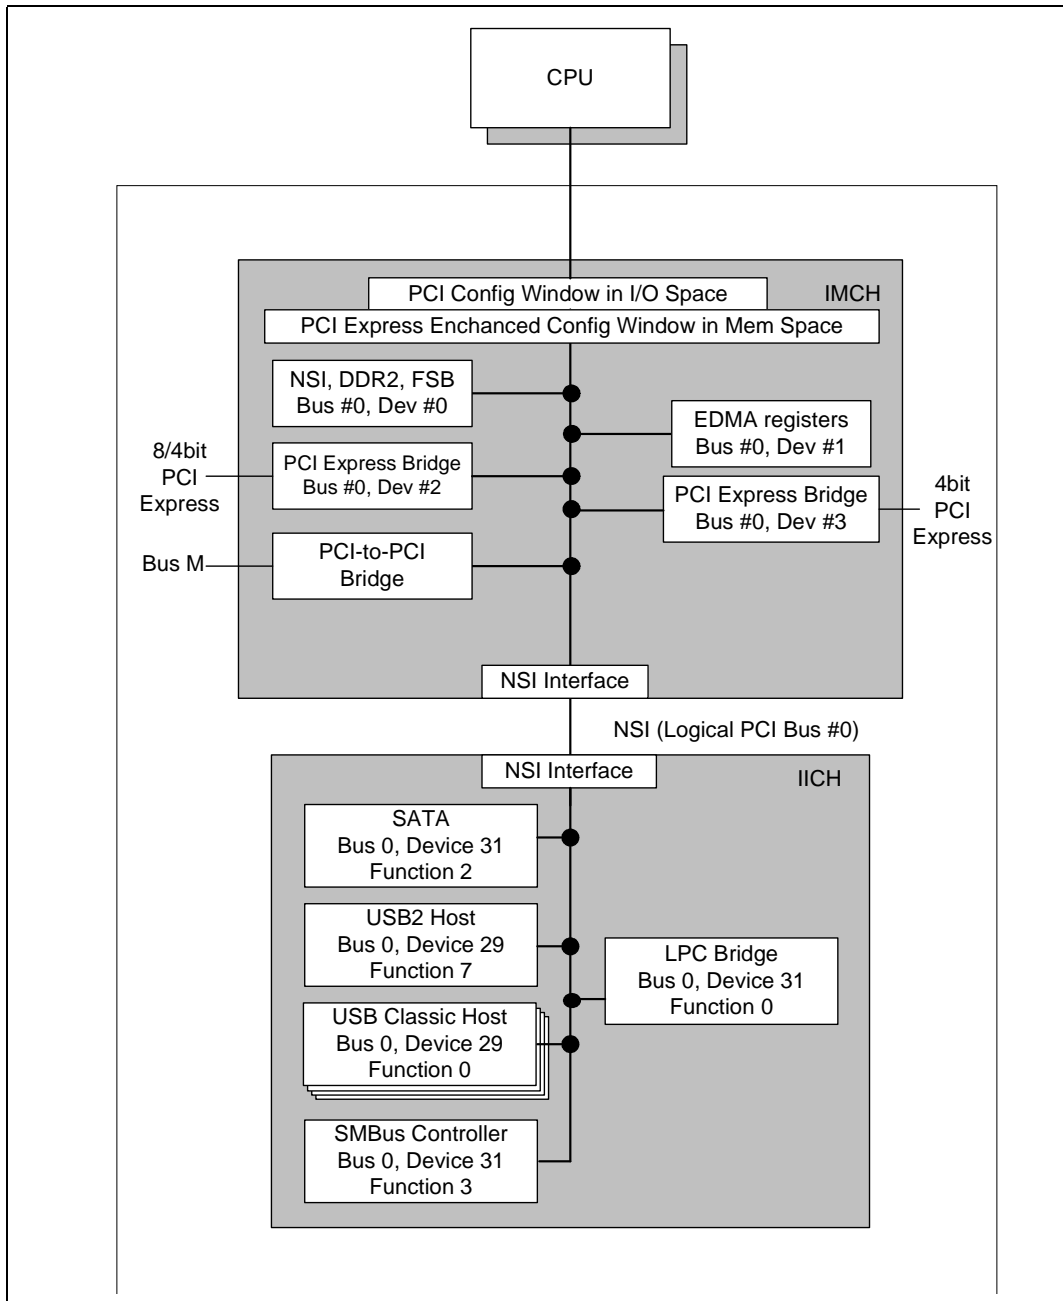

### 13.2.2 IICH PCI Devices

Logically, the IICH appears as multiple PCI devices within a single physical component also residing on PCI bus #0. One of the IICH devices is a PCI-to-PCI bridge. Logically, the primary side of the bridge resides on PCI #0 while the secondary is a standard PCI expansion bus.

*Note:* The internal devices in the IMCH and IICH (except host switch devices) logically constitute as PCI Bus #0 to configuration software (see [Figure 13-1](#)).

Figure 13-1. Bus 0 Device Map

### 13.3 Routing Configuration Accesses

The IMCH supports up to two x4 PCI Express interfaces:

- PEA0
- PEA1

These two interfaces can be combined to form a x8 interface, PEA.

The IMCH is responsible for routing PCI configuration cycles to the proper interface. PCI configuration cycles to IICH internal devices and downstream devices are routed to the IICH via the internal NSI bus. PCI configuration cycles to the IMCH PCI Express interfaces are routed to PEA(0:1). Routing of configuration accesses to PEA(0:1) is controlled via the standard PCI-to-PCI bridge mechanism using information contained within the PRIMARY BUS NUMBER, the SECONDARY BUS NUMBER, and the SUBORDINATE BUS NUMBER registers of the corresponding PCI-to-PCI bridge device.

A detailed description of the mechanism for translating IA-32 core I/O bus cycles to configuration cycles on one of the buses is described below.

*Note:* The IMCH supports a variety of connectivity options. When any of the IMCH's interfaces are disabled, the associated interface's device registers are hidden. All configuration cycles (reads and writes) to disabled devices on bus #0 are forwarded to the NSI where they will Master Abort.

#### 13.3.1 Standard PCI Bus Configuration Mechanism

The PCI Bus defines a slot based "configuration space" that allows each device to contain up to eight functions with each function containing up to 256 8-bit configuration registers. The *PCI Specification* defines two bus cycles to access the PCI configuration space: Configuration Read and Configuration Write. Memory and I/O spaces are supported directly by the IA-32 core. Configuration space is supported by a mapping mechanism implemented within the IMCH. The *PCI Specification* defines two mechanisms to access configuration space, Mechanism #1 and Mechanism #2. CMI supports Mechanism #1.

The configuration access mechanism makes use of the CONFIG\_ADDRESS Register and CONFIG\_DATA Register. To reference a configuration register a Dword (32-bit) I/O write cycle is used to place a value into CONFIG\_ADDRESS that specifies the PCI bus, the device on that bus, the function within the device, and a specific configuration register of the device function being accessed. CONFIG\_ADDRESS[31] must be a '1' to enable a configuration cycle. CONFIG\_DATA then becomes a window into the four bytes of configuration space specified by the contents of CONFIG\_ADDRESS. Any read or write to CONFIG\_DATA will result in the IMCH translating the CONFIG\_ADDRESS into the appropriate configuration cycle.

The IMCH is responsible for translating and routing the IA-32 core I/O accesses to the CONFIG\_ADDRESS and CONFIG\_DATA registers to internal IMCH configuration registers, for NSI, and PCI Express ports PEA(0:1).

*Note:* It is only possible to generate 1-4 byte configuration accesses via this mechanism, which is in line with IMCH capabilities. The IMCH **ONLY** supports accesses up to 1 Dword (32 bits) in size into the configuration register space (internal or external).

### 13.3.2 PCI Bus #0 Configuration Mechanism

The IMCH decodes the Bus Number (bits 23:16) and the Device Number fields of the CONFIG\_ADDRESS register. If the Bus Number field of CONFIG\_ADDRESS is 0, the configuration cycle is targeting a PCI Bus #0 device.

The Host-NSI Bridge entity within the IMCH is hardwired as Device #0 on PCI Bus #0.

The EDMA Controller within the IMCH is hardwired as Device #1 on PCI Bus #0.

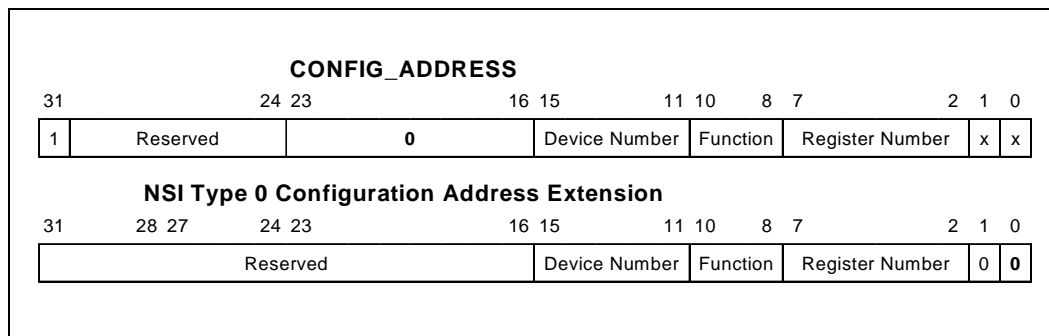

The Host-PEA0 bridge entity within the IMCH is hardwired as Device #2 on PCI Bus #0.

The Host-PEA1 bridge entity within the IMCH is hardwired as Device #3 on PCI Bus #0.

The PCI-to-PCI Bridge entity within the IMCH is hardwired as Device #4 on PCI Bus #0

Configuration cycles to any of the IMCH's enabled internal devices are confined to the IMCH and not sent over NSI. Accesses to disabled IMCH internal devices, or devices #10 to #31 is forwarded over NSI as Type 0 Configuration Cycles. A[1:0] of the NSI Request Packet for the Type 0 configuration cycle is "00". Bits 31:2 of the CONFIG\_ADDRESS register is translated to the A[31:2] field of the NSI Request Packet of the configuration cycle as shown in Figure 13-2. The IICH decodes the Type 0 access and generates a configuration access to the selected internal device.

Figure 13-2. NSI Type 0 Configuration Address Translation

### 13.3.3 Primary PCI and Downstream Configuration Mechanism

If the Bus Number in the CONFIG\_ADDRESS is non-zero, and does not lie between the SECONDARY BUS NUMBER register and the SUBORDINATE BUS NUMBER register for one of the PCI Express ports, the IMCH will generate a Type 1 NSI Configuration Cycle. A[1:0] of the NSI request packet for the Type 1 configuration cycle is "01". Bits 31:2 of the CONFIG\_ADDRESS register is translated to the A[31:2] field of the NSI request packet of the configuration cycle as shown in Figure 13-3. This NSI configuration cycle is sent over NSI.

If the cycle is forwarded to the IICH via NSI, the IICH compares the non-zero Bus Number with the SECONDARY BUS NUMBER and SUBORDINATE BUS NUMBER registers of its P2P bridges to determine if the configuration cycle is meant for the Primary PCI or one of the IICH's PCI Express ports.

Figure 13-3. NSI Type 1 Configuration Address Translation

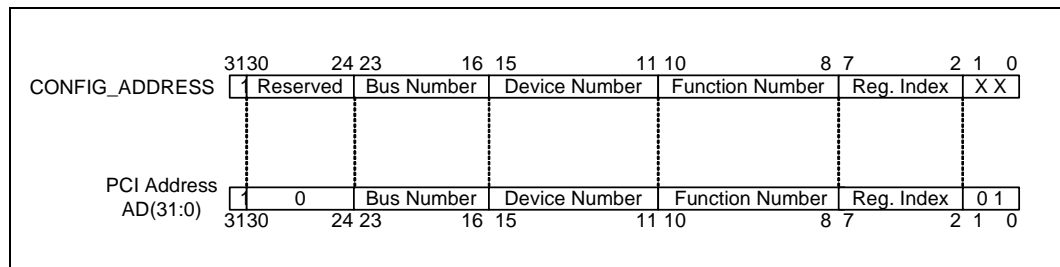

### 13.3.4 IMCH PCI Express Bus Configuration Mechanism

From the configuration perspective, the PCI Express ports are seen as PCI bus interfaces residing on a Secondary Bus side of the “virtual” PCI-to-PCI bridges referred to as the IMCH Host-PCI Express bridge. On the Primary bus side, the “virtual” PCI-to-PCI bridge is attached to PCI Bus #0. Therefore the PRIMARY BUS NUMBER register is hardwired to “0”. The “virtual” PCI-PCI bridge entity converts Type #1 PCI Bus Configuration cycles on PCI Bus #0 into Type 0 or Type 1 configuration cycles on the PCI Express interfaces. Type 1 configuration cycles on PCI Bus #0 that have a BUS NUMBER that matches the SECONDARY BUS NUMBER of one of the IMCH’s “virtual” P2P bridges are translated into Type 0 configuration cycles on the appropriate PCI Express interface. The address bits are mapped as described in Figure 13-3.

If the Bus Number is non-zero, greater than the value programmed into the SECONDARY BUS NUMBER register, and less than or equal to the value programmed into the corresponding SUBORDINATE BUS NUMBER register the configuration cycle is targeting a PCI bus downstream of the targeted PCI Express interface. The IMCH will generate a Type 1 configuration cycle on the appropriate PCI Express interface. The address bits are mapped as described in Figure 13-4.

Figure 13-4. Mechanism #1 Type 1 Configuration Address to PCI Address Mapping

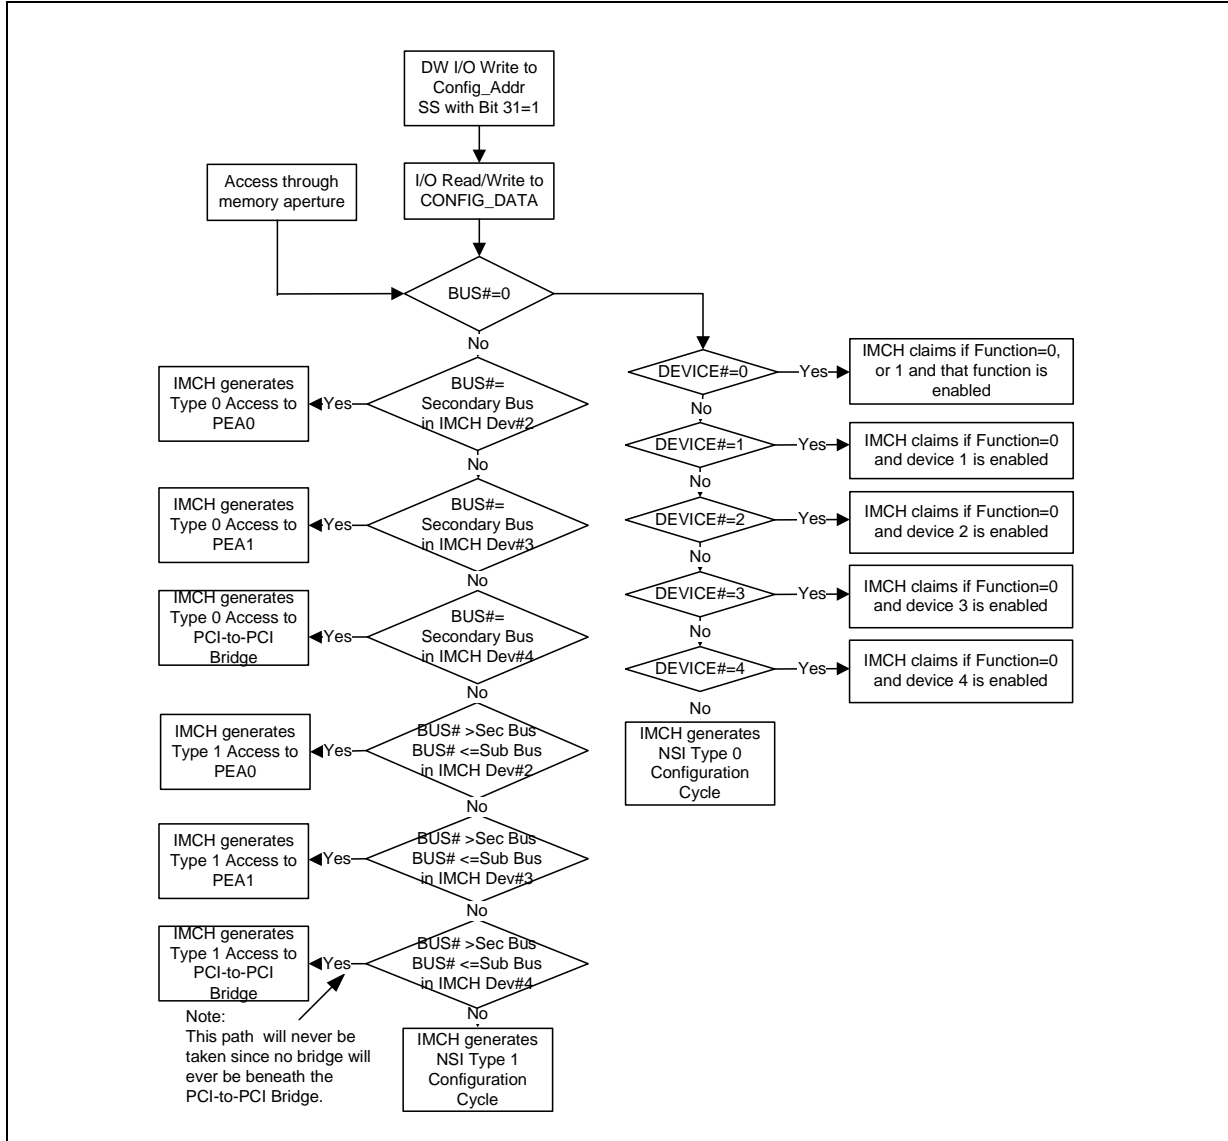

To prepare for mapping of the configuration cycles on PCI Express the initialization software will go through the following sequence:

Scan all devices residing on the PCI Bus #0 using Type 0 configuration accesses.

For every device residing at bus #0 which implements PCI-to-PCI bridge functionality, it will configure the secondary bus of the bridge with the appropriate number and scan further down the hierarchy. This process will include the configuration of the “virtual” PCI-to-PCI bridges within the IMCH used to map the PCI Express device’s address spaces in a software specific manner.

### 13.3.5 IMCH Configuration Cycle Flow Chart

Figure 13-5. IMCH Configuration Flow Chart

## 13.4 IMCH Register Introduction

The IMCH contains two sets of software accessible registers, accessed via the IA-32 core I/O address space: control registers I/O mapped into the IA-32 core I/O space, which control access to PCI configuration space, and internal configuration registers residing within the IMCH, which are partitioned into multiple logical device register sets (“logical” since they reside within a single physical device).

The IMCH internal registers (I/O Mapped and Configuration registers) are accessible by the IA-32 core. The registers can be accessed as Byte, Word (16-bit), or Dword (32-bit) quantities, with the exception of CONFIG\_ADDRESS, which can only be accessed as a Dword. All multi-byte numeric fields use “little-endian” ordering (i.e., lower addresses contain the least significant parts of the field).

### Note:

Irrespective of the access mechanism used (I/O register mechanism, or memory-mapped mechanism), the IMCH **ONLY** supports 1-4 byte accesses into configuration space. Software must (if necessary) take steps to prevent use of opcodes that would treat configuration space destinations as objects greater than a single Dword (32 bits) in size. Such attempted usage will result in spurious behavior up to and including hanging the platform.

Some of the IMCH registers described in this section contain reserved bits which are labeled “Reserved”. Software must deal correctly with fields that are reserved. On reads, software must use appropriate masks to extract the defined bits and not rely on reserved bits being any particular value. On writes, software must ensure that the values of reserved bit positions are preserved. That is, the values of reserved bit positions must first be read, merged with the new values for other bit positions and then written back. Note the software does not need to perform read, merge, write operation for the configuration address register.

In addition to reserved bits within a register, the IMCH contains address locations in the configuration space of the Host-NSI Bridge entity that are marked either “Reserved” or “Intel Reserved”. The IMCH responds to accesses to “Reserved” address locations by completing the host cycle. When a “Reserved” register location is read, a zero value is returned. (“Reserved” registers can be 8-, 16-, or 32-bit in size). Write operations to “Reserved” registers have no effect on the IMCH. Registers that are marked as “Intel Reserved” must not be modified by system software. Writes to “Intel Reserved” registers may cause system failure. Reads to “Intel Reserved” registers may return a non-zero value.

Upon a Reset, CMI sets its entire internal configuration registers to predetermined default states. At reset, some register values are determined by external strapping options. A register’s default value represents the minimum functionality feature set required to successfully bring up the system. It is the responsibility of the system initialization software (usually the BIOS) to properly determine the DRAM configurations, operating parameters and optional system features that are applicable, and to program CMI registers accordingly.

## 13.5 IMCH Sticky Registers

Certain registers in the IMCH are sticky through a hard-reset. They will only be reset on a Power-good reset. In general, these registers are the error logging registers and a few special cases. The error command registers are not sticky, so that on reset bogus errors are not reported and that errors are not reported through a mechanism that hasn’t been set up in code yet. Only those registers that are explicitly marked as “Sticky: YES” are sticky. Those not marked or those marked as NO are not sticky.

The following registers are sticky:

- Device 0, Function 0: Critical DRAM control registers, a portion of DRC, DRT clock gearing and clock disable registers
- Device 0, Function 0: ECO sticky register
- Device 0, Function 0, Bar 14: BIOS notepad sticky register
- Device 0, Function 1: error information registers (Not the command registers)
- Device 2, Function 0: error information registers (Not the command registers)
- Device 3, Function 0: error information registers (Not the command registers)
- Device 8, Function 0: PILOT control registers
- Device 8 Function 0: Power On Configuration bits

### 13.6 IMCH I/O Mapped Registers

The IMCH contains two registers that reside in the IA-32 core I/O address space – the Configuration Address (CONFIG\_ADDRESS) Register and the Configuration Data (CONFIG\_DATA) Register. The Configuration Address Register enables/disables the configuration space and determines what portion of configuration space is visible through the Configuration Data window.

**Table 13-2. Summary of IMCH PCI Configuration Registers Mapped in I/O Space**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|
| 0CF8h        | 0CF8h      | "Offset 0CF8h: CONFIG_ADDRESS: Configuration Address Register" on page 354 | 00000000h     |
| 0CFCh        | 0CFCh      | "Offset 0CFCh: CONFIG_DATA: Configuration Data Register" on page 355       | 00000000h     |

#### 13.6.0.1 Offset 0CF8h: CONFIG\_ADDRESS - Configuration Address Register

CONFIG\_ADDRESS is a 32-bit register that can be accessed only as a Dword. A Byte or Word reference will "pass through" the Configuration Address Register and NSI onto the ICH as an I/O cycle. The CONFIG\_ADDRESS register contains the Bus Number, Device Number, Function Number, and Register Number for which a subsequent configuration access is intended.

**Table 13-3. Offset 0CF8h: CONFIG\_ADDRESS: Configuration Address Register (Sheet 1 of 2)**

| Description: |             |   |  |                     |                 |                   |
|--------------|-------------|---|--|---------------------|-----------------|-------------------|
| View: IA F   |             | Base Address: 0000h (IO)  |  | Offset Start: 0CF8h |                 | Offset End: 0CF8h |
| Size: 32 bit |             | Default: 00000000h  |  | Power Well: Core    |                 |                   |
| Bit Range    | Bit Acronym | Bit Description   |  | Sticky              | Bit Reset Value | Bit Access        |
| 31           | CFGE        | <b>Configuration Enable.</b><br>0 = Accesses to PCI configuration space are disabled.<br>1 = Accesses to PCI configuration space are enabled. |  |                     | 0h              | RW                |
| 30 : 24      | Reserved    | <b>Reserved.</b> These bits are read only and have a value of 0.  |  |                     | 0h              | RO                |
| 23 : 16      | Bus_Number  | Contains the bus number being targeted by the configuration cycle.  |  |                     | 0h              | RW                |

**Table 13-3. Offset 0CF8h: CONFIG\_ADDRESS: Configuration Address Register (Sheet 2 of 2)**

| Description: |                 |  |  |        |                 |  |
|--------------|-----------------|--|--|--------|-----------------|--|
| View: IA F   |                 | Base Address: 0000h (IO)   |  |        |                 | Offset Start: 0CF8h<br>Offset End: 0CF8h |
| Size: 32 bit |                 | Default: 00000000h   |  |        |                 | Power Well: Core                         |
| Bit Range    | Bit Acronym     | Bit Description  |  | Sticky | Bit Reset Value | Bit Access                               |
| 15:11        | Device_Number   | Selects one of the 32 possible devices per bus.  |  |        | 0h              | RW                                       |
| 10:08        | Function_Number | Selects one of eight possible functions within a device.   |  |        | 0h              | RW                                       |
| 07:02        | Register_Number | This field selects one register within the particular Bus, Device, and Function as specified by the other fields in the Configuration Address Register. This field is mapped to A[07:02] during NSI or PCI Express Configuration cycles. |  |        | 0h              | RW                                       |
| 01:00        | Reserved        | <b>Reserved</b>  |  |        | 0h              |  |

### 13.6.0.2 Offset 0CFCh: CONFIG\_DATA - Configuration Data Register

CONFIG\_DATA is a 32-bit read/write window into configuration space. The portion of configuration space that is referenced by CONFIG\_DATA is determined by the contents of CONFIG\_ADDRESS.

**Table 13-4. Offset 0CFCh: CONFIG\_DATA: Configuration Data Register**

| Description: |             |  |  |        |                 |  |
|--------------|-------------|--|--|--------|-----------------|--|
| View: IA F   |             | Base Address: 0000h (IO)   |  |        |                 | Offset Start: 0CFCh<br>Offset End: 0CFCh |
| Size: 32 bit |             | Default: 00000000h   |  |        |                 | Power Well: Core                         |
| Bit Range    | Bit Acronym | Bit Description  |  | Sticky | Bit Reset Value | Bit Access                               |
| 31:00        | CDW         | <b>Configuration Data Window.</b> If bit 31 of CONFIG_ADDRESS is one any I/O access to the CONFIG_DATA register is mapped to configuration space using the contents of CONFIG_ADDRESS. |  |        | 0h              | RW                                       |

## 13.7 IMCH Memory Mapped Registers

Certain DRAM compensation control, EDMA control/status registers, NSI control/status and PCI Express will reside in memory mapped space instead of configuration space. These memory mapped address regions are setup through base address registers and capability pointers, which will reside in configuration address space. These registers are documented in the configuration register chapter. These base address registers follow the standard definition as found in the *PCI Express Specification*.

These memory mapped register regions must not be marked as WC (Write-Combining), as all accesses to the registers within these regions are limited to Dword access, and write-combining is not allowed. Further, these registers must not be accessed utilizing IA-32 core operations with a data operand size greater than 32-bits, as such access is strictly unsupported by the IMCH.

## 13.8 PCI Express Enhanced Configuration Mechanisms

PCI Express extends the configuration space to 4096 bytes per device/function as compared to 256 bytes allowed by PCI 2.2 configuration space. PCI Express configuration space is divided into a PCI 2.2 compatible region, which consists of the first 256 B of a logical device's configuration space and an extended PCI Express region which consists of the remaining configuration space. The PCI 2.2 compatible region can be accessed using either the mechanisms defined in the PCI 2.2 or using the enhanced PCI Express configuration access mechanism. All changes made using either access mechanism are equivalent; however, software is not allowed to interleave PCI Express and PCI access mechanisms to access the configuration registers of devices. The extended PCI Express region can only be accessed using the enhanced PCI Express configuration access mechanism.

### 13.8.1 PCI Express Configuration Transaction Header

The PCI Express Configuration Transaction Header includes an additional four bits for the Register Number field (ExtendedRegisterAddress[3:0]) to provide additional configuration space.

Figure 13-6. PCI Express Configuration Transaction Header

The PCI 2.2 compatible configuration access mechanism uses the same Request format as the enhanced PCI Express mechanism. For PCI compatible Configuration Requests, the Extended Register Address field must be all zeros.

To maintain compatibility with PCI configuration addressing mechanisms, system software must access the enhanced configuration space using Dword operations (Dword-aligned) only.

### 13.8.2 Enhanced Configuration Hardware Implications

The IMCH must translate the memory-mapped extended enhanced PCI Express configuration access cycles from the host processor to PCI Express configuration cycles.

Devices are required to respond to an additional four bits for decoding configuration register access. Devices must decode the ExtendedRegisterAddress[3:0] field of the Configuration Request Header. This field is used in conjunction with the Register Number to specify the Dword address of the register being accessed.

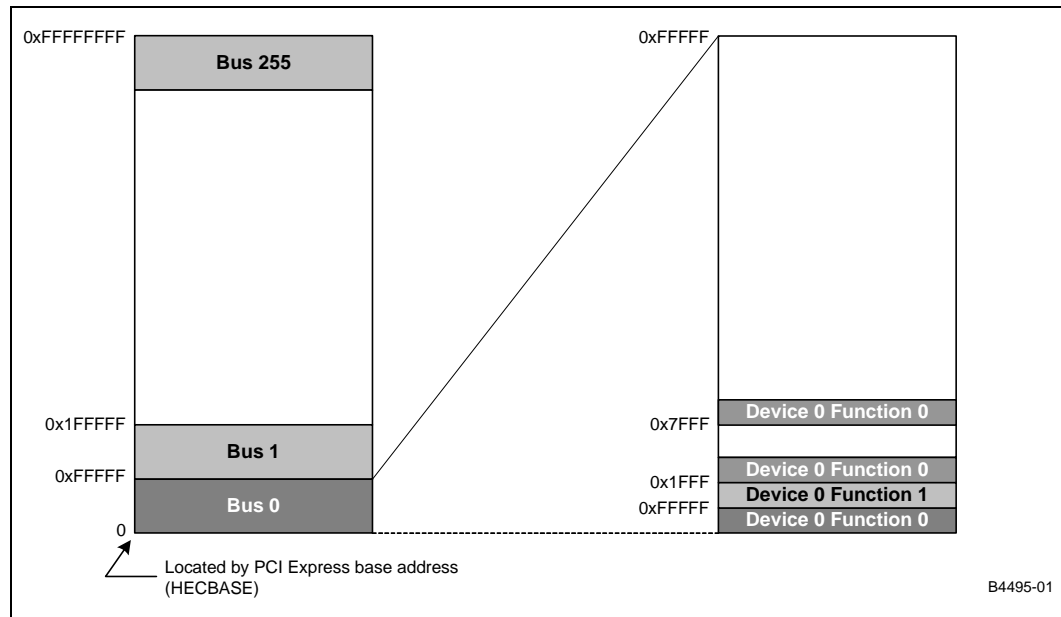

A PCI Express device must be able to operate with basic required functionality in a legacy environment without requiring access to any extended PCI Express configuration.

### 13.8.3 Enhanced Configuration Memory Address Map

The Enhanced Configuration Memory Address Map is positioned into CMI memory space by use of the PCI Express Enhanced Configuration Base register known as HECBASE. This register contains the address that corresponds to bits 31 to 28 of the base address for PCI Express enhanced configuration space below 4 GB. Configuration software will read this register to determine where the 256 Mbyte range of memory addresses resides for enhanced configuration. This register defaults to a value of E, which corresponds to E000 0000 for the IMCH. It is not intended that this value is ever changed by BIOS.

Figure 13-7. Enhanced Configuration Memory Address Map

### 13.8.4 Enhanced Configuration FSB Address Format

Table 13-5 presents the enhanced configuration address format for the front side bus. Note that bits 31:28 of Table 13-5 correspond to the default value of HECBASE.

Table 13-5. Enhanced Configuration FSB Address Format

| Bits  | Description     |
|-------|-----------------|
| 35:32 | 0h              |
| 31:28 | Eh              |
| 27:20 | Bus Number      |
| 19:15 | Device Number   |
| 14:12 | Function Number |
| 11:00 | Register Offset |

§ §

## 14.0 RAS Features and Exception Handling

---

CMI is designed to bring enterprise level reliability, availability, serviceability, usability, and manageability (RASUM) to the embedded platform.

### 14.1 RAS Features

#### 14.1.1 Data Protection

Due to the nature of having various data protection schemes on the different interfaces (ECC, parity, and CRC) it is necessary to be able to convert between them when transferring data internally. To accomplish this, protection of internal data is done with parity.

##### 14.1.1.1 DRAM ECC

The DRAM interface uses a standard SEC/DED ECC across a 64-bit data quantity.

##### 14.1.1.2 PCI Express Interface

These high-speed serial interfaces have traditional CRC protection. The data packets utilize a 32-bit CRC protection scheme, specifically the same CRC-32 used by Ethernet - 0x04C11DB7. The smaller and less error-prone link packets utilize a 16-bit CRC scheme. Since packets utilize 8B/10B encoding and not all encodings are used, this provides further data protection because illegal codes can be detected. Also, if errors are detected on the reception of data packets due to various transients, these data packets can be retransmitted. Hardware logic supports this link-level retry without software intervention.

##### 14.1.1.3 Data Error Propagation Between Interfaces/Units

Due to the nature of having various data protection schemes; ECC, parity, and CRC - it is necessary to be able to convert between the separate schemes. Beyond this requirement, it is necessary to indicate whether or not incoming data is corrupted. Also, it is useful to know when internal data has been corrupted during transit. To accomplish this, the IMCH uses parity to protect internal data. This requires units to add two parity bits for each 64 bits of data path width. Data received by a unit from outside the chip creates two parity bits to travel with the data, one provides parity on the upper 32 bits, and the other provides parity on the lower 32 bits. If either of the 32-bit halves is required to be poisoned, both halves are poisoned. This provides the user of the data a mechanism to recognize when a bit was flipped in transit by detecting when only one of the parity bits is bad. The user will flag this error condition as well as mark both halves bad. This covers both cases of the data starting out as either good or bad. If it started out as good, but a bit was flipped, it is indeed corrupted and must be marked as such. In the case where it started out as bad, and a bit was flipped, it is still corrupted, although probably a different data value than its starting value. This scheme works when all quantities being passed are 64 bits or greater. If a data path must be padded, it must be padded with zeroes. Even parity will be used for

this scheme; meaning that the total number of asserted bits including the parity bits is an even number of bits. This parity protection scheme applies to different interfaces on the chip hence the name: “Chip Two Bit Parity” or CTB parity.

*Note:* Due to EDMA byte realignment and parity manipulation, a single CTB parity bit error observed by the EDMA unit may poison either 2 or 4 DWords depending on the resultant alignment. Refer to the EDMA chapter for more details.

## 14.1.2 DRAM Data Integrity

### 14.1.2.1 Periodic Memory Scrubbing

When enabled a special DRAM memory scrubbing unit will walk through all DRAM, on a periodic basis, doing reads. Correctable errors found by the read are corrected and then the good data written back to DRAM. A write is only performed when a single bit error has been detected and is correctable, except when an incoming write to the same memory address is detected. In this case the scrub write is dropped and the scrub counter is advanced since this location is already being written. These transactions are treated as non-coherent, since these addresses are not placed on the FSB.

The scrub unit starts at an address that can be programmed and counts to 0. The scrub rate is also programmable so using this method, a 4 GB system can be completely scrubbed in less than a day. The cumulative effect of these scrub writes do not cause any noticeable degradation to memory bandwidth, although they will cause a greater latency for that one very infrequent read that is delayed due to the scrub write cycle.

### 14.1.2.2 DRAM Hardware Initialization

Hardware will be used to initialize main memory under the direction of BIOS. Once BIOS has programmed the IMCH with the DIMM profile, and has configured and calibrated the IMCH and populated DIMMs, it can utilize the MBIST CSRs to initialize and/or test populated memory. The initialization of MBISTCSR will traverse the target range of memory addresses as rapidly as possible, providing an order of magnitude performance improvement over IA-32 core-generated initialization or test.

The MBIST engine can be configured to choose values other than zero. The eight fixed hex data values selectable are alternating pairs of 0/F, A/5, 3/C, or 6/9. Alternate modes are provided in which LFSR random data may be used, or software explicitly specifies the full pattern of bits to be written in a collection of MBIST DATA registers with or without a shift after every write. In all cases of pattern based initialization and test, the MBIST function does NOT calculate ECC on the fixed pattern or programmed value to be written across the target address range. Rather, the fixed pattern is extended to cover the data devices as well as the ECC devices in the target DIMM, and a strict bit-wise comparison is utilized to determine whether read-back verification passes or fails.

Once all desired testing has been completed, WHQL requirements dictate that memory be completely initialized to “0” prior to transferring control to the operating system. To accomplish this, BIOS must clear all the MBISTDATA registers and utilize the explicit pattern mode of MBIST. It is possible to initialize memory a rank at a time, or en-masse, at the discretion of BIOS.

### 14.1.2.3 Uncorrectable Retries

The memory controller will not support uncorrectable retries.

#### 14.1.2.4 DRAM Refresh

As with any DRAM device, the storage element is inherently leaky, and must be recharged periodically to avoid loss of data integrity. Circuitry in the memory subsystem will ensure that refresh cycles occur in a periodic fashion across all active DIMMS to meet the specific DRAM requirements.

#### 14.1.2.5 DDR I/O Hardware Assisted Calibration

To determine read capture timing, hardware assisted calibration logic writes a pattern into memory and then reads the data back with different hardware settings until the optimum timing is found. Such calibration is described in the initialization walk-through provided in the clocking and reset chapter of this document. Hardware provides the capability to tune receive-enable timing, DQS centering within the received data eye (both vertical and horizontal), output drive strength, and receive termination.

### 14.1.3 PCI Express Data Integrity

The PCI Express interfaces will incorporate several features to make this interface as robust as possible without software intervention.

#### 14.1.3.1 PCI Express Training

To establish a connection between PCI Express endpoints, they both participate in a sequence of steps known as training. This sequence will establish the operational width of the link as well as adjust skews of the various lanes within a link so that the data sample points can correctly take a data sample off of the link. The x4 link pairs capable of collapsing to x8 will first attempt to train independently, and will collapse to a single link at the x8 width upon detection of a single device returning link ID information upstream. Once the number of links has been established, they will negotiate to train at the highest common width, and will step down in its supported link widths in order to succeed in training. The ultimate result may be that the link has trained as a X1 link. Although the bandwidth of this link size is substantially lower than a X8 link or even a X4 link, it will allow communication between the two devices. Software will then be able to interrogate the device at the other end of the link to determine why it failed to train at a higher width, something that would not be possible without support for the X1 link width. It should be noted that width negotiation is only done during training or retraining, but not recovery.

#### 14.1.3.2 PCI Express Retry

The PCI Express interface incorporates a link level retry mechanism. The hardware detects when a transmission packet is corrupted and a retry of that particular packet and all following packets will be performed. Although this will cause a temporary interruption in the delivery of packets, it does so in order to maintain the link integrity.

#### 14.1.3.3 PCI Express Recovery

When numerous errors occur, the hardware may determine that the quality of the connection is in question, and the end points can enter a quick training sequence known as recovery. The width of the connection will not be renegotiated, but the adjustment of skew between lanes of the link may occur. This occurs without any software intervention, but the software may be notified.

#### 14.1.3.4 PCI Express Retrain

If the hardware is unable to perform a successful recovery then the link will automatically revert to the polling state, and initiate a full retraining sequence. This is a drastic event with an implicit reset to the downstream device and all subordinate

devices, and is logged by the IMCH as a “Link Down” error. If escalation of this event is enabled, software is notified of the link DL\_DOWN condition. Once software has to be involved, then data will likely be lost, and processes need to be restarted, but this is still preferred to having to shut the system down, or go offline for an extended period of time.

#### 14.1.4 Test/Support Major Buses

##### 14.1.4.1 IICH XOR

The IICH supports XOR chain test mode. This non-functional test mode is a dedicated test mode when the chip is not operating in its normal manner.

##### 14.1.4.2 SMB (IMCH)

Full access to internal configuration registers via the System Management Bus is supported. This will allow a server management card to control system configuration and to read various error/status information. Accesses to devices marked as not present will still be possible through SMB.

##### 14.1.4.3 SMB (IICH)

The IICH SMB is SMBus 2.0 compliant and it is compatible with most 2-wire components that are also I2C compatible. The host interface allows IA-32 core to communicate via SMBus, the slave interface allows external microcontroller to access system resource in IICH. This IICH SMB does not support access to internal configuration registers.

##### 14.1.4.4 I<sup>2</sup>C

Access to the external DIMMs will be through the IICH, via I<sup>2</sup>C. This will be used to determine the nature of the DIMMs present in order to configure the memory subsystem correctly.

### 14.2 Exception Handling

There are a variety of exception conditions. Some are internally detected; some are detected on input pins; some are passed on behalf of other devices. All recognized exceptions eventually cause the IMCH to do one of the following: Send a SERR message, send a SCI message to the IICH, send a SMI message to the IICH, assert MCERR# on the front side bus, or do nothing. There is no determination of which errors go to which of the three error message schemes; it merely provides the capability for all combinations. It is the responsibility of the BIOS to determine the ultimate error reporting scheme. There will be an attempt to classify errors to whether they are fatal or non-fatal to more closely match the enterprise error presentation.

#### 14.2.1 FERR/NERR Global Register Scheme

Figure 14-1. Global FERR/NERR Register Representation

|             |                 |               |
|-------------|-----------------|---------------|
| Fatal (14b) | Non-Fatal (14b) | Reserved (4b) |
|-------------|-----------------|---------------|

The Global FERR register consists of three fields. The first or fatal field has 14b indicates the first signaled fatal global error from 14 different units. The second or non-fatal field indicates the first non-fatal global error that occurs from the same 14 different units. A non-fatal error may be either correctable or uncorrectable, but not

fatal. These two fields usually have at most one bit asserted in each field. In the event of simultaneous errors occurring in the same core clock, more than one bit in a field may be set. The third 4-bit field is reserved for future enhancements.

The Global NERR register consists of these same three fields with slightly different functionality. Instead of just the first fatal or non-fatal global errors recorded, this register indicates the second, third, fourth, etc. global errors that are reported by the IMCH.

These two registers do not indicate what the error was, they just indicate the severity of the error and what unit has more specific error information.

#### 14.2.1.1 FERR/NERR Unit Registers

Each major unit will have a minimum of a pair of registers, known as the first error (FERR) and next error (NERR). Each unit has different and specific error bit definitions, and provides the specific type of error; information that is not found in the global registers. It is important to note that the unit FERR/NERR registers are simpler than the global for purposes of reuse and ease of implementation. While the global FERR register has a fatal and a non-fatal field, which lock down separately, the unit FERR register only has one field. The unit is however still required to send out separate fatal and non-fatal indications to the global FERR register if they detect both classifications of errors. Some units will support only one type. A unit that doesn't detect errors would not support either type.

#### 14.2.1.2 Clearing FERR/NERR Registers

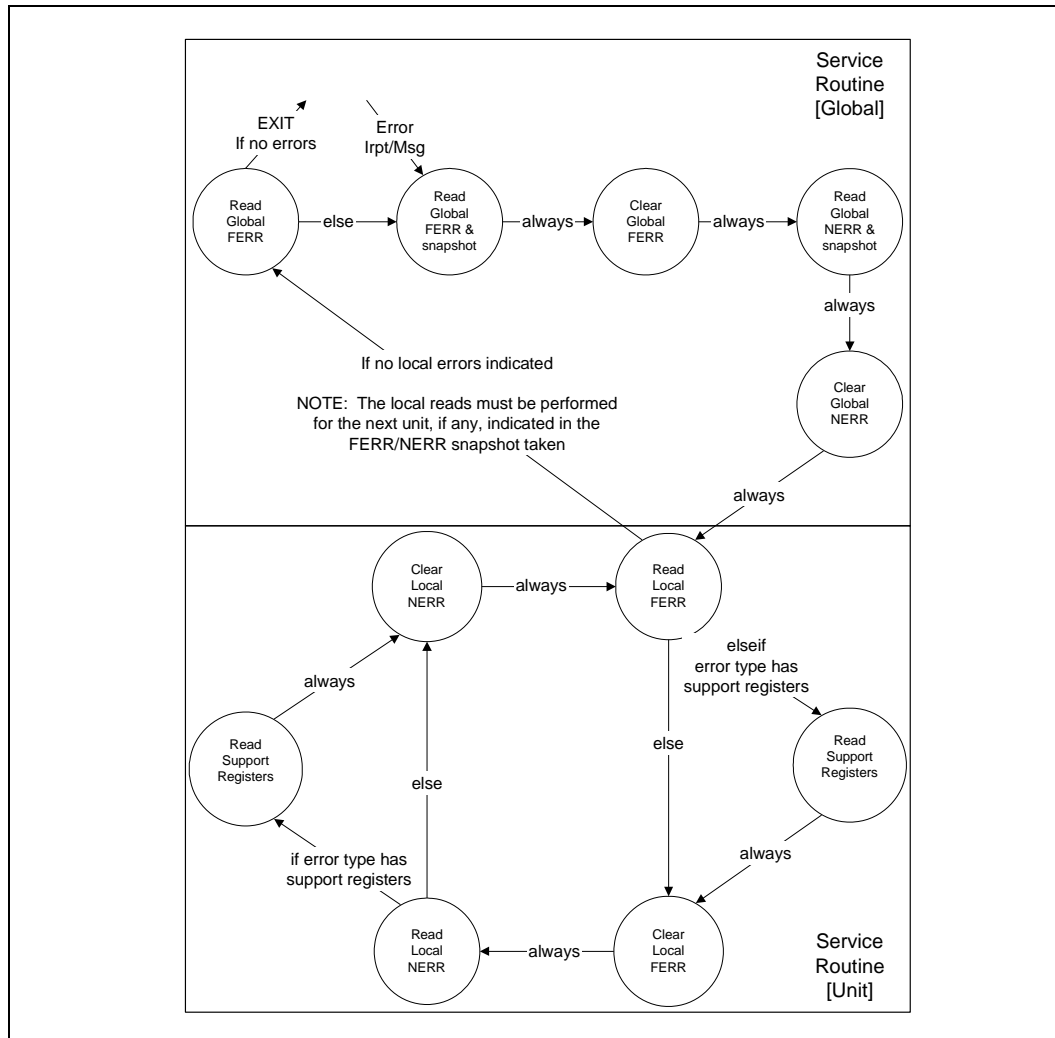

The following write-up is the recommended guideline to minimize the loss of errors information.

For a given FERR/NERR register pair, the FERR is read and then cleared first, and followed by the NERR. This sequence is true for either the global FERR/NERR register pair or any given unit. Any errors occurring after the FERR is cleared will then cause the FERR to have a non-zero value.

After the global FERR/NERR register pair is cleared, the unit FERR/NERR register pairs are interrogated, but only those indicated by the global FERR/NERR registers. Once the unit pair has been cleared, the unit FERR can be read again to ensure that no errors occurred during this local unit sequence. After the first unit FERR/NERR register pair has been serviced, this same sequence is performed for all other unit FERR/NERR register pairs that indicated errors in the global FERR/NERR registers. Once all unit error registers have been serviced, the final step is to read the global FERR register to determine if all system errors have been serviced. It is possible that errors could have occurred for a particular unit after that unit was serviced during the error routine, or that a unit had errors after the reading of the global FERR/NERR registers.

When clearing errors, software must clear all the FERR/NERR bits in the local interface registers before clearing the global FERR/NERR registers. If the local registers are not cleared first, then the global FERR/NERR registers will latch the same error again as soon as they are cleared. This implementation allows software to clear the local FERR/NERR registers, and then go clear the global FERR/NERR. S/W then reads back the global FERR/NERR and if it is non-zero, then a new error has occurred. If the global FERR/NERR has no bits set, then there are no more system errors.

Figure 14-2. FERR/NERR Service Routine

### 14.2.1.3 FERR/NERR Unit Specific

Each unit has different and specific error bit definitions.

### 14.2.1.4 SERR/SMI/SCI Enabling Registers

Each error reported has a full matrix of direction as to what error message it generates. For each unit FERR/NERR pair there are three more registers that enable each error for one of the three specific error messages. The logic does not appear to preclude the generation of all three messages for a single error, but this would not be a recommended configuration, and this needs to be looked into further. SERR stands for system error and is for reporting address and data parity errors, or any other catastrophic system error. SCI stands for system control interrupt and is a shareable interrupt used to notify the OS of ACPI events. SMI stands for System Management Interrupt and is an OS-transparent interrupt generated by events on legacy systems.

#### 14.2.1.5 MCERR Enabling Registers

An additional entry to the matrix of error signaling paths is the MCERR (machine check error) enabling register. In addition to the SERR, SMI, and SCI enabling registers, the MCERR enabling register allows the occurrence of an error to result in the MCERR# signal to be asserted on the front side bus. Machine check error is asserted to indicate an unrecoverable error, which is not a bus protocol violation.

#### 14.2.1.6 Error Escalation Register

Since all error bits in the error registers are fully configurable, meaning that a given error can be configured to go to any of the four messaging methods, no global error escalation mechanism is required. Although, the errors occurrence is accumulated in the global FERR/NERR registers, all error messaging is initiated from the units themselves, and not from a central location.

#### 14.2.1.7 Error Masking

A new feature being added for CMI is the concept of an error masking register. Each unit has a mask register, which blocks the recognition/logging/reporting of each specific error type. Since the error will not be recognized when the corresponding mask bit is set, no error messages can be generated. This feature allows intelligent software to ignore specific error types during critical areas of code, where it does not want to be informed of errors that it will create, without ignoring other error types that it doesn't expect to happen. These mask bits will default to unmasked, and must be set by software or BIOS to take effect.

##### 14.2.1.7.1 Locking DRAM Address and Syndrome on Errors

The first pair of error logging registers for CE (correctable errors) DRAM\_SECF\_ADD and DRAM\_SECF\_SYNDROME are locked when bit 0 of the DRAM\_FERR is set. The second pair of error logging registers for CE (correctable errors) DRAM\_SECN\_ADD and DRAM\_SECN\_SYNDROME are locked when bit 0 of the DRAM\_NERR is set. These pairs of two registers will retain their value even if new CE's are found. This allows the first (and possibly next) error to be captured and held instead of retaining the last. Corrected data errors as a result of either demand reads or scrubber-initiated traffic will be reflected in these error registers.

The logging register for UE (uncorrectable errors), DRAM\_DED\_ADD is locked when bit 1 of the DRAM\_FERR or DRAM\_NERR is set. This register holds the address of uncorrectable errors on data reads not initiated by the scrubber for either periodic or demand scrubbing.

The logging register for Scrub detected errors, DRAM\_SCRUB\_ADD should be locked when bit 2 of the DRAM\_FERR or DRAM\_NERR is set. This register holds the address for scrubber-initiated transactions for either demand or periodic memory scrubbing.

When the FERR/NERR registers are cleared the logging registers are free to update their contents until such time that either of these FERR/NERR registers again lock.

#### 14.2.1.8 PCI Express Errors and Errors on Behalf of PCI Express

IMCH-specific error detection, masking, and escalation mechanisms operate on a parallel path to their standardized counterparts included in the *PCI Express\* Interface Specification, Rev 1.0a*. PCI Express errors are classified as either correctable or uncorrectable. Uncorrectable errors are further broken down as fatal or non-fatal.

PCI Express specified correctable errors are logged in the Correctable Error Status Register (Device 2-3, Function 0, Offset 110 - 113h), unless they are masked by a corresponding bit in the Correctable Error Detect Mask Register (Device 2-3, Function 0, Offset 150-153h).

PCI Express specified uncorrectable errors are logged in the Uncorrectable Error Status Register (Device 2-3, Function 0, Offset 104-107h), unless they are masked by a corresponding bit in the Uncorrectable Error Detect Mask Register (Device 2-3, Function 0, Offset 14C-14Fh). The Uncorrectable Error Severity Register (Device 2-3, Function 0, Offset 10C - 10Fh) determines if bits in the Uncorrectable Status register are treated as uncorrectable fatal or uncorrectable non-fatal errors. The Device Status register (6Eh) bits are set when the corresponding category of bit is set in the uncorrectable and correctable status registers.

Reporting of non-masked error bits to the root complex hierarchy of PCI Express error registers is controlled on three different levels. Individual errors are masked for reporting by the Uncorrectable Error Mask (Device 2-3, Function 0, Offset 108-10Bh) and the Correctable Error Mask (Device 2-3, Function 0, Offset 114-117h) registers. Individual error category (fatal, non-fatal, correctable, or unsupported) reporting is enabled in the Device Control Register (Device 2-3, Function 0, Offset 6Ch) bits 3:0. Finally, uncorrectable error reporting (fatal or non-fatal) reporting may also be enabled by setting the SERR Enable bit in the PCI Command Register (Device 2-3, Function 0, Offset 04-05h).

There is an error pointer, in the Advanced Error Capability and Control Register (Device 2-3, Function 0, Offset 118-11Bh) which will log the first uncorrectable error that is enabled for reporting. Also some uncorrectable errors, when they are the first uncorrectable error, will log their corresponding header log in the Header Log Registers (Device 2-3, Function 0, Offset 11C-12Bh). An error pointer for unmasked correctable errors has been added in the Error Do Command Register (Device 2-3, Function 0, Offset 148-14Bh).

These internally detected errors when they are reported are referred to as virtual error messages. These are different from errors which are detected by the downstream device which then sends an error message to the root complex, which are referred to as externally detected or "received" error messages. The received system error bit in the Secondary Status Register (Device 2-3, Function 0, Offset 1E-1F) is set when either fatal or non-fatal messages are received at the root complex.

At this point in the PCI Express error hierarchy, these virtual error messages are logically ORed with the received error messages, and will just be referred to as fatal, non-fatal, or correctable error messages, no reference to either virtual or received.

When enabled by the enable system error bit in the PCI Command Register, any fatal or non-fatal messages will set the signaled system error bit in the PCI Status register (Device 2-3, Function 0, Offset 06-07h). The Root Port Error Message Status Register (Device 2-3, Function 0, Offset 130-133h) will indicate first and multiple errors of each error message category, and the corresponding error source IDs of the first correctable and uncorrectable error messages will be the logged in the Error Source ID register (134h).

These errors that have been reported to the root complex can now be reported to the system, via the category enables in the Root Port Error Command Register (Device 2-3, Function 0, Offset 12C-12Fh) for interrupts. These interrupts can be in the form of

legacy type interrupts if so enabled in the PCI command register and MSI is not enabled, or message signaled interrupts if so enabled in the MSI Capabilities register (Device 2-3, Function 0, Offset 5A-5Bh).

The Root Port Control register (Device 2-3, Function 0, Offset 80-83h) enables errors to be reported to the system via other IMCH specific methods, again on a category basis. The Error Do Command register, selects between the four methods of system signaling, SERR, SCI, SMI, and MCERR.

The error model outside of PCI Express includes a local FERR/NERR pair of registers in each unit and a global FERR/NERR pair of registers that indicates which unit had problems. The Local FERR/NERR register pair (Device 2-3, Function 0, Offset 160-163h & 164-167h) includes PCI Express defined errors and additional detected errors within the PCI Express unit. This register pair has three sets of error bits for the three categories of errors: the first set for received messages, the second set for internally detected errors (virtual messages need not have been generated), and unit specific errors outside of the PCI Express spec, and the third set for device errors. This error scheme sets FERR/NERR error bits regardless whether or not they were reported via interrupt or other signaling method.

The signaling due to unit specific errors has its logic dependent on the PCI Express Unit Error Register (Device 2-3, Function 0, Offset 140-143h). The errors flagged in this register must be cleared before exiting the error service routine.

The signaling due to received messages has its logic dependent on the Root Error Message Status register (Device 2-3, Function 0, Offset 130-133h). The Root Error Status register must be cleared before exiting the error service routine.

The signaling due to internally detected PCI Express errors has its logic dependent on the Device Status register (Device 2-3, Function 0, Offset 6E-6Fh). The Device Status register must be cleared before exiting the error service routine.

Software must clear the global FERR first, and then the global NERR. Software then clears the local FERR register and the local NERR register of each unit in that order. After clearing FERR and then clearing NERR, the local FERR must be read to make sure that remains '0' indicating no more errors have occurred during the clearing of these registers. After all units' FERR & NERR registers have been cleared, the global FERR is again read to ensure that no additional errors occurred during the clearing sequence.

Since the PCI Express units have more hierarchy than other units, more registers must be cleared other than just the local FERR and NERR registers. After clearing the local FERR & NERR, one must also clear the Root Error Status, Unit Error Status, Device Status, Uncorrectable Error Status, and Correctable Error Status registers. One only needs to clear the PCI Status and Secondary Status registers if these are being utilized in a given particular error model. No logic depends on the state of any of these status bits. If not utilized, they can be ignored.

If a PCI Express error handler is used, with no knowledge of the FERR/NERR registers, then clear the PCI Express specific registers: Device Status, Uncorrectable Error Status, Correctable Error Status, and Root Error Status. The IMCH specific unit errors would not be enabled for reporting errors. [Figure 14-3](#) helps to illustrate the relationship of the error registers from the *PCI Express\* Specification*.

#### 14.2.1.9 Configurable Error Containment at the Legacy Interface

Depending on the I/O devices in use, data errors could have catastrophic effects when allowed to propagate. The Legacy interface has the configurability of allowing the poisoning and propagation of data errors or to stop the data from transferring at all and escalate the data errors to the system. This is extreme behavior, which can be enabled or disabled, in order to prevent data corruption on a critical device, and is referred to as "stop and scream". Refer to the Error Injection section for more details.

Figure 14-3. PCI Express Error Handling

### 14.3 Error Conditions Signaled

The IICH-notification action taken by the IMCH upon detection of an error is controlled through three registers. The SERRCMD register enables the generation of the SERR message, the SCICMD register enables the generation of the SCI message, and the SMICMD register enables the generation of SMI messages. Special cycle types of DO\_SERR, DO\_SCI, or DO\_SMI may be transmitted to the IICH. The IICH receives the exception notification from the IMCH and may be configured to notify the processor of the condition.

Once the processor has been interrupted, it polls the system to determine the cause of the exception. If the IMCH initiated the exception condition by sending a message over NSI, then the processor is so informed by the IICH. At this point, the processor may read the IMCH's error status registers to determine the exact cause of the condition. The processor explicitly clears the status bit that points to the exception condition.

The IMCH in addition to signaling errors to the IICH for further handling, has added the capability of signaling the processor directly by use of the front side bus error signal MCERR#. The processor, upon observing this signal active, enters into special error handling code known as machine check code.

For each type of error detected in a given unit, there is a bit that corresponds to that error in the unit\_FERR, unit\_NERR, SERRCMD\_unit, SMICMD\_unit, SCICMD\_unit, and MCERRCMD\_unit registers. (Note that one and only one xCMD bit can be enabled per error type.) The first occurrence of an error type will be indicated by the bit assertion in the unit\_FERR. If that error occurs again than the corresponding bit will be set in the unit\_NERR register. When a bit is asserted in either the unit\_FERR or unit\_NERR, and if the corresponding enable bit is set in one of the named CMD registers, then an error signal will be asserted, corresponding to the name of the CMD register: DO\_SERR, DO\_SCI, DO\_SMI, or DO\_MCERR. The assertion of the DO\_SERR signal also requires that the SERR enable in the PCICMD register is set. The assertion of the DO\_SERR signal also causes the appropriate SERR signaled status bit to be set in the PCISTS register.

**Table 14-1. Pseudocode for EDMA Errors (Sheet 1 of 2)**

| Condition   | Source   | Action  | Status        |
|---|----------|---|---------------|
| The descriptor pointer in next descriptor address register is of incorrect type or range for EDMA channel 3.                | Internal | <b>DO_SERR</b> and set PCISTS10[SSE] if (PCICMD10[SERRE]=1 AND EDMA_EMASK[7]=0 AND SERRCMD_EDMA[7]=1 AND R_EDGE{EDMA_FERR[31] OR EDMA_NERR[31]});<br><b>DO_SMI</b> if EDMA_EMASK[7]=0 AND SMICMD_EDMA[7]=1 AND R_EDGE{EDMA_FERR[31] OR EDMA_NERR[31]});<br><b>DO_SCI</b> if EDMA_EMASK[7]=0 AND SCICMD_EDMA[7]=1 AND R_EDGE{EDMA_FERR[31] OR EDMA_NERR[31]});<br><b>DO_MCERR</b> if EDMA_EMASK[7]=0 AND MCERRCMD_EDMA[7]=1 AND R_EDGE{EDMA_FERR[31] OR EDMA_NERR[31]}); | EDMA_FERR[31] |
| The descriptor pointer in next descriptor address register is not aligned to eight double-word boundary for EDMA channel 3. | Internal | <b>DO_SERR</b> and set PCISTS10[SSE] if (PCICMD10[SERRE]=1 AND EDMA_EMASK[6]=0 AND SERRCMD_EDMA[6]=1 AND R_EDGE{EDMA_FERR[30] OR EDMA_NERR[30]});<br><b>DO_SMI</b> if EDMA_EMASK[6]=0 AND SMICMD_EDMA[6]=1 AND R_EDGE{EDMA_FERR[30] OR EDMA_NERR[30]});<br><b>DO_SCI</b> if EDMA_EMASK[6]=0 AND SCICMD_EDMA[6]=1 AND R_EDGE{EDMA_FERR[30] OR EDMA_NERR[30]});<br><b>DO_MCERR</b> if EDMA_EMASK[6]=0 AND MCERRCMD_EDMA[6]=1 AND R_EDGE{EDMA_FERR[30] OR EDMA_NERR[30]}); | EDMA_FERR[30] |
| The source address does not comply with the source type or range for EDMA channel 3.  | Internal | <b>DO_SERR</b> and set PCISTS10[SSE] if (PCICMD10[SERRE]=1 AND EDMA_EMASK[5]=0 AND SERRCMD_EDMA[5]=1 AND R_EDGE{EDMA_FERR[29] OR EDMA_NERR[29]});<br><b>DO_SMI</b> if EDMA_EMASK[5]=0 AND SMICMD_EDMA[5]=1 AND R_EDGE{EDMA_FERR[29] OR EDMA_NERR[29]});<br><b>DO_SCI</b> if EDMA_EMASK[5]=0 AND SCICMD_EDMA[5]=1 AND R_EDGE{EDMA_FERR[29] OR EDMA_NERR[29]});<br><b>DO_MCERR</b> if EDMA_EMASK[5]=0 AND MCERRCMD_EDMA[5]=1 AND R_EDGE{EDMA_FERR[29] OR EDMA_NERR[29]}); | EDMA_NERR[29] |
| The source address is not aligned as specified by the source address bit for EDMA channel 3.                                | Internal | <b>DO_SERR</b> and set PCISTS10[SSE] if (PCICMD10[SERRE]=1 AND EDMA_EMASK[4]=0 AND SERRCMD_EDMA[4]=1 AND R_EDGE{EDMA_FERR[28] OR EDMA_NERR[28]});<br><b>DO_SMI</b> if EDMA_EMASK[4]=0 AND SMICMD_EDMA[4]=1 AND R_EDGE{EDMA_FERR[28] OR EDMA_NERR[28]});<br><b>DO_SCI</b> if EDMA_EMASK[4]=0 AND SCICMD_EDMA[4]=1 AND R_EDGE{EDMA_FERR[28] OR EDMA_NERR[28]});<br><b>DO_MCERR</b> if EDMA_EMASK[4]=0 AND MCERRCMD_EDMA[4]=1 AND R_EDGE{EDMA_FERR[28] OR EDMA_NERR[28]}); | EDMA_FERR[28] |
| The destination address does not comply with the destination type or range for EDMA channel 3.                              | Internal | <b>DO_SERR</b> and set PCISTS10[SSE] if (PCICMD10[SERRE]=1 AND EDMA_EMASK[3]=0 AND SERRCMD_EDMA[3]=1 AND R_EDGE{EDMA_FERR[27] OR EDMA_NERR[27]});<br><b>DO_SMI</b> if EDMA_EMASK[3]=0 AND SMICMD_EDMA[3]=1 AND R_EDGE{EDMA_FERR[27] OR EDMA_NERR[27]});<br><b>DO_SCI</b> if EDMA_EMASK[3]=0 AND SCICMD_EDMA[3]=1 AND R_EDGE{EDMA_FERR[27] OR EDMA_NERR[27]});<br><b>DO_MCERR</b> if EDMA_EMASK[3]=0 AND MCERRCMD_EDMA[3]=1 AND R_EDGE{EDMA_FERR[27] OR EDMA_NERR[27]}); | EDMA_FERR[27] |

Table 14-1. Pseudocode for EDMA Errors (Sheet 2 of 2)

| Condition  | Source   | Action   | Status        |
|--|----------|--|---------------|
| The destination address is not aligned as specified by the destination address bit for EDMA channel 3. | Internal | <b>DO_SERR</b> and set PCISTS10[SSE] if (PCICMD10[SERRE]=1 AND EDMA_EMASK[2]=0 AND SERRCMD_EDMA[2]=1 AND R_EDGE{EDMA_FERR[26] OR EDMA_NERR[26]});<br><b>DO_SMI</b> if EDMA_EMASK[2]=0 AND SMICMD_EDMA[2]=1 AND R_EDGE{EDMA_FERR[26] OR EDMA_NERR[26]};<br><b>DO_SCI</b> if EDMA_EMASK[2]=0 AND SCICMD_EDMA[2]=1 AND R_EDGE{EDMA_FERR[26] OR EDMA_NERR[26]};<br><b>DO_MCERR</b> if EDMA_EMASK[2]=0 AND MCERRCMD_EDMA[2]=1 AND R_EDGE{EDMA_FERR[26] OR EDMA_NERR[26]}; | EDMA_FERR[26] |
| Data parity Error in reading source data from system memory for EDMA channel 3.                        | Internal | <b>DO_SERR</b> and set PCISTS10[SSE] if (PCICMD10[SERRE]=1 AND EDMA_EMASK[1]=0 AND SERRCMD_EDMA[1]=1 AND R_EDGE{EDMA_FERR[25] OR EDMA_NERR[25]});<br><b>DO_SMI</b> if EDMA_EMASK[1]=0 AND SMICMD_EDMA[1]=1 AND R_EDGE{EDMA_FERR[25] OR EDMA_NERR[25]};<br><b>DO_SCI</b> if EDMA_EMASK[1]=0 AND SCICMD_EDMA[1]=1 AND R_EDGE{EDMA_FERR[25] OR EDMA_NERR[25]};<br><b>DO_MCERR</b> if EDMA_EMASK[1]=0 AND MCERRCMD_EDMA[1]=1 AND R_EDGE{EDMA_FERR[25] OR EDMA_NERR[25]}; | EDMA_FERR[25] |
| Received configuration write command when EDMA is in Normal Mode for EDMA channel 3.                   | Internal | <b>DO_SERR</b> and set PCISTS10[SSE] if (PCICMD10[SERRE]=1 AND EDMA_EMASK[0]=0 AND SERRCMD_EDMA[0]=1 AND R_EDGE{EDMA_FERR[24] OR EDMA_NERR[24]});<br><b>DO_SMI</b> if EDMA_EMASK[0]=0 AND SMICMD_EDMA[0]=1 AND R_EDGE{EDMA_FERR[24] OR EDMA_NERR[24]};<br><b>DO_SCI</b> if EDMA_EMASK[0]=0 AND SCICMD_EDMA[0]=1 AND R_EDGE{EDMA_FERR[24] OR EDMA_NERR[24]};<br><b>DO_MCERR</b> if EDMA_EMASK[0]=0 AND MCERRCMD_EDMA[0]=1 AND R_EDGE{EDMA_FERR[24] OR EDMA_NERR[24]}; | EDMA_FERR[24] |
| EDMA channel 2 errors  | Internal | Same bit functionality as bits 31:24 except these are for EDMA channel 2. (Use bits 23:16)   |               |
| EDMA channel 1 errors  | Internal | Same bit functionality as bits 31:24 except these are for EDMA channel 1. (Use bits 15:8)  |               |
| EDMA channel 0 errors  | Internal | Same bit functionality as bits 31:24 except these are for EDMA channel 0. (Use bits 7:0)   |               |

§ §

## 15.0 Platform Management (IMCH)

---

This chapter provides an overview of the system management support provided by the IMCH. There are two primary management support features in the IMCH:

- Integrated system management bus (SMBus) interface
- Architectural support for platform power management

*Note:* Material in this chapter is specific to the IMCH and does not apply to the IICH.

### 15.1 Integrated SMBus Interface

The IMCH provides a fully functional System Management Bus (SMBus) target interface, which provides direct access to all internal IMCH configuration register space. SMBus access is available to all internal configuration registers, regardless of whether or not the register in question is normally accessed via the memory-mapped mechanism or the standard configuration mechanism. This provides for highly flexible platform management architectures, particularly given a baseboard management controller (BMC) with an integrated network interface controller (NIC) function.

### 15.2 SMBus Target Architecture

The SMBus target integrated into the IMCH is compatible with the *System Management Bus (SMBus) Specification, Version 2*. A brief overview of the SMBus architecture is provided below for reference.

#### 15.2.1 High Level Operation

The SMBus interface consists of two interface pins: a clock and serial data. Multiple initiator and target devices may be electrically present on the same pair of signals. Each target recognizes a start signaling semantic and recognizes its own seven-bit address to identify pertinent bus traffic. The IMCH address is hard-coded to 011\_0000.

The protocol allows for traffic to stop in “midsentence,” requiring all targets to tolerate and properly “clean up” in the event of an access sequence that is abandoned by the initiator prior to normal completion. The IMCH is compliant with this requirement.

The protocol comprehends “wait states” on read and write operations, which the IMCH takes advantage of to keep the bus busy during internal configuration space accesses.

##### 15.2.1.1 SMBus Register Summary

Table 15-1 provides a quick-reference summary of the SMBus target register space. These registers are part of the target itself and therefore not accessible by any other means other than the direct SMBus connection.

**Table 15-1. SMBus Register Summary**

| Symbol | Full Name/Function                                    |
|--------|---|
| CMD    | Command   |
| BYTCNT | Byte Count  |
| ADDR3  | Bus Number (Only lower five bits are utilized)        |
| ADDR2  | Device/Function Number                                |
| ADDR1  | Extended Reg Number (Bits 03:00 - 4 k page extension) |
| ADDR0  | Register Number (offset into function space)          |
| DATA3  | Data, fourth byte (31:24)                             |
| DATA2  | Data, third byte (23:16)                              |
| DATA1  | Data, second byte (15:08)                             |
| DATA0  | Data, first byte (07:00)                              |
| STS    | Status, only for reads                                |

**Table 15-2. SMBus Memory-Mapped Register Summary**

| Symbol | Full Name/Function                                      |
|--------|---|
| CMD    | Command   |
| BYTCNT | Byte Count  |
| ADDR3  | Destination Memory (BAR Selection)                      |
| ADDR2  | Address Offset 23:16 (Filler-used to zero out register) |
| ADDR1  | Address Offset 15:08 (15:12 not used)                   |
| ADDR0  | Address Offset 07:00 (11:00 used for 4 K page)          |
| DATA3  | Data, fourth byte (31:24)                               |
| DATA2  | Data, third byte (23:16)                                |
| DATA1  | Data, second byte (15:08)                               |
| DATA0  | Data, first byte (07:00)                                |
| STS    | Status, only for reads                                  |

**Table 15-3. ADDR3 Memory Assignments**

| ADDR3      | Destination Memory Assignments |
|------------|--------------------------------|
| 00_000000  | NSI                            |
| 00_000001  | EDMA                           |
| 00_001000  | DDR2                           |
| All others | Reserved                       |

Table 15-1 and Table 15-2 indicate the sequence of data as it is presented on the SMBus following the byte address of the IMCH itself. This is not necessarily to indicate any specific register stack or array implemented in the IMCH. The registers can take on different meanings depending on whether it is a configuration or memory-mapped access type. The command indicates how to interpret the registers. Refer to the *System Management Bus (SMBus) Specification, Version 2* for interface protocol details.

### 15.2.1.2 Internal Register Access Mechanism

All SMBus accesses to the internal register space are initiated via a write to the CMD register. Any register writes received by the IMCH while a command is already in progress receive a NAK to prevent spurious operation. The master is no longer expected to poll the CMD register to prevent clobbering a command in progress prior to issuing further writes. The SMBus access is delayed by stretching the clock until such time that the data is delivered. Note that per the *System Management Bus (SMBus) Specification, Version 2*, this interval can not be longer than 25 ms. To set up an internal access, the four ADDR bytes are programmed, followed by a command indicator to execute a read or write. Depending on the type of access, these four bytes indicate either the Bus number, Device, Function, Extended Register Offset, and Register Offset; or the Memory-mapped region selected and the address within the region. The configuration type access utilizes the traditional bus number, device, function, and register offset; but also uses an extended register offset, which expands the addressable register space from 256B to 4 KB. The memory-mapped type access redefines these bytes to be a memory-mapped region selection byte and the memory address within the region. [Table 15-2](#) and [Table 15-3](#) show this information.

FSB-initiated accesses to registers are serviced through the configuration ring. For these registers, it is perfectly legal for an SMBus access to be requested while an FSB-initiated access is already in progress. The IMCH supports “wait your turn” arbitration to resolve all collisions and overlaps, such that the access that reaches the configuration ring arbiter first is serviced first while the conflicting access is held off. An absolute tie at the arbiter is resolved in favor of the FSB. Note that SMBus accesses must be allowed to proceed even if the internal transaction handling hardware and one or more of the other external interfaces are hung or otherwise unresponsive.

### 15.2.1.3 SMBus Register Definitions

#### 15.2.1.3.1 CMD – Command Register

When written, this Command Register indicates the type and size of transfer. All configuration accesses from the SMBus port are initiated by writing to this register. While a command is in progress, all future writes or reads are NACK'ed by the IMCH to avoid overwriting registers while in use. The two command size fields allow for more flexibility on how the data payload is transferred, both internally and externally. The begin and end bits support the breaking of the transaction up into smaller transfers, by defining the start and finish of an overall transfer.

**Table 15-4. Command (CMD) Register (Sheet 1 of 2)**

| Bit | Description  |
|-----|--|
| 07  | Begin Transaction Indicator<br>0 = Current transaction is NOT the first of a read or write sequence.<br>1 = Current transaction is the first of a read or write sequence. On a single transaction sequence this bit is set along with the End Transaction Indicator. |
| 06  | End Transition Indicator<br>0 = Current transaction is NOT the last of a read or write sequence.<br>1 = Current transaction is the last of a read or write sequence. On a single transaction sequence this bit is set along with the Begin Transaction Indicator.    |
| 05  | Address Mode: Indicates whether memory or configuration space is being accessed in this SMBus sequence.<br>0 = Memory Mapped Mode<br>1 = Configuration Register Mode   |

**Table 15-4. Command (CMD) Register (Sheet 2 of 2)**

| Bit    | Description  |
|--------|--|
| 04     | Reserved - Set to 0.   |
| 03: 02 | Internal Command Size: All accesses are naturally aligned to the access width. This field specifies the internal command to be issued by the SMBus slave logic to the IMCH core.<br>00 = Read Dword<br>01 = Write Byte<br>10 = Write Word<br>11 = Write Dword                        |
| 01: 00 | SMBus Command Size: This field specifies the SMBus command to be issued on the SMBus. This field is used as an indication of the length of the transfer so that the slave knows when to expect the PEC packet (if enabled).<br>00 = Byte<br>01 = Word<br>10 = Dword<br>11 = Reserved |

**15.2.1.3.2 BYTCNT – Byte Count Register**

The byte count register indicates the number of bytes following the byte count register when performing a write or when setting up for a read. The byte count is also used when returning data to indicate the following number of bytes (including the status byte), which are returned prior to the data. Note that the byte count is only transmitted for block type accesses on SMBus. SMBus word or byte accesses do not use the byte count.

**Table 15-5. Byte Count Register**

| Position | Description   |
|----------|---|
| 07:00    | Byte Count: Number of bytes following the byte count for a transaction. |

**15.2.1.3.3 ADDR3 – Address Byte 3 Register**

This register must be programmed with the Bus Number of the desired configuration register in the lower five bits for a configuration access. For a memory-mapped access this field selects which memory-map region is being accessed. There is no status bit to poll to see if a transfer is currently in progress, because by definition, if the transfer completed, the task is done. The clock stretch is used to guarantee the transfer is truly complete.

The EP80579 does not support access to other logical bus numbers via the SMBus port. All registers “attached” to the configuration mechanism that the SMBus has access to, reside on logical bus#0.

**Table 15-6. Address Byte 3 Register**

| Position | Configuration Register Mode Description  | Memory Mapped Mode Description                             |
|----------|--|--|
| 07:05    | Ignored.   | Memory map region to access.                               |
| 04:00    | Bus Number: Must be zero: the SMBus port can only access devices on the IMCH and all devices are bus zero. | 00h = NSI<br>01h = EDMA<br>08h = DDR2<br>Others = Reserved |

#### 15.2.1.3.4 ADDR2 – Address Byte 2 Register

This register must be programmed with the Device Number and Function Number of the desired configuration register if for a configuration type access, otherwise it must be set to zero.

**Table 15-7. ADDR2 – Address Byte 2 Register**

| Position | Configuration Register Mode Description         | Memory Mapped Mode Description |
|----------|---|--------------------------------|
| 07:03    | Device Number. Can only be devices on the IMCH. | Zeros used for padding.        |
| 02:00    | Function Number.                                |                                |

#### 15.2.1.3.5 ADDR1 – Address Byte 1 Register

This register must be programmed with the upper address bits for the register with the 4K region. Whether it is a configuration or memory-map type of access, only the lower bits are utilized, the upper four bits are ignored.

**Table 15-8. ADDR1 – Address Byte 1 Register**

| Position | Description   |
|----------|---|
| 07:04    | Ignored.  |
| 03:00    | Extended Register Number. Upper address bits for the 4 K region of register offset. |

#### 15.2.1.3.6 ADDR0 – Address Byte 0 Register

This register indicates the lower eight address bits for the register within the 4 K region, regardless of whether it is a configuration or memory-map type of access.

**Table 15-9. ADDR0 – Address Byte 0 Register**

| Position | Description      |
|----------|------------------|
| 07:00    | Register Offset. |

#### 15.2.1.3.7 DATA – Data Register

This field is used to receive the read data or to provide the write data associated with the desired register.

At the completion of a read command, this field contains the data retrieved from the selected register. All reads return an entire aligned Dword (32 bits) of data.

The appropriate number of byte(s) of this 32-bit logical register must be written with the desired write data prior to issuing a write command. For a byte write only, bits 7:0 are used, for a Word write, only bits 15:0 are used, and for a Dword write, all 32 bits are used.

Table 15-10. Offset 04-07: DATA - Data Register

| Bits  | Type | Reset | Description                       |
|-------|------|-------|-----------------------------------|
| 31:24 | RW   | 00h   | Byte 3 (DATA3): Data bits [31:24] |
| 23:16 | RW   | 00h   | Byte 2 (DATA2): Data bits [23:16] |
| 15:08 | RW   | 00h   | Byte 1 (DATA1): Data bits [15:8]  |
| 07:00 | RW   | 00h   | Byte 0 (DATA0): Data bits [7:0]   |

#### 15.2.1.3.8 STS – Status Register

For a read cycle, the data is preceded by a byte of status. Table 15-11 shows how these bits are defined.

Table 15-11. Status Register

| Position | Description  |
|----------|--|
| 07       | Internal Timeout<br>0 = SMBus request is completed within 2 ms internally<br>1 = SMBus request is not completed in 2 ms internally       |
| 06       | Ignored  |
| 05       | Internal Master Abort<br>0 = No Internal Master Abort Detected<br>1 = Detected an Internal Master Abort                                  |
| 04       | Internal Target Abort<br>0 = No Internal Target Abort Detected<br>1 = Detected an Internal Target Abort                                  |
| 03:01    | Ignored  |
| 00       | Successful<br>0 = The last SMBus transaction was not completed successfully<br>1 = The last SMBus transaction was completed successfully |

#### 15.2.1.4 Unsupported Access Addresses

It is possible for an SMBus master to program an unsupported bit combination into the ADDR registers. The IMCH does not support such usage, and may not gracefully terminate such accesses.

#### 15.2.1.5 SMBus Transaction Pictograms

Since the new SMBus target interface is of enterprise origin, it is more complex than the original SMBus target interface of desktop origin. The following drawings are included to demonstrate the different types of transactions, especially how they can be broken up into multiple smaller transfers.

## 15.2.2 Suggested SMBus Usage Models

### 15.2.2.1 Remote Error Handling

The EP80579 supports error escalation via both SMI and MCERR FSB signaling, thus error handling may be implemented in system management mode (SMM) software, machine check architecture (MCA) software, or a combination of the two. Such software could direct a BMC with an integrated NIC to “call home” when errors are reported by the IMCH. The BMC could then interrogate internal IMCH error logging registers under remote control across the network interface, providing full identification and isolation of reported errors as described elsewhere in this document. The possibility also exists for remotely managed reconfiguration via the SMBus target port, as well as remotely managed system reboot via the BMC (if necessary).

### 15.2.2.2 Remote Platform Monitoring

The SMBus target also provides a sophisticated BMC with the capability to monitor the health of an EP80579-based platform, such that statistics on correctable error location and frequency may be tracked remotely in an effort to anticipate and prevent more serious failures.

The IMCH includes significant RASUM functionality on both its memory subsystem and its PCI Express interfaces. Some types of errors are expected at a modest frequency within a platform of this complexity, and the IMCH provides internal hardware to track the frequency of such errors. These include correctable ECC errors on the memory interface, as well as transient communication errors on the high-speed serial PCI Express interfaces – refer to [Chapter 14.0, “RAS Features and Exception Handling”](#) for further details.

The BMC could be remotely directed to periodically poll the internal error logging registers of the IMCH, permitting a remote management software package to maintain a running profile of error types and frequencies experienced by an EP80579-based platform. Changes in error frequency or type could be flagged by the remote monitoring software to prompt follow-up preventative maintenance on the platform.

## 15.3 Platform Power Management Support

The IMCH is compatible with the *PCI Bus Power Management Interface Specification, Revision 1.1* (referred to here as PCI-to-PMI). The IMCH is also compatible with the *Advanced Configuration and Power Interface Specification, Rev. 2.0 (ACPI)*. The EP80579 is designed to operate seamlessly with operating systems employing these specifications.

The anticipated implementation for platform power management control is an add-on component connected to the IICH component of the core logic via its LPC and/or SMBus interfaces.

### 15.3.1 Supported System Power States

The IMCH and the system power states are analogous, thus no “device” power states are defined for the IMCH. As a result, the IMCH power state may be directly inferred from the system power state.

Like all systems, EP80579-based platforms must support the S0 (fully active) state at a minimum. The IMCH also supports S1 (Idle), S3 cold (suspend to RAM), S4 (suspend to disk), and S5 (soft off).

S2 (power-on suspend) and S3 hot are not supported.

S3 support requires specialized internal hardware. A request to enter the S3 power state is communicated to the IMCH by the IICH. In response, the IMCH flushes all data from the internal coherent write buffer, sequences all active DIMM rows into their “self-refresh” state, and then returns an Ack\_Sx special cycle to the IICH. Upon completion of this sequence, the IMCH tolerates the removal of all clock references and power sources, save the DDR2 interface power. DDR2 interface power must be supplied so that the IMCH may hold the DIMMs in self-refresh. A full system initialization and configuration sequence is required upon system exit from the S3 state, as all (non-AUX) internal configuration information has been throughout the platform, but exit latency is much lower than it would be from S5, as the memory image has been maintained.

*Note:* The Go\_S3 message indicates that the IICH is getting ready to put the system into S3, S4 or S5 state.

The extra internal logic support for S3 and S4 is not required for the S5 (soft off) system power state because all data in the memory array is lost regardless, and the coherent write buffer is architecturally part of the data stored in main memory.

#### 15.3.1.1 Supported CPU Power States

EP80579-based platforms support the C0, C1, C2 and C3 states as defined by the *Advanced Configuration and Power Interface Specification (ACPI)*. This implies that the core logic anchored by the IMCH properly understands and handles messaging between the IMCH and the FSB to facilitate transitions into and out of these states.

#### 15.3.1.2 Supported Device Power States

The IMCH supports all PCI-to-PMI and PCI Express messaging required to place any subordinate device on any of its PCI Express ports into any of the defined device low power states. Peripherals attached to the PCI segments provided via a PXH component may be placed in any of their supported low power states via messaging directed from the IMCH through the intervening PCI Express hierarchy. Directly attached native PCI Express devices are not limited in their available low power states, although not all available states support the downstream device “wake-up” semantic.

Further details about PCI Express power management support and accompanying PCI Express and subordinate device power management support are provided in [Section 15.3.3, “PCI Express Interface Power Management” on page 382](#).

#### 15.3.1.3 Supported Bus Power States

No low power bus states are supported by the EP80579 on its internal NSI interface between the IMCH and the IICH. Also, IMCH does not support placement of the IICH only into any low-power state below D0, other than as a side-effect of placing the entire system into one of the S3 cold, S4, or S5 states.

Significant low power mode support is provided for the several IMCH PCI Express ports, as detailed in [Section 15.3.3, “PCI Express Interface Power Management” on page 382](#).

### 15.3.2 DDR2 Interface Power Management

DDR2 self-refresh is supported as an integral piece of the S3 support.

### 15.3.3 PCI Express Interface Power Management

In PCI Express, the traditional bus (B\*) power states assigned to system buses are replaced by link (L\*) power states, which are largely managed by hardware without software intervention. Entry into and out of these states may be initiated by two distinct mechanisms:

- traditional PCI-PMI type software managed state changes
- non-traditional PCI Express autonomous hardware state changes

The latter transition type is designated “Active State Power Management,” (ASPM) and included with the *PCI Express Interface Specification, Rev. 1.0a*.

#### 15.3.3.1 PCI Express Link Power State Definitions

Support for all of the following PCI Express link power states is required for *PCI Express Specification* compatibility:

*Note:* The IMCH does not support all PCI Express link power states.

- L0 – Active state with all operations enabled (default state after platform initialization).
- L0s –Low latency, energy saving standby state, disabling exchange of both transaction layer packets and device link layer messages. This state is used exclusively by the ASPM PCI Express function, with entry and exit managed autonomously by PCI Express interface hardware.
- L1 – (Only supported in software managed state changes) Moderate to high latency, very low power, standby state, disabling exchange of both transaction layer packets and device link layer messages. Entered when the downstream device is programmed to a device power state below the D0 active state, or optionally under hardware control during ASPM. The clock remains active in L1, and exit from this state may be initiated by either the upstream or the downstream device.
- L2/L3 Ready – Staging point for removal of main power and clocking. New intermediate state not directly related to PCI PM D-state transitions, nor to ASPM. Hand-shaking lands the link in this state in anticipation of power removal, at which point the link moves to either L2 or L3 depending upon the presence of Vaux.
- L2 – High latency, very low deep sleep state, disabling exchange of transaction layer packets and device link layer messages. L2 is characterized by removal of clocking and main power, but presence of Vaux power. Exit is initiated by restoring clocking and power, and full initialization.
- L3 – High latency, link off state with power, Vaux, and clock reference removed. Exit is initiated by restoring clocking and power, and full initialization.

The IMCH is fully compliant with the *PCI Express Specification*, but does not support the optional L1 state via the ASPM mechanism. Refer to the *PCI Express\* Interface Specification, Rev. 1.0a* for further detail on the link states and specific information on entry and exit mechanisms.

#### 15.3.3.2 Software Controlled PCI Express Link States

Software managed device power state changes do not explicitly control the power L-state of PCI Express links. Instead the L-state is inferred by hardware from the PCI-PMI power state of the devices attached to that link. When PM software transitions a PCI Express device to a low power state, that device automatically negotiates with hardware to bring its upstream link into the appropriate link power state.

No link is allowed to be in a link power state “below” that which is dictated by its attached components.

Table 15-12 defines the legal relationships between link and attached device power states.

**Table 15-12. Relationship Between Link and Device PM States**

| Downstream Component D-State | Permissible Upstream Component D-State             | Permissible Interconnect L-State |
|------------------------------|--|----------------------------------|
| D0                           | D0   | L0, L0s, L1 <sup>†</sup>         |
| D1                           | D0, D1   | L1                               |
| D2                           | D0, D1, D2   | L1                               |
| D3 <sub>hot</sub>            | D0, D1, D2, D3 <sub>hot</sub>                      | L1, L2/L3 Ready                  |
| D3 <sub>cold</sub>           | D0, D1, D2, D3 <sub>hot</sub> , D3 <sub>cold</sub> | L2, L3                           |

<sup>†</sup> Entry into L0s or L1 while attached devices remain in D0 only occurs as a part of ASPM. Per the PCI Express spec, L0s support is mandatory, while L1 is optional. **L1 is not supported by ASPM.**

Several new semantics are introduced with PCI Express to support PCI-PMI compatible software managed device and link power state transitions. The majority of the new functionality is to accommodate an essentially edge-triggered, in-band message scheme supporting multi chassis cabled system topologies, which must replace the function of traditional level-sensitive board traces for PM event and wake signaling. Further details about PME signaling appears in [Section 15.3.5, “PME Support”](#) on page 385.

The IMCH supports messaging to facilitate transition of attached PCI Express devices to power states D0, D1, D2, and D3 (both D3<sub>HOT</sub> and D3<sub>COLD</sub>). All attached devices are required by the *PCI Express Specification* to support the D0 and both D3 states, while D1 and D2 support are optional. Software should confirm device support of the optional D1 and D2 states prior to attempting their use on any attached PCI Express device.

In the D1, D2, and D3<sub>HOT</sub> states, the attached device is required to suppress initiation of any link traffic other than PME initiation (if enabled) as a master, and must only accept configuration transactions as a target. Functional context is maintained in the D1 and D2 states, such that full initialization of the attached device is not required upon the wake-up transition back to the D0 state. In both D3 states, functional context is not maintained, and full initialization is required after a transition back to D0.

Placing an attached device into a low power state results in automatic transition of the associated PCI Express port to its L1, L2 or L3 link state (depending upon the device power state). To save additional power in the L2 state, the platform power manager must remove the reference clock from the link. The IMCH does not provide the necessary internal clock generation and distribution control to allow clock removal from one PCI Express port interface without impacting the operation of its peer ports on the IMCH. CMI does not provide support on its PCI Express link interfaces for the in-band “tone” required to wake from such a state.

### 15.3.3.3 Hardware Controlled PCI Express Link States

Active-state power management (ASPM) support is a required component of *PCI Express Specification* compliance and is intended to provide granularity and flexibility for PCI Express components to dynamically manage their own power consumption without software supervision and support. All native PCI Express components, regardless of device class, must support active transitions to and from the L0s low power link state as a minimum and may optionally support active transitions to and from the L1 low power link state.

The IMCH does not support ASPM entry into the L1 state under hardware control. CMI negatively acknowledges (NAK) ASPM requests for L1 state transitions. IMCH configuration registers reflect this level of support for ASPM.

All ASPM functionality is disabled by default upon system power-up. It is the responsibility of software to verify a viable platform clocking configuration prior to enabling ASPM functionality within the IMCH or in any attached PCI Express devices. In topologies where independent clock references are used at any point within the PCI Express subsystem hierarchy, the “fast training” sequence associated with ASPM is not guaranteed to successfully revive the associated link, and ASPM must remain disabled in the devices at both ends of that link.

#### 15.3.3.4 System Clocking Solution Dependencies

The topology of the platform clocking solution dictates the viability of ASPM on each of the PCI Express links. This is because the nature of the clocks directly impacts the amount of time required to re-acquire bit and symbol lock in the receiver after an arbitrarily long non-communicative period. When both ends of a link share a clock source, they “wander” together over the period they are out of communication with each other, and accordingly require a relatively brief period of training to re-acquire lock. When the two ends of a link utilize completely independent clock references, they may become arbitrarily out of phase with each other while they are in low power states, and therefore require a significantly longer amount of time to re-acquire lock upon waking. For this reason, the *PCI Express Interface Specification* provides for software discovery and communication of the actual clocking topology within the system prior to enabling the ASPM feature on any link within the system.

There are two primary components to the clocking discovery mechanism. First, all downstream ports, such as those on the IMCH root device, must report whether they use the same clock source as that provided to the slot (or down-device) connected to that port in the platform. This information is recorded in the Slot Clock Configuration bit of the Link Status Register for each port and system BIOS is required to initialize these bits accordingly. Second, all add-in devices must report whether they utilize the clock reference provided on the add-in slot via the same bit in the same register of their capability structure.

System software may examine the settings of the Slot Clock Configuration bits of both the upstream and downstream devices for each port in the system, and determine whether a common clock reference is in use. This information is then communicated to both the upstream and the downstream devices via programming of the Common Clock Configuration bit of the Link Status Register. The setting of this bit determines the reported exit latency requirements for the L1 state. System software may then compare the exit latency requirements with the tolerated exit latencies of the attached device and determine whether or not to enable ASPM for each link the system. All ASPM functionality defaults to disabled at power-on and remain so unless system software determines it may be enabled.

The “N\_FTS” parameters exchanged during initial training corresponds to the “long” exit latencies associated with independent clocks. If software later sets the Common Clock Configuration bits, it is also necessary to force link retraining in order to update the exchanged N\_FTS information.

#### 15.3.3.5 Device and Link PM Initialization

All PCI Express devices power-on into the  $DO_{uninitialized}$  state and remain in that non-communicative state until they have been configured and at least one of the Memory Space Enable, I/O Space Enable, or Bus Master Enable bits has been set by system software, at which point the device automatically transitions to the  $DO_{ACTIVE}$  state indicative of normal operation.

### 15.3.4 Device and Slot Power Limits

All add-in devices must power-on to a state in which they limit their total power dissipation to a default maximum according to their form-factor (10 W for add-in edge-connected cards). When BIOS updates the slot power limit register of the root ports within the IMCH, the IMCH automatically transmits a Set\_Slot\_Power\_Limit message with corresponding information to the attached device. The platform BIOS is responsible for properly configuring the slot power limit registers in the IMCH. Failure to do so may result in attached endpoints remaining completely disabled in order to comply with the default power limitations associated with their form-factors.

### 15.3.5 PME Support

All information in this section refers to the IMCH PME support. See [Chapter 27.0, “Power Management”](#) for PME support in IICH.

In CMI systems, only the system power manager or a device within the PCI Express hierarchy may initiate a power state change. Thus the only Power Management Event (PME) signaling support required in the IMCH is that associated with PCI Express. Note that a device bridging to another technology, such as a PXH bridging to PCI-X, may convert traditional PME signaling into PCI Express in-band PME messaging and thereby meet this requirement of the IMCH.

PME signaling in PCI Express is crafted to accomplish two distinct functions. First, it provides a signaling mechanism for devices requiring service to propagate a wake-up request to the power management controller. Second, it provides a messaging mechanism for devices requesting a power state change to pass their unique location within the PCI Express hierarchy to the power management controller. The combination of these two functions provides great flexibility and controllability for the power manager.

#### 15.3.5.1 PME Wake Signaling

Wake signaling is only required to provide for device-initiated transition out of low power states where clock and/or power have been removed from the sleeping device. The PME mechanism does not require a wake-up function for attached devices still powered and receiving an interface reference clock, as devices in this state may simply initiate PME messaging directly. Wake is only required if the device wishing to initiate a PME message cannot do so without first requesting a change to the system clocking and power profile from the power management controller.

The wake signaling aspect of the system power management solution may vary in elegance and granularity. Depending upon the support level provided by the power management controller, a wake-up request from any given device may cause power and clocking to be restored to the entire system, to just the affected branch of the PCI Express hierarchy, or only to the requesting device.

While the *PCI Express Interface Specification* provides for two distinct wake signaling mechanisms, CMI supports only the legacy mechanism described below.

##### 15.3.5.1.1 Legacy Wake Mechanism

The legacy wake signaling mechanism is analogous to that used in historical PCI-based system designs. In this case, the platform architect is responsible for crafting paths routing collected wake signals between wake-capable devices and the management controller without participation from the IMCH and IICH equivalent devices. The collection of wake logic must run on auxiliary power, and must comprehend the potential for devices both with and without supplied auxiliary power co-existing on the same branch of the PCI Express hierarchy. Refer to the *PCI Express Interface Specification* for further details on legacy wake signaling.

While familiar and well understood, this mechanism does not provide for device-initiated wake-up in the fully A/C coupled implementation of a multi-chassis PCI Express-based system solution. The limitation imposed upon CMI-based system is that remote-chassis devices must not be placed in a low-power state with the PCI Express link clocking and/or power disabled if legacy style wake signaling is desired for any peripheral in that remote chassis. It is still possible for software to place peripheral devices in low power sleep states and to manage the device state of the PCI Express device attached to the inter-chassis cable. Devices in the remote chassis may still initiate power state changes via PME messaging provided the inter-chassis link has not been placed into an uncommunicative state. An alternative for the platform architect would be to place a compatible switch device between the IMCH and the remote chassis that supports the in-band wake mechanism described below and rely on the switch to forward wake events to the management controller.

The platform architect should ensure that the power management controller can adequately isolate the source of a PME wake request as required to take appropriate power management wake-up action.

### 15.3.5.2 PME Messaging

Once the link requesting a power state change has a communicative upstream link, it sends the PM\_PME packet upstream toward the root device (IMCH), which in turn is responsible for notifying the management controller. This constitutes an in-band “virtual wire” signaling mechanism to replace the historical solution that involved multiple independent board traces routing PME requests to the power manager. Because the PM\_PME propagates “in-band” on the PCI Express interface without any side-band signaling support, PME functionality is made available to multi-chassis system solutions.

The IMCH collects and “OR” PME requests from all logical PCI Express ports and propagates it to IICH over the NSI link as an Assert\_PMEGPE message. The IICH then generates a specified interrupt to wake the power manager and invokes power management software. The interrupt service routine may then interrogate the various PM status registers to determine the source(s) of PME. The IMCH would send a Deassert\_PMEGPE message over NSI link after the power state change request has been serviced.

### 15.3.6 BIOS Support for PCI Express PM Messaging

The *PCI Express Specification* stipulates hierarchical messaging semantics enforced by the root device (IMCH) to guarantee proper entry into and exit from unpowered device states. CMI ACPI BIOS must make special allowances for support of these semantics. There are two sets of messages that must be software-assisted in CMI based platforms to support power-off device states within the PCI Express hierarchy.

#### 15.3.6.1 PCI Express PME\_TURN\_OFF Semantic

Prior to removing power from any attached PCI Express links anywhere in the hierarchy, the root device must broadcast a PCI Express “PME\_TURN\_OFF” message to all downstream devices on the affected PCI Express port. The receiving devices propagate this message to all subordinate PCI Express ports (if any), collect “PME\_TO\_ACK” acknowledgement packets, and finally return a “PME\_TO\_ACK” transaction layer packet back to the root device. Once all active ports have acknowledged, the power management device may be notified that it is cleared to modify the collective power state of the PCI Express hierarchy. These message packets have posted semantics on the interface, thus the turn-off “pushes” all prior packets to

their endpoints, and the acknowledge “pushes” any pending inbound traffic all the way to the root. This prevents “trapping” transactions or PME messages somewhere in the hierarchy at the time power is dropped, ultimately causing them to be lost.

In a pure PCI Express design, the PME\_TURN\_OFF packet would originate directly at the power manager, or perhaps at the IICH providing connection between the power manager and the remainder of the core logic. Neither the power manager nor the IICH is aware of the PCI Express messaging mechanism, thus the IMCH provides device-specific control and status bits for use by its ACPI BIOS.

The sequence of events to place a PCI Express device in an unpowered state is as follows:

1. PCI-PM or ACPI-compliant O/S software is called to place the system into a low-power sleep state (S3, S4 or S5), prepares for suspension, and calls ACPI BIOS to carry out the platform power transition.
2. The BIOS then communicates to the root complex that all PCI Express devices must prepare for power-off. This is accomplished through the device-specific configuration space of the internal virtual PCI-to-PCI bridges with subordinate PCI Express hierarchies. The BIOS must configure each active root port to power-down. When the configuration write is received to set the “PM Turn Off” bit, the associated root port transmits a PM\_Turn\_Off message downstream. At this point, any traffic in-flight continues to be handled normally by the IMCH – routed outbound, and completed inbound.
3. The target PCI Express device ceases generation of new transactions inbound, waits for all pending transactions to complete and prepares to lose power and clocking. If the target device has a subordinate hierarchy of its own, it propagates the PM\_Turn\_Off message downstream and waits for acknowledges from all subordinate ports. Once ready to be brought off-line, the target device issues a PM\_TO\_Ack TLP cycle in acknowledgement back to the root. Note that the link is still communicative at this point, with both power and clock available.
4. After issuing the PM\_TO\_Ack cycle, the downstream device then issues a PM\_Enter\_L23 DLLP continuously upstream until it receives an acknowledge. In response to the PM\_TO\_Ack, the root port will commence the PCI Express handshake sequence necessary to sets its “Turn Off Ack” status bit. In response to the PM\_Enter\_L23 DLLP, the root transitions its downstream link to the electrical idle state. (This protocol sequence directly mirrors the L1 entry sequence.)
5. ACPI BIOS, which has been waiting for all of the “Turn Off Ack” status bits to assert, now clears all the command and status bits associated with the PME\_TURN\_OFF. The routine then informs the power manager to go ahead with the change to the system power state.  
Note that software is required (by the PCI Express specification) to implement a “dead-man” timer such that a failure to receive a full complement of “Turn Off Ack” status bits does not result in an indefinite hang. This timeout is nominally 1 second, after which the power state change proceeds regardless.
6. The power manager drops power and clocking to the target device(s), and all associated links automatically transition to either the L2 or L3 uncommunicative power states. The links enter L2 if Vaux is supplied by the platform, otherwise they enter L3. (Note that the IMCH does not support Vaux, so all downstream lanes will necessarily go to the L3 state.) The platform remains in the low-power state until a wake event is signaled.

In a fully PCI Express aware core logic implementation, the ACPI BIOS would not need to act as the interlock between the IMCH and the power manager, as all that functionality would be handled in hardware via direct messaging.

## 16.0 IMCH Registers

### 16.1 IMCH Registers: Bus 0, Device 0, Function 0

The Integrated Memory Controller Hub (IMCH) registers are in Bus 0, Device 0, Function 0. Table 16-1 provides the register address map for this device and function.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Table 16-1. Bus 0, Device 0, Function 0: Summary of IMCH PCI Configuration Registers (Sheet 1 of 2)**

| Offset Start | Offset End | Register ID - Description   | Default Value |
|--------------|------------|---|---------------|

## 16.1.1 Register Details

### 16.1.1.1 Offset 00h: VID – Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identifies any PCI device. Writes to this register have no effect.

**Table 16-2. Offset 00h: VID – Vendor Identification Register**

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:0:0 | Offset Start: 00h<br>Offset End: 01h |            |
| Size: 16 bit | Default:           | 8086h   |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                     | Bit Reset Value                      | Bit Access |
| 15 : 00      | VID                | <b>Vendor Identification:</b> This register field contains the PCI standard identification for Intel 8086h. |                            | 8086h                                | RO         |

### 16.1.1.2 Offset 02h: DID – Device Identification Register

This 16-bit register combined with the Vendor Identification register uniquely identifies any PCI device. Writes to this register have no effect.

**Table 16-3. Offset 02h: DID – Device Identification Register**

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:0:0 | Offset Start: 02h<br>Offset End: 03h |            |
| Size: 16 bit | Default:           | 5020h  |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 15 : 00      | DID                | <b>Device Identification Number:</b> This is a 16-bit value assigned to the IMCH Host-NSI Bridge Function 0. |                            | 5020h                                | RO         |

### 16.1.1.3 Offset 04h: PCICMD: PCI Command Register

Since IMCH Device 0 does not physically reside on a PCI bus, many of the bits are not supported.

Table 16-4. Offset 04h: PCICMD: PCI Command Register

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:0:0 | Offset Start: 04h<br>Offset End: 05h |            |

#### 16.1.1.4 Offset 06h: PCISTS: PCI Status Register

PCISTS is a 16-bit status register that reports the occurrence of error events on Device 0's PCI interface. Since IMCH Device 0 does not physically reside on a PCI bus many of the bits are not supported.

**Table 16-5. Offset 06h: PCISTS: PCI Status Register**

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:0:0 | Offset Start: 06h<br>Offset End: 07h |            |

### 16.1.1.9 Offset 14h: SMRBASE - System Memory RCOMP Base Address Register

The SMRBASE is a standard PCI Base Address register that is used to set the base of the Memory Mapped Registers used to control the System Memory I/O Buffer RCOMP. In addition to calibration, the DCAL engine which resides within this memory mapped region also performs RAS functions. In addition, there are some BIOS scratch registers within this region. The actual behavior of this register depends on the SMRCOMP MMR Enable bit in the IMCH TST2 register (Device 0, Function 0, Offset F6, Bit 6). When IMCH TST2[6] is set, this register behaves like a standard PCI BAR requesting 4 Kbyte of address space. When IMCH TST2[6] is clear, this register is hardwired to all zeros, effectively disabling the BAR and the corresponding SM MMR region. Because of the more extensive functionality supported by DCAL, it is expected that once this address space has been enabled by System BIOS, it remains enabled to support various RAS features.

**Note:** All accesses to these Memory Mapped Registers must be made as a single Dword (4 bytes) or less. Access must be aligned on a natural boundary.

**Table 16-10. Offset 14h: SMRBASE - System Memory RCOMP Base Address Register**

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:0:0 | Offset Start: 14h<br>Offset End: 17h |            |
| Size: 32 bit | Default:           | 00000000h   |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                     | Bit Reset Value                      | Bit Access |
| 31 : 12      | UPBITS             | <b>Upper Programmable Base Address:</b> These bits are part of the SM MMR region, normally set by configuration software to locate the base address of the region. The actual behavior of this field depends on the SM MMR Enable bit in the IMCH TST2 register (bit 6) as defined above. When IMCH TST2[6] = 1 these bits are Read/Write. When IMCH TST2[6] = 0 these bits are Read-Only as zeros. |                            | 00000h                               | RW or RO   |
| 11 : 04      | LOWBITS            | <b>Lower Bits:</b> These bits are hardwired to 0. This forces the size of the memory region to be 4 Kbyte.  |                            | 00h                                  | RO         |
| 03           | PF                 | <b>Prefetchable:</b> This bit is hardwired to 0 to indicate that the System Memory MMR region is NON-Prefetchable.  |                            | 0b                                   | RO         |
| 02 : 01      | TYPE               | <b>Addressing Type:</b> These bits determine addressing type and they are hardwired to 00 to indicate that address range defined by the upper bits of this register can be located anywhere in the 32-bit address space in order to comply with the PCI specification for base address registers.   |                            | 00b                                  | RO         |
| 00           | MSPACE             | <b>Memory Space Indicator:</b> Hardwired to 0 to identify the MMR range as a memory range as per the specification for PCI base address registers.  |                            | 0b                                   | RO         |

**16.1.1.10 Offset 2Ch: SVID - Subsystem Vendor Identification Register**

This value is used to identify the vendor of the subsystem.

**Table 16-11. Offset 2Ch: SVID - Subsystem Vendor Identification Register**

| Description: |                    |  |                            |                                      |            |

| 15 : 00      | SUBVID             | <b>Subsystem Vendor ID:</b> This field must be programmed during boot-up to indicate the vendor of the system board. |                            | 0000h                                | RWO        |

### 16.1.1.11 Offset 2Eh: SID - Subsystem Identification Register

This value is used to identify a particular subsystem.

**Table 16-12. Offset 2Eh: SID - Subsystem Identification Register**

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:0:0 | Offset Start: 2Eh<br>Offset End: 2Fh |            |
| Size: 16 bit | Default:           | 0000h  |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 15 : 00      | SUBID              | <b>Subsystem ID:</b> This field must be programmed during BIOS initialization. After it has been written once it becomes Read-Only. When any byte or combination of bytes of this register is written, the register value locks and cannot be further updated. |                            | 0000h                                | RWO        |

### 16.1.1.12 Offset 4Ch: NSIBAR - Root Complex Block Address Register

This is the base address for the Root Complex memory-mapped configuration space. This window of addresses contains the Root Complex Register Block for the NSI hierarchy associated with the IMCH. There is no physical memory within this 4 Kbyte window that can be addressed. The 4 Kbyte reserved by this register does not alias to any PCI 2.3 compliant memory mapped space.

All accesses to these Memory Mapped Registers must be made as a single Dword (4 bytes) or less. Access must be aligned on a natural boundary.

**Table 16-14. Offset 4Ch: NSIBAR - Root Complex Block Address Register**

| Description: |                    |  |                            |                                      |            |

| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 31 : 12      | NSI_BA             | <b>NSI Base Address:</b> The BIOS programs this register resulting in a base address for a 4 Kbyte block of contiguous memory address space. This register ensures that a naturally aligned 4 Kbyte space is allocated within total addressable memory space of 4 Gbyte. System Software uses this base address to program the NSI register set. When IMCH TST2[5] = 1, the NSI Memory Mapped Register space is visible and memory mapped accesses are claimed and decoded appropriately. When IMCH TST2[5] = 0, the NSI Memory Mapped Register space is disabled and does not claim any memory. (THE NSIBAR register is still read/write accessible.) |                            | 00000h                               | RW or RO   |

### 16.1.1.24 Offset 9Ch: DEVPRES - Device Present Register

The Device Present bits can be used to enable/disable devices within the IMCH and make their PCI configuration space respectively visible/invisible to software. The Device Present bits convey when cleared that the corresponding device is never available.

When a bit is 0, the configuration space associated with that device is hidden, returning all 1's for all configuration register reads just as if the cycle terminated with a master abort on PCI. For the two PCIe\* devices listed the I/O buffers and compensation associated with those devices are disabled and tri-stated. When a bit is 1, the configuration space associated with that device is accessible. For the two PCIe\* devices the I/O buffers and compensation are enabled.

*Note:* BIOS should write this register as part of its power on configuration sequence.

Bits within this register are broken into two categories "RWO or RO" and "RW" and are functionally defined below.

**“RWO or RO” bits:**

All of the “RWO or RO” bits in this register are gated with a SKU value. The SKU value has priority over values written by software. This means that if the SKU value of this bit is set to a 0, neither a configuration write or a reset sets this bit.

If a SKU value is not present then the register will have RO access.

When a SKU value is not present, the device is invisible to software. Writes to this register when the SKU value is not present, will have no effect, always returning ‘0’ when read.

If a SKU value is present the register will have RWO access.

*Note:* BIOS must write a bit to a 0 to disable a device, or a 1 to enable a device. This register can only be written once. After the first write, the register is locked.

*Note:* RWO Devices that are disabled via software can only be re-enabled via a reset. This register should only be written to at boot time when there is no traffic to or from the PEA.

Once software or BIOS has written these RWO register bits for the first time after power-up, the register value locks, and cannot be further updated.

In other words, once software has disabled RWO devices, they can only be re-enabled via a reset. For RWO access bits the IMCH does not support turning off a device, and then turning it back on. (The reverse is also true: once software has enabled RWO devices, they can only be re-disabled via a reset.)

**RW bits:**

Two devices have RW bit access. These devices need to be enabled/disabled for power management during normal operation

**Table 16-26. Offset 9Ch: DEVPRES - Device Present Register (Sheet 1 of 2)**

| 06           | MDAP               | <p><b>MDA Present:</b> This bit works with the VGA Enable bits in the BCTRL registers of Devices 2–3 to control the routing of CPU initiated transactions targeting MDA compatible I/O and memory address ranges. This bit should not be set if none of the VGA Enable bits are set. If none of the VGA enable bits are set, then accesses to IO address range x3BCh-x3BFh are forwarded to NSI. If the VGA enable bit is not set then accesses to IO address range x3BCh-x3BFh are treated just like any other IO accesses. For example, the cycles are forwarded to PEA[0:1] if the address is within the corresponding IOBASE and IOLIMIT and ISA enable bit is not set, otherwise they are forwarded to NSI.</p> <p><b>Note:</b> Since the logic performs the address decoding on a DW boundary, the DW that includes the address 3BF also includes addresses 3BC, 3BD, and 3BE, and accesses to any of these byte addresses are handled as MDA references.</p> <p>MDA resources are defined as the following:<br/>Memory: 0B0000h - 0B7FFFh<br/>I/O: 3B4h, 3B5h, 3B8h, 3B9h, 3BAh, 3BFh,<br/>(Including ISA address aliases, A[15:10] are not used in decode)</p> <p><b>Note:</b> The VGA region includes I/O space ranges 3B0-3BBh, and 3C0-3DFh, so there is an overlap between these two I/O regions.</p> <p>Any I/O reference that includes the I/O locations listed above, or their aliases, are forwarded to NSI even if the reference includes I/O locations not listed above.</p> <p>The following table shows the behavior for all combinations of MDA and VGA:</p> <table border="1"> <thead> <tr> <th>VGA</th> <th>MDA</th> <th>Behavior</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>All References to MDA and VGA go to NSI</td> </tr> <tr> <td>0</td> <td>1</td> <td>Illegal Combination (DO NOT USE)</td> </tr> <tr> <td>1</td> <td>0</td> <td>All References to VGA go to device with VGA enable set. The window is 4KB-aligned and inclusive of this address. This register field specifies bits[31:12] of the address; bits[11:0] are assumed zeros given 4KB alignment. |                            | FFFFFFh                              | RW         |

### 16.1.1.29 Offset BCh: IMCH\_MENCLIMIT - IA/ASU Shared Non-Coherent (AIOC-Direct) Memory Limit Address Register

Table 16-31. Offset BCh: IMCH\_MENCLIMIT - IA/ASU Shared Non-Coherent (AIOC-Direct) Memory Limit Address Register

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:0:0 | Offset Start: BCh<br>Offset End: BFh |            |
| Size: 32 bit | Default:           | 00000000h   |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                     | Bit Reset Value                      | Bit Access |
| 31 : 20      | Reserved           | Reserved  |                            | 00h                                  |            |
| 19 : 00      | MENCLIMIT          | <b>IA/ASU Shared Non-Coherent Memory Limit Address Bits[31:12]:</b> Specifies the address of the upper boundary of the IA/ASU shared non-coherent window in 32-bit system address space. The window is 4KB-aligned and inclusive of this address. This register field specifies bits[31:12] of the address; bits[11:0] are assumed ones. Setting IMCH_MENCLIMIT less than IMCH_MENCBASE indicates a zero-sized window and thus that all memory is coherent. |                            | 00000h                               | RW         |

### 16.1.1.30 Offset C4h: TOLM - Top of Low Memory Register

This register contains the maximum address below 4 Gbyte that must be treated as a memory access and is defined on a 128 Mbyte boundary. Usually it is below the areas configured for PCI Express, NSI, and PCI memory. The memory address found in DRB3 reflects the amount of total memory populated.

**Table 16-32. Offset C4h: TOLM - Top of Low Memory Register**

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:0:0 | Offset Start: C4h<br>Offset End: C5h |            |
| Size: 16 bit | Default:           | 0800h  |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 15 : 11      | TOLM               | <p><b>Top of Low Memory:</b> This register corresponds to bits 31 to 27 of the system address which is 1 greater than the maximum DRAM location below 4 Gbyte. Configuration software must set this value to either the maximum amount of memory in the system or to the minimum address allocated for PCI memory or the graphics aperture, whichever is smaller. Address bits 26:00 are assumed to be 0 for the purposes of address comparison. Addresses equal to or greater than the TOLM, and less than 4 G, are treated as non-memory accesses. All accesses less than the TOLM are treated as DRAM accesses (except for the 15–16 Mbyte or PAM gaps).</p> <p>This register must be set to at least 0800h, for a minimum of 128 Mbyte of DRAM. There is also a minimum of 128 Mbyte of PCI space, since this register is on a 128 Mbyte boundary.</p> <p>Configuration software must set this value to either the maximum amount of memory in the system (same as DRB3), or to the lower 128 Mbyte boundary of the Memory Mapped IO range, whichever is smaller.</p> <p>Programming example:<br/>1100_0b = 3 Gbyte (assuming that DBR7 is set &gt; 4 Gbyte):</p> <p>An access to 0_C000_0000h or above (but &lt;4 Gbyte) is considered above the TOLM and therefore not to DRAM. It may go to one of the PEA ports or NSI or be subtracted and decoded to NSI. An access to 0_BFFF_FFFFh and below is considered below the TOLM and go to DRAM.</p> |                            | 00001b                               | RW         |
| 10 : 00      | Reserved           | Reserved   |                            | 000h                                 |            |

### 16.1.1.31 Offset C6h: REMAPBASE - Remap Base Address Register

Note: This register should not be enabled since the IA-32 core only supports 32-bit addressing.

Table 16-33. Offset C6h: REMAPBASE - Remap Base Address Register

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:0:0 | Offset Start: C6h<br>Offset End: C7h |            |

### 16.1.1.39 Offset 60h: DRB[0-3] – DRAM Row [3:0] Boundary Register

DRAM row boundary register defines the upper boundary address for each DRAM row with a granularity of 64MB. Each row has its own single byte DRB register. The value in a given DRB corresponds to the cumulative memory size including that row. For example, a value of 1 (0000 0001) in DRB0 (address lines 33 to 26) indicates that 64 Mbytes of DRAM has been populated in the first row.

DRB0 = Total memory in row0 (64 Mbyte increments)

DRB1 = Total memory in row0 + row1 (64 Mbyte increments)

DRB2 = Total memory in row0 + row1 + row2 (64 Mbyte increments)

DRB3 = Total memory in row0 + row1 + row2 + row3 (64 Mbyte increments)

The functionality of DRB3 is somewhat different than DRB[2:0]. In order to avoid a 64MByte “hole” at the top of memory, a value of 0x00 in DRB3, is interpreted as 0x100. In practice, this 0x00 value should not be set, since it implies addressing more memory than the EP80579 supported.

*Note:* The memory controller does not implement any hardware checks to prevent accesses to DRAM locations beyond what is populated in the DRB3 register. Such accesses are software programming errors and will result in unreliable operation.

Table 16-41 shows the DRBx to DIMM mapping. Please note that before populating the DIMM’s, all limitation described in Section 11.3.1, “Rules for Populating DIMM Slots” need to be followed.

Table 16-41. DRB to DIMM designation

|              | Even Row       |                | Odd Row        |                |
|--------------|----------------|----------------|----------------|----------------|
|              | Row/DRB Number | Address or DRB | Row/DRB Number | Address or DRB |
| <b>DIMM0</b> | DRB0           | 60h            | DRB2           | 62h            |
| <b>DIMM1</b> | DRB2           | 62h            | NA             | NA             |

Rules for programming the DRBx registers:

- DRB1 and DRB3 are unused and reserved.
  - DRB1 and DRB3 should be programmed to be the same value as what was programmed in the even row. (DRB1 = DRB0, DRB3 = DRB2).
- Unpopulated rows must be programmed with a value of the last populated slot. This guarantees the unpopulated row will not be selected.
- Depending upon the configuration and amount of memory populated in each row, DRB0 and DRB2 should be programmed. This will correspond to on the EP80579, CS0# and CS1#.
  - Single rank, 1 DIMM system programs DRB0 with the encoding for memory capacity in row 0. Further, DRB1 = DRB2 = DRB3 = DRB0.
  - Single ranks in a 2 DIMM system programs DRB0 with the encoding for memory capacity in row 0 and DRB2 with the encoding for memory capacity in row 0 + row 1 + row 2. Further, DRB1 = DRB0 and DRB3 = DRB2.

- Single DIMM with dual ranks should program DRB0 with the encoding for memory capacity in row 0 and DRB2 with the encoding for memory capacity in row 0 + row 1 + row 2. Further, DRB1 = DRB0 and DRB3 = DRB2.
- It must always be the case with the EP80579 memory controller that for single rank, 1 DIMM systems, DRB0 = DRB1 = DRB2 = DRB3 and for all other configurations, DRB0 = DRB1 < DRB2 = DRB3.

Table 11-7, “Supported Rank Configurations in Single and Dual DIMM mode” on page 293 shows the mapping of the chip selects in the different legal rank populations on the EP80579.

Note: DRB0=DRAM Row 0, DRB1=DRAM Row 1, etc.

This 8 bit value is compared against a set of address lines to determine the upper address limit of a particular row. This field corresponds to bits 33:26of the system address. | N                                 | ffh  | RW                |

**16.1.1.40 Offset 70h: DRA[0-1] – DRAM Row [0:1] Attribute Register**

The DRAM Row Attribute register defines the DRAM technology. DRA is used to calculate the address mapping for column and row addresses as a function of DRAM technology specified in the DTYPE, DW and DIMMTECH fields.

- DRA0 describes characteristics of rows 0 (even) and 1 (odd).
- DRA1 describes characteristics of rows 2 (even) and 3 (odd).
- Due to the rules of the EP80579 DDR configuration, many fields of DRA0 and DRA1 are not meaningful (they exist only for backward compatibility). For most configurations, the values in DRA0[DW\_EVEN] and DRA0[DIMMTECH\_EVEN] are used. An exception is DRA1[DIMMTECH\_EVEN] which is used to select the size of the devices on the second DIMM of a two DIMM system. See Table 16-43 for details.
- Bit fields that are not valid because the rank (or row) is not populated should not be changed. For such fields the reset value should be the benign state.
- The controller determines which of rows are populated after decoding the DRB registers. Please see Section 16.1.1.39, “Offset 60h: DRB[0-3] – DRAM Row [3:0] Boundary Register” for more details.

Note: All fields of the DRA[1:0] register need to be consistent or else unreliable operation will occur. For example the value programmed in NC\_ODD should be consistent with the DIMMTECH\_ODD field. The number of columns depends on the device technology.

Table 16-43. DRA[1:0] Field Selection

| Case                     | DRA0 [DTYPE_MSB]         | Address                                 | Value used for DIMMTECH | Value used for num_column / num_row | Value used for DW | Value used for DTYPE |

### 16.1.1.41 Offset 78h: DRT0 - DRAM Timing Register 0

The DRT register defines the DRAM timing parameter. For the EP80579, there are 2 DRT registers that need to be programmed based on the external capabilities of the memory devices, number of ranks/DIMM's, supported EP80579 memory configurations etc.

For details about the DRT1 register see "Offset 64h: DRT1 – DRAM Timing Register 1" on page 431.

**Table 16-45. Offset 78h: DRT0 - DRAM Timing Register 0 (Sheet 1 of 7)**

| 2 : 00  | PRGRPD                     | <p>Programmable Read Pointer Delay: This bit field determines the read delay, which is based on both DIMM topology and technology. The round trip timing budget has been estimated to be about 11.5 ns. Since an encoding of "000" means less than one command clock, the encoding values in this table refer to additional delays beyond one command clock.</p> <p>Note that the PRGRPD encoding shown below is for 4 bits. The 4 bits are formed by concatenating DRT1[0] and DRT0[2:0]. Please refer to <a href="#">Section 16.1.1.42</a> for details on the DRT1 register.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>PRGRPD[3:0] Encoding<br/>DRT1[0],<br/>DRT0[2:0]</th> <th>Number of<br/>CMDCLK delays</th> </tr> </thead> <tbody> <tr><td>0000</td><td>0</td></tr> <tr><td>0001</td><td>1</td></tr> <tr><td>0010</td><td>2</td></tr> <tr><td>0011</td><td>3</td></tr> <tr><td>0100</td><td>4</td></tr> <tr><td>0101</td><td>5</td></tr> <tr><td>0110</td><td>6</td></tr> <tr><td>0111</td><td>7</td></tr> <tr><td>1000</td><td>8</td></tr> <tr><td>1001</td><td>9</td></tr> <tr><td>1010</td><td>10</td></tr> <tr><td>Others</td><td>Reserved</td></tr> </tbody> </table> | PRGRPD[3:0] Encoding<br>DRT1[0],<br>DRT0[2:0] | Number of<br>CMDCLK delays           | 0000       | 0 | 0001 | 1 | 0010 | 2 | 0011 | 3 | 0100 | 4 | 0101 | 5 | 0110 | 6 | 0111 | 7 | 1000 | 8 | 1001 | 9 | 1010 | 10 | Others | Reserved | N | 000b | RW |

### 16.1.1.42 Offset 64h: DRT1 – DRAM Timing Register 1

This register controls the DRAM timing parameters.

For details about the DRT1 register see “Offset 78h: DRT0 - DRAM Timing Register 0” on page 424.

**Table 16-46. Offset 64h: DRT1 - DRAM timing Register 1 (Sheet 1 of 4)**

| Description: |                    |  |                            |               |                                      |                 |            |                          |

### 16.1.1.43 Offset 7Ch: DRC – DRAM Controller Mode Register

This register controls the mode of the DRAM controller.

**Table 16-47. Offset 7Ch: DRC - DRAM Controller Mode Register (Sheet 1 of 2)**

| Description: |                    |   |                                      |                 |            |

#### 16.1.1.44 Offset 84h: ECCDIAG – ECC Detection/Correction Diagnostic Register

The MEMPEN bit of this register controls if the memory controller poisons write data to the DRAM when it detects a parity error on its interface. By default, this bit is clear and the memory controller will not poison the write data to DRAM when it detects a parity error on its interface. If MEMPEN is set, and a write transaction with bad parity is sent to memory controller from either IMCH or AIOC, the write to DDR will be poisoned as follows: each bit of ECC will be flipped from the value otherwise calculated for that data write, based on the “bad” data sent from either IMCH or AIOC.

| 18 : 18      | MEMPEN             | <p><b>Memory Poison Enable:</b> Allows for propagation of data errors not initiated by this feature to DRAM. Error injection via bit 20 is possible regardless of this bit setting. The setting of this bit has no effect on the reporting or logging of data errors.</p> <p>0 = Error poisoning is disabled, data errors are not propagated, meaning that only good ECC is generated ECC mode even when bad parity is detected on its interface.</p> <p>1 = Error poisoning enabled when in ECC mode. The memory controller will poison the write data to DRAM when it detects a parity error on its interface.</p>  | N                          | 0b                                   | RW         |
| 17 : 16      | DPRSL              | <p><b>Data pair selector:</b> This two-bit field selects which pair of quad-words in a cache line the inversion vector is applied against. Regardless of what operational mode the memory subsystem is in, this field always applies to the same QW pair. QW0 corresponds to data bits 63:00, QW1 to [127:64] ... and QW7 corresponds to [511:448]</p> <p>00 QW0 and QW1<br/>01 QW2 and QW3<br/>10 QW4 and QW5<br/>11 QW6 and QW7</p>   | N                          | 00b                                  | RW         |
| 15 : 00      | ECCBIN             | <p><b>ECC bit invert vector:</b> This vector operates individually for every ECC bit in the selected High or Low ECC block, during writes to DRAM.</p> <p>For all k between 0 and 15, when bit (k) set to 1, the value of the k ECC bit (which corresponds with the k data byte lane) is inverted. Otherwise, the value the k ECC bit is not affected.</p> <p>In other words, bits 15:08 are applied to the ECC vector of the high Qword in the selected pair, and bits 07:00 are applied to the ECC vector of the low Qword in the selected pair.</p> <p>For Example:<br/>Data Pair Selector bits 17:16 = 00<br/>ECC bit invert vector bits 15:08 are applied to the ECC vector for QW1<br/>ECC bit invert vector bits 07:00 are applied to the ECC vector for QW0</p> | N                          | 0000h                                | RW         |

**16.1.1.45 Offset 88h: SDRC – DDR SDRAM Secondary Control Register**

This register is used for setting memory controller parameters such as queue depths, scheduler parameters, arbiter parameters, AIOC and IA-32 core stream enabling, IA-32 core parity checking, bank remapping, etc.

**Table 16-49. Offset 88h: SDRC - DDR SDRAM Secondary Control Register (Sheet 1 of 3)**

#### 16.1.1.46 Offset 8Ch: CKDIS – CK/CK# Clock Disable Register

This register is used to enable or disable the CK/CK# pins to the DIMMS. This feature is intended to reduce EMI and power consumption due to clocks toggling to DIMMs that are not populated.

Table 16-50. Offset 8Ch: CKDIS - CK/CK# Clock Disable Register

| Description: |                    |  |                            |                                      |            |

### 16.1.1.49 Offset B0h: DDR2ODTC - DDR2 ODT Control Register

The DDR2ODTC controls the behavior of the ODT[1:0] output pins. The ODT pins control the on-die termination on the DDR DRAM devices. (To control the ODT behavior on the EP80579 please refer to [Section 11.4.3, “On-Die Termination \(ODTZ\) on the EP80579”](#).)

The DDR2ODTC control register provides separate fields to control the ODT pin behavior for each of the four possible active cases: read to rank0, read to rank1, write to rank0, and write to rank1. Each field is two bits wide as there are two ODT pins on the EP80579. Please refer the different ODT configurations that the EP80579 supports as shown in [Figure 11-4, “ODT Timing on Back-to-Back Reads to Different Slots”](#) on page 300 and [Figure 11-5, “ODT Timing on Back-to-Back Writes to Different Slots”](#) on page 301.

## 16.2 DRAM Controller Error Reporting Registers: Bus 0, Device 0, Function 1

The DRAM Controller Error Reporting registers are in Bus 0, Device 0, Function 1. Table 16-54 provides the register address map for this device and function.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

## 16.2.1 Register Details

### 16.2.1.1 Offset 00h: VID - Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identify any PCI device.

**Table 16-55. Offset 00h: VID - Vendor Identification Register**

| Description:        |                           |   |                                   |  |            |
|---------------------|---------------------------|---|-----------------------------------|--|------------|
| <b>View:</b> PCI    | <b>BAR:</b> Configuration |   | <b>Bus:Device:Function:</b> 0:0:1 | <b>Offset Start:</b> 00h<br><b>Offset End:</b> 01h |            |
| <b>Size:</b> 16 bit | <b>Default:</b> 8086h     |   |                                   | <b>Power Well:</b> Core                            |            |
| Bit Range           | Bit Acronym               | Bit Description   | Sticky                            | Bit Reset Value                                    | Bit Access |
| 15 : 00             | VID                       | <b>Vendor Identification:</b> This register field contains the PCI standard identification for Intel 8086h. |                                   | 8086h  | RO         |

### 16.2.1.2 Offset 02h: DID - Device Identification Register

This 16-bit register combined with the Vendor Identification register uniquely identifies any PCI device.

**Table 16-56. Offset 02h: DID - Device Identification Register**

| Description:        |                           |  |                                   |  |            |
|---------------------|---------------------------|--|-----------------------------------|--|------------|

| Bit Range           | Bit Acronym               | Bit Description  | Sticky                            | Bit Reset Value                                    | Bit Access |
| 15 : 00             | DID                       | <b>Device Identification Number:</b> This is a 16-bit value assigned to the IMCH Host-Bridge Function 1. |                                   | 5021h  | RO         |

### 16.2.1.3 Offset 04h: PCICMD - PCI Command Register

Since IMCH Device 0 does not physically reside on PCI\_A (internal bus) many of the bits are not implemented.

Table 16-57. Offset 04h: PCICMD - PCI Command Register

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:0:1 | Offset Start: 04h<br>Offset End: 05h |            |

| Bit Range    | Bit Acronym        | Bit Description   | Sticky                     | Bit Reset Value                      | Bit Access |
| 15 : 09      | Reserved           | Reserved  |                            | 00h                                  |            |
| 08           | SERRE              | <p><b>SERR Enable:</b> This bit is a global enable bit for Device 0 SERR messaging.<br/>           0 = Disable, SERR message is not generated by the IMCH for Device 0, Function 1.<br/>           1 = The IMCH is enabled to generate SERR messages over the NSI for specific Device 0, Function 1 error conditions that are individually enabled in the ERRCMD registers.</p> <p>The IMCH communicates the SERR condition by sending a DO_SERR message over NSI to the IICH. If this bit is set to a 1, the IMCH is enabled to generate SERR messages over NSI for specific Device 0, Function 1 error conditions that are individually enabled in the NSI_SERRCMD, FSB_SERRCMD, BUF_SERRCMD, and DRAM_SERRCMD registers. The error status is reported in the PCISTS register as well as the corresponding FERR/NERR registers.</p> <p><b>Note:</b> Reporting via SERR for detected parity error which is essentially NSI Poisoned TLP's, can ALSO be reported through by the Device 0, Function 0.</p> |                            | 0b                                   | RW         |
| 07 : 00      | Reserved           | Reserved  |                            | 0b                                   |            |

### 16.2.1.4 Offset 06h: PCISTS - PCI Status Register

PCISTS is a 16-bit status register that reports the occurrence of error events on Device 0's PCI interface.

Table 16-58. Offset 06h: PCISTS - PCI Status Register

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:0:1 | Offset Start: 06h<br>Offset End: 07h |            |
| Size: 16 bit | Default:           | 0000h  |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 15           | Reserved           | Reserved   |                            | 0b                                   |            |

| Bit Range    | Bit Acronym   | Bit Description   | Sticky | Bit Reset Value | Bit Access |
| 07 : 00      | RID           | <b>Revision Identification Number:</b> This value indicates the revision identification number for the IMCH Device 0. |        | Variable        | RO         |

### 16.2.1.6 Offset 0Ah: SUBC - Sub-Class Code Register

**Table 16-60. Offset 0Ah: SUBC - Sub-Class Code Register**

| Description: |               |   |        |                 |            |
|--------------|---------------|---|--------|-----------------|------------|
| View         | BAR           | Bus:Device:Function   |        | Offset Start    | Offset End |
| PCI          | Configuration | 0:0:1   |        | 0Ah             | 0Ah        |
| Size         | Default       |   |        | Power Well      |            |
| 8 bit        | 00h           |   |        | Core            |            |
| Bit Range    | Bit Acronym   | Bit Description   | Sticky | Bit Reset Value | Bit Access |
| 07 : 00      | SUBC          | <b>Sub-Class Code:</b> This value indicates the Sub Class Code into which the IMCH falls.<br>00h = Bridge |        | 00h             | RO         |

### 16.2.1.7 Offset 0Bh: BCC - Base Class Code Register

**Table 16-61. Offset 0Bh: BCC - Base Class Code Register**

| Description: |               |   |        |                 |            |
|--------------|---------------|---|--------|-----------------|------------|
| View         | BAR           | Bus:Device:Function   |        | Offset Start    | Offset End |
| PCI          | Configuration | 0:0:1   |        | 0Bh             | 0Bh        |
| Size         | Default       |   |        | Power Well      |            |
| 8 bit        | FFh           |   |        | Core            |            |
| Bit Range    | Bit Acronym   | Bit Description   | Sticky | Bit Reset Value | Bit Access |
| 07 : 00      | BASEC         | <b>Base Class Code:</b> This value indicates the Base Class Code for the IMCH Device 0, Function 1.<br>FFh = A 'non-defined' device. Since this function is used for error conditions, it does not fall into any other class. |        | FFh             | RO         |

### 16.2.1.8 Offset 0Dh: MLT - Master Latency Timer Register

Device 0 in the IMCH is not a PCI master so this register is not implemented.

Table 16-62. Offset 0Dh: MLT - Master Latency Timer Register

| Description: |                    |                 |                            |                                      |                 |            |

### 16.2.1.12 Offset 40h: GLOBAL\_FERR - Global First Error Register

This register is used to log various error conditions at the “unit” level. These bits are “sticky” through reset, and are set regardless of whether or not any error messages (SCI, SMI, SERR#, MCERR#) are enabled and generated at the unit level. Specific error conditions within the various functional units are logged in the unit-specific error registers that follow.

This register captures the FIRST global Fatal and the FIRST global Non-Fatal errors. For these global error registers, a non-fatal error can be either an uncorrectable error which is non-fatal, or a correctable error. Any future errors (NEXT errors) are captured in the Global\_NERR register. No further error bits in this register are set until the existing error bit is cleared.

*Note:* If multiple errors are reported in the same clock as the first error, all errors are latched.

**Table 16-66. Offset 40h: GLOBAL\_FERR - Global First Error Register (Sheet 1 of 2)**

| Description: |               |  |        |                 |             |

#### 16.2.1.16 Offset 50h: NSI\_SCICMD - NSI SCI Command Register

This register enables various errors to generate an SCI special cycle. When an error flag is set in the FERR or NERR registers, it can generate an SCI special cycle when enabled in the SCICMD registers. Note that one and only one message type can be enabled.

### 16.2.1.17 Offset 54h: NSI\_SMICMD - NSI SMI Command Register

This register enables various errors to generate an SMI NSI special cycle. When an error flag is set in the FERR or NERR registers it generates an SMI NSI special cycle when enabled in the SMICMD register. Note that one and only one message type can be enabled.

### 16.2.1.19 Offset 5Ch: NSI\_MCERRCMD - NSI MCERR Command Register

This register enables various errors to generate the MCERR signal on the FSB. When an error flag is set in the FERR or NERR registers it generates a MCERR when enabled in the MCERRCMD.

### 16.2.1.20 Offset 60h: FSB\_FERR - FSB First Error Register

This register stores the first error related to the FSB. Only one error bit is set in this register. Any future errors (NEXT errors) are set in the FSB\_NERR register. No further error bits in the FSB\_FERR register are set until the existing error bit is cleared. These bits are sticky through reset. Software clears these bits by writing a 1 to the bit location.

*Note:* If multiple errors are reported in the same clock as the first error, all errors are latched.

### 16.2.1.25 Offset 6Ch: FSB\_SERRCMD - FSB SERR Command Register

This register enables various errors to generate an SERR NSI special cycle. When an error flag is set in the FSB\_FERR or FSB\_NERR register, it generates an SERR NSI special cycle when enabled in the SERRCMD register. Note that one and only one message type can be enabled.

**Table 16-79. Offset 6Ch: FSB\_SERRCMD - FSB SERR Command Register**

### 16.2.1.30 Offset 78h: BUF\_SCI\_CMD - Memory Buffer SCI Command Register

This register enables various errors to generate an SCI NSI special cycle. When an error flag is set in the FERR or NERR registers, it generates an SCI NSI special cycle when enabled in the SCICMD registers. Note that one and only one message type can be enabled.

**Table 16-84. Offset 78h: BUF\_SCI\_CMD - Memory Buffer SCI Command Register**

### 16.2.1.35 Offset E8h: BERRINJCTL - Buffer Error Injection Control Register

This register enables the injection of errors on data read out of the posted write buffer. The lower 16 bits are the corresponding flip parity bits for the cacheline of data. The upper bits in the register are for the use and control of the associated flip parity bits.

**Table 16-89. Offset E8h: BERRINJCTL - Buffer Error Injection Control Register**

| Description: |                    |  |                            |                                      |            |

**16.2.1.36 Offset 80h: DRAM\_FERR - DRAM First Error Register**

This register signals the first error occurring in the memory system. Refer to [Section 11.5, "Error Handling"](#) to understand the error handling mechanism implemented in Core.

This register stores the first error related to the DRAM Controller. Typically, only one error bit is set in this register. However, in the case of multiple errors in the same cycle, multiple bits can be set in this register.

No further error bits in the DRAM\_FERR register are set until the existing error bit is cleared by software. Any future errors (NEXT errors) are set in the DRAM\_NERR register defined in [Table 16-91](#).

The bits defined in this register are sticky through reset. Software clears these bits by writing a 1 to the bit location.

The errors in this register are reported up into the GLOBAL\_FERR registers as either "fatal" or "non-fatal" errors from the memory controller as noted in the descriptions below.

*Note:* All memory controller errors are "not-fatal".

*Note:* Logging of these errors can be masked only by setting the corresponding bit in [Section 16.2.1.38, "Offset 84h: DRAM\\_EMASK - DRAM Error Mask Register"](#).

### 16.2.1.37 Offset 82h: DRAM\_NERR - DRAM Next Error Register

This register captures the errors related to the DRAM Controller that occur after the first error is detected and captured in DRAM\_FERR. Refer to [Section 11.5, “Error Handling”](#) to understand the error handling mechanism implemented in the memory controller.

Multiple bits can be set in this register if multiple errors occur following the first error prior to software clearing the first error register. These bits are sticky through reset. Software clears these bits by writing a 1 to the bit location.

The errors in this register are reported up into the GLOBAL\_NERR registers as either “fatal” or “non-fatal” errors from the memory controller as noted in the descriptions below.

Unlike the DRAM\_FERR register, multiple errors are accumulated in the DRAM\_NERR register.

*Note:* All memory controller errors are “not-fatal”.

*Note:* Logging of these errors can be masked only by setting the corresponding bit in [Section 16.2.1.38, “Offset 84h: DRAM\\_EMASK - DRAM Error Mask Register”](#).

### 16.2.1.38 Offset 84h: DRAM\_EMASK - DRAM Error Mask Register

This register masks the DRAM Controller errors and events from being recognized, preventing them from being logged at either the unit level (via the DRAM\_FERR or DRAM\_NERR registers, see [Section 16.2.1.36, “Offset 80h: DRAM\\_FERR - DRAM First Error Register”](#) and [Section 16.2.1.37, “Offset 82h: DRAM\\_NERR - DRAM Next Error Register”](#)) or global level (via GLOBAL\_FERR or GLOBAL\_NERR) and preventing an interrupt/messages from being generated.

These bits are sticky through reset.

**Note:** If ETD\_MASK is changed from 0 to 1 and any error count is already above threshold, then the error(s) will be immediately reported via FERR/NERR.

**Table 16-92. Offset 84h: DRAM\_EMASK - DRAM Error Mask Register**

| Description: |                    |  |                            |                                      |            |

**16.2.1.39 Offset 88h: DRAM\_SCICMD - DRAM SCI Command Register**

This register enables the memory controller to generate an SCI NSI special cycle for various error flags. When an error flag is set in either the DRAM\_FERR or DRAM\_NERR registers (see Section 16.2.1.36, “Offset 80h: DRAM\_FERR - DRAM First Error Register” and Section 16.2.1.37, “Offset 82h: DRAM\_NERR - DRAM Next Error Register”), hardware generates an SCI NSI special cycle when enabled in the DRAM\_SCICMD register.

Note that software should enable one and only one message type for a given error flag.

Table 16-93. Offset 88h: DRAM\_SCI\_CMD - DRAM SCI Command Register

| Description: |                    |   |                                      |                 |            |

#### 16.2.1.40 Offset 8Ah: DRAM\_SMICMD - DRAM SMI Command Register

This register enables the memory controller to generate an SMI NSI special cycle for various error flags. When an error flag is set in either the DRAM\_FERR or DRAM\_NERR registers (see Section 16.2.1.36, “Offset 80h: DRAM\_FERR - DRAM First Error Register” and Section 16.2.1.37, “Offset 82h: DRAM\_NERR - DRAM Next Error Register”), hardware generates an SMI NSI special cycle when enabled in the DRAM\_SMICMD register.

Note that software should enable one and only one message type for a given error flag.

**Table 16-94. Offset 8Ah: DRAM\_SMICMD - DRAM SMI Command Register**

**16.2.1.41 Offset 8Ch: DRAM\_SERRCMD - DRAM SERR Command Register**

This register enables the memory controller to generate an SERR NSI special cycle for various error flags. When an error flag is set in either the DRAM\_FERR or DRAM\_NERR registers (see Section 16.2.1.36, “Offset 80h: DRAM\_FERR - DRAM First Error Register” and Section 16.2.1.37, “Offset 82h: DRAM\_NERR - DRAM Next Error Register”), hardware generates an SERR NSI special cycle when enabled in the DRAM\_SERRCMD register.

*Note:* Software should enable one and only one message type for a given error flag.

**16.2.1.42 Offset 8Eh: DRAM\_MCERRCMD - DRAM MCERR Command Register**

This register enables the memory controller to generate an MCERR# signal on the FSB for various error flags. When an error flag is set in either the DRAM\_FERR or DRAM\_NERR registers (see Section 16.2.1.36, “Offset 80h: DRAM\_FERR - DRAM First Error Register” and Section 16.2.1.37, “Offset 82h: DRAM\_NERR - DRAM Next Error Register”), hardware generates an MCERR# signal on the FSB when enabled in the DRAM\_MCERRCMD register.

Note that software should enable one and only one message type for a given error flag.

**Table 16-96. Offset 8Eh: DRAM\_MCERRCMD - DRAM MCERR Command Register**

### 16.2.1.43 Offset 98h: THRESH\_SEC0 - Rank 0 SEC Error Threshold Register

Threshold compare value for SEC errors. An Error Threshold Detect event is signaled via bit 3 of DRAM\_FERR or DRAM\_NERR (see Section 16.2.1.36, “Offset 80h: DRAM\_FERR - DRAM First Error Register” and Section 16.2.1.37, “Offset 82h: DRAM\_NERR - DRAM Next Error Register”) if the rank 0 SEC counter (see Section 16.2.1.48, “Offset B0h: DRAM\_SEC\_R0 - DRAM Rank 0 SEC Error Counter Register”) exceeds the value programmed into this register. The bits in this register are sticky through reset.

**Table 16-97. Offset 98h: THRESH\_SEC0 - Rank 0 SEC Error Threshold Register**

| Description: |                    |  |                            |                                      |            |

### 16.2.1.44 Offset 9Ah: THRESH\_SEC1 - Rank 1 SEC Error Threshold Register

Threshold compare value for SEC errors. An Error Threshold Detect event is signaled via bit 3 of DRAM\_FERR or DRAM\_NERR (see Section 16.2.1.36, “Offset 80h: DRAM\_FERR - DRAM First Error Register” and Section 16.2.1.37, “Offset 82h: DRAM\_NERR - DRAM Next Error Register”) if the rank 1 SEC counter (see Section 16.2.1.50, “Offset B4h: DRAM\_SEC\_R1 - DRAM Rank 1 SEC Error Counter Register”) exceeds the value programmed into this register. The bits in this register are sticky through reset.

**Table 16-98. Offset 9Ah: THRESH\_SEC1 - Rank 1 SEC Error Threshold Register**

| Description: |                    |  |                            |                                      |            |

### 16.2.1.45 Offset A0h: DRAM\_SECF\_ADD - DRAM First Single Bit Error Correct Address Register

Captures the address of the SEC error occurring in the memory system (including scrubs). The value in this register is only valid if the Correctable Read Memory Error bit in the DRAM\_FERR register has been set. The bits in this register are sticky through reset. (see Section 16.2.1.36, “Offset 80h: DRAM\_FERR - DRAM First Error Register”).

**Table 16-99. Offset A0h: DRAM\_SECF\_ADD - DRAM First Single Bit Error Correct Address Register**

| Description: |                    |   |                            |                                      |            |

### 16.2.1.47 Offset A8h: DRAM\_SCRB\_ADD - DRAM Scrub Error Address Register

Captures the address of the first uncorrectable error encountered by the scrub engine for a periodic memory scrub. The value in this register is only valid if the Uncorrectable Scrubber Data Error bit in the DRAM\_FERR register or DRAM\_NERR register has been set. The bits in this register are sticky through reset.

**Table 16-101. Offset A8h: DRAM\_SCRB\_ADD - DRAM Scrub Error Address Register**

| Description: |                    |   |        |                   |                 |

### 16.2.1.48 Offset B0h: DRAM\_SEC\_R0 - DRAM Rank 0 SEC Error Counter Register

Counter for SEC errors occurring for rank 0 in the memory system. The rank counters for SEC and DED errors are implemented using a leaky bucket algorithm (see [Section 11.4.7, "DDR2 MR and EMR settings"](#)). The error count returned when this register is read is not an absolute count over time, but the sum of errors during a current specified time period plus half of the accumulated errors from past time periods. When a time period expires (determined by the Spare Control register, (see [Section 16.1.1.48, "Offset 90h: SPARECTL - SPARE Control Register"](#)), the sum of the current time period accumulated errors and a value equal to half of the past accumulated errors is retained. Half of this registered error value will be added to the errors accumulated during the next time period. This method is employed, because it is not the absolute number of errors that is most interesting, but the rate that errors occur.

When this register is written, the counter holding the number of errors with the current time period is updated. Because of this described structure, reading back the register will only return the same value written if no time period has expired between the write and the read. A write to this register does clear out any error residue that may exist from past time periods. The EP80579 tracks SEC and DED events on a per-rank basis within the DIMMs installed in the system.

The bits in this register are sticky through reset.

*Note:* Writing this register with a value above threshold will trigger an error.

### 16.2.1.52 Offset C2h: THRESH\_DED - DED Error Threshold Register

This register is the threshold compare value for DED errors. An Error Threshold Detect is signaled via bit 3 of DRAM\_FERR or DRAM\_NERR (see [Section 16.2.1.36, “Offset 80h: DRAM\\_FERR - DRAM First Error Register”](#) and [Section 16.2.1.37, “Offset 82h: DRAM\\_NERR - DRAM Next Error Register”](#)) if either of the DED event counters DRAM\_DED\_RO or DRAM\_DED\_R1 (see [Section 16.2.1.49, “Offset B2h: DRAM\\_DED\\_RO - DRAM Rank 0 DED Error Counter Register”](#) or [Section 16.2.1.51, “Offset B6h: DRAM\\_DED\\_R1 - DRAM Rank 1 DED Error Counter Register”](#)) exceeds the value programmed into this register. The bits in this register are sticky through reset. The RANKTHREX register preserves knowledge of threshold exceeded events for software (see [Section 16.2.1.56, “Offset DCh: RANKTHREX - Rank Error Threshold Exceeded Register”](#) on page 497).

**Table 16-106.Offset C2h: THRESH\_DED - DED Error Threshold Register**

| Description: |                    |  |                            |                                      |            |

### 16.2.1.53 Offset C4h: DRAM\_SECF\_SYNDROME - DRAM First Single Error Correct Syndrome Register

Syndrome for correctable errors occurring in the memory system. The contents of this register are set when correctable error bit (bit 0) is set in the DRAM\_FERR register (see Section 16.2.1.36, “Offset 80h: DRAM\_FERR - DRAM First Error Register”). Syndrome is always logged for QW0/1 or QW2/3 pairs (block), if transferring the lower half of the cache line, and logged for QW4/5 or QW6/7 if transferring the upper half of the cache line. ECC is checked ½ cacheline at a time. The syndrome logged in this register is for the lowest ordered QW pair. For example: If both QW0/1 and QW2/3 have correctable errors, the syndrome stored is for QW0/1. A syndrome indicates error when it is a non-zero value. The bits in this register are sticky through reset.

**Table 16-107. Offset C4h: DRAM\_SECF\_SYNDROME - DRAM First Single Error Correct Syndrome Register**

| <b>Description:</b> |                           |   |                                   |  |            |

### 16.2.1.56 Offset DCh: RANKTHREX - Rank Error Threshold Exceeded Register

Preserves knowledge of DIMM error thresholds exceeded on a per-rank basis. Software writes bits individually to 1 to clear them. Hardware sets these bits when the count of SEC or DED errors transitions from being less than or equal to the defined threshold value (see the threshold registers such as [Section 16.2.1.52, "Offset C2h: THRESH\\_DED - DED Error Threshold Register" on page 495](#)) to being greater than the threshold value for a particular rank. This threshold exceeded bit is cleared by software and is only rearmed once the threshold is not exceeded. In other words, if the threshold count has been exceeded and the count is still greater than the threshold, then when software clears a given indicator bit, this same bit is not automatically set again until rearmed by the time decay of the error count and the threshold exceeded event occurs again. The bits in this register are sticky through reset.

Table 16-110. Offset DCh: RANKTHREX - Rank Error Threshold Exceeded Register

| Description: |                    |  |                            |                                      |            |

### 16.2.1.57 Offset ECh: DERRINJCTL - DRAM Error Injection Control Register

This register controls the IMCH handling of errors on incoming data streams into the IMCH core from the DRAM interface. This register enables the injection of parity errors on incoming data streams into the core. The lower 16 bits are the corresponding flip parity bits for the cacheline of data. The upper bits in the register are for the use and control of the associated flip parity bits.

The “flip on next data transfer (bit 16)” feature is not supported in the the memory controller.

DERRINJCTL is used to inject parity errors into the data returned to MCH during data reads. The other complementary function, ECCDIAG is used to inject parity errors into DDR upon data writes.

**Table 16-111.Offset ECh: DERRINJCTL - DRAM Error Injection Control Register**

| Description: |                    |  |                   |                 |            |

## 16.3 EDMA Registers: Bus 0, Device 1, Function 0

The EDMA registers are in Bus 0, Device 0, Function 1. Table 16-112 provides the register address map for this device and function.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Table 16-112. Bus 0, Device 1, Function 0: Summary of EDMA PCI Configuration Registers**

### 16.3.1 Register Details

#### 16.3.1.1 Offset 00h: VID - Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identifies a PCI device.

**Table 16-113. Offset 00h: VID - Vendor Identification Register**

| Description: |               |  |  |                  |            |
|--------------|---------------|--|--|------------------|------------|
| View         | BAR           | Bus:Device:Function  |  | Offset Start/End |            |
| PCI          | Configuration | 0:1:0  |  | 00h<br>01h       |            |
| Size         | Default       |  |  | Power Well       |            |

### 16.3.1.16 Offset 80h: EDMA\_FERR - EDMA First Error Register

This register captures the first occurrence of errors on a EDMA channel basis. This register only designates which channel had an error. Once an error has been captured for a given channel, this register is locked and needs to be written with ones to clear it. All DMA errors are considered non-fatal because they cause the DMA engine to stop further processing, thus avoiding any data corruption. The errors are fatal to the process, but not to the system.

Table 16-128.Offset 80h: EDMA\_FERR - EDMA First Error Register (Sheet 1 of 2)

| Description: |                                     |  |                            |                                      |            |

**16.3.1.17 Offset 84h: EDMA\_NERR - EDMA Next Error Register**

This register captures EDMA channel errors after the FERR register is locked. This register accumulates all subsequent errors for the EDMA channels. See [Table 16-129](#) for bit definitions.

Table 16-129.Offset 84h: EDMA\_NERR - EDMA Next Error Register (Sheet 1 of 2)

**16.3.1.18 Offset 88h: EDMA\_EMASK - EDMA Error Mask Register**

This register masks the unit errors from being recognized and therefore not logged at the unit or global level and no interrupt/messages are generated. All channels are expected to use the same reporting structure, so only one 8-bit register is implemented.

Table 16-130. Offset 88h: EDMA\_EMASK - EDMA Error Mask Register

| Description: |                    |  |                            |                                      |            |

### 16.3.1.19 Offset A0h: EDMA\_SCICMD - EDMA SCI Command Register

This register enables various errors to generate an SCI special cycle to the IICH. When an error flag is set in the EDMA\_FERR or EDMA\_NERR registers, it generates an SERR, SMI, or SCI special cycle when enabled in the SERRCMD, SMICMD, or SCICMD registers, or a MCERR# on the FSB when enabled in the MCERRCMD, respectively. Note that only one message type can be enabled. All channels are expected to use the same reporting structure, so only one 8-bit register is implemented.

**Table 16-131. Offset A0h: EDMA\_SCICMD - EDMA SCI Command Register**

### 16.3.1.22 Offset ACh: EDMA\_MCERRCMD - EDMA MCERR Command Register

This register enables various errors to generate the MCERR# signal on the FSB. When an error flag is set in the EDMA\_FERR or EDMA\_NERR registers, it generates an SERR, SMI, or SCI special cycle when enabled in the SERRCMD, SMICMD, or SCICMD registers, or a MCERR# on the FSB when enabled in the MCERRCMD, respectively. Note that only one message type can be enabled. All channels are expected to use the same reporting structure, so only one 8-bit register is implemented.

**Table 16-134. Offset ACh: EDMA\_MCERRCMD - EDMA MCERR Command Register**

### 16.3.1.23 Offset B0h: MSICR - MSI Control Register

The EDMA controller generates an upstream interrupt message using Message Signaled Interrupts (MSI) to the processor, bypassing the IOxAPIC. The MSI is generated by a memory write to address 0FEEx\_xxxxh. The MSI Control Register (MSICR), MSI Address Register (MSIAR) and MSI Data Register (MSIDR) support this mechanism. The default values of these registers are compatible with the default value of IOxAPIC. System software can reprogram these values, if required.

The MSI Control Register (MSICR) contains all the information related to the capability of EDMA MSI interrupts.

**Table 16-135.Offset B0h: MSICR - MSI Control Register**

| Description: |                    |  |                            |                                      |            |

## 16.4 PCI Express\* Port A Standard and Enhanced Registers: Bus 0, Devices 2 and 3, Function 0

Bus 0, Device 2, Function 0 is the PCI Express\* Port A (in x8 mode) or port A0 (in x4 mode) virtual PCI-to-PCI bridge. The registers described here include both the standard configuration space and the enhanced configuration space (starting at offset 100h).

Device 3 is the PCI Express\* Port A1 virtual PCI-to-PCI bridge. Device 2 is PCI Express\* Port A (in x8 mode) or A0 (in x4 mode). Port A1's associated PCI Express\* link has a maximum lane width of x4. When Device 2 is configured as a x8 PCI Express\* link, device 3 is not available. The registers described here include both the standard configuration space and the enhanced configuration space (starting at offset 100h). Except for the registers listed below, all registers for Device 3 are exactly the same as for Device 2.

*Note:* All registers are located in the Core power well.

*Note:* For platforms not using PCIe should also disable PCI Express\* logic per [Section 9.2.1.1, "Low power SKU with PCI Express ports removed"](#)

## 16.4.1 Register Details

### 16.4.1.1 Offset 00h: VID - Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identify any PCI device.

**Table 16-140.Offset 00h: VID - Vendor Identification Register**

| Description:        |                           |  |                                   |  |            |
|---------------------|---------------------------|--|-----------------------------------|--|------------|
| <b>View:</b> PCI 1  | <b>BAR:</b> Configuration |  | <b>Bus:Device:Function:</b> 0:2:0 | <b>Offset Start:</b> 00h<br><b>Offset End:</b> 01h |            |
| <b>View:</b> PCI 2  | <b>BAR:</b> Configuration |  | <b>Bus:Device:Function:</b> 0:3:0 | <b>Offset Start:</b> 00h<br><b>Offset End:</b> 01h |            |
| <b>Size:</b> 16 bit | <b>Default:</b> 8086h     |  |                                   | <b>Power Well:</b> Core                            |            |
| Bit Range           | Bit Acronym               | Bit Description  | Sticky                            | Bit Reset Value                                    | Bit Access |
| 15 : 00             | VID                       | <b>Vendor Identification Device:</b> This is a 16-bit value assigned to Intel. |                                   | 8086h  | RO         |

### 16.4.1.2 Offset 02h: DID - Device Identification Register

This 16-bit register combined with the Vendor Identification register uniquely identifies any PCI device. Note that the Device ID changes for each of the PCI Express\* ports, starting with 5024h for Device 2.

**Table 16-141.Offset 02h: DID - Device Identification Register**

| Description:        |                           |  |                                   |  |            |

| 15 : 00      | DID            | <b>Device Identification Number:</b> This is a 16-bit value assigned to the IMCH Device 3, Function 0. |  |                  | 5025h           | RO         |

### 16.4.1.4 Offset 04h: PCICMD - PCI Command Register

Many of these bits are not applicable since the primary side of this device is not an actual PCI bus.

Table 16-143.Offset 04h: PCICMD - PCI Command Register (Sheet 1 of 2)

| Description: |                |   |  |                  |                 |            |
|--------------|----------------|---|--|------------------|-----------------|------------|
| View         | BAR            | Bus:Device:Function   |  | Offset Start     | Offset End      |            |
| PCI 1        | Configuration  | 0:2:0   |  | 04h              | 05h             |            |
| PCI 2        | Configuration  | 0:3:0   |  | 04h              | 05h             |            |
| Size: 16 bit | Default: 0000h |   |  | Power Well: Core |                 |            |
| Bit Range    | Bit Acronym    | Bit Description   |  | Sticky           | Bit Reset Value | Bit Access |
| 15 : 11      | Reserved       | Reserved.   |  |                  | 00h             |            |
| 10           | INTXD          | <b>INTx Assertion Disable:</b> Controls the ability of the PCI Express* device to assert INTx interrupts. When set, devices are prevented from asserting INTx. This bit only applies to legacy interrupts and not MSIs. Also this bit has no affect on PCI Express* messages that are converted to legacy interrupts. These are only internal, device generated interrupts.<br>0 = Enable INTx assertion<br>1 = Disable INTx assertion    |  |                  | 0b              | RW         |
| 09           | FB2B           | <b>Fast Back-to-Back Enable:</b> Not Applicable-hardwired to 0.   |  |                  | 0b              | RO         |
| 08           | SERRE          | <b>SERR Enable:</b> This bit is a global enable bit for Device SERR messaging. The IMCH does not have an SERR# signal. The IMCH communicates the SERR# condition by sending an SERR message to the IICH via NSI.<br>0 = No SERR message is generated by the IMCH for Device (unless enabled through enhanced configuration registers).<br>1 = Enable SERR, SCI, or SMI messages or asserting MCERR# for specific Device error conditions. |  |                  | 0b              | RW         |
| 07           | ADSTEP         | <b>Address/Data Stepping:</b> Not applicable.   |  |                  | 0b              | RO         |

Table 16-143. Offset 04h: PCICMD - PCI Command Register (Sheet 2 of 2)

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|

### 16.4.1.5 Offset 06h: PCISTS - PCI Status Register

PCISTS is a 16-bit status register that reports the occurrence of error conditions associated with the primary side of the “virtual” PCI-PCI bridge embedded within the IMCH.

Table 16-144. Offset 06h: PCISTS - PCI Status Register (Sheet 1 of 2)

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI 1  | BAR: Configuration |   | Bus:Device:Function: 0:2:0 | Offset Start: 06h<br>Offset End: 07h |            |
| View: PCI 2  | BAR: Configuration |   | Bus:Device:Function: 0:3:0 | Offset Start: 06h<br>Offset End: 07h |            |
| Size: 16 bit | Default:           | 0010h   |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                     | Bit Reset Value                      | Bit Access |
| 15           | DPE                | <b>Detected Parity Error:</b> Parity is supported on the primary side of this device. Since the parity is not checked on the downstream side from the core, this bit can never be set.<br>0 = No Parity Error detected  |                            | 0b                                   | RO         |
| 14           | SSE                | <b>Signaled System Error:</b> Indicates whether or not a NSI SERR message was generated by this device. For the root port the fatal and non-fatal messages can be either received or virtual messages that are forwarded for reporting.<br>0 = SERR message not generated by this device.<br>1 = This device was the source of fatal or non-fatal error that has been enabled for generation of a System Error.<br>Software clears this bit by writing a '1' to the bit location. |                            | 0b                                   | RWC        |
| 13           | RMAS               | <b>Received Master Abort Status:</b> Indicates whether or not this PCI Express* device received a completion with Unsupported Request Completion status.<br>0 = No Master Abort received. Software clears this bit by writing a '1' to the bit location.<br>1 = Set when this PCI Express* device receives a completion with Unsupported Request Completion Status.   |                            | 0b                                   | RWC        |
| 12           | RTAS               | 0 = <b>Received Target Abort Status:</b> Indicates whether or not this PCI Express* device received a completion with Completer Abort Completion Status. No Target Abort received. Software clears this bit by writing a '1' to the bit location.<br>1 = Set when this PCI Express* device receives a completion with Completer Abort Completion Status.  |                            | 0b                                   | RWC        |
| 11           | STAS               | <b>Signaled Target Abort Status:</b> Not applicable to the primary side.<br>0 = This PCI Express* device has not completed a request using Completer Abort Completion Status.<br>1 = This PCI Express* device completed a request using Completer Abort Completion Status.  |                            | 0b                                   | RO         |
| 10 : 09      | DEVT               | <b>DEVSEL# Timing:</b> Not Applicable. Hardwired to 0.  |                            | 00b                                  | RO         |
| 08           | DPD                | 0 = <b>Master Data Parity Error Detected:</b> Parity is supported on the primary side of this device. No Master Parity Error detected. Software clears this bit by writing a '1' to the bit location.<br>1 = Set when this PCI Express* device receives a completion marked poisoned, or when this device poisons a write Request. This bit can only be set if the Parity Error Enable bit is set.  |                            | 0b                                   | RWC        |

| Bit Range    | Bit Acronym        | Bit Description   | Sticky                     | Bit Reset Value                      | Bit Access |
| 07 : 00      | RID                | Revision Identification Number: This value indicates the revision identification number for the device 2. It is always the same as the value in Device 0 RID. |                            | Variable                             | RO         |

### 16.4.1.7 Offset 0Ah: SUBC - Sub-Class Code Register

This register contains the Sub-Class Code for the device.

**Table 16-146.Offset 0Ah: SUBC - Sub-Class Code Register**

| Description: |                    |  |                            |                                      |                 |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|-----------------|------------|
| View: PCI 1  | BAR: Configuration |  | Bus:Device:Function: 0:2:0 | Offset Start: 0Ah<br>Offset End: 0Ah |                 |            |
| View: PCI 2  | BAR: Configuration |  | Bus:Device:Function: 0:3:0 | Offset Start: 0Ah<br>Offset End: 0Ah |                 |            |
| Size: 8 bit  | Default:           | 04h  |                            | Power Well: Core                     |                 |            |
| Bit Range    | Bit Acronym        | Bit Description  |                            | Sticky                               | Bit Reset Value | Bit Access |
| 07 : 00      | SUBC               | Sub-Class Code: This value indicates the category of Bridge into which device falls.04h = PCI to PCI Bridge. |                            |                                      | 04h             | RO         |

### 16.4.1.8 Offset 0Bh: BCC - Base Class Code Register

This register contains the Base Class Code of the IMCH Device 2.

**Table 16-147.Offset 0Bh: BCC - Base Class Code Register**

| Description: |                    |  |                            |                                      |                 |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|-----------------|------------|
| View: PCI 1  | BAR: Configuration |  | Bus:Device:Function: 0:2:0 | Offset Start: 0Bh<br>Offset End: 0Bh |                 |            |
| View: PCI 2  | BAR: Configuration |  | Bus:Device:Function: 0:3:0 | Offset Start: 0Bh<br>Offset End: 0Bh |                 |            |
| Size: 8 bit  | Default:           | 06h  |                            | Power Well: Core                     |                 |            |
| Bit Range    | Bit Acronym        | Bit Description  |                            | Sticky                               | Bit Reset Value | Bit Access |
| 07 : 00      | BASEC              | Base Class Code: This value indicates the Base Class Code for the device. 06h = Bridge device. |                            |                                      | 06h             | RO         |

### 16.4.1.9 Offset 0Ch: CLS - Cache Line Size Register

This register is normally set by system firmware and OS to the system cache line size.

**Table 16-148.Offset 0Ch: CLS - Cache Line Size Register**

| Description: |                    |   |                            |                                      |                 |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|-----------------|------------|
| View: PCI 1  | BAR: Configuration |   | Bus:Device:Function: 0:2:0 | Offset Start: 0Ch<br>Offset End: 0Ch |                 |            |
| View: PCI 2  | BAR: Configuration |   | Bus:Device:Function: 0:3:0 | Offset Start: 0Ch<br>Offset End: 0Ch |                 |            |
| Size: 8 bit  | Default:           | 00h   |                            | Power Well: Core                     |                 |            |
| Bit Range    | Bit Acronym        | Bit Description   |                            | Sticky                               | Bit Reset Value | Bit Access |
| 07 : 00      | CLS                | <b>Cache Line Size:</b> This register is set by BIOS or OS to the system cache line size. Implemented as read-write field only for compatibility reasons. It has no effect on the device's functionality. |                            |                                      | 00h             | RW         |

### 16.4.1.10 Offset 0Eh: HDR - Header Type Register

This register identifies the header layout of the configuration space.

**Table 16-149.Offset 0Eh: HDR - Header Type Register**

| Description: |                    |  |                            |                                      |                 |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|-----------------|------------|
| View: PCI 1  | BAR: Configuration |  | Bus:Device:Function: 0:2:0 | Offset Start: 0Eh<br>Offset End: 0Eh |                 |            |

### 16.4.1.14 Offset 1Ch: IOBASE - I/O Base Address Register

The IOBASE and IOLIMIT registers control the processor-to-PCI Express\* I/O access routing based on the following formula:

$$IO\_BASE = < address = < IO\_LIMIT$$

Only the upper four bits are programmable. For the purpose of address decode address bits A[11:00] are treated as 0. Thus the bottom of the defined I/O address range is aligned to a 4 Kbyte boundary.

**Table 16-153.Offset 1Ch: IOBASE - I/O Base Address Register**

| Description: |                    |   |                            |                                      |                 |            |

### 16.4.1.15 Offset 1Dh: IOLIMIT - I/O Limit Address Register

This register controls the CPU to PCI Express\* I/O access routing based on the following formula:

$$IO\_BASE = \langle address \rangle \ll IO\_LIMIT$$

Only the upper four bits are programmable. For the purpose of address decode address bits A[11:00] are assumed to be FFFh. Thus, the top of the defined I/O address range is at the top of a 4 Kbyte aligned address block.

**Table 16-154. Offset 1Dh: IOLIMIT - I/O Limit Address Register**

| Description: |                    |  |                            |                                      |            |

### 16.4.1.17 Offset 20h: MBASE - Memory Base Address Register

This register controls the processor to PCI Express\* non-prefetchable memory access routing based on the following formula:

$$\text{MEMORY\_BASE} = \langle \text{address} = \langle \text{MEMORY\_LIMIT}$$

Note:

The upper 12 bits of the register are read/write and correspond to the upper 12 address bits A[31:20] of the 32-bit address. The bottom four bits of this register are read-only and return zeroes when read. This register must be initialized by the configuration software. For the purpose of address decode address bits A[19:00] of the Memory Base Address are assumed to be 0. Similarly, the bridge assumes that the lower 20 bits of the Memory Limit Address (A[19:00]) are F\_FFFh. Thus, the bottom of the defined memory address range are aligned to a 1 Mbyte boundary, and the top of the defined memory range is at the top of a 1 Mbyte memory block. Memory range covered by MBASE and MLIMIT registers are used to map non-prefetchable PCI Express\* address ranges (typically where control/status memory-mapped I/O data structures of the graphics controller resides) and PMBASE and PMLIMIT are used to map prefetchable address ranges (typically graphics local memory). This segregation allows application of USWC space attribute to be performed in a true plug-and-play manner to the prefetchable address range for improved PCI Express\* memory access performance.

Configuration software is responsible for programming all address range registers (prefetchable, non-prefetchable) with the values that provide exclusive address ranges (for example, to prevent overlap with each other and/or with the ranges covered with the main memory). There is no provision in the CMI hardware to enforce prevention of overlap and operations of the system in the case of overlap are not guaranteed.

Table 16-156. Offset 20h: MBASE - Memory Base Address Register

| Description: |                    |   |                            |                                      |                 |            |

### 16.4.1.18 Offset 22h: MLIMIT - Memory Limit Address Register

This register controls the processor to PCI Express\* non-prefetchable memory access routing based on the following formula:

$$\text{MEMORY\_BASE} = \langle \text{address} = \langle \text{MEMORY\_LIMIT}$$

The upper 12 bits of the register are read/write and correspond to the upper 12 address bits A[31:20] of the 32-bit address. The bottom four bits of this register are read-only and return zeroes when read. This register must be initialized by configuration software. For the purpose of address decode address bits A[19:00] are assumed to be FFFFh. Thus, the top of the defined memory address range is at the top of a 1 Mbyte aligned memory block.

**Note:** Memory range covered by MBASE and MLIMIT registers, are used to map non-prefetchable PCI Express\* address ranges (typically where control/status memory-mapped I/O data structures of the graphics controller reside) and PMBASE and PMLIMIT are used to map prefetchable address ranges (typically graphics local memory). This segregation allows application of USWC space attribute to be performed in a true plug-and-play manner to the prefetchable address range for improved PCI Express\* memory access performance.

Configuration software is responsible for programming all address range registers (prefetchable, non-prefetchable) with the values that provide exclusive address ranges; for example, to prevent overlap with each other and/or with the ranges covered with the main memory. There is no provision in the CMI hardware to enforce prevention of overlap and operations of the system in the case of overlap are not guaranteed.

#### 16.4.1.19 Offset 24h: PMBASE - Prefetchable Memory Base Address Register

This PMBASE and PMLIMIT register controls the processor to PCI Express\* prefetchable memory accesses. The upper 12 bits of the register are read/write and correspond to the upper 12 address bits A[31:20] of the 32-bit address. For the purpose of address decode, bits A[19:00] of the Prefetchable Memory Base Address are assumed to be 0. Similarly, the bridge assumes that the lower 20 bits of the Prefetchable Memory Limit Address (A[19:00]) are F\_FFFFh. Thus, the bottom of the defined memory address range are aligned to a 1 Mbyte boundary, and the top of the defined memory range are at the top of a 1 Mbyte memory block.

The bottom 4 bits of both the Prefetchable Memory Base and Prefetchable Memory Limit registers are read-only, contain the same value, and encode whether or not the bridge supports 64-bit addresses. If these four bits have the value 0h, then the bridge supports only 32 bit addresses. If these four bits have the value 01h, then the bridge supports 64-bit addresses and the Prefetchable Base Upper 32 Bits and Prefetchable Limit Upper 32 Bits registers hold the rest of the 64-bit prefetchable base and limit addresses respectively. All other encodings are reserved.

**Table 16-158.Offset 24h: PMBASE - Prefetchable Memory Base Address Register**

Once this register is written, the register value locks and cannot be further updated. |                            |                                      | 01h             | RWO        |

### 16.4.1.26 Offset 3Eh: BCTRL - Bridge Control Register

This register provides extensions to the PCICMD register that are specific to PCI-PCI bridges. The BCTRL provides additional control for the secondary interface (e.g. PCI Express\*) and some bits that affect the overall behavior of the “virtual” PCI-PCI bridge embedded within, e.g. VGA compatible address range mapping.

Table 16-165.Offset 3Eh: BCTRL - Bridge Control Register (Sheet 1 of 2)

| Description: |                    |   |                            |                                      |                 |            |

### 16.4.1.37 Offset 58h: MSICAPID - MSI Capabilities Structure Register

This register identifies the MSI capability structure.

**Table 16-176. Offset 58h: MSICAPID - MSI Capabilities Structure Register**

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI 1  | BAR: Configuration |  | Bus:Device:Function: 0:2:0 | Offset Start: 58h<br>Offset End: 58h |            |
| View: PCI 2  | BAR: Configuration |  | Bus:Device:Function: 0:3:0 | Offset Start: 58h<br>Offset End: 58h |            |
| Size: 8 bit  | Default:           | 05h  |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 07 : 00      | CAP_ID             | This field has the value 05h to identify the CAP_ID assigned by the PCI SIG for a message signaled interrupts capability list. |                            | 05h                                  | RO         |

### 16.4.1.38 Offset 59h: MSINPTR - MSI Next Capabilities Pointer Register

This register points to the next capability structure.

Table 16-177. Offset 59h: MSINPTR - MSI Next Capabilities Pointer Register

| Description: |                    |  |                            |                                      |                 |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|-----------------|------------|
| View: PCI 1  | BAR: Configuration |  | Bus:Device:Function: 0:2:0 | Offset Start: 59h<br>Offset End: 59h |                 |            |
| View: PCI 2  | BAR: Configuration |  | Bus:Device:Function: 0:3:0 | Offset Start: 59h<br>Offset End: 59h |                 |            |
| Size: 8 bit  | Default:           | 64h  |                            | Power Well: Core                     |                 |            |
| Bit Range    | Bit Acronym        | Bit Description  |                            | Sticky                               | Bit Reset Value | Bit Access |
| 07 : 00      | MSI_NCP            | Next Capability Pointer: This field points to the next Capability ID in this device, which is the Hot Plug Controller. |                            |                                      | 64h             | RO         |

### 16.4.1.39 Offset 5Ah: MSICAPA - MSI Capabilities Register

The PCI Express\* controller generates upstream interrupt message using MSI to the processor bypassing IOxAPIC. The MSI is generated by a Memory Write to address OFEEx\_xxxxh. Three 32-bit registers are required in the PCI Express\* controller to support this mechanism. The default values of these registers are compatible to the default value of IOxAPIC. The software can reprogram these registers to required value. The three registers are MSI Control Register (MSICR), MSI Address Register (MSIAR) and MSI Data Register (MSIDR). Depending on system requirement each PCI Express\* channel can have a MSI block (provides better flexibility) or the PCI Express\* controller as a whole has one MSI block and all channels raise hardware interrupts to this block.

The MSI Control Register (MSICR) contains all the information related to the capability of PCI Express\* MSI interrupts. The MSICR register has been broken down into its components, MSICAPID, MSINPTR, and MSICAPA for purposes of separate register definitions.

Table 16-178.Offset 5Ah: MSICAPA - MSI Capabilities Register

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI 1  | BAR: Configuration |   | Bus:Device:Function: 0:2:0 | Offset Start: 5Ah<br>Offset End: 5Bh |            |

### 16.4.1.59 Offset 104h: UNCERRSTS - Uncorrectable Error Status Register

The Uncorrectable Error Status register reports the status of individual error sources on the PCI Express\* device. An individual error status bit that is set indicates that a particular error occurred. Software may clear an error status bit by writing a '1' to the bit location. These bits are sticky through reset.

Table 16-198. Offset 104h: UNCERRSTS - Uncorrectable Error Status Register (Sheet 1 of 2)

### 16.4.1.60 Offset 108h: UNCERRMSK - Uncorrectable Error Mask Register

The Uncorrectable Error Mask register controls reporting of individual errors by device to the PCI Express\* Root Complex via a PCI Express\* error message. A masked error (respective bit set in mask register) is not reported to the PCI Express Root Complex by an individual device. However, masked errors are still logged in the Uncorrectable Error Status register. There is one mask bit corresponding to every implemented bit in the Uncorrectable Error Status register. These bits are sticky through reset.

**Table 16-199.Offset 108h: UNCERRMSK - Uncorrectable Error Mask Register**

### 16.4.1.61 Offset 10Ch: UNCERRSEV - Uncorrectable Error Severity Register

The Uncorrectable Error Severity register controls whether an individual error is reported as a nonfatal or fatal error. An error is reported as fatal when the corresponding error bit in the severity register is set. If the bit is cleared, the corresponding error is considered nonfatal. These bits are sticky through reset.

#### 16.4.1.62 Offset 110h: CORERRSTS - Correctable Error Status Register

The Correctable Error Status register reports the status of individual error sources on the PCI Express\* device. An individual error status bit that is set indicates that a particular error occurred. Software may clear an error status bit by writing a '1' to the bit location. These bits are sticky through reset.

Table 16-201.Offset 110h: CORERRSTS - Correctable Error Status Register (Sheet 1 of 2)

| Description: |                    |  |                            |  |            |

### 16.4.1.63 Offset 114h: CORERRMSK - Correctable Error Mask Register

The Correctable Error Mask register controls reporting of individual errors by device to the PCI Express\* Root Complex via a PCI Express\* error message. A masked error (respective bit set in mask register) is not reported to the PCI Express\* Root Complex by an individual device. However, masked errors are still logged in the Correctable Error Status register. There is one mask bit corresponding to every implemented bit in the Correctable Error Status register. These bits are sticky through reset.

**Table 16-202.Offset 114h: CORERRMSK - Correctable Error Mask Register**

#### 16.4.1.64 Offset 118h: AERCACR - Advanced Error Capabilities and Control Register

This register identifies the capability structure and points to the next structure. The first error pointer rearms after the unmasked errors have been cleared. Software after clearing the errors must read the register again to ensure that it is indeed cleared. If it finds that another error occurred, it can not rely on the pointer or header, unless it detects that the error pointer changed from the last time it was read for the previous error. Bits in this register also declare the ECRC capability of this device. These bits are sticky through reset.

**Table 16-203. Offset 118h: AERCACR - Advanced Error Capabilities and Control Register**

| Description: |                    |   |                            |  |            |

| 04 : 00      | FEP                | <b>First error pointer</b> identifies the bit position of the first error reported in the Uncorrectable Error Status register. However, if a subsequent Uncorrectable Error occurs with a higher severity, this field is over-written with the bit position of the subsequent error status bit. Also, if multiple errors of equal severity are logged simultaneously, this field identifies the bit position of the most significant (leftmost) bit that has been set in the Uncorrectable Error Status register. In the event of simultaneous errors, the pointer indicates the least significant bit of the group. This bit is sticky through system reset. | Y                          | 00000b                                 | RO         |

### 16.4.1.65 Offset 11Ch: HDRLOG0 - Header Log DW 0 (1st 32 bits) Register

This register contains the first 32 bits of the header log locked down when the first uncorrectable error occurs that saves the header. To rearm this register all report uncorrectable errors must be cleared from the register. Software after clearing the errors must read the register again to ensure that it is indeed cleared. If it finds that another error occurred, it can not rely on the pointer or header, unless it detects that the error pointer changed from the last time it was read for the previous error. Byte 0 of the header is located in byte 3 of the Header Log Register 0, byte 1 of the header is in byte 2 of the Header Log Register 0 and so forth. For 12 byte headers, only the first three of the four Header Log Registers are used, and values in HDRLOG3 are undefined. These bits are sticky through reset.

**Table 16-204. Offset 11Ch: HDRLOG0 - Header Log DW 0 (1st 32 bits) Register**

These bits are sticky through system reset. | Y                          | 00000000h                              | RO         |

### 16.4.1.69 Offset 12Ch: RPERRCMD - Root (Port) Error Command Register

This register controls the generation of interrupts (beyond the basic root complex capability to generate system errors) upon detection of errors. System error generation in response to PCI Express\* error messages may be turned off by system software using the PCI Express\* Capability Structure when advanced error reporting via interrupts is enabled. These bits are sticky through reset.

### 16.4.1.70 Offset 130h: RPERRMSTS - Root (Port) Error Message Status Register

This register reports the status of errors received by the root complex. Each correctable and uncorrectable (nonfatal and fatal) error source has a First Error bit and a Next Error bit. When an error is received by the root complex, the associated First Error bit is set and the Requestor ID is logged in the Error Source Identification register. Software may clear an error status bit by writing a '1' to the bit location. If software does not clear the first reported error before another error is received, the Next Error status bit is set, but the Requestor ID of the subsequent error message is discarded. These bits are sticky through reset.

These bits are sticky through system reset.                            | Y                                 | 0000h  | RO         |

### 16.4.1.72 Offset 140h: PEAUNITERR - PCI Express\* Unit Error Register

This register is specific to the IMCH. It captures the non-PCI Express\* unit errors (those beyond the scope of the bus specification). The unit error mechanism is parallel to that used by "compatible" error registers and masks, but cannot feed back into standard registers because that would confuse standardized error handling software (which would not understand the extracurricular error bits). Escalation is controlled via the PEAERRDOCMD register (D2, F0:140-143h) for both standard and -specific error types. Uncorrectable fatal errors feed into the fatal reporting select, Uncorrectable non-fatal errors feed into the non-fatal reporting select, and correctable errors feed into the correctable reporting select. The lower nibble is for HPC related errors.

#### 16.4.1.74 Offset 148h: PEAERRDOCMD - PCI Express\* Error Do Command Register

This register supports PCI Express\* error commands for doing various signaling. DO\_SCI, DO\_SMI, and DO\_MCERR, DO\_SERR must further be enabled by the PCI Express\* Host Do Command register.

**Table 16-213.Offset 148h: PEAERRDOCMD - PCI Express Error Do Command Register (Sheet 1 of 2)**

### 16.4.1.75 Offset 14Ch: UNCEDMASK - Uncorrectable Error Detect Mask Register

The Uncorrectable Error Detect Mask register controls detection of the individual errors. An error event that is masked in this register, is treated as though the error never happened, and is subsequently not logged in the Uncorrectable Error Status register, nor is it ever reported. There is one mask bit corresponding to every implemented bit in the Uncorrectable Error Status register. This register is specific to the IMCH. These bits are sticky through reset.

**16.4.1.76 Offset 150h: COREDMASK - Correctable Error Detect Mask Register**

The Correctable Error Detect Mask register controls detection of the individual errors. An error event that is masked in this register is not logged in the Correctable Error Status register, and is never reported. There is one mask bit corresponding to every implemented bit in the Correctable Error Status register. These bits are sticky through reset.

**Table 16-215.Offset 150h: COREDMASK - Correctable Error Detect Mask Register (Sheet 1 of 2)**

### 16.4.1.80 Offset 168h: PEARRINJCTL - Error Injection Control Register

This register enables the injection of errors on incoming data streams into the core. The lower 16 bits are the corresponding flip parity bits for the cacheline of data. The upper bits in the register are for the use and control of the associated flip parity bits.

**Table 16-219.Offset 168h: PEARRINJCTL - Error Injection Control Register (Sheet 1 of 2)**

| Description: |               |   |  |                  |                 |            |

## 16.5.1 Detailed Register Description

### 16.5.1.1 Offset 00h: NOTESPAD - Note (Sticky) Pad for BIOS Support Register

This dedicated 16-bit register is provided for BIOS.

This CSR is in the memory-mapped IO region of Bus 0, Device 0, Function 0 of the memory controller. The SMRBASE register described in [Section 16.1.1.9, “Offset 14h: SMRBASE - System Memory RCOMP Base Address Register”](#) on page 395, provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

The value for BAR for all registers in this section is BAR14h.

**Table 16-221.Offset 00h: NOTESPAD - Note (Sticky) Pad for BIOS Support Register**

| Description: |                |  |                            |                                      |            |

### 16.5.1.3 Offset 40h: DCALCSR – DDR Calibration Control and Status Register

This CSR is in the memory-mapped IO region of Bus 0, Device 0, Function 0 of the memory controller. The SMRBASE register described in [Section 16.1.1.9, “Offset 14h: SMRBASE - System Memory RCOMP Base Address Register”](#) on page 395, provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

The value for BAR for all registers in this section is BAR14h.

Note: DCALCSR is used only for calibration. MBCSR is used for Memory Test.

**Table 16-223.Offset 40h: DCALCSR – DCAL Control and Status Register (Sheet 1 of 2)**

| Description: DCALCSR - DCAL Control and Status Register |                    |   |                                      |                 |            |
|---|--------------------|---|--------------------------------------|-----------------|------------|
| View: PCI   | BAR: SMRBASE       | Bus:Device:Function: 0:0:0  | Offset Start: 40h<br>Offset End: 43h |                 |            |
| Size: 32 bit  | Default: 00000000h |   | Power Well: Core                     |                 |            |
| Bit Range   | Bit Acronym        | Bit Description   | Sticky                               | Bit Reset Value | Bit Access |
| 31  | START              | <b>Start Operation</b><br>When set to 1 by software, the operation selected by the DCALCSR.OPCODE is initiated. Hardware clears this bit when the operation is complete.  | N                                    | 0b              | RWS        |
| 30 : 28   | FAIL               | <b>Completion Status</b><br>1xx = Fail, 0xx = Pass<br>Note: Best practice is to rely on MemBIST following calibration to confirm a reliable DRAM interface.   | N                                    | 000b            | RW         |
| 27  | BASPAT             | <b>Basic Data Pattern Enable:</b> This controls which data pattern is used for the DQS Delay calibration. Setting this field enables the use of the basic data pattern selected by the DCALCSR.PATTERN bits. When cleared, the extended data pattern specified in the DDQSCVDP and DDQSCADP registers is used. Note: extended data pattern mode is not to be used in 2T configurations.   | N                                    | 0b              | RW         |
| 26  | RSTREGSS           | <b>Reset Registers in Single Step Mode:</b> Reset DCALDATA CSR in single step calibration mode. This bit should be set during the first step of a single step calibration. It will enable hardware to clear all registers and status bits during the calibration step the same way hardware does on the first step of an automatic “all passes” calibration.  | N                                    | 0b              | RW         |
| 25 : 24   | Reserved           | Reserved  | N                                    | 00b             | RO         |
| 23  | SGLSTP             | <b>Single Step Calibration Operation:</b><br>Applies only to Receive enable and DQS cal.<br>“1” = Single step - a single step of the algorithm selected by the DCALCSR.OPCODE is run by hardware. No data analysis is run.<br>“0” = All passes - all steps of the algorithm selected by the DACLCSR.OPCODE is run by hardware including data analysis.  | N                                    | 0b              | RW         |
| 22 : 21   | CS                 | <b>Chip select:</b><br>This field corresponds to the chip select outputs: CS[1:0]. This field Applies to NOP, Refresh, Precharge all, and MRS/EMRS commands. It also applies to Receive Enable, and DQS Delay cal in single step mode.<br>01: select Rank 0<br>10: select Rank 1<br>00: Reserved<br>11: Reserved<br><b>Note:</b> Set CS to 01 for Self Refresh Entry. Hardware will automatically detect presence of a second rank/DIMM and sequence Self Refresh Entry via both chip selects if necessary. | N                                    | 00b             | RW         |

Table 16-223. Offset 40h: DCALCSR – DCAL Control and Status Register (Sheet 2 of 2)

| Description: DCALCSR - DCAL Control and Status Register |                    |  |                            |                                      |            |
|---|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI   | BAR: SMRBASE       |  | Bus:Device:Function: 0:0:0 | Offset Start: 40h<br>Offset End: 43h |            |
| Size: 32 bit  | Default: 00000000h |  |                            | Power Well: Core                     |            |
| Bit Range   | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 20 : 19   | Reserved           | Reserved   | N                          | 00b                                  | RO         |
| 18 : 16   | PAT                | <p><b>Data pattern:</b> for DQS cal. This sets the burst length 4 pattern for a nibble of data. The pattern is repeated for BL8. This pattern is replicated on all nibbles of the data bus.</p> <p>"000" = F &gt; 0 &gt; F &gt; 0<br/>           "001" = 0 &gt; F &gt; 0 &gt; F<br/>           "010" = A &gt; 5 &gt; A &gt; 5<br/>           "011" = 5 &gt; A &gt; 5 &gt; A<br/>           "100" = C &gt; 3 &gt; C &gt; 3<br/>           "101" = 3 &gt; C &gt; 3 &gt; C<br/>           "110" = 9 &gt; 6 &gt; 9 &gt; 6<br/>           "111" = 6 &gt; 9 &gt; 6 &gt; 9</p>  | N                          | 000b                                 | RW         |
| 15  | DARWPR             | <p><b>Disable FIFO reset:</b> in single pass mode. Applies only to Receiver enable and DQS cal. When set to 1, this bit inhibits the core to DDR cluster reset signal generated during the calibration modes. This prevents the DDR cluster synchronizer FIFO write pointer and data latches from being reset so that they can be read out of the cluster using the error monitor function. The reset signal can only be disabled in single step mode. When the DCALCSR.SGLSTP bit is set to 0, the DARWPR bit has no effect.</p>  | N                          | 0b                                   | RW         |
| 14 : 04   | OPMODS             | <p><b>Operation modifiers:</b> See Table 16-224, Table 16-224, Table 16-227, and Table 16-235 for details</p>  | N                          | 000h                                 | RW         |
| 3 : 00  | OPCODE             | <p><b>OPCODE:</b></p> <p>"0000" = NOP<br/>           "0001" = Refresh (See Table 16-226)<br/>           "0010" = Pre-Charge<br/>           "0011" = MRS/EMRS<br/>           "0100" = Self-Refresh-Exit (See Table 16-226)<br/>           "0101" = Automatic DQS Delay Calibration<br/>           "0110" = Reserved<br/>           "0111" = DLL BIST<br/>           "1100" = Automatic Receive Enable Calibration<br/>           "1101" = Self-Refresh Entry (See Table 16-226)<br/>           "1110" = Error Monitor/Read DDRIO FIFO<br/>           "1111" = ZQ Calibration<br/>           All other settings are reserved</p> | N                          | 0000b                                | RW         |

Table 16-224.DCALCSR.OPMODS in Receive Enable Mode

| Bit  | Description  |
|------|--|
| 14:7 | DRRTC override value to use in single step mode  |
| 6:4  | Test point repeat number: The number of times each receive enable delay value is tested in order to reduce the effects of noise when near a timing threshold. When set to zero, hardware will repeat each step 8 times, the maximum number possible. |

Table 16-225.DCALCSR.OPMODS in ZQ Calibration Mode

| Bit  | Description                                       |
|------|---|
| 14:3 | Ignored   |
| 4    | =0 ZQ Calibration Long<br>=1 ZQ Calibration Short |

Table 16-226.Rules about issuing Self-Refresh and Refresh commands using DCALCSR.OPCODE

|   |   |
|---|---|
| 1 | The hardware does not enforce blocking of commands for tRFC period when a REFRESH cycle is launched using the DCALCSR.OPCODE. SW is responsible for ensuring that the refresh cycle time requirement is met.  |
| 2 | Hardware will update DRC.CKE[1:0] bits with a self-refresh (SR) entry or exit command is issued using DCALCSR.OPCODE.   |
| 3 | When issuing a self-refresh entry command using DCALCSR.OPCODE, the DCALCSR.CS needs to be set appropriately. The self-refresh entry commands will be issued on a per rank basis.   |
| 4 | When issuing a self-refresh exit command using DCALCSR.OPCODE, the DCALCSR.CS will be ignored. Hardware will issue the second SR exit command if a second rank is present. Also note that a self-refresh exit command using the DCALCSR.OPCODE can be issued only once per reset cycle. Hardware does support an additional mechanism through which a self-refresh command can be issued via DRC.CKE[1:0] (please refer to Section 11.4.5, "Self-Refresh" on page 302 for more details) |

Table 16-227.DCALCSR.OPMODS in DQS Cal Mode

| Bit   | Description   |
|-------|---|
| 14:12 | Single step fine DLL delay: This is equivalent to DRAMDLLC.SLVLEN[4:0] when running DQS cal in single step mode   |
| 11:8  | Single step coarse DLL delay: This is equivalent to DQSOFCFS when running DQS cal in single step mode.  |
| 6:4   | Test point repeat number: The number of times each delay value is tested in order to reduce the effects of noise when near a timing threshold. When the DCALCSR.BASPAT bit is set to select the basic data pattern, this field sets the number of times to repeat, with zero setting a max repeat value of 8. When the extended data pattern is selected, the max repeat value becomes 15. The max repeat is still selected with a value of zero, and other values result in a number of repeats equal to 2x-1. |

Table 16-228.DCALCSR.OPMODS in Error Monitor/Read DDRIO FIFO Mode

| DCALDATA Receiver Enable "First edge position" byte detail |   |
|--|---|
| Bit  | Description   |
| 7:0  | At the end of a successful calibration, this register holds the DRRTC setting that enables the DQS receiver as close as possible to but no earlier than the first rising DQS transition after the preamble. At the start of the calibration, this register is loaded with a value of 0xFF. During the calibration, while the "strobe toggle status" bit is low, this register will be updated with the DRRTC value for the current calibration step if the DQS is found to have a value of zero. After "strobe toggle status" goes high, this register will be updated with the DRRTC value when the DQS is found to have a value of one at a calibration step. This register will no longer be updated after the "preamble found status" bit goes high, so that it will retain the position of the rising DQS edge following immediately after the preamble. |

| DCALDATA Receiver Enable "Preamble status" byte detail |  |
|--|--|
| Bit  | Description  |
| 7  | Strobe toggle status. Hardware sets this bit if a valid high pulse is found in the strobe waveform. The requirement is $(DCALDATA.First\_edge\_position - \text{last receiver enable delay value}) > RCVENAC.HWIDTH$               |
| 6  | Preamble found status. Hardware sets this bit if the "preamble found" bit asserts at any time during the calibration.  |
| 5  | Preamble found. Last receiver enable delay value meets or exceeds the preamble width requirement setting. Hardware sets this bit if: $(DCALDATA.First\_edge\_position - \text{last receiver enable delay value}) > RCVENAC.PWIDTH$ |
| 4:0  | Count of "lows" minus count of "highs" found during one set of repeated tests at the last receiver enable delay setting. See DCALCSR opmods field for a description of the repeat test function.                                   |

| DCALDATA DQS Cal Min Delay detail |   |
|-----------------------------------|---|
| Bit                               | Description   |
| 7:6                               | reserved  |
| 5:0                               | At the end of a successful calibration, this field will hold the minimum DQS delay setting that results in correct data capture in the DDR I/O capture flop. This is the left edge of the DQ data eye. During the calibration, this field is updated with the DQS delay setting of the current calibration step, until correct data capture is found. After this point no further updates are made. |

| DCALDATA DQS Cal Max Delay detail |  |
|-----------------------------------|--|
| Bit                               | Description  |
| 7:6                               | reserved   |
| 5:0                               | At the end of a successful calibration, this field will hold the maximum DQS delay setting that results in correct data capture in the DDR I/O capture flop. This is the right edge of the DQ data eye. During the calibration, this field is updated with the DQS delay setting at each calibration step until the minimum delay setting is found and a subsequent failure to capture correct read data occurs. |

### 16.5.1.6 Offset 94h: RCVENAC - Receiver Enable Algorithm Control Register

This register contains controls for the preamble detection algorithm of the automatic receiver enable logic. RCVENAC.PWIDTH is used to determine if a “low” pulse in a DQS waveform is wide enough to be a preamble. RCVENAC.POFFSET is subtracted from the DCALDATA first edge position result and programmed into the DRRTC registers

**Table 16-233.Offset 94h: RCVENAC - Receiver Enable Algorithm Control Register**

**16.5.1.8 Offset 9Ch: DQSFAIL1 - DQSFAIL1 Configuration Register**

There are two DQSFAIL registers that contain a total of 18 individual DQS failure status bits. There is one status bit for each DQS on each rank. These bits are set automatically by hardware during the receiver enable calibration if a valid DQS waveform is not detected. Hardware will not clear any bits that are set prior to the calibration even if a valid waveform is detected.

Hardware uses the DQSFAIL information to exclude calibration data during the data gathering portion and/or the data analysis portion of the both the receiver enable and DQS delay calibrations as well as MBIST. This prevents a failed DQS pin from corrupting the calibration of neighboring functional DQS pins that may share internal logic resources with a failing DQS pin.

For normal calibration, initialize all DQSFAIL bits to 0.

### 16.5.1.10 DRRTC: Receive Enable Reference Output Timing Control Registers

*Note:* These registers have to be saved and restored on S3.

The DRRTC is a set of three registers with DQS receiver enable window timing control for each byte on the DDR data bus. There is a single control for each byte for both ranks. A correct register setting will delay the start of the enable window so that it coincides with the middle of the DQS pre-ambule. Enabling the window before or after the pre-ambule would cause valid DQS edges to be missed or invalid edges or noise to be received.

The range of the enable delay, controlled by the DRRTC registers, is eight cycles, with a granularity defined by the DDRIOMC2.MASTCNTL register (controls setting for the Master DLL). The delay is measured from the memory controller clock edge that launches a “read” command on the DDR command bus. The minimum delay is equal to the DDR SDRAM read latency defined in the DRT0.CL register field. The maximum delay is the read latency plus eight cycles. In order words the DRRTC registers can introduce up to 8 cycles of delay. This DRRTC delay does not included the contributions of CL and registered DIMM to the total read latency. In addition to these major sources of delay, there is also a small “uncompensated delay” as shown in the formulas below.

The RCVEN fields of the DRRTC register control the delay as follows: bits [7:5] control whole clock increments, bits [4:3] control in quarter clock increments, and bits [2:0] control the sub-quarter cycle increments. Setting RCVEN to 0x0 produces the minimum delay, and 0xFF sets the maximum delay. The sub-quarter cycle delay is defined by the equations and “RCVEN\_OUT” lookup table below:

Delay\_Uncomp = 100ps; Note: estimate only

Delay Element = (quarter CMDCLK period - Delay\_Uncomp) / (MASTCNTL + 0.5)

sub quarter cycle delay = Delay\_Uncomp + (Delay Element \* RCVEN\_OUT[2:0])

| RCVEN_OUT Lookup Table |                   |   |   |   |   |   |   |   |
|------------------------|-------------------|---|---|---|---|---|---|---|
| DDR10MC2 [MASTCNTL]    | DRRTC RCVEN [2:0] |   |   |   |   |   |   |   |
|                        | 7                 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 7                      | 7                 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 6                      | 6                 | 5 | 5 | 4 | 3 | 2 | 1 | 0 |
| 5                      | 5                 | 4 | 4 | 3 | 2 | 1 | 1 | 0 |
| 4                      | 4                 | 4 | 3 | 3 | 2 | 1 | 1 | 0 |
| 3                      | 3                 | 3 | 2 | 2 | 1 | 1 | 0 | 0 |
| 2                      | 2                 | 2 | 2 | 1 | 1 | 0 | 0 | 0 |
| 1                      | 1                 | 1 | 1 | 1 | 0 | 0 | 0 | 0 |
| 0                      | 0                 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |

For example, if the DDR10MC2.MASTCNTL is set to 0x7, the receiver enable delay can be varied over eight cycle in 256 steps, one step for each DRRTC RCVEN setting. If DDR10MC2.MASTCNTL is set to 0x3, however, the number of steps is reduced to 128, such that half of the DRRTC RCVEN settings do not produce an increase in delay from the previous setting.

### 16.5.1.11 Offset A4h: DRRTC00 - Receive Enable Reference Output Timing Control Register

This register determines DQS 3, 2, 1, & 0 input buffer enable timing delay

### 16.5.1.14 DQS Calibration Registers

The DQSOFCs is a group of six registers that control the fine delay used to center DOS edges to the DQ data eye during read operations. There is a delay entry for each nibble of the DDR data bus for each rank. The coarse delay is controlled by the DRAMDLLC register. The equations for the fine and coarse delays are shown below. Note that "Delay Element" and "Delay\_Uncomp" are defined in the DRRTC register section. Also note that there is a separate coarse delay control for each "chunk" of the DDR I/O cluster as defined in the DRAMDLLC register section.

Note: these registers may have to be saved and restored on S3

### 16.5.1.15 Offset B4h: DQSOFC00 - DQS Calibration Register

This register determines DQS3, 2, 1, & 0 fine DQS delay when reading from rank 0.

**Table 16-240.Offset B4h: DQSOFC00 - DQS Calibration Register**

### 16.5.1.21 WPTRTC DDR I/O Write Pointer Timing

The two WPTRTC registers control the fine delay of the DDR I/O FIFO write pointers. The formulas for delay shown in the DQSOFCS and DRRTC register sections are identical to the write pointer delay formulas. To find the WPTRTC portion of write pointer delay, use the DQSOFCS formulas, and substitute WPTRTC fields for all the DQSOFCS fields. The only difference in the application of these formulas is that there is only one WPTRTC field per byte of the DDR I/O, whereas the DQSOFCS has a field per byte per rank. The total write pointer delay, measured from the same reference point as the DQS receiver enable timing, is equal to the DQS receiver enable timing, including the quarter clock and sub-quarter clock delays, plus one full clock cycle, plus the coarse and fine DRAMDLLC.SLVLEN/WPTRTC delays calculated with the formulas from the DQSOFCS register section.

### 16.5.1.22 Offset CCh: WPTRTC0 - Write Pointer Timing Control 0 Register

This register determines the DDR I/O FIFO write pointer fine delay timing for all DQS signals except DQS8 when reading from rank 0 or rank 1.

**Table 16-246. Offset CCh: WPTRTC0 - Write Pointer Timing Control Register**

### 16.5.1.24 DDQSCVDP and DDQSCADP

This set of 4 registers defines two 64 bit long data patterns used in the DQS Delay Calibration. They are only used when DCALCSR.BASPAT is low. The 64 bit patterns cover a data burst that is 32 DRAM clock cycles long. The DDQSCVDP registers define the “victim” pattern, and the DDQSCADP defines the “aggressor” pattern. The victim pattern is applied to one bit of each byte of the DDR data bus for 32 clock cycles, and the aggressor pattern is applied to all other bits. The victim pattern is applied in turn to each bit of each byte, creating a complete data pattern that is 8\*32 data cycles long.

### 16.5.1.25 Offset D4h: DDQSCVDP0 - DQS DELAY CALIBRATION VICTIM PATTERN 0 Register

This register defines the last 32 bits of the 64 bit long “victim” data pattern.

**Table 16-248.Offset D4h: DDQSCVDP0 - DQS Delay Calibration Victim Pattern 0 Register**

### 16.5.1.31 Offset C8h: DRAMDLLC - DDR I/O DLL Control Register

The formulas that show how the SLVLEN fields affect DQS delay timing are shown in the DQSOFCs register definition section. The SLVLEN fields are set by hardware during the DQS delay calibration. There are five SLVLEN fields, one for each two bytes of the DDR I/O DQ pins. The SLVBYP bit can be toggled to reset the master DLL's in the DDR I/O.

**Table 16-254.Offset C8h: DRAMDLLC - DDR I/O DLL Control Register**

### 16.5.1.34 Memory BIST Registers

The following set of registers cover the MemBIST logic which is used for testing the external DDR devices, as well as the connections between the EP80579 and the DDR chips. The following must be complete prior to running MemBist:

- Memory controller internal CSRs are set to match external DDR configuration.
- JEDEC DDRII/III initialization sequence.
- EP80579 DDR pad (Receive Enable and DQS) calibration.

The CSR's following this CSR are the memory-mapped registers for the memory controller. The SMRBASE register described in [Section 16.1.1.9, "Offset 14h: SMRBASE - System Memory RCOMP Base Address Register"](#) on page 395, provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

The value for BAR for all registers in this section is BAR14h.

### 16.5.1.35 Offset 140h: MBCSR - MemBIST Control Register
