**NOTE:** In the later half part of data burst length 8 test, 144 bits user-defined data pattern will be repeat as the same sequence of burst length 4.

### 16.5.1.37.1 MBDATA Failure Address Mapping

To compress the failure address into 32 bits, bits that are always zero are removed from the logging. These removed bits include AutoPrecharge Column address [10] and least significant bits assumed by burst length.

**Table 16-260.MBDATA Failure Address Register Correspondence to DRAM Address**

|      |    |    |     |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |                       |    |    |   |   |   |   |   |   |   |   |   |   |
|------|----|----|-----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------------------|----|----|---|---|---|---|---|---|---|---|---|---|
| 31   | 30 | 29 | 28  | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12                    | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 2    | 1  | 0  | 15  | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  | see description below |    |    |   |   |   |   |   |   |   |   |   |   |
| Bank |    |    | Row |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    | Column and Chunk      |    |    |   |   |   |   |   |   |   |   |   |   |

**BL4: 1 bit chunk indicates the location of 2 failure burst data chunks.**

The above Column plus Chunk is equal to DRAM column address as the following:

**Table 16-261.BL4 Column and Chunk Correspondence to DRAM Address**

|                       |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-----------------------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Register Bit Location | 12 | 11 | 10 | 9  | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |   |
| DRAM Col Address      | 14 | 13 | 12 | 11 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 |   |   |
| Data Chunk            |    |    |    |    |   |   |   |   |   |   |   |   | 1 | X |

- Where the auto-precharge address bit 10 is assumed zero.
- Since data is logged in 144 bits (two chunks), address bit zero is not needed.

**BL8: 2 bit chunk indicates the location of 4 failure burst data chunks.**

The above Column plus Chunk is equal to DRAM column address as the following:

**Table 16-262.BL8 Column and Chunk Correspondence to DRAM Address**

|                       |    |    |    |    |   |   |   |   |   |   |   |   |   |   |
|-----------------------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| Register Bit Location | 12 | 11 | 10 | 9  | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |   |
| DRAM Col Address      | 14 | 13 | 12 | 11 | 9 | 8 | 7 | 6 | 5 | 4 | 3 |   |   |   |
| Data Chunk            |    |    |    |    |   |   |   |   |   |   |   | 2 | 1 | X |

- Where the auto-precharge address bit 10 is assumed zero.
- Since data is logged in 144 bits (two chunks), Data chunk address bit zero is not needed.

### 16.5.1.38 Offset 19Ch: MB\_START\_ADDR - Memory Test Start Address Register

MB\_END\_ADDR row and column address must be larger than MB\_START\_ADDR row and column address in either increasing or decreasing address mode.

During FastX, FastY and FastXY operation, only one memory bank is tested. Specify the desired bank in MB\_START\_ADDR[2:0]. MB\_END\_ADDR[2:0] is ignored.

In XZY address mode, bank address wraps around either in the 4 banks or 8 banks case. In XZY mode, MB\_END\_ADDR bank address may be smaller than MB\_START\_ADDR bank address.

This register is only used when MBCSR.atype = 2b'10, and when MBCSR.algo is non-zero.

**Table 16-263.Offset 19Ch: MB\_START\_ADDR - Memory Test Start Address Register**

| <b>Description:</b> MB_START_ADDR: Memory Test Start Address |                     |  |  |                 |            |

### 16.5.1.62 Offset 260h: DDRIOMC0 - DDR IO Mode Control Register 0

This register controls functionality of the DDRIO.

This CSR is in the memory-mapped IO region of Bus 0, Device 0, Function 0 of the memory controller. The SMRBASE register described in Section 16.1.1.9, "Offset 14h: SMRBASE - System Memory RCOMP Base Address Register" on page 395, provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

The value for BAR for all registers in this section is BAR14h.

One function of DDRIOMC0 is to control the Voltage Crossing (VOX) analog control loop used to minimize any mismatch between the clock to output (Tco) on a low-to-high or high-to-low transition.

Table 16-287. Offset 260h: DDRIOMC0 - DDRIO Mode Register Control Register

### 16.5.1.63 Offset 264h: DDRIOMC1 - DDR IO Mode Control Register 1

This register controls functionality of the DDRIO.

This CSR is in the memory-mapped IO region of Bus 0, Device 0, Function 0 of the memory controller. The SMRBASE register described in [Section 16.1.1.9, "Offset 14h: SMRBASE - System Memory RCOMP Base Address Register"](#) on page 395, provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

The value for BAR for all registers in this section is BAR14h.

### 16.5.1.64 Offset 268h: DDRIOMC2 - DDR IO Mode Control Register 2

This register controls functionality of the DDRIO.

This CSR is in the memory-mapped IO region of Bus 0, Device 0, Function 0 of the memory controller. The SMRBASE register described in [Section 16.1.1.9, “Offset 14h: SMRBASE - System Memory RCOMP Base Address Register”](#) on page 395, provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

The value for BAR for all registers in this section is BAR14h.

Acceptable values for legoverrride[4:0] are 0-30d

Example(R\_DQ, dynamic): Assume Rext = 249 ohms

$$R\_DQ = Rext * 2 / (31 - legoverrride[4:0])$$

When legoverrride[4:0] = 00000, R\_DQ = (249\*2)/(31-0) = 16.1 ohms

When legoverrride[4:0] = 11110, R\_DQ = (249\*2)/(31-30) = 498 ohms

**Table 16-289. Legoverrride details**

| Mode (select via legoverrride[5:4]) | Legoverrride[9:6], [4:0]                               | Details  |
|-------------------------------------|--|--|
| static: legoverrride[5:4] = 10b     | [9:6] static impedance control setting of CMD/ADD/CLK  | See gray code below (valid for 1 to 10)  |

This CSR is in the memory-mapped IO region of Bus 0, Device 0, Function 0 of the memory controller. The SMRBASE register described in Section 16.1.1.9, "Offset 14h: SMRBASE - System Memory RCOMP Base Address Register" on page 395, provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

The value for BAR for all registers in this section is BAR14h.

Table 16-293. Offset 284h: WL\_CNTL[4:0] - Write Levelization Control Register

| 0 : 0  | BYP_WDLL           | Bypass Write DLL. This bit is used only for centering DQS to the DQ eye. For write leveling, see <a href="#">Table 16-294</a> .<br>0 – Bypass DLL<br>1 – Output with WDLL<br>Before enabling/setting this bit to 1, software needs to first program the appropriate values in DRAMDLLC.SLVLEN & WL_CNTL[x].WDLL_CNTL. | Y                          | 0b   | RW         |

### 16.5.1.65.1 Control of delay for DQ/DQS

There are two methods to control delay:

- Adding portions of a clock cycle
- Adding portions of a clock cycle as well as delay from the WDLL

The full control is encoded by combining the appropriate bit of WDLL\_MISC.WL\_PHSEL\_MODE with WL\_CNTL[x].WL\_CNTRL as shown in [Table 16-294](#)

**Table 16-294. Delay of DQ/DQS**

| WDLL_MISC.WL_PHSEL_MODE, WL_CNTL[x].WL_CNTRL | Delay              |
|--|--------------------|
| 00xxx  | 0                  |
| 01000  | WDLL_DLY           |
| 01011  | 1/4 CLK + WDLL_DLY |
| 01100  | 1/2 CLK + WDLL_DLY |
| 01101  | 3/4 CLK + WDLL_DLY |
| 10xxx  | 0                  |
| 11001  | 1/4 CLK            |
| 11000  | 1/2 CLK            |
| 11011  | 3/4 CLK            |
| 11100  | 1 CLK              |

### 16.5.1.65.2 Formula to calculate delay through DLL

$$\text{delay\_uncomp} = 100 \text{ ps (approximate value)}$$

$$\text{delay\_element} = (\text{1/4 CLK period} - \text{delay\_uncomp}) / (\text{DDR10MC2.MASTCNTL} + \text{1/2})$$

$$\text{WDLL\_DLY} = (\text{delay\_element} * \text{WL\_CNTL.WDLL\_CNTL}) / 8$$

### 16.5.1.66 Offset 298h: WDLL\_MIS C - DLL Miscellaneous Control

This register controls miscellaneous functions of the DDRIO DLL.

This CSR is in the memory-mapped IO region of Bus 0, Device 0, Function 0 of the memory controller. The SMRBASE register described in [Section 16.1.1.9, "Offset 14h: SMRBASE - System Memory RCOMP Base Address Register"](#) on page 395, provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

The value for BAR for all registers in this section is BAR14h.

Table 16-295. Offset 298h: WDLL\_MISC - DLL Miscellaneous Control

| Description: WDLL_MISC- DLL Miscellaneous Control |                    |  |  |                 |            |

## 16.6 Memory Mapped I/O for EDMA Registers

The EDMA is a reuse module capable of 64-bit addressing on both source and destination interfaces.

For the EP80579 the EDMA will only be used in 32-bit addressing mode

This section describes the memory-mapped registers for the EDMA Controller. The EDMALBAR register, described in [Section 16.3.1.9, "Offset 10h: EDMALBAR - EDMA Low Base Address Register"](#), provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

The BAR value for all registers in this section is BAR10h.

Each DMA channel consists of twelve 32-bit registers contiguous in memory mapped address space. The first of the four sets is described in detail, the others are copies at different offsets for the other channels. The abbreviations for the other channel register names replace the 0 at the end of the name with the appropriate channel number 1, 2, or 3.

**Table 16-296. Bus 0, Device 1, Function 0: Summary of EDMA Configuration Registers Mapped Through EDMALBAR Memory BAR (Sheet 1 of 2)**

## 16.6.1 Register Details

### 16.6.1.1 Offset 00h: CCR0 - Channel 0 Channel Control Register

The Channel Control Register (CCR) is cleared to zero on power-on or system reset. The CCR specifies the overall operating environment for the channel. Software initializes this register only after initializing the chain descriptors in system memory, and the Next Address registers as pointer to the first chain descriptor in memory. CCR can be written when the DMA channel is active. The CCR is a read/write register.

**Table 16-297. Offset 00h: CCR0 - Channel 0 Channel Control Register (Sheet 1 of 3)**

| Size: 32 bit | Default: 00000000h |   |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                     | Bit Reset Value                      | Bit Access |
| 03           | CRSM               | <p>Channel Resume:</p> <p>0 = Cleared when:</p> <ul style="list-style-type: none"> <li>The channel completes a DMA transfer and the Next Descriptor Address Register is not zero. In this case, the channel proceeds to the next descriptor in the chain (resumes).</li> <li>The channel is idle or the channel completes a DMA transfer and the Next Descriptor Address Register is zero.</li> </ul> <p>1 = Causes the channel to resume chaining by re-reading the current descriptor located in local system memory and reloading the Next Descriptor Address Register when the channel is idle (the Channel Active bit in the CSR is clear) or when the channel completes execution of the current descriptor.</p> <p>Once set, software cannot clear this bit. The IMCH prevents this bit from being set when either the stopped or aborted bit is set in the CSR. Software must clear the CSR stopped and aborted bits before attempting to resume the current descriptor chain. If the CSR end of chain bit was set, the DMA channel clears the end of chain bit when the current descriptor chain resumes. Refer to <a href="#">Chapter 12.0, "Enhanced Direct Memory Access Controller (EDMA)"</a> for details on the suspend and resume function.</p> |                            | 0b                                   | RWS        |
| 02           | STPDMA             | <p><b>Stop:</b></p> <p>0 = Cleared only by the IMCH, once the Channel Active bit is cleared and the DMA Stopped bit is set.</p> <p>1 = Causes the current DMA transfer to stop. The channel does not request the bus on the source side. Any data in the queue is emptied to the destination side, and all relevant bits in the CCR (bits 03:00) and CSR (Channel Active bit) are cleared. This bit has priority over the Suspend DMA bit. Once set, this bit cannot be cleared by the software. Software must be very careful in setting this bit since any DMA transfer, once stopped, cannot be restarted from that point.</p>   |                            | 0b                                   | RWS        |
| 01           | SUSDMA             | <p><b>Suspend:</b> This has no effect on the Channel Active bit.</p> <p>0 = Software clears this bit once the DMA Suspended bit is set. Clearing this bit restarts the DMA transfer from the point it was suspended, and clears the DMA Suspended bit in the CSR. Refer to <a href="#">Chapter 12.0, "Enhanced Direct Memory Access Controller (EDMA)"</a> for details on the DMA suspend function.</p> <p>1 = Allows the current descriptor to finish, but suspends channel chaining. The channel continues to request the bus on the source side for the current descriptor. When the data in the queue for this descriptor is emptied to the destination side, the channel sets the DMA Suspended bit in the CSR.</p>  |                            | 0b                                   | RW         |

**Table 16-297.Offset 00h: CCR0 - Channel 0 Channel Control Register (Sheet 3 of 3)**

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|

| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 00           | STRTDMA            | <p><b>Start:</b><br/>                     0 = Cleared by the IMCH when the DMA transfer is complete, when the DMA is stopped by software, or when the DMA encounters any unrecoverable error. The IMCH prevents this bit from being set when the stopped or aborted bit is set in the CSR. The DMA channel must be idle and software must clear the CSR before starting the DMA channel with a new descriptor chain.<br/>                     1 = Channel is enabled for DMA transfer. Once set, this bit cannot be cleared by software.</p> |                            | 0b                                   | RWS        |

### 16.6.1.2 Offset 04h: CSRO - Channel 0 Channel Status Register

The Channel Status Register (CSR) contains status flags that indicate the channel status. The register is read by application software to get the current channel status and to examine the source of an interrupt. Table 16-298 shows the format for the CSR.

Table 16-298. Offset 04h: CSRO - Channel 0 Channel Status Register (Sheet 1 of 2)

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: EDMALBAR      |  | Bus:Device:Function: 0:1:0 | Offset Start: 04h<br>Offset End: 07h |            |
| Size: 32 bit | Default: 00000000h |  |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 31 : 06      | Reserved           | Reserved   |                            | 0000000h                             |            |
| 05           | CACTV              | <b>Channel Active:</b><br>0 = Channel is inactive and available to be configured for DMA transfer by software.<br>1 = Set by the IMCH, indicates the channel is in use and actively performing DMA data transfers.<br>The channel active flag is set by the IMCH when: <ul style="list-style-type: none"> <li>• Software initiates a DMA transfer by setting the Start bit of CCR and the DMA channel in response loads the chain descriptor from the local system memory</li> <li>• Software initiates a DMA transfer by setting the Channel Resume bit of the CCR and the NDAR/NDUAR point to a legal non-null address in memory.</li> </ul> |                            | 0b                                   | RO         |
| 04           | DABRT              | <b>Aborted:</b><br>0 = Software clears this bit by writing a 1 to the bit location.<br>1 = Indicates that the current DMA transfer for this channel encountered an unrecoverable error. If the Aborted Interrupt Enable bit in the DCR is set, this generates an interrupt to the processor. Software polls this bit if an interrupt is not enabled. Error details are logged in the DMA_FERR and DMA_NERR registers.  |                            | 0b                                   | RWC        |

If the End of Chain Interrupt Enable bit in the DCR is set, this generates an interrupt to the processor. Software can use this bit for polling if interrupts are not enabled. |                            | 0b                                   | RWC        |

### 16.6.1.3 Offset 08h: CDARO - Channel 0 Current Descriptor Address Register

The Current Descriptor Address Register (CDAR) contains the lower 32-bit address of the current chain descriptor in local system memory. This register is loaded by the IMCH when a new chain descriptor is read. All chain descriptors are aligned on an eight double-word (32-bit) boundary.

Table 16-299.Offset 08h: CDARO - Channel 0 Current Descriptor Address Register

| Description: |                    |  |                            |                                      |            |

### 16.6.1.4 Offset 0Ch: CDUARO - Channel 0 Current Descriptor Upper Address Register

The upper address will not be used in the EP80579, which is limited to 32bit addressing.

The Current Descriptor Upper Address Register (CDUAR) contains the upper 32-bit address of the current chain descriptor in local system memory. This register is loaded by the IMCH when a new chain descriptor is read.

*Note:* Because the EP80579 supports 32 bit addressing only, this register needs to be set to "0" at all times.

**Table 16-300.Offset 0Ch: CDUARO - Channel 0 Current Descriptor Upper Address Register**

| Description: |                    |  |                            |                                      |            |

### 16.6.1.6 Offset 14h: SUARO - Channel 0 Source Upper Address Register

The upper address will not be used in the EP80579, which is limited to 32bit addressing

The Source Upper Address Register (SUAR) contains the upper 32-bit source address for the current DMA transfer. This register is loaded by the IMCH when the source upper address field of a new chain descriptor is read.

**Note:** Because the EP80579 supports 32 bit addressing only, this register needs to be set to "0" at all times.

**Table 16-302.Offset 14h: SUARO - Channel 0 Source Upper Address Register**

| Description:        |                           |   |                                   |  |            |

### 16.6.1.8 Offset 1Ch: DUAR0 - Channel 0 Destination Upper Address Register

The upper address will not be used in the EP80579, which is limited to 32bit addressing.

The Destination Upper Address Register (DUAR) contains the upper 32-bit destination address for the current DMA transfer. This register is loaded by the IMCH when the destination upper address field of a new chain descriptor is read.

*Note:* Because the EP80579 supports 32 bit addressing only, this register needs to be set to "0" at all times.

**Table 16-304.Offset 1Ch: DUAR0 - Channel 0 Destination Upper Address Register**

| Description:        |                           |   |                                   |  |            |

### 16.6.1.9 Offset 20h: NDAR0 - Channel 0 Next Descriptor Address Register

The Next Descriptor Address Register (NDAR) contains the lower 32-bit address of the next descriptor chain in the local system memory. This register is loaded when the next descriptor address field of a new chain descriptor is read. Additionally, software writes this register with the address of the first chain descriptor in local memory. All chain descriptors are required to be aligned on an eight double-word (32-bit) boundary or the CMI flags an error.

*Note:* Software must make sure that the Start bit in the CCR and the Channel Active bit in the CSR are clear prior to writing to the NDAR. The IMCH prevents writing to this register when these bits are not clear. Writing zero into the NDAR and NDUAR by software does not start a DMA transfer.

**Table 16-305.Offset 20h: NDAR0 - Channel 0 Next Descriptor Address Register**

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: EDMALBAR      |   | Bus:Device:Function: 0:1:0 | Offset Start: 20h<br>Offset End: 23h |            |
| Size: 32 bit | Default: 00000000h |   |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                     | Bit Reset Value                      | Bit Access |

The address must be aligned on an eight DWord (32-bit) boundary or else the IMCH flags an error. This field can only be written when the Start bit in the CCR and the Channel Active bit in the CSR are clear. |                            | 0000000h                             | RWL        |

### 16.6.1.10 Offset 24h: NDUAR0 - Channel 0 Next Descriptor Upper Address Register

The upper address will not be used in the EP80579, which is limited to 32bit addressing.

The Next Descriptor Upper Address Register (NDUAR) contains the upper 32-bit address of the next descriptor chain in the local system memory. This register is loaded when the next descriptor address field of a new chain descriptor is read. Additionally, software writes this register with the address of the first chain descriptor in local memory.

*Note:* Software must make sure that the Start bit in the CCR and the Channel Active bit in the CSR are clear prior to writing to the Next Descriptor Upper Address Register (NDAR). The IMCH prevents writing to this register when these bits are not clear. Writing zero into the NDAR and NDUAR by application software does not start a DMA transfer.

*Note:* Because the EP80579 supports 32 bit addressing only, this register needs to be set to "0" at all times.

**Table 16-306.Offset 24h: NDUARO - Channel 0 Next Descriptor Upper Address Register**

| Description: |                    |  |                            |                                      |            |

This field can only be written when the Start bit in the CCR and the Channel Active bit in the CSR are clear. |                            | 0000000h                             | RWL        |

**16.6.1.11 Offset 28h: TCR0 - Channel 0 Transfer Count Register**

The Transfer Count Register (TCR) contains the number of bytes it transfers. This register is loaded when the transfer count field of the chain descriptor is read from memory. The maximum allowed value for the TCR is 16 Mbytes. Values greater than 16 Mbytes are truncated to 16 Mbytes and no error is reported. A value of zero is valid and results in no data being transferred and no cycles are generated on the source or destination buses and an interrupt is generated if enabled. During transfers, this register contains the remaining byte bytes to be written to the destination.

**Table 16-307.Offset 28h: TCR0 - Channel 0 Transfer Count Register**

| Description: |                    |   |                            |                                      |            |

## 16.7 Memory Mapped I/O for NSI Registers

This section describes the memory-mapped registers for the North South Interface (NSI). The NSIBAR register, described in [Section 16.1, "IMCH Registers: Bus 0, Device 0, Function 0"](#) provides the base address for these registers. The offsets listed for the following registers are relative to this base address.

This Root Complex Register Block (RCRB) controls CMI's internal serial interconnect bus..

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

**Table 16-347. Bus 0, Device 0, Function 0: Summary of IMCH Configuration Registers Mapped Through NSIBAR Memory BAR**

| Offset Start | Offset End | Register ID - Description  | Default Value |

## 16.7.1 Register Details

### 16.7.1.1 Offset 00h: NSIVCECH - NSI Virtual Channel Enhanced Capability Header Register

This register indicates NSI Virtual Channel capabilities.

**Table 16-348.Offset 00h: SNSIVCECH - NSI Virtual Channel Enhanced Capability Header Register**

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: NSIBAR        |  | Bus:Device:Function: 0:0:0 | Offset Start: 00h<br>Offset End: 03h |            |
| Size: 32 bit | Default: 04010002h |  |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 31 : 20      | PNC                | <b>Pointer to Next Capability:</b> This field contains the offset to the next PCI Express capability structure in the linked list of capabilities (Link Declaration Capability). Bits [21:20] are reserved and software must mask them to allow for future uses of these bits. |                            | 040h                                 | RO         |
| 19 : 16      | PCIEVCC            | <b>PCI Express Virtual Channel Capability Version:</b> Hardwired to 1 to indicate compliances with the 1.0 version of the PCI Express Specification.   |                            | 1h                                   | RO         |
| 15 : 00      | ECID               | <b>Extended Capability ID:</b> Value of 0002h identifies this linked list item (capability structure) as being for PCI Express Virtual Channel registers.  |                            | 0002h                                | RO         |

### 16.7.1.2 Offset 04h: NSIPVCCAP1 - NSI Port VC Capability Register 1

This register describes the configuration of PCI Express Virtual Channels associated with this port.

**Table 16-349.Offset 04h: NSIPVCCAP1 - NSI Port VC Capability Register 1 (Sheet 1 of 2)**

| Description: |                    |                 |                            |                                      |            |
|--------------|--------------------|-----------------|----------------------------|--------------------------------------|------------|

### 16.7.1.6 Offset 14h: NSIVC0RCTL - NSI VCO Resource Control Register

This register controls the resources associated with PCI Express Virtual Channel 0.

**Table 16-353. Offset 14h: NSIVC0RCTL - NSI VCO Resource Control Register**

| Description: |                   |  |                            |                                      |            |
|--------------|-------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: NSIBAR       |  | Bus:Device:Function: 0:0:0 | Offset Start: 14h<br>Offset End: 17h |            |
| Size: 32 bit | Default: 80000FFh |  |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 31           | VCOEN             | <b>VCO Enable:</b> Hardwired to 1. VCO can never be disabled.  |                            | 1b                                   | RO         |
| 30 : 27      | Reserved          | Reserved   |                            | 0h                                   |            |
| 26 : 24      | VC0ID             | <b>VCO ID:</b> Assigns a VC ID to the VC resource. For VCO this is hardwired to 0 and read only.   |                            | 000b                                 | RO         |
| 23 : 20      | Reserved          | Reserved   |                            | 0h                                   |            |
| 19 : 17      | PARBSEL           | <b>Port Arbitration Select:</b> Configures the VC resource to provide a particular Port Arbitration service. Valid value for this field is a number corresponding to one of the asserted bits in the Port Arbitration Capability field of the VC resource. Because only bit 0 of that field is asserted. This field is always programmed to '1'.   |                            | 0h                                   | RW         |
| 16 : 08      | Reserved          | Reserved   |                            | 000h                                 |            |
| 07 : 01      | TCVCOM            | <b>TC/VCO Map:</b> Indicates the TCs (Traffic Classes) that are mapped to the VC resource. Bit locations within this field correspond to TC values. For example, when bit 7 is set in this field, TC7 is mapped to this VC resource. When more than one bit in this field is set, it indicates that multiple TCs are mapped to the VC resource. In order to remove one or more TCs from the TC/VCO Map of an enabled VC, software must ensure that no new or outstanding transactions with the TC labels are targeted at the given Link. |                            | 7Fh                                  | RW         |
| 00           | TC0VCOM           | <b>TC0/VCO Map:</b> Traffic Class 0 is always routed to VCO. This is will always read as 1b.   |                            | 1b                                   | RO         |

### 16.7.1.7 Offset 1Ah: NSIVCORSTS - NSI VCO Resource Status Register

This register reports the Virtual Channel specific status.

**Table 16-354.Offset 1Ah: NSIVCORSTS - NSI VCO Resource Status Register**

| Description: |                |  |                            |                                      |            |

## 17.0 Bridging and Configuration

### 17.1 Root Complex Memory-Mapped Configuration Register Details

This section describes all registers and base functionality that are related to configuration and not a specific interface (such as LPC). It contains the root complex register block, which describes the behavior of the upstream internal link.

The root complex register block is mapped into memory space using register RCBA (see [Section 19.2.7.1, "Offset F0h: RCBA: Root Complex Base Address Register"](#)). Accesses in this space must be limited to 32-bit (Dword) quantities. Burst accesses are not allowed.

*Note:* Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failures or undetermined behavior. For more information on the format of the register description tables that follow in this chapter, see [Section 7.1.1, "Register Description Tables"](#).

**Table 17-1. Bus 0, Device 31, Function 0: Summary of Root Complex Configuration Registers Mapped Through RCBA Memory BAR (Sheet 1 of 2)**

The strap jumper must be removed and the system rebooted.                    |                             | Strap                                    | RW         |

#### 17.1.6.5 Offset 3418h: FD - Function Disable Register

When disabling USB1 host controllers, the USB 2.0 EHCI Structural Parameters Registers must be updated with coherent information in "Number of Companion Controllers" and "N\_Ports" fields.

When disabling a function, only the configuration space is disabled. Software must ensure that all functionality within a controller that is not desired (such as memory spaces, I/O spaces, and DMA engines) is disabled prior to disabling the function.

## 18.0 System Management

---

### 18.1 Overview

The CMI provides various functions to make a system easier to manage and lower the Total Cost of Ownership (TCO) of the system. Features and functions can be augmented via external A/D converters and GPIO, as well as an external microcontroller.

The following features and functions are supported by CMI:

- First timer to generate SMI# after programmable time.
  - First timeout causes SMI#; allows for SMM-based recovery from operating system lockup.
  - Operating system-based software agent accesses CMI to periodically reload timer.
- Ability for SMM handler to generate “TCO” interrupt to operating system.
  - Allows for operating system-based code augmentation.
- Ability for operating system to generate SMI#.
  - Call-back from operating system to TCO code in SMM handler.
- Second hard coded timeout to generate reboot.
  - Used only after first timeout occurs.
  - Second timeout allows for automatic system reset and reboot if hardware error detected. Various system states are preserved via this special reset to allow for possible error detection and correction.
  - Reset associated with reboot may attempt to preserve some registers for diagnostic purposes.
  - SMI# handler must reload the main timer within 2.4 s to prevent the second timer from causing a reboot (timeout during SMI is assumed as broken CPU or stuck hardware).
  - Option to prevent reset if second timeout occurs.
- Processor present detection.
  - Detects if processor fails to fetch the first instruction after reset.
  - If CPU failure detected, option to pulse a GPIO or send SMBus message. The SMBus message can be used to indicate to an External LAN controller to send a distress message. The GPIO can control an LED with optional blink.
- Ability to handle various errors (such as ECC errors) indicated by the IMCH.
  - Can generate SMI# or TCO interrupt.
- Intruder detect input.
  - Can generate TCO interrupt or SMI# when the system cover is removed.
- Ability for TCO messages to coexist with standard SMBus devices.
- Detection of bad FWH programming.

— Detects if data on first read is FFh (indicates unprogrammed Firmware Hub).

## 18.2 TCO I/O-Mapped Configuration Register Details

The TCO logic is accessed via registers mapped to the PCI configuration space (Device 31, Function 0) and the system I/O space. For TCO PCI Configuration registers, see Section 19.0, “LPC Interface: Bus 0, Device 31, Function 0”.

**Note:** For more information on the format of the register description tables that follow in this chapter, see Section 7.1.1, “Register Description Tables” on page 183).

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values and are read only. Writes to reserved locations may cause system failure and unpredictable results.

**Note:** Reserved bits are Read Only.

**Table 18-1. Bus 0, Device 31, Function 0: Summary of TCO Configuration Registers Mapped Through TCOBASE I/O BAR**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|
| 00h          | 01h        | “Offset 00h: TRLD - TCO Timer Reload and Current Value Register” on page 715 | 0000h         |

## 18.2.1 TCO PCI Configuration Registers

See Chapter 19.0, “LPC Interface: Bus 0, Device 31, Function 0.”

Allows setting of the Base Address for the I/O space and routing of the TCO interrupt.

## 18.2.2 Bus 0, Device 31, Function 0: TCO Configuration Register (I/O-Mapped via ABASE BAR) Summary Table

The TCO I/O registers reside in a 32-byte range that starts 96 bytes above the power management (ACPI) I/O space (Section 19.2.2.1, “Offset 40h: ABASE: ACPI Base Address Register”). Thus **TCOBASE (IO) = ABASE (IO) + 60h** in the PCI configuration space. Table 18-2 shows the mapping of the registers within that 32-byte range. Each register is described in the following sections.

### 18.2.2.1 Offset 00h: TRLD - TCO Timer Reload and Current Value Register

Table 18-2. Offset 00h: TRLD - TCO Timer Reload and Current Value Register

| Description: |                   |  |                             |                                      |            |
|--------------|-------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: TCOBASE (IO) |  | Bus:Device:Function: 0:31:0 | Offset Start: 00h<br>Offset End: 01h |            |
| Size: 16 bit | Default: 0000h    |  |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 15 : 10      | Reserved          | Reserved.  |                             | 00h                                  | RO         |
| 09 : 00      | TRLD              | <b>TCO Timer Value:</b> Reading this register returns the current count of the TCO timer. Writing any value to this register reloads the timer to prevent the timeout. |                             | 000h                                 | RW         |

### 18.2.2.2 Offset 02h: TDI - TCO Data In Register

Table 18-3. Offset 02h: TDI - TCO Data In Register

| Description: |                   |   |                             |                                      |            |
|--------------|-------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: TCOBASE (IO) |   | Bus:Device:Function: 0:31:0 | Offset Start: 02h<br>Offset End: 02h |            |
| Size: 8 bit  | Default: 00h      |   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym       | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 07 : 00      | TDI               | This data register field is used for passing commands from the operating system to the SMI handler. Writes to this register cause an SMI and set the OS_TCO_SMI bit in the TCO_STS register (D31, F0, 04h). |                             | 00h                                  | RW         |

### 18.2.2.3 Offset 03h: TDO - TCO Data Out Register

Table 18-4. Offset 03h: TDO - TCO Data Out Register

|                     |                          |   |                                    |  |                   |
|---------------------|--------------------------|---|------------------------------------|--|-------------------|
| <b>Description:</b> |                          |   |                                    |  |                   |
| <b>View:</b> PCI    | <b>BAR:</b> TCOBASE (IO) |   | <b>Bus:Device:Function:</b> 0:31:0 | <b>Offset Start:</b> 03h<br><b>Offset End:</b> 03h |                   |
| <b>Size:</b> 8 bit  | <b>Default:</b> 00h      |   |                                    | <b>Power Well:</b> Core                            |                   |
| <b>Bit Range</b>    | <b>Bit Acronym</b>       | <b>Bit Description</b>  | <b>Sticky</b>                      | <b>Bit Reset Value</b>                             | <b>Bit Access</b> |
| 07 : 00             | TDO                      | This data register field is used for passing commands from the SMI handler to the operating system. Writes to this register sets the TCO_INT_STS bit in the TCO_STS register. It also causes an interrupt, as selected by the TCO_IRO_SEL bits. |                                    | 00h  | RW                |

### 18.2.2.4 Offset 04h: TSTS1 - TCO 1 Status Register

Unless otherwise indicated, these bits are “sticky” and are cleared by writing a one to the corresponding bit position.

Table 18-5. Offset 04h: TSTS1 - TCO 1 Status Register (Sheet 1 of 3)

|                     |                          |  |                                    |  |                   |

| View: PCI    | BAR: TCOBASE (IO) |  | Bus:Device:Function: 0:31:0 | Offset Start: 04h<br>Offset End: 04h |            |
| Size: 16 bit | Default: 0000h    |  |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 08           | BIOSWR_STS        | <p>0 = Software clears this bit by writing a 1 to it.<br/>           1 = The CMI sets this bit and generates an SMI# to indicate an illegal attempt to write to the BIOS. This occurs when either:<br/>           a) The BIOSWP bit is changed from 0 to 1 and the BLD bit is also set, or<br/>           b) any write is attempted to the BIOS and the BIOSWP bit is also set.</p> <p><b>Note:</b> On write cycles attempted to the 4 Mbyte lower alias to the BIOS space, the BIOSWR_STS is not set.</p>   |                             | 0h                                   | RWC        |
| 07           | NEWCENTURY_STS    | <p>This bit is in the RTC well.<br/>           0 = Cleared by writing a 1 to the bit position or by RTEST# going active.<br/>           1 = This bit is set when the Year byte (index offset 09h) rolls over from 1999 to 2000. If the bit is already 1, it remains 1.</p> <p>When this bit is set, an SMI# is generated. However, this is not a wake event (i.e., if the system is in a sleeping state when the NEWCENTURY_STS bit is set, the system does not wake up).</p> <p><b>Note:</b> The NEWCENTURY_STS is not valid when the RTC battery is first installed (or if the RTC battery does not provide sufficient power when the system is unplugged). Software can determine that the RTC well was not maintained by checking the RTC_PWR_STS bit (D31:F0:A4, bit 2) or by other means (such as doing a checksum on the RTC RAM array). If the RTC power is determined to not have been maintained, the BIOS must set the time to a legal value and then clear the NEWCENTURY_STS bit.</p> <p>The NEWCENTURY_STS bit may take up to 3 RTC clocks for the bit to be cleared when a 1 is written to the bit to clear it. After writing a 1 to the NEWCENTURY_STS bit, software must not exit the SMI handler until verifying that the bit has actually been cleared. This ensures that the SMI is not reentered.</p> |                             | 0h                                   | RWC        |
| 06 : 04      | Reserved          | Reserved   |                             | 0h                                   | RO         |
| 03           | TIMEOUT           | <p>0 = Software clears this bit by writing a 1 to it.<br/>           1 = Set to indicate that the SMI was caused by the TCO timer reaching 0.</p> <p><b>Note:</b> The SMI handler must clear this bit to prevent an immediate reentry to the SMI handler.</p>  |                             | 0h                                   | RWC        |

|--------------|-------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: TCOBASE (IO) |  | Bus:Device:Function: 0:31:0 | Offset Start: 06h<br>Offset End: 07h |            |
| Size: 16 bit | Default: 0000h    |  |                             | Power Well: Resume                   |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 02           | DOACPU_STS        | <p>0 = Cleared based on RSMRST# or by software writing a 1 to this bit. Software must first clear the SECOND_TO_STS bit before writing a 1 to clear the BOOT_STS bit.</p> <p>1 = Set to 1 when the SECOND_TO_STS bit goes from 0 to 1 and the processor has not fetched the first instruction.</p> <p>If rebooting due to a SECOND_TO_STS bit set (= 1) and the DOACPU_STS bit is:</p> <p>0 = The BIOS can conclude that the system rebooted due to some lockup (such as on NSI), but not due to a processor booting issue.</p> <p>1 = Reboots using the 'safe' multiplier (1111). This allows the system to recover from a processor frequency multiplier that is too high, and allows the BIOS to check the DOACPU_STS bit at boot. If the bit is set and the frequency multiplier is 1111, then the BIOS knows that the processor has been programmed to an illegal multiplier.</p> <p><b>Note:</b> Software must clear the SECOND_TO_STS bit first, then the DOACPU_STS bit (use two separate I/O write operations).</p>   |                             | 0h                                   | RWC        |
| 01           | SECOND_TO_STS     | <p>0 = Software clears this bit by writing a 1 to it or by a RSMRST#.</p> <p>1 = Sets this bit to 1 to indicate that the TIMEOUT bit had been (or is currently) set and a second timeout occurred before the TCO_RLD register was written. If this bit is set and the NO_REBOOT configuration bit is 0, then reboots the system after the second timeout. The reboot is done by asserting PLTRST#.</p>   |                             | 0h                                   | RWC        |
| 00           | INTRD_DET         | <p><b>Intruder Detect.</b> This bit resides in the RTC well.</p> <p>0 = Software clears this bit by writing a 1 to this bit or by RTEST#.</p> <p>1 = Set to indicate that an intrusion was detected. This bit is latched. The INTRUDER# signal must be asserted for a minimum of 1 ms to guarantee that the INTRD_DET bit is set.</p> <p>This bit has a recovery time. After writing a 1 to this bit position (to clear it), the bit may be read back as a 1 for up to 65 <math>\mu</math>s before it is read as a 0. Software must be aware of this recovery time when reading this bit after clearing it.</p> <p>If the INTRUDER# signal is active when the software attempts to clear the INTRD_DET bit, the bit remains one, and the SMI# is generated again immediately. The SMI handler can clear the INTRD_SEL bits (TCOBASE + 0Ah, bits 2:1) to avoid further SMIs. However, if the INTRUDER# signal goes inactive and then active again, there is not further SMIs (because the INTRD_SEL bits would select that no SMI# be generated).</p> <p>If the INTRUDER# signal goes inactive some point after the INTRD_DET bit is written as a 1, then the INTRD_DET signal goes to a 0 when INTRUDER# input signal goes inactive. This is slightly different than a classic sticky bit, since most sticky bits would remain active indefinitely when the signal goes active and would immediately go inactive when a 1 is written to the bit.</p> |                             | 0h                                   | RWC        |

| 00           | IRQ1_CAUSE        | 0 = When software sets the bit to 0, IRQ1 is low (not asserted).<br>1 = When software sets the bit to 1, IRQ1 is high (asserted).   |                             | 1                                    | RW         |

### 18.2.2.11 Offset 12h: TTMR - TCO Timer Initial Value Register

Table 18-12. Offset 12h: TTMR - TCO Timer Initial Value Register

| Description: |                   |   |                             |                                      |            |
|--------------|-------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: TCOBASE (IO) |   | Bus:Device:Function: 0:31:0 | Offset Start: 12h<br>Offset End: 13h |            |
| Size: 16 bit | Default: 0004h    |   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym       | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 15 : 10      | Reserved          | Reserved  |                             | 00h                                  | RO         |
| 09 : 00      | TTMR              | Value that is loaded into the timer each time the TCO_RLD register is written. Values of 0000h or 0001h are ignored and must not be attempted. The timer is clocked at approximately 0.6 s, and thus allows timeouts ranging from 1.2 s to 613.8 s.<br><b>Note:</b> The timer has an error of +/- 1 tick (0.6 s). The TCO Timer only counts down in the S0 state. |                             | 004h                                 | RW         |

## 18.3 TCO Signal Usage

### 18.3.1 INTRUDER# Signal

This signal can be used to detect the chassis being opened. The activation of this signal can be used to cause an SMI#, and is reported via the event mechanism. If SMI# is desired, the signals level can be read, so this can be used as a type of general purpose input.

### 18.3.2 Pin Straps

Some of the TCO functions are decided at power up (rising edge of PWROK). See the pinlist for specific assignments of pin straps.

### 18.3.3 SMLINK Signals

The CMI supports TCO compatible mode connectivity. The ICH supports External LAN controllers. An external LAN Controller can be used to receive or retrieve TCO message or information on Host SMBus if needed. In Legacy TCO mode messages are driven via SMLink.

For the CMI, messages on this link use SMBus protocol at the rates described in [Chapter 24.0, "SMBus Controller Functional Description: Bus 0, Device 31, Function 3,"](#) for TCO compatible mode.

## 18.4 TCO Theory of Operation

### 18.4.1 Overview

The system management functions are designed to allow the system to diagnose failing subsystems. The intent of this logic is that the system management functionality be provided without the aid of an external micro controller.

The CMI's System Management logic allows for diagnostic and recovery software to be distributed between an SMI handler and operating system-based code.

## 18.4.2 Detecting a DOA CPU or System

When the processor is reset, it is expected to fetch its first instruction. If the processor fails to fetch the first instruction after reset, the TCO timer times out twice and CMI asserts PLTRST#.

If TCO Reboots are not enabled, then:

- a. The SMLink sends out the first eight bits of the message. After the eighth bit, the logic stalls because there is no integrated LAN controller to send the ACK. The logic then aborts the transfer. External logic monitors the toggling and use that to drive an LED.
- b. If an External LAN controller is connected send the appropriate message to the External LAN controller.

If TCO Reboots are enabled, then the CMI attempts to reboot the system.

1. If the NO-REBOOT bit (NR field in [Table 17-27, "Offset 3410h: GCS - General Control and Status Register" on page 706](#)) is set (no reboots are intended)

and

SECOND\_TO\_STS bit (TCO I/O Offset 06h, bit 1) is set

and

DOACPU\_STS bit (TCO I/O Offset 06h, bit 2) is set,

then the CMI indicates this in the TCO message by setting the CPU Missing bit in the message.

2. If the NO-REBOOT bit (NR field in [Table 17-27, "Offset 3410h: GCS - General Control and Status Register" on page 706](#)) is not set (reboots intended)

and

SECOND\_TO\_STS bit TCO I/O Offset 06h, bit 1) is set,

then the CMI attempts to reboot. After the reboot, the SECOND\_TO\_STS bit is still set. If the CPU fails to fetch the first instruction, the DOA\_CPU\_STS bit is set, and when the TCO timer times out (actually for the third time, the first two caused the SECOND\_TO\_STS bit to be set), then the CMI sets the CPU MISSING EVENT bit for the TCO message.

## 18.4.3 Handling an Operating System Lockup

Under some conditions, the operating system may lock up. To handle this, the TCO Timer is used with the following algorithm:

1. BIOS programs the TCO Timer, via the TCO\_TMR register with an initial value.
2. An operating system-based software agent periodically writes to the TCO\_RLD register to reload the timer and keep it from generating the SMI#. The software agent can read the TCO\_RLD register to see if it is close to timing out, and possibly determine if the time-out should be increased. The operating system can also modify the values in the TCO\_TMR register.
3. If the timer reaches 0, an SMI# can be generated. This should only occur if the operating system was not able to reload the timer. It is assumed that the operating system is not able to reload the timer if it has locked up.
4. Upon generating the SMI#, the TCO Timer automatically reloads with the default value of 04h and start counting down.

5. The SMI handler can then:
  - a. Read the TIMEOUT bit in the TCO\_STS register to check that the SMI# was caused by the TCO timer. The SMI handler must also clear the TIMEOUT bit.
  - b. Write to the TCO\_RLD register to reload the timer to make sure the TCO timer does not reach 0 again.
  - c. Attempt to recover. May need to periodically reload the TCO timer.

The exact recovery algorithm is system-specific.

**Note:** If the SMI handler was not able to clear the TIMEOUT bit and write to the TCO\_RLD register, the timer reaches zero a second time approximately 2.4 s later. At that point, the hardware is assumed to be locked up, and the timer reads zero a second time, which causes the SECOND\_TO\_STS bit to be set. At that point the logic resets the platform if the reboots are enabled.

#### 18.4.4 Handling a CPU or Other Hardware Lockup

If after the TIMEOUT SMI is generated, and the TCO timer again reaches 0, and reboots are enabled, the System Management logic resets (and reboot) the system. This is in the case where the CPU or other system hardware is locked up. During every boot, BIOS must read the SECOND\_TO\_STS bit in the TCO\_STS register to see if this is normal boot or a reboot due to the timeout. The BIOS may also check the OS\_POLICY bits to see if it should try another boot or shutdown.

#### 18.4.5 Handling an Intruder

The CMI has an input signal, INTRUDER#, that can be attached to a switch that is activated by the system's case being open. This input has a two RTC clock debounce. If INTRUDER# goes active (after the debouncer), this sets the INTRD\_DET bit in the TCO\_STS register. INTRUDER# can go active in any power state.

The INTRD\_SEL bits in the TCO\_CNT register can enable the CMI to cause an SMI# or TCO interrupt. The software can also directly read the status of the INTRUDER# signal (high or low) by clearing and then reading the INTRD\_DET bit. This allows the signal to be used as a GPI if the intruder function is not required.

**Note:** The INTRD\_DET bit resides in the CMI's RTC well, and is set and cleared synchronously with the RTC clock. Thus, when software attempts to clear INTRD\_DET (by writing a one to the bit location) there may be as much as two RTC clocks (about 65  $\mu$ s) delay before the bit is actually cleared. Also, the INTRUDER# signal must be asserted for a minimum of 1 ms to guarantee that the INTRD\_DET bit is set.

**Note:** If the INTRUDER# signal is still active when software attempts to clear the INTRD\_DET bit, the bit remains set and the SMI is generated again immediately. The SMI handler can clear the INTRD\_SEL bits to avoid further SMIs. However, if the INTRUDER# signal goes inactive and then active again, there is not further SMIs, since the INTRD\_SEL bits would select that no SMI# be generated.

#### 18.4.6 Handling a Potentially Failing Power Supply

It may be possible to detect that a power supply may fail in the near future by monitoring its voltages for fluctuations. To support such an application, external A/Ds with programmable thresholds could be included via SMBus/I<sup>2</sup>C. Upon receiving the SMBus/I<sup>2</sup>C message, the CMI can generate an SMI or interrupt. The SMI handler (or operating system-based extension) could then attempt to send a message before the power completely fails.

Another option would be to build an A/D into the power supply itself. Another signal, other than PWROK, could report that the power supply might soon fail.

#### 18.4.7 Handling an ECC Error or Other Memory Error

The IMCH provides a message to indicate that it would like to cause an SMI#, SCI, SERR#, or NMI. The software must check the IMCH as to the exact cause of the error.

#### 18.4.8 SMM to Operating System and Operating System to SMM Calls

There may be interaction between an SMI handler and operating system-related code. Two 8-bit data registers are provided.

1. The SMI handler generates an interrupt to the operating system by writing to the TCO\_DAT\_OUT register. This sets the TCO\_INT\_STS bit in the TCO\_STS register. The interrupt is cleared by writing a one to the TCO\_INT\_STS bit.
2. The operating system (or driver) can generate an SMI# by writing to the TCO\_DAT\_IN register. This sets the OS\_SMI\_STS bit in the TCO\_STS register. The SMI# is cleared by writing a one to the OS\_SMI\_STS bit.

Reads to the TCO\_DAT\_IN and TCO\_DAT\_OUT register do not effect the SMI# or INTERRUPT.

Writing a one to the NMI\_NOW bit allows for an immediate NMI.

#### 18.4.9 Detecting an Improper FWH Programming

The CMI can detect the case where the FWH is not programmed. This results in the first instruction fetched to have a value of FFh. If this occurs, the CMI sets the BAD\_BIOS bit.

#### 18.4.10 IRQ1 and IRQ12 for Legacy Elimination

The new IRQ1 and IRQ12 sources are each logically ANDed with the respective IRQ1 and IRQ12 that come from the SERIRQ logic. This is necessary because the SERIRQ logic reports IRQ1 and IRQ12 to be high (active), since there is no Super I/O to drive them low.

*Note:*

In a system that does have a Super I/O, the new bits must be left at one, since it is ANDed with the Super I/Os IRQ. **Do not attempt to write these bits to 0 in a system that has a keyboard controller (such as in a Super I/O).** It is not validated, and is highly likely to cause errors.

The following algorithm assumes the byte is being sent from the keyboard. The byte being sent from the mouse is equivalent. The setup to the area of interest is left at a high level in this description. The area of interest is then described in more detail.

1. An SMI is received and discovered to be a USB interrupt.
2. The interrupt is discovered to be due to a TD associated with a keyboard device.
3. The data is analyzed and it is determined that the interrupt is due to a new key press.
4. The USB key-code is translated into the equivalent scan code set 2 (SS2) PS/2 scan code.
5. The result is queued on a queue of data to be sent from the keyboard to the system.
6. Other USB interrupts are handled.

7. The keyboard controller emulation code is executed at exit. It determines if the conditions are correct to return a byte to the system (e.g., emulated OBF indicates empty, keyboard interface not disabled, etc.). If not, the emulation exits awaiting the next event.
8. The queue of data to be sent from the keyboard to the system is found to contain a byte to be returned.
9. Given the typical keyboard controller configuration, it is translated from SS2 to SS1.

*End of Setup.*

10. The byte to be returned is stored in the emulated output buffer.
11. The emulation does the out to the port to enable IRQ 1.
12. The emulation exits.
13. time passes
14. The system code services the interrupt and reads port 60h.
15. The UHCI traps the read and causes an SMI trap.
16. The trap is determined to be caused by the read from port 60h (TBY60R in LEGSUP).
17. The emulation code clears the interrupt register thus turning off IRQ 1 and / or IRQ 12.

*Note:* The emulation code can validly do this each time there is a read from 60h since that is what the keyboard controller would do as well. (There is no time where both IRQ 1 and IRQ 12 must be asserted simultaneously by either the kbc or the emulated kbc. This would be a violation of the kbc/system protocol.)

## 18.5 Event Reporting via SMLink/SMBus

The CMI has SMLINK signals to support TCO compatible mode. Event reporting is accomplished via the SMLINK signals.

### 18.5.1 Overview

#### 18.5.1.1 TCO Compatible Mode

The CMI can function directly with a LAN controller to report message to a network management console without the aid of the system CPU. This is crucial in cases where the CPU is malfunctioning or cannot function due to being in a low-power state.

The basic scheme is to send specific messages via the SMLink Interface to the LAN. Upon receiving the SMLink message, the LAN has a prepared ethernet message that it can send to a network management console. The prepared message is stored in a non-volatile memory connected directly to the LAN.

Messages are sent by the CMI to the LAN either because a specific event has occurred (see [Table 18-13](#)), or they are sent periodically. The event messages have exactly the same form.

Table 18-13. Event Transitions that Cause Messages

| Event                  | Assertion | Deassertion | Comments  |
|------------------------|-----------|-------------|---|
| INTRUDER# pin          | yes       | no          |   |
| PROCHOT# pin           | yes       | yes         | The PROCHOT# pin is isolated when the core power is off, thus preventing this event in S3,S5. |
| Watchdog Timer Expired | yes       | no (NA)     |   |
| SEND_NOW bit           | yes       | NA          | Occurs in G0  |
| GPIO[11]/SMBALERT# pin | yes       | yes         |   |
| BATLOW#                | yes       | yes         |   |
| CPU_PWR_FLR            | yes       | no          |   |

**Note:** The GPIO[11]/SMBALERT# pin triggers an event message (when enabled by the GPIO11\_ALERT\_DISABLE bit) regardless of whether it is configured as a GPI or not.

Whenever an event occurs that causes the CMI to send a new message, it increments the SEQ[03:00] field.

If a triggering event occurs while a message is already being generated and sent, the new event may not appear in the current message. If not, then a second message is generated, the SEQ[03:00] field increments to report the new event.

The following rules/steps apply if the system is in a G0 state and the policy is to reboot the system after a hardware lockup:

1. Upon detecting the lockup the SECOND\_TO\_STS bit is set. The CMI may send up to one event message to the LAN. The CMI then attempts to reboot the CPU.
2. If the reboot at step 1 is successful then the BIOS must clear the SECOND\_TO\_STS bit. This prevents any further messages from being sent. The BIOS may then perform addition recovery/boot steps.

**Warning:** It is important the BIOS clears the SECOND\_TO\_STS bit, as the alerts interfere with the LAN device driver from working properly. The alerts reset part of the LAN and would prevent an operating system's device driver from sending or receiving some messages.

3. If the reboot attempt in step 1 is not successful, then the timer timeouts a third time. At this point the system has locked up and was unsuccessful in rebooting. The CMI does not attempt to automatically reboot again. The CMI starts sending a message every period (30-32 seconds). This continues until some external intervention occurs (reset, power failure, etc.).
4. After step 3 (unsuccessful reboot after third timeout), if the user presses a Power Button Override, the system goes to an S5 state. The CMI continues sending the messages every period.
5. After step 4 (power button override after unsuccessful reboot) if the user presses the Power Button again, the system must wake to an S0 state and the CPU must start executing the BIOS.
6. If step 5 (power button press) is successful in waking the system, the CMI continues sending messages every period until the BIOS clears the SECOND\_TO\_STS bit.

**Warning:** It is important the BIOS clears the SECOND\_TO\_STS bit, as the messages interfere with the LAN device driver from working properly. The alerts reset part of the LAN and prevents an operating system's device driver from sending or receiving some LAN packets.

7. If step 5 (power button press) is unsuccessful in waking the system, the CMI continues sending a message every period. The CMI does not attempt to automatically reboot again. The CMI starts sending a message every period (30-32 seconds). This continues until some external intervention occurs (reset, power failure, etc.).

**Note:** A system that has locked up and can not be restarted with the power button press is assumed to have broken hardware (bad power supply, short circuit on some bus, etc.), and is beyond the CMI's recovery mechanisms.

8. After step 3 (unsuccessful reboot after third timeout), if a reset is attempted (using a button that pulses PWROK low or via the message on the SMBus Slave Interface), the CMI attempts to reset the system.
9. After step 8 (reset attempt) if the reset is successful, then the BIOS is run. The CMI continues sending a message every period until the BIOS clears the SECOND\_TO\_STS bit.

**Warning:** It is important the BIOS clears the SECOND\_TO\_STS bit, as the messages interfere with the LAN device driver from working properly. The alerts reset part of the LAN and prevent an operating system's device driver from sending or receiving some LAN packets.

10. After step 8 (reset attempt), if the reset is unsuccessful, then the CMI continues sending a message every period. The CMI does not attempt to reboot the system again without external intervention.

**Note:** A system that has locked up and can not be restarted with the power button press is assumed to have broken hardware (bad power supply, short circuit on some bus, etc.), and is beyond the CMI's recovery mechanisms.

The following rules/steps apply if the system is in a G0 state and the policy is for the CMI to **not** reboot the system after a hardware lockup:

1. Upon detecting the lockup the SECOND\_TO\_STS bit is set. The CMI sends a message with the Watchdog (WD) Event status bit set (and any other bits that must also be set). This message is sent as soon as the lockup is detected, and is sent with the next (increment) sequence number.
2. After step 1, the CMI sends a message every period until some external intervention occurs.
3. Rules/steps 4-10 apply if no user intervention (resets, power button presses, SMBus reset messages) occur after a third timeout of the watchdog timer. If the intervention occurs before the third timeout, then jump to step 11.
4. After step 3 (third timeout), if the user does a Power Button Override, the system goes to an S5 state. The CMI continues sending messages at this point.
5. After step 4 (power button override), if the user presses the power button again, the system must wake to an S0 state and the CPU must start executing the BIOS.
6. If step 5 (power button press) is successful in waking the system, the CMI continues sending messages until the BIOS clears the SECOND\_TO\_STS bit.

**Warning:** It is important the BIOS clears the SECOND\_TO\_STS bit, as the alerts interfere with the LAN device driver from working properly. The alerts reset part of the LAN and would prevent an operating system's device driver from sending or receiving some messages.

7. If step 5 (power button press) is unsuccessful in waking the system, the CMI continues sending messages. The CMI does not attempt to reboot the system again until some external intervention occurs (reset, power failure, etc.).

**Note:** A system that has locked up and can not be restarted with power button press is probably very broken (bad power supply, short circuit on some bus, etc.) and beyond the CMI's recovery mechanisms.

8. After step 3 (third timeout), if a reset is attempted (using a button that pulses PWROK low or via the message on the SMBus Slave Interface), the CMI attempts to reset the system.
9. If step 8 (reset attempt) is successful, then the BIOS is run. The CMI continues sending messages until the BIOS clears the SECOND\_TO\_STS bit.

**Warning:** It is important the BIOS clears the SECOND\_TO\_STS bit, as the alerts interfere with the LAN device driver from working properly. The alerts reset part of the LAN and would prevent an operating system's device driver from sending or receiving some messages.

10. If step 8 (reset attempt), is unsuccessful, then the CMI continues sending messages. The CMI does not attempt to reboot the system again without external intervention.

**Note:** A system that has locked up and can not be restarted with the power button press is broken (bad power supply, short circuit on some bus, etc.)

11. This and the following rules/steps apply if the user intervention (power button press, reset, SMBus message, etc.) occur prior to the third timeout of the watchdog timer.
12. After step 1 (second timeout), if the user does a Power Button Override, the system goes to an S5 state. The CMI continues sending messages at this point.
13. After step 12 (power button override), if the user presses the power button again, the system must wake to an S0 state and the CPU must start executing the BIOS.
14. If step 13 (power button press) is successful in waking the system, the CMI continues sending messages until the BIOS clears the SECOND\_TO\_STS bit.

**Warning:** It is important the BIOS clears the SECOND\_TO\_STS bit, as the alerts interfere with the LAN device driver from working properly. The alerts reset part of the LAN and would prevent an operating system's device driver from sending or receiving some messages.

15. If step 13 (power button press) is unsuccessful in waking the system, the CMI continues sending messages. The CMI does not attempt to reboot the system again until some external intervention occurs (reset, power failure, etc.).

**Note:** A system that has locked up and can not be restarted with power button press is broken (bad power supply, short circuit on some bus, etc.) and beyond the CMI's recovery mechanisms.

16. After step 1 (second timeout), if a reset is attempted (using a button that pulses PWROK low or via the message on the SMBus Slave Interface), the CMI attempts to reset the system.
17. If step 16 (reset attempt) is successful, then the BIOS is run. The CMI continues sending messages until the BIOS clears the SECOND\_TO\_STS bit.

**Warning:** It is important the BIOS clears the SECOND\_TO\_STS bit, as the alerts interfere with the LAN device driver from working properly. The alerts reset part of the LAN and would prevent an operating system's device driver from sending or receiving some messages.

18. If step 16 (reset attempt), is unsuccessful, then the CMI continues sending messages. The CMI does not attempt to reboot the system again without external intervention.

**Note:** A system that has locked up and can not be restarted with power button press is broken (bad power supply, short circuit on some bus, etc.)

The following rules apply if the system is in a G1 (S1 - S4) state:

- The CMI sends a message every period (30-32 seconds).
  - If an event occurs prior to the system being shut down, the CMI immediately sends another event message with the next (incremented) sequence number.
  - After the event, it resumes sending messages.

*Note:* There is a boundary condition when a hardware event happens right as the system transitions into a G0 state. In this condition, the hardware sends messages even though the system is in a G0 state (and the status bits could potentially indicate that). Normally the IICH does not send messages in the G0 state (except in the case of a lockup).

*Note:* A spurious alert could occur in the following sequence:

- a. The CPU has initiated an alert using the SEND\_NOW bit
- b. During the alert, the PROCHOT#, INTRUDER# or GPI[11] changes state
- c. The system then goes to a non-S0 state

Once the system transitions to the non-S0 state, it may send a single alert with an incremented SEQUENCE number.

*Note:* An inaccurate alert message can be generated in the following scenario:

- a. The system successfully boots after a second watchdog Timeout occurs.
- b. PWROK goes low (typically due to a reset button press) or a power button override occurs (before the SECOND\_TO\_STS bit is cleared).
- c. An alert message indicating that the CPU is missing or locked up is generated with a new sequence number.

### 18.5.2 Message Format

The Event message is an SMBus Block Write sent to the External LAN Controller's SMBus address, as shown in [Table 18-14](#).

**Table 18-14. SMBus Message Format**

|                    |   |   |   |   |   |   |   |                    |   |   |   |   |   |   |        |                    |   |   |   |       |      |   |   |
|--------------------|---|---|---|---|---|---|---|--------------------|---|---|---|---|---|---|--------|--------------------|---|---|---|-------|------|---|---|

Table 18-14. SMBus Message Format

|             |   |   |   |   |   |   |   |             |          |   |   |   |   |   |   |   |  |   |
|-------------|---|---|---|---|---|---|---|-------------|----------|---|---|---|---|---|---|---|--|---|
| Data Byte 7 |   |   |   |   |   |   |   | Data Byte 8 |          |   |   |   |   |   |   |   |  |   |
| Reserved    |   |   |   |   |   |   |   |             | Reserved |   |   |   |   |   |   |   |  | P |
| 0           | 0 | 0 | 0 | 0 | 0 | 0 | 0 |             | 0        | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  | 1 |

Table 18-15. Message Address Byte

| Field   | Bit Length | Comment                               |
|---------|------------|---------------------------------------|
| Start   | 1          | '1' to indicate the start of a packet |
| Address | 7          | LAN SMBus Address. Is always 1100100. |
| Dir     | 1          | '0' to indicate write cycle           |
| Ack     | 1          | Returned by External LAN Controller   |

*Note:* For the System Power State field: 00 = G0, 01 = G1, 10 = G2, 11=PreBoot. The preboot state is entered when the SLP\_S3#, SLP\_S4# and SLP\_S5# signals go from low to high. The indication switches to the G0 state when CPURESET Done ACK completion packet sent to the IMCH. This corresponds to the time when the CPU has been reset. If the CPU is locked up, then the CPU EVENT bit is set.

### 18.5.3 Connecting an External LAN Controller

The CMI's TCO logic sends the message on the SMLINK signals in TCO compatible mode. An External LAN Controller claims these cycles.

When sending the messages to the external LAN Controller, the CMI's IICH abides by the standard SMBus rules associated with collision detection. It delays starting a message until the link is idle, and detects collisions. If a collision is detected, the CMI drops that message.

## 19.0 LPC Interface: Bus 0, Device 31, Function 0

### 19.1 Overview

The LPC bridge function IICH resides in PCI Device 31, Function 0. This contains many other functional units, such as DMA and Interrupt controllers, Timers, Power Management, System Management, GPIO, RTC, and LPC Configuration Registers.

### 19.2 LPC Interface Configuration Register Details

*Note:* Address locations that are not listed are considered reserved register locations. Reserved registers are read only and return all zeros. For more information on the format of the register description tables that follow in this chapter, see [Section 7.1.1, "Register Description Tables"](#).

**Table 19-1. Bus 0, Device 31, Function 0: Summary of LPC Interface PCI Configuration Registers (Sheet 1 of 2)**

### 19.2.1.4 Offset 08h: RID - Revision ID Register

Writing to this register controls what is reported in all of the RID registers in the component. The value written does not get directly loaded in this register. However, the value is checked to determine which value to report.

Once written, additional writes to this register must not have any affect until a core-well reset occurs. BIOS must always write to this register in order to guarantee that the functionality is locked.

Table 19-5. Offset 08h: RID: Revision ID Register

| Description: |                   |  |  |                  |            |

## 19.2.2 ACPI/GPIO Configuration Registers

### 19.2.2.1 Offset 40h: ABASE: ACPI Base Address Register

ABASE sets the base address in I/O space for the ACPI and TCO I/O registers (see [Section 27.3.3, "General Power Management I/O-Mapped Registers" on page 1055](#)). These registers can be mapped anywhere in the 64 K I/O space on 128-byte boundaries.

Table 19-10. Offset 40h: ABASE: ACPI Base Address Register

| Description: |                    |  |                             |                                      |            |

If not using the APIC, the SCI must be routed to IRQ9-11, and that interrupt is not sharable with the SERIRQ stream, but is shareable with other PCI interrupts. If using the APIC, the SCI can also be mapped to IRQ20-23, and can be shared with other interrupts.</p> <p>Bits    SCI Map</p> <p>000    IRQ9</p> <p>001    IRQ10</p> <p>010    IRQ11</p> <p>011    Reserved</p> <p>100    RQ20 (only if APIC enabled)</p> <p>101    IRQ21 (only if APIC enabled)</p> <p>110    IRQ22 (only if APIC enabled)</p> <p>111    IRQ23 (only if APIC enabled)</p> <p><b>Note:</b> When the interrupt is mapped to APIC interrupts 9, 10 or 11, the APIC must be programmed for active-high reception. When the interrupt is mapped to APIC interrupts 20 through 23, the APIC must be programmed for active-low reception.</p> |                             | 000h                                 | RW         |

19.2.2.3 Offset 48h: GBA: GPIO Base Address Register

GBA sets the base address in I/O space for the GPIO I/O registers (see Section 22.2, “General Purpose I/O-Mapped Configuration Register Details” on page 806). These registers can be mapped anywhere in the 64 K I/O space on 64-byte boundaries.

#### 19.2.4.4 Offset 88h: LG2: LPC Generic Decode Range 2 Register

LG2 sets the base address in I/O space for the I/O registers. These registers can be mapped anywhere in the 64 K I/O space on 16-byte boundaries. The size of this region can be either 16B, 32B, or 64B based on the setting of ETR3.

**Table 19-26. Offset 88h: LG2: LPC Generic Decode Range 2 Register**

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:31:0 | Offset Start: 88h<br>Offset End: 88h |            |

### 19.2.5 Power Management Configuration Registers

Offsets A0h – CFh are described in the power management section. Refer to Chapter 27.0, “Power Management”.

### 19.2.6 FWH Configuration Registers

#### 19.2.6.1 Offset D0h: FS1: FWH ID Select 1 Register

This register contains the IDSEL fields the LPC Bridge uses for memory cycles going to the FWH.

Table 19-27. Offset D0h: FS1: FWH ID Select 1 Register

| Description: |                    |   |                             |                                      |            |
|--------------|--------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:31:0 | Offset Start: D0h<br>Offset End: D3h |            |
| Size: 32 bit | Default: 00112233h |   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 31 : 28      | IF8                | <b>F8-FF IDSEL:</b> Is used in FWH cycle for ranges enabled by FDE.EF8. Used for two 512-KB Firmware Hub memory ranges and one 128-KB memory range. This field is fixed at 0000. The IDSEL programmed in this field addresses the following memory ranges:<br>FFF8 0000h – FFFF FFFFh<br>FFB8 0000h – FFBF FFFFh<br>000E 0000h – 000F FFFFh |                             | 0h                                   | RO         |
| 27 : 24      | IF0                | <b>F0-F7 IDSEL:</b> Is used in FWH cycle for range enabled by FDE.EF0. Used for two 512-KB Firmware Hub memory ranges. The IDSEL programmed in this field addresses the following memory ranges:<br>FFF0 0000h – FFF7 FFFFh<br>FFB0 0000h – FFB7 FFFFh  |                             | 0h                                   | RW         |
| 23 : 20      | IE8                | <b>E8-EF IDSEL:</b> Is used in FWH cycle for range enabled by FDE.EE8. Used for two 512-KB Firmware Hub memory ranges. The IDSEL programmed in this field addresses the following memory ranges:<br>FFE8 0000h – FFEF FFFFh<br>FFA8 0000h – FFAF FFFFh  |                             | 1h                                   | RW         |
| 19 : 16      | IE0                | <b>E0-E7 IDSEL:</b> Is used in FWH cycle for range enabled by FDE.EE0. Used for two 512-KB Firmware Hub memory ranges. The IDSEL programmed in this field addresses the following memory ranges:<br>FFE0 0000h – FFE7 FFFFh<br>FFA0 0000h – FFA7 FFFFh  |                             | 1h                                   | RW         |
| 15 : 12      | ID8                | <b>D8-DF IDSEL:</b> Is used in FWH cycle for range enabled by FDE.ED8. Used for two 512-KB Firmware Hub memory ranges. The IDSEL programmed in this field addresses the following memory ranges:<br>FFD8 0000h – FFD7 FFFFh<br>FF98 0000h – FF97 FFFFh  |                             | 2h                                   | RW         |
| 11 : 08      | ID0                | <b>D0-D7 IDSEL:</b> Is used in FWH cycle for range enabled by FDE.ED0. Used for two 512-KB Firmware Hub memory ranges. The IDSEL programmed in this field addresses the following memory ranges:<br>FFD0 0000h – FFD7 FFFFh<br>FF90 0000h – FF97 FFFFh  |                             | 2h                                   | RW         |
| 07 : 04      | IC8                | <b>C8-CF IDSEL:</b> Is used in FWH cycle for range enabled by FDE.EC8. Used for two 512-KB Firmware Hub memory ranges. The IDSEL programmed in this field addresses the following memory ranges:<br>FFC8 0000h – FFC7 FFFFh<br>FF88 0000h – FF87 FFFFh  |                             | 3h                                   | RW         |
| 03 : 00      | IC0                | <b>C0-C7 IDSEL:</b> Is used in FWH cycle for range enabled by FDE.EC0. Used for two 512-KB Firmware Hub memory ranges. The IDSEL programmed in this field addresses the following memory ranges:<br>FFC0 0000h – FFC7 FFFFh<br>FF80 0000h – FF87 FFFFh  |                             | 3h                                   | RW         |

### 19.2.6.2 Offset D4h: FS2: FWH ID Select 2 Register

This register contains the additional IDSEL fields the LPC Bridge uses for memory cycles going to the FWH.

**Table 19-28. Offset D4h: FS2: FWH ID Select 2 Register**

| Bit Range    | Bit Acronym        | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 07 :04       | Reserved           | Reserved  |                             | 0h                                   |            |
| 03 02        | SRC                | <p><b>SPI Read Configuration:</b><br/>This 2-bit field controls two policies related to BIOS reads on the SPI interface<br/>Bit 3 - Prefetch Enable<br/>Bit 2 - Cache Disable</p> <p><b>00b -&gt; No prefetching, but caching enabled.</b> 64B demand reads load the read buffer cache with "valid" data, allowing repeated code fetches to the same line to complete quickly</p> <p><b>01b -&gt; No prefetching and no caching.</b> One-to-one correspondence of the host BIOS reads to SPI cycles. This value can be used to invalidate the cache.</p> <p><b>10b -&gt; Prefetching and Caching enabled.</b> This mode is used for long sequences of short reads to consecutive addresses (i.e. shadowing)</p> <p><b>11b -&gt; Reserved.</b> This is an invalid configuration.</p> |                             | 00h                                  | RW         |
| 01           | LE                 | <p><b>Lock Enable:</b><br/>0 = Setting the WP will not cause SMIs<br/>1 = Enables setting the WP bit to cause SMIs. Once set, this bit can only be cleared by a PLTRST#</p>   |                             | 0h                                   | RWO        |
| 00           | WP                 | <p><b>Write Protect:</b><br/>0 = Only read cycles result in Firmware Hub Interface cycles<br/>1 = Access to the BIOS space is enabled for both read and write cycles. When this bit is written from a 0 to a 1 and Lock Enable (LE) is also set, an SMI# is generated. This ensures that only SMI code can update BIOS.</p>   |                             | 0h                                   | RW         |

## 19.2.7 Root Complex Register Block Configuration Register

### 19.2.7.1 Offset F0h: RCBA: Root Complex Base Address Register

RCBA sets the base address in memory space for the Root Complex Configuration registers (see [Section 17.1, "Root Complex Memory-Mapped Configuration Register Details" on page 689](#)). These registers can be mapped anywhere in the 32-bit memory space on 16KB boundaries.

The SPI register space resides in this BAR. The base address offset is 3020h. Refer to [Chapter 21.0, "Serial Peripheral Interface"](#).

Table 19-31. Offset F0h: RCBA: Root Complex Base Address Register

## 19.3 Interface

The LPC bridge function resides in Device 31, Function 0. In addition to the LPC bridge function, D31, F0 contains other functional units including DMA, Interrupt controllers, Timers, Power Management, System Management, GPIO, and RTC.

### 19.3.1 Overview

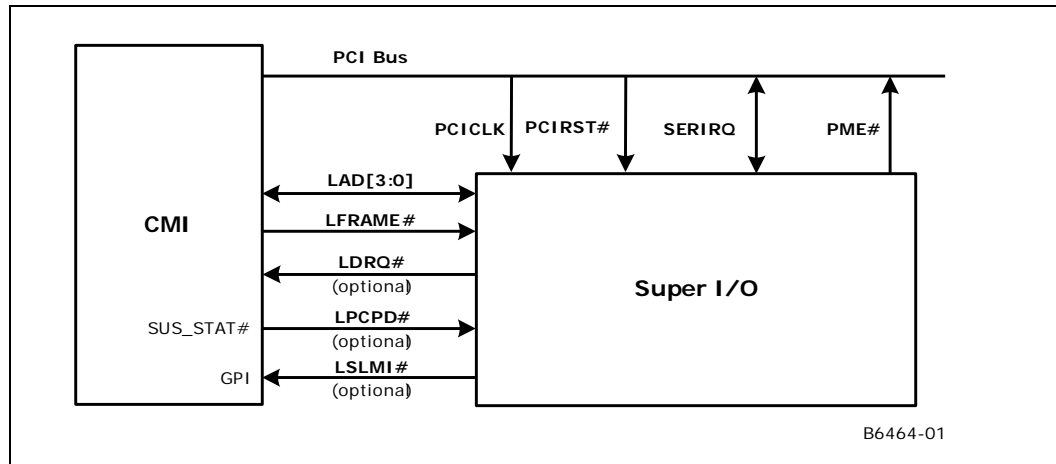

The LPC interface is described in the *Low Pin Count (LPC) Interface Specification, Revision 1.1*. The LPC interface to the IICH is shown in [Figure 19-1](#). The LPC Controller implements all of the signals that are shown as optional, but peripherals are not required to do so.

For the LPC Controller:

- LSMI# can be connected to any of the SMI capable GPIO signals.
- The Super I/O's PME# can be connected to the PCI PME# signal, however this may cause software problems. A better choice is to connect it to one of the LPC Controller's SCI capable GPIO signals.
- The LPC Controller's SUS\_STAT# signal is connected directly to the LPCPD# signal.

All the other signals have the same name on the LPC Controller and on the LPC Interface.

Figure 19-1. LPC Interface Diagram

| Signal Name | During Reset | After Reset | S3  | S5  |
|-------------|--------------|-------------|-----|-----|
| LAD[3:0]    | See          |             | Off | Off |
| LFRAME#     |              |             | Off | Off |
| LDREQ[1:0]# |              |             | Off | Off |

### 19.3.2 Cycle Types

All of the cycle types implemented are described in the *LPC Interface Specification, Revision 1.1*. [Table 19-33](#) shows the supported cycle types.

Table 19-33. LPC Cycle Types Supported

| Cycle Type       | Comment   |
|------------------|---|
| Memory Read      | Single: 1 byte only   |
| Memory Write     | Single: 1 byte only   |
| I/O Read         | 1 byte only. breaks up 16- and 32-bit processor cycles into multiple 8-bit transfers. See Note 1 below. |
| I/O Write        | 1 byte only. breaks up 16- and 32-bit processor cycles into multiple 8-bit transfers. See Note 1 below. |
| DMA Read         | Can be 1, or 2 bytes  |
| DMA Write        | Can be 1, or 2 bytes  |
| Bus Master Read  | Can be 1, 2, or 4 bytes. (See Note 2 below)   |
| Bus Master Write | Can be 1, 2, or 4 bytes. (See Note 2 below)   |

**Notes:**

- For memory cycles below 16 MB that do not target enabled firmware hub ranges, performs standard LPC memory cycles. It only attempts 8-bit transfers. If the cycle appears on PCI as a 16-bit transfer, it appears as two consecutive 8-bit transfers on LPC. Likewise, if the cycle appears as a 32-bit transfer on PCI, it appears as four consecutive 8-bit transfers on LPC. If the cycle is not claimed by any peripheral, it is subsequently aborted, and returns a value of all ones to the processor. This is done to maintain compatibility with legacy memory cycles where pull-up resistors would keep the bus high if no device responds.
- Bus Master Read or Write cycles must be naturally aligned. For example, a 1-byte transfer can be to any address. However, the 2-byte transfer must be word aligned (i.e., with an address where A0=0). A DWord transfer must be DWord aligned (i.e., with an address where A1 and A0 are both 0).

The *Low Pin Count (LPC) Interface Specification, Revision 1.1* allows DMA cycles to be 4-bytes in length, but the LPC controller will only allow a maximum of 16-bit transfers. Additionally, the *LPC Specification* allows for firmware memory cycles to be 1, 2, or 4 bytes, and in the case of firmware reads, 128 bytes. However, the LPC controller will only perform 8-bit transfers.

Bus master read or write cycles must be naturally aligned. A 1 byte transfer can be to any address. A 2-byte transfer must be word aligned (address bit A0 = 0). A 4-byte transfer must be Dword aligned (address bits A[1:0] = 00).

### 19.3.3 Aborting a Cycle

The usage of LFRAME# is followed as it is defined in the *LPC Specification*.

The LPC Controller performs an abort for the following cases (possible failure cases):

- LPC Controller starts a Memory, I/O, or DMA cycle, but no device drives a valid SYNC after four consecutive clocks.
- LPC Controller starts a Memory, I/O, or DMA cycle, and the peripheral drives an invalid SYNC pattern.
- A peripheral drives an illegal address when performing bus master cycles.
- A peripheral drives an invalid value.

### 19.3.4 Memory Cycle Notes

For cycles below 16M and not targeting firmware, the LPC Controller will perform standard LPC memory cycles. For cycles targeting firmware, firmware memory cycles are used. For cycles targeting the fixed token, the fixed token format is used. Only 8-bit transfers are performed. If a larger transfer occurs, the LPC controller will break it into multiple 8-bit transfers until the request is satisfied.

**Note:** If the cycle is not claimed by any peripheral (and subsequently aborted), a value of all 1s (FFh) is returned to the processor. This is to maintain compatibility with legacy memory cycles where pull-up resistors would keep the bus high if no device responds.

### 19.3.5 I/O Cycle Notes

For I/O cycles targeting registers specified in the decode ranges, CMI performs I/O cycles as defined in the *LPC Specification*. These are 8-bit transfers. If the processor attempts a 16-bit or 32-bit transfer, CMI breaks the cycle up into multiple 8-bit transfers to consecutive I/O addresses until the request is satisfied.

**Note:** If the cycle is not claimed by any peripheral (and subsequently aborted), CMI returns a value of all 1s (FFh) to the processor. This is to maintain compatibility with legacy I/O cycles where pull-up resistors would keep the bus high if no device responds.

### 19.3.6 DMA Cycle Notes

Only 8-bit and 16-bit DMA transfers are supported. Peripherals must not attempt 32-bit transfers.

### 19.3.7 Bus Master Cycle Notes

CMI supports Bus Master cycles and requests (using LDRQ#) as defined in the *LPC Specification*. CMI has two LDRQ# inputs, and thus supports two separate bus master devices. It uses the associated START fields for Bus Master 0 (0010b) or Bus Master 1 (0011b).

**Note:** CMI does not support LPC Bus Masters performing I/O cycles. LPC Bus Masters must only perform memory read or memory write cycles and must only target main memory.

### 19.3.8 FWH Cycle Notes

A FWH device is not allowed to assert an Error SYNC. If the LPC controller receives any SYNC returned from the device other than short wait (0101), long wait (0110), or ready more (0000) when running a FWH cycle, indeterminate results will occur.

### 19.3.9 LPC PD# Protocol

The LPCPD# pin must follow the same timings as for SUS\_STAT#. Upon driving SUS\_STAT# low, LPC peripherals will drive LDRQ# low or tri-state it. The LPC Controller must shut the LDRQ# input buffers. After driving SUS\_STAT# active, the LPC Controller drives LFRAME# low, and tri-states (or drive low) LAD[3:0].

**Note:** The LPC Controller does not follow one part of the *LPC Specification* that says "LRESET# is always asserted after LPCPD#". LRESET# is not always asserted after LPCPD#. The *Low Pin Count Interface Specification, Revision 1.1* defines the LPCPD# protocol where there is at least 30  $\mu$ s from LPCPD# assertion to LRST# assertion. This specification explicitly states that this protocol only applies to entry/exit of low power states which does not include asynchronous reset events. CMI asserts both SUS\_STAT# (connects to LPCPD#) and PLTRST# (connects to LRST#) at the same time when the core logic is reset (via CF9h, PWROK, or SYS\_RESET#, etc.). This is not inconsistent with the LPC LPCPD# protocol.

### 19.3.10 Cycle Posting Policies

Three main policies are assumed.

1. I/O cycles and memory read cycles from the processor are not posted. Memory write Cycles from the processor are posted.
2. DMA cycles can be pipelined. For example, after reading data from memory, the LPC Controller can then release PHOLD# while it writes the data to the peripheral on the LPC Interface. This is because there are no processor/SMI#-based retry capabilities for DMA cycles. In the other direction, after reading data from a peripheral, PHOLD# can be released while the DMA controller writes data to main memory.
3. When bus masters read from main memory, the LPC Controller can treat this much like DMA, and release the memory and PCI buses while the data is being transferred to the bus master on the LPC Interface. When a bus master writes to main memory, the LPC Controller can use the LPC Interface while the data is being written to main memory.

### 19.3.11 Configuration

#### 19.3.11.1 LPC Interface Decoders

To allow the I/O cycles and memory mapped cycles to go to the LPC interface, CMI includes several decoders. During configuration, CMI must be programmed with the same decode ranges as the peripheral. The decoders are programmed via the Device 31, Function 0 configuration space at offset 80h–87h.

*Note:* CMI cannot accept PCI write cycles from PCI-to-PCI bridges or devices with similar characteristics (specifically those with a “Retry Read” feature which is enabled) to an LPC device if there is an outstanding LPC read cycle towards the same PCI device or bridge. These cycles are not part of normal system operation, but may be encountered as part of platform validation testing using custom test fixtures.

#### 19.3.11.2 Bus Master Device Mapping and START Fields

Bus Masters must have a unique START field. In the case of the LPC Controller, which supports two bus masters, it will drive 0010 for the START field for grants to bus master 0 (requested via LDRQ[0]#) and 0011 for grants to bus master 1 (requested via LDRQ[1]#).

#### 19.3.11.3 Firmware Memory IDSEL fields

The LPC Controller uses a unique IDSEL field for each EPROM. The IDSEL used is determined through the programming of the FS1 and FS2 configuration registers.

### 19.3.12 SERR# Generation

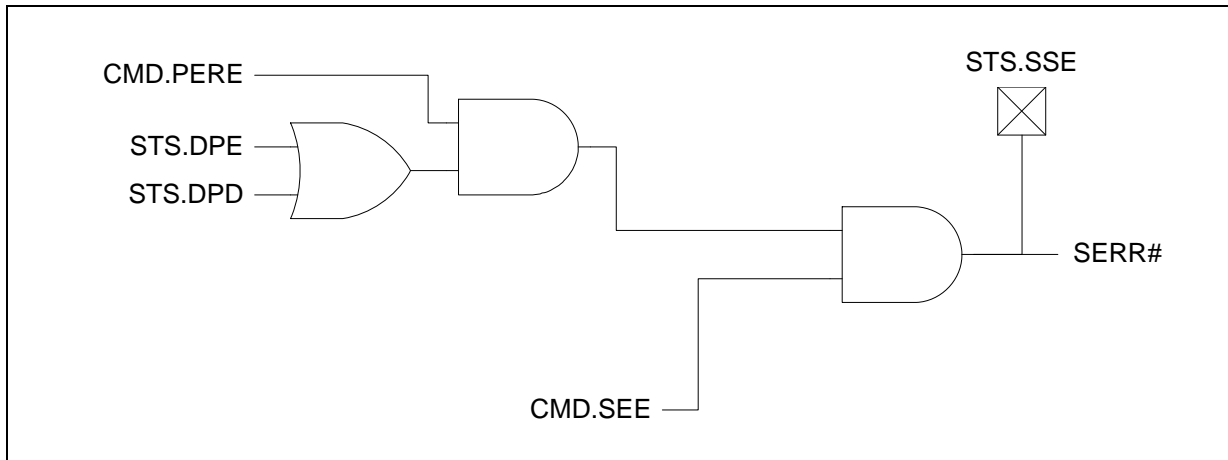

Several internal and external sources of the LPC Bridge can cause SERR#, and are described below.

The first class of errors is parity errors related internally to CMI. The LPC Bridge captures generic data parity errors (errors it finds internally), as well as, errors returned on internal cycles where the bridge was the master. If either of these two conditions are met, and the bridge is enabled for parity error response, SERR# is captured.

Additionally, if the bridge receives a target abort or master abort, and the bridge policy is to SERR# on these types of aborts, SERR# is generated.

Figure 19-2. LPC Bridge SERR#

CMD.PERE - Offset 04-05h bit 06

STS.DPE - Offset 06-07h bit 15

STS.RTA - Offset 06-07h bit 12

STS.RMA - Offset 06-07h bit 13

§ §

## 20.0 LPC DMA

### 20.1 Overview

LPC DMA is supported using the IICH DMA controller. The DMA controller has registers that are fixed in the lower 64 Kbyte of I/O space. The DMA controller is configured using registers in the PCI configuration space. These registers allow configuration of the channels for use by LPC DMA.

The DMA circuitry incorporates the functionality of two 8237 DMA controllers with seven independently programmable channels; Channels 0–3 and Channels 5–7. DMA Channel 4 cascades the two controllers together and is not available for other use.

In addition to accepting requests from DMA slaves, the DMA controller also responds to requests that software initiates. Software may initiate a DMA service request by setting any bit in the DMA Channel Request Register to a one. The DMA controller is used for LPC DMA.

**Figure 20-1. IICH DMA Controller**

Feature set of the IICH DMA controller:

- Channels 0–3 provide 8-bit, count-by-bytes transfers.
- Channels 5–7 provide 16-bit, count-by-words transfers.
- 24-bit addressing. Each channel includes a 16-bit, legacy-compatible Current Address Register (CAR), which holds the 16 least-significant bits, and an legacy Compatible Page Register, which contains the eight next most significant bits of address.
- Auto-initialization following a DMA termination.

The DMA controller has registers that are fixed in the lower 64 Kbyte of I/O space.

The DMA controller is configured using registers in the PCI configuration space. These registers allow configuration of individual channels for use by LPC.

The RPR bit effects the register decoding for the Reserved Page register (Addresses 80, 84-86, 88, 8C-8E and their aliases in the 9x range). See [Section 17.1.6.3, "Offset 3410h: GCS: General Control and Status Register" bit 2.](#)

## 20.2 LPC DMA I/O-Mapped Register Details

*Note:* Some registers are normally read-only, but are writable in Alt-Access mode. Likewise, there are some registers that are normally write-only, but are readable in Alt-Access mode. The individual register descriptions may not indicate this. See Alt-Access mode for more details.

**Table 20-1. Summary of LPC DMA Registers Mapped in I/O Space**

## 20.2.1 Register Descriptions

### 20.2.1.1 Offset 00h: DMA\_BCA[0-3] - DMA Base and Current Address Registers for Channels 0-3

Table 20-4. Offset 00h: DMA\_BCA[0-3] - DMA Base and Current Address Registers for Channels 0-3

| <b>Description:</b> Ch. 0: 00h - 10h; Ch.1: 02h - 12h; Ch.2: 04h - 14h; Ch.3: 06h - 16h |                                 |  |        |  |            |
|---|---------------------------------|--|--------|--|------------|
| <b>View:</b> IA F   | <b>Base Address:</b> 0000h (IO) |  |        | <b>Offset Start:</b> 00h at 02h<br><b>Offset End:</b> 10h at 02h |            |
| <b>Size:</b> 16 bit <sup>a</sup>  | <b>Default:</b> XXXX            |  |        | <b>Power Well:</b> Core  |            |
| Bit Range   | Bit Acronym                     | Bit Description  | Sticky | Bit Reset Value  | Bit Access |
| 15 : 00   | BCADD                           | <p><b>Base and Current Address:</b> This register determines the address for the transfers to be performed. The address specified points to two separate registers. On writes, the value is stored in the Base Address register and copied to the Current Address register. On reads, the value is returned from the Current Address register.</p> <p>The address increments/decrements in the Current Address register after each transfer, depending on the mode of the transfer. If the channel is in auto-initialize mode, the Current Address register is reloaded from the Base Address register after a terminal count is generated. For transfers to/from a 16-bit slave (channels 5-7), the address is shifted left one bit location. Bit 15 is shifted into bit 16.</p> <p>The register is accessed in 8-bit quantities. The byte is pointed to by the current byte pointer flip/flop. Before accessing an address register, the byte pointer flip/flop must be cleared to ensure that the low byte is accessed first.</p> |        | XXXX   | RW         |

a. This register provides an 8-bit window into a 16-bit quantity. The byte accessed depends on the current byte pointer flip/flop.

## 20.2.1.2 Offset C4h: DMA\_BCA[5-7] - DMA Base and Current Address Registers for Channels 5-7

Table 20-5. Offset C4h: DMA\_BCA[5-7] - DMA Base and Current Address Registers for Channels 5-7

### 20.3 DMA Channel Arbitration

The IICH DMA controller consists of two logical channel groups; channels 0–3 and channels 4–7. Each group may be in either fixed or rotate mode as described in detail below.

The mode of operation for each controller is determined by the DMA Command register; address 08h for channels 0–3 and address D0h for channels 4–7. Since channels 0–3 are cascaded onto channel 4, any request on channel 0–3 appears as a request on channel 4.

The DMA controller stops rotating when an NMI is pending.

In fixed mode, the lowest numbered channel in a channel group receives highest priority. Therefore, channel 0 is the highest priority device of channels 0–3, and channel 4 is the highest priority device of channels 4–7. When both channels are programmed in fixed mode, channel 0 has highest priority and channel 7 the lowest.

In rotating mode, the lowest numbered channel starts out with highest priority. When it is serviced, the next numbered channel receives highest priority and the previous channel receives lowest priority. For example, if channel 0 has highest priority and is requesting, it wins arbitration, then is the lowest priority channel until channels 1, 2, and 3 have been serviced.

Due to the nature of channel 0–3 being cascaded onto channel 4, rotating mode adds some peculiarities to the arbitration scheme. Table 20-18 lists arbitration winners assuming all channels are requesting.

Table 20-18. DMA Channel Priority

| Current | Both Fixed          | Lower Fixed, Upper Rotating | Lower Rotating, Upper Fixed | Both Rotating       |
|---------|---------------------|-----------------------------|-----------------------------|---------------------|
| 0       | 0, 1, 2, 3, 5, 6, 7 | 5, 6, 7, 0, 1, 2, 3         | 1, 2, 3, 0, 5, 6, 7         | 5, 6, 7, 1, 2, 3, 0 |
| 1       | 0, 1, 2, 3, 5, 6, 7 | 5, 6, 7, 0, 1, 2, 3         | 2, 3, 0, 1, 5, 6, 7         | 5, 6, 7, 2, 3, 0, 1 |
| 2       | 0, 1, 2, 3, 5, 6, 7 | 5, 6, 7, 0, 1, 2, 3         | 3, 0, 1, 2, 5, 6, 7         | 5, 6, 7, 3, 0, 1, 2 |
| 3       | 0, 1, 2, 3, 5, 6, 7 | 5, 6, 7, 0, 1, 2, 3         | 0, 1, 2, 3, 5, 6, 7         | 5, 6, 7, 0, 1, 2, 3 |
| 5       | 0, 1, 2, 3, 5, 6, 7 | 6, 7, 0, 1, 2, 3, 5         | 0, 1, 2, 3, 5, 6, 7         | 6, 7, 0, 1, 2, 3, 5 |
| 6       | 0, 1, 2, 3, 5, 6, 7 | 7, 0, 1, 2, 3, 5, 6         | 0, 1, 2, 3, 5, 6, 7         | 7, 0, 1, 2, 3, 5, 6 |
| 7       | 0, 1, 2, 3, 5, 6, 7 | 0, 1, 2, 3, 5, 6, 7         | 0, 1, 2, 3, 5, 6, 7         | 0, 1, 2, 3, 5, 6, 7 |

## 20.4 Special Cases in Address/Count

### 20.4.1 Address Overrun/Underrun

Whenever the DMA is operating, the addresses do not increment or decrement through the High Page and Low Page registers. Therefore, if a 24-bit address is 01FFFFh and increments, the next address is 010000h, not 020000h. Similarly, if a 24-bit address is 020000h and decrements, the next address is 02FFFFh, not 01FFFFh.

However, when the DMA is operating in 16-bit mode, the addresses do not increment or decrement through the High Page and Low Page registers but the page boundary is now 128 Kbyte. Therefore, if a 24-bit address is 01FFFEh and increments, the next address is 000000h, not 010000h. Similarly, if a 24-bit address is 020000h and decrements, the next address is 03FFFEh, not 02FFFEh.

### 20.4.2 16-Bit Channels

For 16-bit channels, the DMA controller addressing is different than for 8-bit channels. The DMA controller shifts the lower 16 bits of address left 1 bit and shifts in a '0', as shown in [Table 20-19](#). The count register is also redefined to represent words instead of bytes.

**Table 20-19. Address Shifting in 16-bit DMA Transfers**

| Register |           |          | Address on 8 bit channels<br>(hex) | Address on 16 bit channels<br>(hex) |
|----------|-----------|----------|------------------------------------|-------------------------------------|
| Page     | High Byte | Low Byte |                                    |                                     |
| 00       | 01        | 01       | 00.01.01                           | 00.02.02                            |
| 01       | FE        | 85       | 01.FE.85                           | 01.FD.0A                            |
| 01       | FF        | FF       | 01.FF.FF                           | 01.FF.FE                            |
| 00       | FE        | 85       | 00.FE.85                           | 01.FD.0A                            |
| 00       | FF        | FF       | 00.FF.FF                           | 01.FF.FE                            |

### 20.4.3 Autoinitialize

By programming a bit in the DMA Channel Mode Register, a channel may be set up as an autoinitialize channel. When a channel undergoes autoinitialization, the original values of the Current Page, Current Address and Current Byte/Word Count Registers are automatically restored from the Base Page, Address, and Byte/Word Count Registers of that channel following TC. The Base Registers are loaded simultaneously with the Current Registers by the microprocessor when the DMA channel is programmed and remain unchanged throughout the DMA service. The mask bit is not set when the channel is in autoinitialize. Following autoinitialize, the channel is ready to perform another DMA service, without processor intervention, as soon as a valid DREQ is detected.

### 20.4.4 Software Commands

There are three additional special software commands that the DMA controller can execute. The three software commands are:

- Clear Byte Pointer Flip-Flop
- Master Clear
- Clear Mask Register

They are independent of any specific bit pattern on the data bus.

## 20.5 Theory of Operation for LPC DMA

DMA on LPC is handled through the use of the LDRQ# lines from peripherals and special encodings on LAD[3:0] from the host. Single, Demand, Verify, and Increment modes are supported on the LPC interface. Channel 0–3 are 8 bit channels. Channel 5–7 are 16 bit channels. Channel 4 is reserved as a generic bus master request (see Section 20.5.1 on LPC bus masters).

### 20.5.1 Asserting DMA Requests

Peripherals that need DMA service encode their requested channel number on the LDRQ# signal. To simplify the protocol, each peripheral on the LPC Interface has its own dedicated LDRQ# signal (they may not be shared between two separate peripherals). The IICH has two LDRQ# inputs, allowing at least two devices to support DMA or bus mastering.

LDRQ# is synchronous with LCLK (PCI clock). As shown in Figure 20-2, the peripheral uses the following serial encoding sequence:

- Peripheral starts the sequence by asserting LDRQ# low (start bit). LDRQ# is high during idle conditions.
- The next three bits contain the encoded DMA channel number (MSB first).
- The next bit (ACT) indicates whether the request for the indicated DMA channel is active or inactive. The ACT bit is a 1 (high) to indicate if it is active and a 0 (low) if it is inactive. The case where ACT is low is rare, and is only used to indicate that a previous request for that channel is being abandoned. See Section 20.5.2 for reasons for abandoning DMA requests.
- After the active/inactive indication, the LDRQ# signal must go high for at least one clock. After that one clock, LDRQ# signal can be brought low to the next encoding sequence.

If another DMA channel also needs to request a transfer, another sequence can be sent on LDRQ#. For example, if an encoded request is sent for channel 2, and then channel 3 needs a transfer before the cycle for channel 2 is run on the interface, the peripheral can send the encoded request for channel 3. This allows multiple DMA agents behind an I/O device to request use of the LPC interface, and the I/O device does not need to self-arbitrate before sending the message.

Figure 20-2. DMA Request Assertion through LDRQ#

### 20.5.2 Abandoning DMA Requests

DMA Requests can be deasserted in two fashions: on error conditions by sending an LDRQ# message with the 'ACT' bit set to '0', or normally through a SYNC field during the DMA transfer. This section describes boundary conditions where the DMA request needs to be removed prior to a data transfer. See Section 20.5.6 to see how DMA requests are terminated through a DMA transfer.

There may be some special cases where the peripheral desires to abandon a DMA transfer. The most likely case of this occurring is due to a floppy disk controller which has overrun or enduring its FIFO, or software stopping a device prematurely.

In these cases, the peripheral wishes to stop further DMA activity. It may do so by sending an LDRQ# message with the ACT bit as '0'. However, since the DMA request was seen, there is no guarantee that the cycle hasn't been granted and runs on LPC. Therefore, peripherals must take into account that a DMA cycle may still occur. The peripheral can choose not to respond to this cycle, in which case the host aborts it, or it can choose to complete the cycle normally with any random data.

This method of DMA deassertion must be prevented whenever possible in order to limit boundary conditions both on the IICH and the peripheral.

The LDREQ DMA abort scheme should not be used if a transfer is in progress (a cycle has started) and more than one transfer has been completed. In these cases, the peripheral must use the SYNC field encoding 0000.

### 20.5.3 General Flow of DMA Transfers

Arbitration for DMA channels is performed through the 8237 within the host. Once the host has won arbitration on behalf of a DMA channel assigned to LPC, it asserts LFRAME# on the LPC Interface and begins the DMA transfer. The general flow for a basic DMA transfer is as follows:

1. The IICH starts the transfer by asserting '0000b' on LAD[3:0] with LFRAME# asserted.
2. The IICH asserts 'cycle type' of DMA. The direction is based on the DMA transfer direction.
3. The IICH asserts the channel number and, if applicable, terminal count.
4. The IICH indicates the size of the transfer; 8 or 16 bits.
5. If a DMA reads:
  - a. The IICH drives the first 8 bits of data and turns the bus around.
  - b. The peripheral acknowledges the data with a valid SYNC.
  - c. If a 16 bit transfer, the process is repeated for the next 8 bits.
6. If a DMA writes:
  - a. The IICH turns the bus around and waits for data.
  - b. The peripheral indicates data ready through SYNC and transfers the first byte.
  - c. If a 16-bit transfer, the peripheral indicates data ready and transfers the next byte.
7. The peripheral turns around the bus.

### 20.5.4 Terminal Count

Terminal count is communicated through LAD[03] on the same clock that DMA channel is communicated on LAD[02:00]. This field is the CHANNEL field. Terminal count indicates the last byte of transfer, based upon the size of the transfer.

For example, on an 8-bit transfer size (SIZE field is '00b'), if the TC bit is set, then this is the last byte. On a 16-bit transfer (SIZE field is '01b'), if the TC bit is set, then the second byte is the last byte. The peripheral, therefore, must internalize the TC bit when the CHANNEL field is communicated and only signal TC when the last byte of that transfer size has been transferred.

## 20.5.5 Verify Mode

Verify mode is supported on the LPC interface. A verify transfer to the peripheral is similar to a DMA write, where the peripheral is transferring data to main memory. The indication from the host is the same as a DMA write, so the peripheral is driving data onto the LPC interface. However, the host does not transfer this data into main memory.

## 20.5.6 DMA Request Deassertion

An end of transfer is communicated to the IICH through a special SYNC field transmitted by the peripheral. If a DMA transfer is several bytes, such as a transfer from a demand mode device, the IICH needs to know when to deassert the DMA request based on the data currently being transferred.

The DMA agent uses a SYNC encoding on each byte of data being transferred, which indicates to the IICH whether this is the last byte of transfer or if more bytes are requested. To indicate the last byte of transfer, the peripheral uses a SYNC value of '0000b' (ready with no error), or '1010b' (ready with error). These encodings tell the IICH that this is the last piece of data transferred on a DMA read (IICH to peripheral), or the byte which follows is the last piece of data transferred on a DMA write (peripheral to IICH).

When the IICH sees one of these two encodings, it ends the DMA transfer after this byte and deasserts the DMA request to the 8237. Therefore, if the IICH indicated a 16 bit transfer, the peripheral can end the transfer after one byte by indicating a SYNC value of '0000b' or '1010b'. The IICH does not attempt to transfer the second byte, and deasserts the DMA request internally. This allows the peripheral, therefore, to terminate a DMA burst.

If the peripheral indicates a '0000b' or '1010b' SYNC pattern on the last byte of the indicated size, then the IICH only deasserts the DMA request to the 8237 since it does not need to end the transfer.

If the peripheral wishes to keep the DMA request active, then it uses a SYNC value of '1001b' (ready plus more data). This tells the 8237 that more data bytes are requested after the current byte has been transferred, so the IICH keeps the DMA request active to the 8237. Therefore, on an 8 bit transfer size, if the peripheral indicates a SYNC value of '1001b', the data is transferred and the DMA request remains active to the 8237. At a later time, the IICH starts with another START ⇒ CYCTYPE ⇒ CHANNEL ⇒ SIZE etc. combination to initiate another transfer to the peripheral.

The peripheral must not assume that the next START indication from the IICH is another grant to the peripheral if it had indicated a SYNC value of '1001b'. On a single mode DMA device, the 8237 rearbitrates after every transfer. Only demand mode DMA devices can be guaranteed that they receive the next START indication from the IICH.

*Note:* Indicating a '0000b' or '1010b' encoding on the SYNC field of an odd byte of a 16 bit channel (first byte of a 16 bit transfer) is an error condition.

*Note:* The host stops the transfer on the LPC bus as indicated, fill the upper byte with random data on DMA writes (peripheral to memory), and indicate to the 8237 that the DMA transfer occurred, incrementing the 8237s address and decrementing its byte count.

## 20.5.7 SYNC Field/LDRQ# Rules

Since DMA transfers on LPC are requested through an LDRQ# assertion message, and end through a SYNC field during the DMA transfer, the peripheral must obey the following rule when initiating back-to-back transfers from a DMA channel.

The peripheral must not assert another message for eight LCLKs after a deassertion is indicated through the SYNC field. This is needed to allow the 8237, which typically runs off a much slower internal clock, to see a message deasserted before it is reasserted so that it can arbitrate to the next agent.

Under default operation, the host only performs 8-bit transfers on 8-bit channels and 16-bit transfers on 16-bit channels. In order to enable 16-bit transfers on 8-bit channels, the peripheral must communicate to system BIOS that larger transfer sizes are allowed. If the host has this capability, the BIOS programs the host to attempt larger transfer sizes. The IICH does not support 32-bit DMA transfer.

The method by which this communication between host and peripheral through system BIOS is performed is beyond the scope of this specification. Since the host and peripheral are motherboard devices, no "plug-n-play" registry is required.

The peripheral must not assume that the host is able to perform transfer sizes that are larger than the size allowed for the DMA channel, and be willing to accept a SIZE field that is smaller than what it may currently have buffered.

To that end, it is recommended that future devices which may appear on the LPC bus, which require higher bandwidth than 8-bit or 16-bit DMA allow, do so with a bus mastering interface and not rely on the 8237.

## 21.0 Serial Peripheral Interface

### 21.1 Overview

The Serial Peripheral Interface (SPI) is a 4-pin interface that provides a potentially lower-cost alternative for system flash versus the Firmware Hub interface that is available on the LPC pins.

#### 21.1.1 Features

- Support for Multiple SPI Flash Vendors
- Simple Hardware
- Equivalence to LPC-Based Firmware Hubs
  - Provide the EP80579 Write Protection scheme
  - Equivalent Performance (Boot time, Resume Time)
  - Top Swap Functionality
  - Support for E & F segments below 1 MB
  - 64 Kb-Granular Protection

Note that the SPI does not provide support for very large BIOS sizes as easily as the FWH interface. The EP80579 SPI interface is restricted to one Chip Select pin.

The Serial Peripheral Interface (SPI) is a 4-pin interface that provides a potentially lower-cost alternative for system flash versus the Firmware Hub interface that is available on the LPC pins.

### 21.2 External Interface

Table 21-1. SPI Pin Interface

| Signal(s) | Width | Type | IO Type     | Description                        |
|-----------|-------|------|-------------|------------------------------------|
| SPI_SCLK  | 1     | O    | LVTTL, 3.3V | Serial bit-rate clock<br>17.86 MHz |
| SPI_CS#   | 1     | O    | LVTTL, 3.3V | CS for slave                       |
| SPI_MOSI  | 1     | O    | LVTTL, 3.3V | Master data out / Slave In         |
| SPI_MISO  | 1     | I    | LVTTL, 3.3V | Master data in/ Slave out          |

Table 21-2. GPIO Boot Source Selection

| GPIO17 | GPIO33 | Description            |
|--------|--------|------------------------|
| 1      | 1      | Default. Boot from LPC |
| 0      | 1      | Reserved.              |
| 1      | 0      | Reserved.              |
| 0      | 0      | Boot from SPI          |

### 21.3 SPI Protocol

Communication on the SPI bus is done with a Master – Slave protocol. Typical bus topologies call for a single SPI Master with a single SPI Slave. The SPI interface consists of a four wire interface: clock (CLK), master data out (Master Out Slave In (MOSI)), master data in (Master In Slave Out (MISO)) and an active low chip select (CS#).

#### 21.3.1 SPI Pin-Level Protocol

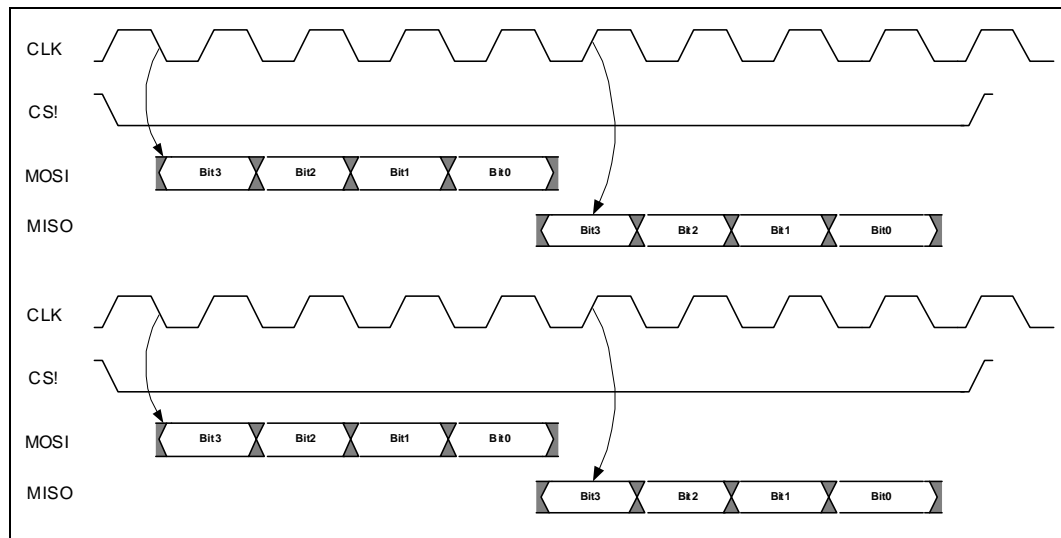

SPI communicates utilizing a synchronous protocol with the clock being driven by the Master. After selecting a Slave by asserting the SPI\_CS# signal, the Master generates eight clock pulses per byte on the SPI\_CLK wire, one clock pulse per data bit. <sup>1</sup> Data flows from master to slave on the SPI\_MOSI wire and from slave to master on the SPI\_MISO wire<sup>2</sup>. Data is setup and sampled on opposite edges of the SPI\_CLK signal. Master drives data off of the falling edge of the clock and slave samples on the rising edge of the clock. Similarly, Slave drives data off of the falling edge of the clock. The master has more flexibility on sampling schemes since it controls the clock. Note that SPI\_CLK flight times and the device SPI\_MISO max valid times indicate that the rising edge is not feasible for sampling the SPI\_MISO input at the master for a 20 MHz clock period with 50% duty cycle.

---

1. SPI supports 8 or 16 bit words, however all devices on the supported list only operate on 8 bit words.  
2. SPI specifies that data can be shifted MSB or LSB first, however all devices on the supported list only operate MSB first.

Figure 21-1. Basic SPI Protocol

Only Mode 0 is supported.

Commands, Addresses and Data are shifted most significant bit (MSB) first. For the 24-bit address, this means bit 23 is shifted first while bit 0 is shifted last. However, for data bursts, bytes are shifted out from *least significant byte to most significant byte*, where each byte is shifted (MSB to LSB).

### 21.3.1.1 Addressing

A Slave is targeted for a cycle when its SPI\_CS# pin is asserted. Besides Slave addressing there is register addressing within the Slave itself. The list of EP80579 supported devices' includes only FLASH devices. See supported devices data sheets for more information.

### 21.3.1.2 Data Transaction

All transactions on the SPI bus must be a multiple of 8 bits. A frame consists of any number of 8-bit data packets. To initiate a data transfer, the SPI Master asserts (high to low transition) the SPI\_CS# signal informing the SPI Slave that it is being targeted for a cycle. The Master will then shift out the 8-bit opcode followed by the Slave's internal address.

In the case of a Read transaction, the Slave will interpret the Slave address and begin driving data out on the SPI\_MISO pin and ignore any transactions on the SPI\_MOSI pin. The Master indicates Read complete by deasserting the SPI\_CS# signal on an 8-bit boundary.

In the case of a Write transaction, the Slave will continue to receive Master data on the SPI\_MOSI pin. The Write transaction is completed upon deassertion of the SPI\_CS# signal on an 8-bit boundary.

The SPI bus does include a mechanism for flow control, however some devices include the support of a HOLD signal. See Slave documentation for more information. If the Slave receives an un-recognized or invalid opcode it should ignore the rest of the packet and wait for the deassertion of SPI\_CS#.

### 21.3.1.3 Bus Errors

If the first 8 bits specify an opcode which is not supported the slave will not respond and wait for the next high to low transition on SPI\_CS#.

SPI hardware should automatically discard 8-bit words that were not completely received upon deassertion of the SPI\_CS# signal.

Any other error correction or detection mechanisms must be implemented in firmware/software.

### 21.3.1.4 Instructions

| Instruction                 | ST M25P80 (8 Mb) | ST M45PE80 (8 Mb) | NexFlash NX25P* | SST 25V040 (4Mb), SST 25VF080 (8 Mb) | Ching is (1 Mb) |
|-----------------------------|------------------|-------------------|-----------------|--------------------------------------|-----------------|
| Write Status                | 01               | -                 | 01              | 01                                   | 01              |
| Data Program                | 02               | 02                | 02              | 02                                   | 02              |
| Read Data                   | 03               | 03                | 03              | 03                                   | 03              |
| Write Disable               | 04               | 04                | 04              | 04                                   | 04              |
| Read Status                 | 05               | 05                | 05              | 05                                   | 05              |
| Write Enable                | 06               | 06                | 06              | 06                                   | 06              |
| Page Write                  | -                | 0A                | -               | -                                    | -               |
| Fast Read <sup>(1)</sup>    | 0B               | 0B                | 0B              | -                                    | 0B              |
| Ena Write Status            | -                | -                 | -               | 50                                   | -               |
| 256B Erase                  | -                | DB                | -               | -                                    | -               |
| 4KByte Erase                | -                | -                 | -               | 20                                   | D7              |
| 64KB Erase                  | D8               | D8                | D8              | 52                                   | D8              |
| Chip Erase                  | C7               | -                 | C7              | 60                                   | C7              |
| Auto Add Inc <sup>(2)</sup> | -                | -                 | -               | AF                                   | -               |
| Power Down/Up               | B9 / AB          | B9 / AB           | B9              | -                                    | -               |
| Read ID                     | -                | 9F                | 90              | AB or 90                             | AB              |

**Notes:**

1. Fast Read Protocol is not supported
2. The Auto Address Increment type is not supported.

### 21.3.1.5 SPI Timings

The SPI interface is designed to fall within the following protocol timing specs. These specs are intended to operate with most SPI Flash devices.

**Table 21-3. SPI Cycle Timings**

| Parameter     | Minimum Value | Description                                       |
|---------------|---------------|---|
| SPI_CS# Setup | 30 ns         | SPI_CS# low to SPI_CLK high                       |
| SPI_CS# Hold  | 30 ns         | SPI_CLK low to SPI_CS# low                        |
| Clock High    | 22 ns         | Time that SPI_CLK is Driven high per clock period |
| Clock Low     | 22 ns         | Time that SPI_CLK is Driven Low per clock period  |

## 21.4 Host Side Interface

### 21.4.1 SPI Host Interface Registers

The SPI Host Interface registers are memory-mapped in the RCRB Chipset Memory Space in the range 3020h to 308Fh.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

The table below does NOT include the 3020h offset.

### 21.4.2 Register Overview

**Table 21-4. Bus 0, Device 31, Function 0, PCI Registers Mapped Through RCBA Bar**

| Offset Start | Offset End  | Register ID - Description   | Default Value |
|--------------|-------------|---|---------------|
| 3020h        | 3021h       | "Offset 3020h: SPIS - SPI Status" on page 790   | 0001h         |
| 3022h        | 3023h       | "Offset 3022h: SPIC - SPI Control" on page 791  | 2005h         |

21.4.2.1 Offset 3020h: SPIS – SPI Status

Table 21-5. Offset 3020h: SPIS - SPI Status

| Description: |             |   |                             |  |            |
|--------------|-------------|---|-----------------------------|--|------------|
| View: PCI    | BAR: RCBA   |   | Bus:Device:Function: 0:31:0 | Offset Start: 3020h<br>Offset End: 3021h |            |
| Size: 16 bit | Default:    | 0001h   |                             | Power Well: Core                         |            |
| Bit Range    | Bit Acronym | Bit Description   | Sticky                      | Bit Reset Value                          | Bit Access |
| 15           | SCL         | <b>SPI Configuration Lock-Down:</b> When set to 1, the SPI Static Configuration information in offsets 50h through 6Bh can not be overwritten. Once set to 1, this bit can only be cleared by a hardware reset.   |                             | 0  | RWL        |
| 14 :4        | Rsvd        | Reserved  |                             | 0  | RV         |
| 3            | BAS         | <b>Blocked Access Status:</b> Hardware sets this bit to 1 when an access is blocked from running on the SPI interface due to one of the protection policies or when any of the programmed cycle registers are written while a programmed access is already in progress. This bit is set for both programmed accesses and direct memory reads that get blocked. This bit remains asserted until cleared by software writing a 1 or hardware reset.   |                             | 0  | RWC        |
| 2            | CDS         | <b>Cycle Done Status:</b> The EP80579 sets this bit to 1 when the SPI Cycle completes (i.e., SCIP bit is 0) after software sets the GO bit. This bit remains asserted until cleared by software writing a 1 or hardware reset. When this bit is set and the SPI bit in <a href="#">Offset 3022h: SPIC – SPI Control</a> is set, an internal signal is asserted to the SMI# generation block. Software must make sure this bit is cleared prior to enabling the SPI SMI# assertion for a new programmed access. This bit gets set after the Status Register Polling sequence completes after reset deasserts. It is cleared before and during that sequence. |                             | 0  | RWC        |
| 1            | Rsvd        | <b>Reserved.</b>  |                             | 0  | RV         |
| 0            | SCIP        | <b>SPI Cycle In Progress (SCIP):</b> Hardware sets this bit when software sets the SPI Cycle Go bit in the <a href="#">Offset 3022h: SPIC – SPI Control</a> . This bit remains set until the cycle completes on the SPI interface. Hardware automatically sets and clears this bit so that software can determine when read data is valid and/or when it is safe to begin programming the next command. Software must only program the next command when this bit is 0. This bit reports 1b during the Status Register Polling sequence after reset deasserts; it is cleared when that sequence completes.  |                             | 1  | RO         |

### 21.4.2.2 Offset 3022h: SPIC – SPI Control

Table 21-6. Offset 3022h: SPIC - SPI Control

| Description: |             |   |                             |  |            |
|--------------|-------------|---|-----------------------------|--|------------|
| View: PCI    | BAR: RCBA   |   | Bus:Device:Function: 0:31:0 | Offset Start: 3022h<br>Offset End: 3023h |            |
| Size: 16 bit | Default:    | 2005h   |                             | Power Well: Core                         |            |
| Bit Range    | Bit Acronym | Bit Description   | Sticky                      | Bit Reset Value                          | Bit Access |
| 15           | SSMIE       | <b>SPI SMI# Enable:</b> When set to 1, the SPI asserts an SMI# request whenever the Cycle Done Status bit is 1.   |                             | 00                                       | RW         |
| 14           | DC          | <b>Data Cycle:</b> When set to 1, there is data that corresponds to this transaction. When 0, no data is delivered for this cycle, and the DBC and data fields themselves are don't cares.  |                             | 1  | RW         |
| 13:08        | DBC         | <b>Data Byte Count (DBC):</b> This field specifies the number of bytes to shift in or out during the data portion of the SPI cycle. The valid settings (in decimal) are any value from 0 to 63. The number of bytes transferred is the value of this field plus 1.<br>Note that when this field is 00_0000b, then there is 1 byte to transfer and that 11_1111b means there are 64 bytes to transfer.   |                             | 0  | RW         |
| 7            | Rsvd        | Reserved  |                             | 0  | RV         |
| 6:4          | COP         | <b>Cycle Opcode Pointer:</b> This field selects one of the programmed opcodes in the <a href="#">Offset 3078h: OPMENU – Opcode Menu Configuration</a> to be used as the SPI Command/Opcode. In the case of an Atomic Cycle Sequence, this determines the second command.  |                             | 0  | RW         |
| 3            | SPOP        | <b>Sequence Prefix Opcode Pointer:</b> This field selects one of the two programmed prefix opcodes for use when performing an Atomic Cycle Sequence. A value of 0 points to the opcode in the least significant byte of the <a href="#">Offset 3074h: PREOP – Prefix Opcode Configuration</a> register. By making this programmable, the EP80579 supports flash devices that have different opcodes for enabling writes to the data space vs. status register.  |                             | 0  | RW         |
| 2            | ACS         | <b>Atomic Cycle Sequence (ACS):</b> When set to 1 along with the SCGO assertion, the EP80579 will execute a sequence of commands on the SPI interface. The sequence is composed of:<br>Atomic Sequence Prefix Command (8-bit opcode only)<br>Primary Command specified by software (can include address and data)<br>Polling the Flash Status Register (opcode 05h) until bit 0 becomes 0b.<br>The SPI Cycle in Progress bit remains set and the Cycle Done Status bit in <a href="#">Offset 3020h: SPIS – SPI Status</a> register remains unset until the Busy bit in the Flash Status Register returns 0. |                             | 1  | RW         |
| 1            | SCGO        | <b>SPI Cycle Go (SCGO):</b> This bit always returns 0 on reads. However, a write to this register with a '1' in this bit starts the SPI cycle defined by the other bits of this register. The SPI Cycle in Progress (SCIP) bit in <a href="#">Offset 3020h: SPIS – SPI Status</a> register gets set by this action. Hardware must ignore writes to this bit while the SPI Cycle In Progress bit is set.<br>Hardware allows other bits in this register to be programmed for the same transaction when writing this bit to 1. This saves an additional memory write.   |                             | 0  | RWS        |
| 0            | Rsvd        | <b>Reserved</b>   |                             | 1  | RV         |

21.4.2.3 Offset 3024h: SPIA – SPI Address

Table 21-7. Offset 3024h: SPIA - SPI Address

| Description: |             |  |  |               |                 |            |
|--------------|-------------|--|--|---------------|-----------------|------------|

| 31 : 24      | RSVD        | Reserved   |  |               | 0               | RV         |
| 23 : 00      | SCA         | SPI Cycle Address (SCA): This field is shifted out as the SPI Address (MSB first). |  |               | 0               | RW         |

21.4.2.4 Offset 3028h: SPID0 – SPI Data 0

Table 21-8. Offset 3028h: SPID0 - SPI Data 0

| Description: |             |  |  |               |                 |            |
|--------------|-------------|--|--|---------------|-----------------|------------|
| View:        | BAR:        | Bus:Device:Function:   |  | Offset Start: | Offset End:     |            |
| PCI          | RCBA        | 0:31:0   |  | 3028h         | 302Bh           |            |
| Size:        | Default:    |  |  | Power Well:   |                 |            |
| 64 bit       | XXXXXXXXh   |  |  | Core          |                 |            |
| Bit Range    | Bit Acronym | Bit Description  |  | Sticky        | Bit Reset Value | Bit Access |
| 63 : 00      | SCD         | <p><b>SPI Cycle Data 0 (SCD0):</b> This field is shifted out as the SPI Data on the Master-Out Slave-In Data pin (SPI_MOSI) during the data portion of the SPI cycle.</p> <p>This register also shifts in the data from the Master-In Slave-Out pin (SPI_MISO) into this register during the data portion of the SPI cycle.</p> <p>The data is always shifted starting with the least significant byte, MSB to LSB, followed by the next least significant byte, MSB to LSB, etc. Specifically, the shift order on SPI in terms of bits within this register is: 7-6-5-4-3-2-1-0-15-14-13-...8-23-22-...16-31...24-39...32...etc. Bit 56 is the last bit shifted out/in. There are no alignment assumptions; byte 0 always represents the value specified by the cycle address.</p> <p>Note that the data in this register may be modified by the hardware during any programmed SPI transaction. Direct Memory Reads do not modify the contents of this register. (This last requirement is needed in order to properly handle the collision case described in <a href="#">Section 21.4.3.2.</a>)</p> <p>This register is initialized to 0 by the reset assertion. However, the least significant byte of this register is loaded with the first Status Register read of the Atomic Cycle Sequence that the hardware automatically runs out of reset. Therefore, bit 0 of this register can be read later to determine if the platform encountered the boundary case in which the SPI flash was busy with an internal instruction when the platform reset deasserted.</p> |  |               | see description | RW0        |

### 21.4.2.5 SPID[0-6] – SPI Data N

**Table 21-9. Offset 3030h, 3038h, 3040h, 3048h, 3050h, 3058h, 3060h: SPI [0-6] - SPI Data [0-6]**

| Description: |             |   |                             |  |            |
|--------------|-------------|---|-----------------------------|--|------------|
| View: PCI    | BAR: RCBA   |   | Bus:Device:Function: 0:31:0 | Offset Start: 3030h at 4h<br>Offset End: 306Ch at 4h |            |
| Size: 64 bit | Default:    | 00000000h   |                             | Power Well: Core                                     |            |
| Bit Range    | Bit Acronym | Bit Description   | Sticky                      | Bit Reset Value                                      | Bit Access |
| 63 : 00      | SCD         | <b>SPI Cycle Data N (SCD[N]):</b> Similar definition as SPI Cycle Data 0. However, this register does not begin shifting until SPID[N-1] has completely shifted in/out. |                             | 0  | RW         |

### 21.4.2.6 Offset 3070h: BBAR – BIOS Base Address

This register is not writable when the SPI Configuration Lock-Down bit in [Offset 3020h: SPIS – SPI Status](#) register is set.

**Table 21-10. Offset 3070h: BBAR - BIOS Base Address**

| Description: |             |  |                             |  |            |
|--------------|-------------|--|-----------------------------|--|------------|
| View: PCI    | BAR: RCBA   |  | Bus:Device:Function: 0:31:0 | Offset Start: 3070h<br>Offset End: 3073h |            |
| Size: 32 bit | Default:    | 00000000h  |                             | Power Well: Core                         |            |
| Bit Range    | Bit Acronym | Bit Description  | Sticky                      | Bit Reset Value                          | Bit Access |
| 31 : 24      | Rsvd        | Reserved   |                             | 0  | RV         |
| 23 : 08      | BSP         | <b>Bottom of System Flash:</b> This field determines the bottom of the System BIOS. The EP80579 will not run programmed commands nor memory reads whose address field is less than this value. This field corresponds to bits 23:8 of the 3-byte address; bits 7:0 are assumed to be 00h for this vector when comparing to a potential SPI address. Software must always program 1's into the upper, Don't Care bits of this field based on the flash size. Hardware does not know the size of the flash array and relies upon the correct programming by software. The default value of 0000h results in all cycles allowed.<br><b>Note:</b> The SPI Host Controller prevents any Programmed cycle using the Address Register with an address less than the value in this register. Some flash devices specify that the Read ID command must have an address of 0000h or 0001h. If this command must be supported with these devices, it must be performed with the BBAR - BIOS Base Address programmed to 0h. Some of these devices have actually been observed to ignore the upper address bits of the Read ID command. |                             | 0  | RWS        |
| 7 : 00       | Rsvd        | Reserved   |                             | 0  | RV         |

### 21.4.2.7 Offset 3074h: PREOP – Prefix Opcode Configuration

This register is not writable when the SPI Configuration Lock-Down bit in [Offset 3020h: SPIS – SPI Status](#) register is set.

**Table 21-11. Offset 3074h: PREOP - Prefix Opcode Configuration**

| Description: |             |  |                             |  |            |
|--------------|-------------|--|-----------------------------|--|------------|
| View: PCI    | BAR: RCBA   |  | Bus:Device:Function: 0:31:0 | Offset Start: 3074h<br>Offset End: 3075h |            |
| Size: 16 bit | Default:    | 0004h  |                             | Power Well: Core                         |            |
| Bit Range    | Bit Acronym | Bit Description  | Sticky                      | Bit Reset Value                          | Bit Access |
| 15 :08       | PO1         | <b>Prefix Opcode 1:</b> Software programs an SPI opcode into this field that is permitted to run as the first command in an atomic cycle sequence. |                             | 0  | RWS        |
| 7 :00        | PO0         | <b>Prefix Opcode 0:</b> Software programs an SPI opcode into this field that is permitted to run as the first command in an atomic cycle sequence. |                             | 04h                                      | RWS        |

### 21.4.2.8 Offset 3076h: OPTYPE – Opcode Type Configuration

This register is not writable when the SPI Configuration Lock-Down bit in [Offset 3020h: SPIS – SPI Status](#) register is set. Entries in this register correspond to the entries in the [Offset 3078h: OPMENU – Opcode Menu Configuration](#) register. Note that the definition below only provides write protection for opcodes that have addresses associated with them. Therefore, any erase or write opcodes that do not use an address should be avoided (for example, “Chip Erase” and “Auto-Address Increment Byte Program”).

**Table 21-12. Offset 3076h: OPTYPE - Op Code Type (Sheet 1 of 2)**

| Description: |             |  |                             |  |            |
|--------------|-------------|--|-----------------------------|--|------------|
| View: PCI    | BAR: RCBA   |  | Bus:Device:Function: 0:31:0 | Offset Start: 3076h<br>Offset End: 3077h |            |
| Size: 16 bit | Default:    | 0000h  |                             | Power Well: Core                         |            |
| Bit Range    | Bit Acronym | Bit Description  | Sticky                      | Bit Reset Value                          | Bit Access |

This information allows the hardware to 1) know whether to use the address field and 2) provide BIOS protection capabilities. The hardware implementation also uses the read vs. write information for modifying the behavior of the SPI interface logic. The encoding of the two bits is:<br>00 = No Address associated with this Opcode and Read Cycle type<br>01 = No Address associated with this Opcode and Write Cycle type<br>10 = Address required; Read cycle type<br>11 = Address required; Write cycle type |                             | 0  | RWS        |

#### 21.4.2.9 Offset 3078h: OPMENU – Opcode Menu Configuration

This register is not writable when the SPI Configuration Lock-Down bit in [Offset 3020h: SPIS – SPI Status](#) register is set. Eight entries are available in this register to give BIOS a sufficient set of commands for communicating with the flash device, while also restricting what malicious software can do. This keeps the hardware flexible enough to operate with a wide variety of SPI devices.

It is recommended that BIOS avoid programming Write Enable opcodes in this menu. Malicious software could then perform writes and erases to the SPI flash without using the atomic cycle mechanism. Write Enable opcodes should only be programmed in the [Offset 3074h: PREOP – Prefix Opcode Configuration](#).

### 21.4.3 Running SPI Cycles from the Host

#### 21.4.3.1 Memory Reads

Memory Reads to the BIOS Range result in a READ command (03h) with the lower 3 bytes of the address delivered in the SPI cycle. By sending the entire 24 bits of address out to the SPI interface unchanged, the EP80579 hardware can support various flash memory sizes without having straps or automatic detection algorithms in hardware. The flash memory device must ignore the upper address bits such that an address of FFFFFFFh simply aliases to the top of the flash memory. This is true for all supported flash devices. When considering additional flash parts, this behavior should be checked.

For compatibility with the FWH interface, the SPI interface supports decoding the two 64 KB BIOS ranges at the E0000h and F0000h segments just below 1 MB. These ranges must be re-directed (aliased) to the ranges just below 4 GB by the EP80579. This is done by forcing the upper address bits (23:20) to 1s when performing the read on the SPI interface.

When the SPI Prefetch Enable bit in [Offset DCh: BC: BIOS Control Register](#) is set, the EP80579 checks if the starting address for a read is aligned to the start of a 64B block (i.e., address bits 5:0 are 00h). If this is not the case, then the EP80579 only reads the length specified by the current read. If the read is aligned to the start of the 64B block with the SPI Prefetch Enable bit set, then the read burst continues on the SPI pins until 64 bytes have been received. Note that the EP80579 always performs the entire 64B burst when the conditions are met to perform the prefetch when the memory read request is received. This policy can result in a large penalty if the read addresses are not sequential. Software is allowed and encouraged to dynamically turn on prefetching only when the reads are sequential (for example, if shadowing the BIOS using consecutive DWord reads).

When prefetching is enabled, the read buffer must be enabled for caching. If the EP80579 detects a read to the range that is currently in (or being fetched for) the read buffer, it will not perform another read cycle on the SPI pins. Instead, the data is returned from the read buffer. Note that the entire read request must be contained in the cache in order to avoid running the read on the SPI interface.

The following events invalidate the read buffer “cache”:

1. A Programmed Access begins. Note that if the cycle is blocked from running for protection or other reasons, the cache is not flushed.
2. A Memory read to a BIOS range that does not hit the range in the read buffer.
3. System Reset.
4. Software setting the Cache Disable bit (and clearing the Prefetch Enable) in [Offset DCh: BC: BIOS Control Register](#). This can serve as a way to flush the cache in software.

Even when prefetching is disabled, the read buffer can act as a cache for Direct Memory Read Data. This is a potentially valuable boot-time optimization that leverages the basic caching mechanism that is needed for prefetching anyway. The cache is loaded with the data received on every Direct Memory Read that runs on the SPI pins. That data remains valid within the cache until any one of the conditions listed above occurs. For the cache to work properly, the Direct Memory Read must be fully contained within a 64-byte aligned range. The following events result in a valid read buffer cache when the caching is enabled:

1. A host read to the SPI BIOS with a length of 64 Bytes. This cycle must be aligned to a 64B boundary.
2. A host read to the SPI BIOS of any length with a 64B-aligned address and prefetching is enabled.

Note that, although the SPI interface may “burst ahead” for up to 64 bytes, the Host Interface may still have to wait for prefetched data to arrive from the flash before generating the completion back to the processor. The round trip delay for the platform to complete one DWord and run the host read for the next sequential DWord can be shorter than the SPI time to receive another 32 bits.

If a Direct Memory Read targeting the SPI flash is received while the host interface is already busy with either another Direct Memory Read or a Programmed Access, then the SPI Host hardware will hold the new Direct Memory Read (and the host processor) pending until the preceding SPI access completes. Note that it is possible for a second Direct Memory Read to be received while the prefetching continues for a first Direct Memory Read.

The SPI interface provides empty flash detection equivalent to FWH (i.e., all 1’s on the initial boot access.)

It is possible that a Direct Memory Read targeting the SPI flash can be issued with non-contiguous byte enables. While the CPU cannot create these cycles, peer agents can.

The SPI interface handles these Direct Memory Read transactions in the following fashion. Note that the byte enables in the table are active high, and BE[3] is the most significant byte enable of the DWord.

**Table 21-15. Byte Enable Handling on Direct Memory Reads**

| # DWords Requested | First DWord BE[3:0]  | Last DWord BE[3:0] | Action Taken  |
|--------------------|--|--------------------|---|
| 1                  | 0000   | Don't Care         | Zero bytes read from SPI, no SPI transaction started  |
| 1                  | 0001, 0010, 0100, 1000, 0011, 0110, 1100, 0111, 1110, 1111       | Don't Care         | Bytes read from SPI = bytes requested starting from lowest requested byte                                       |
| 1                  | 0101, 1001, 1010, 1011, 1101                                     | Don't Care         | Full DW (4 bytes) requested from SPI  |
| >1                 | 0000   | Don't Care         | Undefined behavior. Illegal protocol  |
| >1                 | 1000, 1100, 1110, 1111   | Don't Care         | Bytes read from SPI = 4* (num DW - 1) + bytes requested in first DW. Address starts from lowest requested byte. |
| >1                 | 0001, 0010, 0011, 0100, 0101, 0110, 0111, 1001, 1010, 1011, 1101 | Don't Care         | Bytes read from SPI = 4* num DW   |

When coming out of a platform reset, the SPI Host Controller must hold the initial Direct Memory Read from the processor pending until the SPI flash is no longer busy with an internal write or erase instruction. In order to achieve this, the host controller reads the Status Register (opcode = 05h) of the flash device until bit 0 is cleared. This is equivalent to the polling performed following an atomic cycle, during which the Direct Memory Reads are held pending. Depending on the type of flash and type of long instruction performed, the delay could be long enough to cause a watchdog timeout in the processor or chipset. Although this error condition is deemed acceptable in response to this rare error scenario (reset during flash update), it can be avoided altogether by selecting flash instructions on SPI devices that complete in less than ~1 second. Note that in the typical boot case, the status read on the SPI interface will complete well before the processor boot fetch due to the delay from PLTRST# deassertion to CPURST# deassertion.

### 21.4.3.2 Generic Programmed Commands

All commands other than the standard (memory) reads must be programmed by the BIOS in the SPI Control, address, data, and opcode configuration registers in [Section 21.4.1](#). The opcode type in [Offset 3076h: OPTYPE – Opcode Type Configuration](#) and data byte count fields in [Offset 3074h: PREOP – Prefix Opcode Configuration](#) determine how many clocks to run before deasserting the chip enable. The flash data is always shifted in for the number of bytes specified and the BIOS out data is always shifted out for the number of data bytes specified. Note that the hardware restricts the burst lengths that are allowed.

The status bit in [Offset 3020h: SPIS – SPI Status](#) indicates when the cycle has completed on the SPI port allowing the host to know when read results can be checked and/or when to initiate a new command.

The EP80579 also provides the “Atomic Cycle Sequence” for performing erases and writes to the SPI flash in [Offset 3022h: SPIC – SPI Control](#). When this bit is 1 (and the SPI Cycle Go bit is written to 1), a sequence of cycles is performed on the SPI interface. In this case, the specified cycle is preceded by the Prefix Command (8-bit programmable opcode) and followed by repeated reads to the Status Register (opcode 05h) until bit 0 indicates the cycle has completed. The hardware does not attempt to check that the programmed cycle is a write or erase.

If a Programmed Access is initiated (SPI Cycle Go written to 1) while the SPI host interface logic is already busy with a Direct Memory Read, then the SPI Host hardware will hold the new Programmed Access pending until the preceding SPI access completes. It will then begin to request the SPI bus for the Programmed Access.

Once the SPI Host hardware has committed to running a programmed access, subsequent writes to the programmed cycle registers that occur before it has completed will not modify the original transaction and will result in the assertion of the Blocked Access Status bit in [Offset 3020h: SPIS – SPI Status](#). Software should never purposely behave in this way and rely on this behavior. However, the Blocked Access Status bit provides basic error-reporting in this situation. Writes to the following registers cause the Blocked Access Status bit assertion in this situation:

- [Offset 3022h: SPIC – SPI Control](#)
- [Offset 3024h: SPIA – SPI Address](#)
- [Offset 3028h: SPID0 – SPI Data 0](#)

### 21.4.3.3 Flash Protection

There are two types of Flash Protection mechanisms:

1. BIOS Range Write Protection
2. SMI#-Based Global Write Protection

The two mechanisms are conceptually ORed together such that if any of the mechanisms indicate that the access should be blocked, then it is blocked. Table 21-16 provides a summary of the three mechanisms.

Table 21-16. Flash Protection Mechanism Summary

| Mechanism                          | Accesses Blocked | Range Specific | Reset-Override or SMI#-Override | Equivalent Function on FWH                         |
|------------------------------------|------------------|----------------|---------------------------------|--|
| BIOS Range Write Protection        | Writes           | Yes            | Reset Override                  | FWH Sector Protection                              |
| SMI#-Based Global Write Protection | Writes           | No             | SMI# Override                   | Same as Write Protect in previous chipsets for FWH |

The EP80579 provides these protections in hardware. Note that it is critical that the hardware must not allow malicious software to modify the address or opcode pointers after determining that a cycle is allowed to run, such that the actual cycle that runs on SPI should have been blocked.

If the command associated with an atomic cycle sequence is blocked according to the EP80579 configuration, the EP80579 must not run any of the sequence.

A blocked command will appear to software to finish, except that the Blocked Access Status bit in Offset 3020h: SPIS – SPI Status register is set in this case.

#### 21.4.3.3.1 BIOS Range Write Protection

The EP80579 provides a method for blocking writes to specific ranges in the SPI flash when the Protected BIOS Ranges are enabled. This is achieved by checking the Opcode type information (which can be locked down by the initial Boot BIOS) and the address of the requested command against the base and limit fields of a Write Protected BIOS range.

Only the initial address is checked. Since writes wrap within a page, there should be no issue with writes illegally occurring in the next page (assuming the BIOS has configured the Protection Limit to align with the edge of a page).

Note that once BIOS has locked down the Protected BIOS Range registers, this mechanism remains in place until the next system reset.

#### 21.4.3.3.2 SMI# Based Global Write Protection

The EP80579 provides a method for blocking writes to the SPI flash when the Write Protect bit is cleared (i.e., protected) in Offset DCh: BC: BIOS Control Register. This is achieved by checking the Opcode type information (which can be locked down by the initial Boot BIOS) of the requested command.

The Write Protect and Lock Enable bits interact in the same manner for SPI BIOS as they do for the FWH BIOS.

#### 21.4.3.4 Decoding Memory Ranges for SPI

The Boot BIOS Destination straps are sampled on the rising edge of PWROK. If the SPI port is selected, then the [Section 19.2.4, “LPC I/O Configuration Registers” on page 747](#) to determine what ranges of memory read addresses are forwarded to SPI. (See [Section 3.7](#) for details of the actual pin(s) used for selecting SPI.) The Feature space ranges are unique to the FWH flash. However, the feature space can be treated just like standard memory from an SPI perspective and therefore allow up to 16 MB of contiguous memory decode. The EP80579 forwards both data and feature space ranges to the SPI interface (although the BIOS BAR may block the feature space accesses in situations where the flash size is less than 4 MB). Since there is only one Flash Chip Enable pin on the EP80579, there is no need to map the various flash ranges to multiple enables. Of course, in order to utilize 16 MB, the single flash device would need to support 128 Mbits of data.

The Top Swap mechanism works in the same way that it does on LPC. Address bit 16 is inverted when Top Swap is enabled for any accesses to the upper two 64 KB blocks. Also like LPC, the Top Swap functionality does not apply to accesses generated to the holes below 1 MB. The SPI interface performs the address bit inversion on only the Direct Memory Read access method; software can control the address directly with the programmed command access method. The prefetching and caching logic consistently comprehends the address inversion to avoid delivering bad data. Also, the protection mechanisms described above observe the address after the inversion logic.

Memory writes to the BIOS memory range are dropped. This forces all of these potentially harmful cycles to go through the Programmed Commands interface.

Note that Direct Memory Reads to the E0000h-FFFFFh segments are remapped to top of flash as mentioned previously in [section 21.4.3.1](#). This range is not remapped when using Programmed Accesses.

## 21.5 BIOS Programming Considerations

### 21.5.1 SPI Initialization

This section provides a high level description of the steps that the BIOS should take upon coming out of RESET when using SPI Flash.

1. Boot vector fetch and other initial BIOS reads using Direct Memory Reads (some of which are 64 byte code reads). Caching is enabled in hardware by default to improve performance on consecutive reads to the same line.
2. Turn on the SPI Prefetching policy in the LPC Bridge Configuration Space ([Offset DCh: BC: BIOS Control Register](#)). This policy bit is in configuration space to avoid requiring protected memory space early in the boot process.
3. Copy the various BIOS modules out of the SPI Flash using Direct Memory Reads. It is assumed that these reads are shorter than 64 bytes and are targeted to consecutive addresses; hence, the prefetch mechanism improves the performance of this sequence.
4. Turn off the SPI Prefetch policy.
5. Program opcode registers in order to discover which Flash device is being used. Four of the six supported Flash devices support the READ ID instruction. Details of the discovery algorithm are outside the scope of this specification.
6. Disable Future Request, [Offset 3022h: SPIC – SPI Control](#) bit 0. Default state is Future Request enabled.
7. Re-program opcode registers to support specific Flash vendor's commands. If not using all of the Opcode Menu and Prefix Opcodes, BIOS should program a “safe”

value in the unused opcodes to minimize what malicious software can do. A suggested safe value is to replicate one of the valid entries.

- a. [Offset 3074h: PREOP – Prefix Opcode Configuration](#)
  - b. [Offset 3076h: OPTYPE – Opcode Type Configuration](#)
  - c. [Offset 3078h: OPMENU – Opcode Menu Configuration](#)
8. Setup protection registers as needed.
- a. [Offset 3070h: BBAR – BIOS Base Address](#)
  - b. [Offset 3080h: PBRO – Protected BIOS Range \[0-2\]](#)
9. Lock down the SPI registers, [Offset 3020h: SPIS – SPI Status](#) bit 15.
10. Set Up SMI based write protection as needed (same as FWH).

## § §

## 22.0 General Purpose I/O: Bus 0, Device 31, Function 0

---

### 22.1 Overview

- The following GPIO pins are implemented:

*Note:* Pin direction is related to GPIO mode.

Input Only : 22 (00:15, 26, 29:31, 40:41)

Output Only : 8 (16:21, 23, 48)

Input/Output : 6 (24:25, 27:28, 33:34).

- GPIO pins [22, 32, 35:39, 42:47, 50:63] do not exist.
- Some of the GPIO pins can be configured to be used for alternate functions. The alternate function and IRQ mapping of function multiplexed GPIO pins is provided in [Table 22-1](#).
- GPIO pins [16:21, 23:25, 27:28, 30:31, 33:34, 40] are configured to generate IRQ interrupt to IO-APIC if ETR3.GPIO\_IRQ\_STRAP\_STS = 1 [strap pulling SIU2\_TXD to Low on the rising edge of PWROK). But BIOS can still change the function of each of these pins to GPIO mode by programming the individual bits in GPIO\_USE\_SELx register.
- Bits in GPIO\_USE\_SELx register enable GPIO[n] (where n is the bit number) to be used as a GPIO, rather than for the alternative function. Pin is used as GPIO when the individual bit in GPIO\_USE\_SELx register is set, otherwise used as alternative function. Example: Software sets bit 2 in this register to enable GPIO[2] (instead of using that signal for PIRQ[E]#).
- If GPIO[n] does not exist, then the bit in GPIO\_USE\_SELx register is always read as 0 and writes have no effect. Example: Bit 22 in GPIO\_USE\_SEL1 is not supported because there is no corresponding GPIO[22].
- GPIO pins [0:1, 6:10, 12:15, 48] do not have an alternative function.
- GPIO pins can not generate IRQ interrupt when ETR3.GPIO\_IRQ\_STRAP\_STS = 0.
- When configured to IRQ mode, the pin direction of the relevant pins are set to "input" by GPIO logic. ICH6 compatibility is expected when the GPIOs are in GPIO mode.
- When configured to GPIO mode, the muxing logic presents the inactive state to alternate mode logic that uses the pin as an input.
- After a full reset (RSMRST#), all multiplexed signals in the resume and core wells are configured as GPIO rather than their alternative function.

Table 22-1. GPIO Pin's Alternative Function

| GPIO PINs | GPIO Mode Capability | Default Pin direction (GPIO Mode) | Default Level Driven Out (GPIO Mode) | Alternative Function | Interrupt Capability |          |            | Pin direction when in alternative mode |
|-----------|----------------------|-----------------------------------|--------------------------------------|----------------------|----------------------|----------|------------|--|
|           |                      |                                   |                                      |                      | SMI #/SCI            | IRQ      | Wake Event |  |
| 1 : 0     | Input Only           | Input                             | N/A                                  | None                 | Yes                  | No       | No         | N/A                                    |
| 2         | Input Only           | Input                             | N/A                                  | PIRQE#               | Yes                  | Yes-PIRQ | No         | Input                                  |
| 3         | Input Only           | Input                             | N/A                                  | PIRQF#               | Yes                  | Yes-PIRQ | No         | Input                                  |
| 4         | Input Only           | Input                             | N/A                                  | PIRQG#               | Yes                  | Yes-PIRQ | No         | Input                                  |
| 5         | Input Only           | Input                             | N/A                                  | PIRQH#               | Yes                  | Yes-PIRQ | No         | Input                                  |
| 7 : 6     | Input Only           | Input                             | N/A                                  | None                 | Yes                  | No       | No         | N/A                                    |
| 11 : 8    | Input Only           | Input                             | N/A                                  | None                 | Yes                  | No       | Yes        | N/A                                    |
| 13 : 12   | Input Only           | Input                             | N/A                                  | None                 | Yes                  | No       | No         | N/A                                    |
| 15 : 14   | Input Only           | Input                             | N/A                                  | None                 | Yes                  | No       | Yes        | N/A                                    |
| 16        | Output Only          | Output                            | High                                 | IRQ[24]              | No                   | Yes      | No         | Input                                  |
| 17        | Output Only          | Output                            | High                                 | IRQ[25]              | No                   | Yes      | No         | Input                                  |
| 18        | Output Only          | Output                            | High                                 | IRQ[36]              | No                   | Yes      | No         | Input                                  |
| 19        | Output Only          | Output                            | High                                 | IRQ[37]              | No                   | Yes      | No         | Input                                  |

### 22.1.1 GPIO Summary Table

Some GPIOs exist in the resume power plane. Care must be taken to make sure GPIO signals are not driven high into powered-down planes.

Some GPIOs may be connected to pins on devices that exist in the core well. If these GPIOs are outputs, there is a danger that a loss of core power (PWROK low) or a Power Button Override event results in CMI driving a pin to a logic '1' to another device that is powered down.

The following table summarizes the GPIOs.

**Table 22-2. GPIO Summary Table (Sheet 1 of 2)**

| GPIO# | PowerWell     | Muxed | GPIO_USE_SEL                   | GP_IO_SEL                 | GP_LVL     | GPO_BLINK | GPI_INV    |
|-------|---------------|-------|--------------------------------|---------------------------|------------|-----------|------------|
| 0     | Core          | No    | Always 1                       | Always 1                  | Always 0   | Always 0  | RW – D=0   |
| 1     | Core          | No    | Always 1                       | Always 1                  | Always 0   | Always 0  | RW – D=0   |
| 2:5   | Core          | Yes   | 1 when GPIO, 0 when PIRQ[E-H]# | Always 1                  | Always 0   | Always 0  | RW – D=0   |
| 6     | Core          | No    | Always 1                       | Always 1                  | Always 0   | Always 0  | RW – D=0   |
| 7     | Core          | No    | Always 1                       | Always 1                  | Always 0   | Always 0  | RW – D=0   |

**Notes:**

1. N/A - Not Applicable, since the relevant registers bit do not exist for these GPIO.
2. Reserved - The bit access type may be RW but it is a reserved bit.
3. RW – D=1: The bit access type is RW; default value is 1.

## 22.2 General Purpose I/O-Mapped Configuration Register Details

The control for the general purpose I/O signals is handled through separate 64-byte I/O space. The General Purpose I/O configuration registers are mapped into I/O space using register GBA in the PCI configuration space for device 31, function 0 (see [Section 19.2.2.3, “Offset 48h: GBA: GPIO Base Address Register”](#) on page 740).

**Note:** For the following registers, if a bit is allocated for a GPIO that doesn’t exist, unless otherwise indicated, the bit always reads 0 and values written to that bit have no effect.

**Table 22-3. Bus 0, Device 31, Function 0: Summary of General Purpose I/O Configuration Registers Mapped Through GBA BAR IO BAR (Sheet 1 of 2)**

## 22.3 Additional GPIO Theory of Operation

### 22.3.1 SMI# and SCI Routing

The routing bits for GPIO[0:15] allow an input to be routed to SMI# or SCI, or neither. See [Chapter 40, "Power Management"](#) for the routing register. A bit can be routed to either an SMI# or an SCI, but not both.

### 22.3.2 Triggering

GPIO[0:15] have "sticky" bits on the input. See [Chapter 40, "Power Management"](#) for the GPE0\_STS register and the ALT\_GPI\_SMI\_STS register. As long as the signal goes active for at least two clocks (PCI clock while in S0-S1 state, RTC clock while in S3-S5 state), CMI keeps the sticky status bit active. The active level (high or low) can be selected via the GP\_INV register.

If the system is in an S0 or S1-D state, the GPI are sampled at 33 MHz, so the signal only needs to be active for about 60 ns to be latched. In S3,-S5 states, the GPI are sampled at 32.768 kHz, and thus must be active for at least 61 µs to be latched.

**Note:** GPIs that are in the core well are not capable of waking the system from sleep states where the core well is not powered.

If the input signal is still active when the latch is cleared, it is again set (another edge is not required). This makes these signals "level" triggered inputs.

§ §

## 23.0 SATA: Bus 0, Device 31, Function 2

### 23.1 SATA PCI Configuration Registers

All of the SATA configuration registers are in the core well. All registers not mentioned are reserved.

| Start | End | Functionality Described                         |
|-------|-----|---|
| 00    | 3F  | PCI Header                                      |
| 40    | 5F  | SFF-8038i Configuration (legacy bus master IDE) |
| 70    | 7F  | PCI Power Management Capability Pointer         |
| 80    | 8F  | Message Signaled Interrupt Capability Pointer   |
| 90    | A7  | Additional Configuration (test modes, etc.)     |
| A8    | AF  | Serial ATA Capability Pointer                   |
| B0    | FF  | Additional Configuration (test modes, etc.)     |

### 23.1.1 PCI Header

The default values are defined with an h for hex, a b for binary, or 00 for zero. If there is not a letter showing the default value, assume it is a binary number.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values and are read only. Writes to reserved locations may cause system failure and unpredictable results.

**Note:** Reserved bits are read only.

23.1.1.3 Offset 06h: STS - Device Status Register

Table 23-4. Offset 06h: STS - Device Status Register (Sheet 1 of 2)

| <b>Description:</b> |                           |   |                                    |  |            |
|---------------------|---------------------------|---|------------------------------------|--|------------|
| <b>View:</b> PCI    | <b>BAR:</b> Configuration |   | <b>Bus:Device:Function:</b> 0:31:2 | <b>Offset Start:</b> 06h<br><b>Offset End:</b> 07h |            |
| <b>Size:</b> 16 bit | <b>Default:</b> 02B0h     |   |                                    | <b>Power Well:</b> Core                            |            |
| Bit Range           | Bit Acronym               | Bit Description   | Sticky                             | Bit Reset Value                                    | Bit Access |
| 15                  | DPE                       | <b>Detected Parity Error (DPE):</b> Set when the SATA Controller detects a parity error on its interface.   |                                    | 0h   | RWC        |
| 14                  | SSE                       | <b>Signaled System Error (SSE):</b> The SATA Controller will never generate an SERR#.   |                                    | 0h   | RO         |
| 13                  | RMA                       | <b>Received Master-Abort Status (RMA):</b> Set when the SATA Controller receives a master abort to a cycle it generated.  |                                    | 0h   | RWC        |
| 12                  | RTA                       | <b>Received Target-Abort Status (RTA):</b> Set when the SATA Controller receives a target abort to a cycle it generated.  |                                    | 0h   | RWC        |
| 11                  | STA                       | <b>Signaled Target-Abort Status (STA):</b> Reserved. The SATA Controller will never generate a target abort.  |                                    | 0h   | RO         |
| 10 : 09             | DEVT                      | <b>DEVSEL# Timing Status (DEVT):</b> Controls the device select time for the SATA Controller's PCI interface.   |                                    | 01h  | RO         |
| 08                  | DPD                       | <b>Master Data Parity Error Detected (DPD):</b> Set when the SATA Controller, as a master, either detects a parity error or sees the parity error line asserted, and the parity error response bit (bit 6 of the command register) is set. This bit can only be set on read completions received from the backbone where there is a parity error. |                                    | 0h   | RWC        |
| 07                  | Reserved                  | Fast Back-to-Back Capable: Reserved   |                                    | 1h   | RO         |
| 06                  | Reserved                  | Reserved  |                                    | 0h   | RO         |
| 05                  | C66                       | 66 MHz Capable  |                                    | 1h   | RO         |

Table 23-4. Offset 06h: STS - Device Status Register (Sheet 2 of 2)

| <b>Description:</b> |                           |  |                                    |  |                   |
|---------------------|---------------------------|--|------------------------------------|--|-------------------|
| <b>View:</b> PCI    | <b>BAR:</b> Configuration |  | <b>Bus:Device:Function:</b> 0:31:2 | <b>Offset Start:</b> 06h<br><b>Offset End:</b> 07h |                   |
| <b>Size:</b> 16 bit | <b>Default:</b> 02B0h     |  |                                    | <b>Power Well:</b> Core                            |                   |
| <b>Bit Range</b>    | <b>Bit Acronym</b>        | <b>Bit Description</b>   | <b>Sticky</b>                      | <b>Bit Reset Value</b>                             | <b>Bit Access</b> |
| 04                  | CL                        | <b>Capabilities List (CL):</b> Indicates the presence of a capabilities list. The minimum requirement for the capabilities list must be PCI power management for the SATA Controller.                          |                                    | 1h   | RO                |
| 03                  | IS                        | <b>Interrupt Status (IS):</b> Reflects the state of INTx# messages. This bit is set when the interrupt is to be asserted. This bit is a 0 after the interrupt is cleared (independent of the state of CMD.ID). |                                    | 0h   | RO                |
| 02 : 00             | Reserved                  | Reserved   |                                    | 0h   | RO                |

#### 23.1.1.4 Offset 08h: RID - Revision ID Register

Table 23-5. Offset 08h: RID - Revision ID Register

| <b>Description:</b> |                           |  |                                    |  |                   |
|---------------------|---------------------------|--|------------------------------------|--|-------------------|
| <b>View:</b> PCI    | <b>BAR:</b> Configuration |  | <b>Bus:Device:Function:</b> 0:31:2 | <b>Offset Start:</b> 08h<br><b>Offset End:</b> 08h |                   |
| <b>Size:</b> 8 bit  | <b>Default:</b> Variable  |  |                                    | <b>Power Well:</b> Core                            |                   |
| <b>Bit Range</b>    | <b>Bit Acronym</b>        | <b>Bit Description</b>   | <b>Sticky</b>                      | <b>Bit Reset Value</b>                             | <b>Bit Access</b> |
| 07 : 00             | RID                       | <b>Revision ID (RID):</b> Indicates stepping of the host controller hardware. This register follows the ICH revision ID scheme as defined in Section 19.2.1.4, "Offset 08h: RID - Revision ID Register" on page 736. |                                    | Variable   | RO                |

### 23.1.1.5 PI - Programming Interface Register

Table 23-6. Programming Interface, DID and CC.SCC Register Value Definitions

| Input Parameters  |        | Resulting Values     |                          |         |
|---|--------|----------------------|--------------------------|---------|
| MAP.SMS:<br>00 - Select IDE<br>01 - Select AHCI<br>10 - Reserved<br>11 - Reserved | MAP.MV | CC.SCC               | PI                       | DID     |
| 00b   | 00b    | 01h<br>(IDE)         | 8Ah <sup>a</sup><br>(RW) | 5028h   |
| 01b   | 00b    | 06h<br>(SATA)        | 01h<br>(RO)              | 5029h   |
| 10b   | 00b    | Illegal <sup>b</sup> | Illegal                  | Illegal |
| 11b   | 00b    | Illegal              | Illegal                  | Illegal |

- a. PI register bits 2 and 0 are write-able at all times when MAP.MV=00h (so the value of this field may be 8Ah, 8Bh, 8Dh, or 8Fh), although the write only affects the SATA controller's operation when CC.SCC is 01h. If PI is written while CC.SCC is 04h, the value shown will not be 8Ah when CC.SCC is changed from 04h to 01h, but rather the value of the last write to PI. BIOS must always check and set PI to the desired mode of operation (legacy or native) when CC.SCC is 01h.
- b. "Illegal" means that SW must not program this combination otherwise the results are undefined.

#### 23.1.1.5.1 Programming Interface when CC.SCC = "01h"

Table 23-7. Programming Interface when CC.SCC = "01h"

| Bit | Type | Reset | Description   |
|-----|------|-------|---|
| 7   | RO   | 1     | Indicates the SATA Controller supports bus master operation.  |
| 6:4 | RO   | 0     | Reserved  |
| 3   | RO   | 1     | <b>Secondary Mode Native Capable (SNC):</b> Indicates that the secondary controller supports both legacy and native modes.  |
| 2   | RW   | 0     | <b>Secondary Mode Native Enable (SNE):</b> Determines the mode that the secondary channel is operating in. '0' corresponds to 'compatibility', '1' means PCI native. If this bit is set by SW, then the PNE bit must also be set by SW. While in theory these bits can be programmed separately, such a configuration is not supported by today's software and is not supported by this hardware. |
| 1   | RO   | 1     | <b>Primary Mode Native Capable (PNC):</b> Indicates that the primary controller supports both legacy and native modes.  |
| 0   | RW   | 0     | <b>Primary Mode Native Enable (PNE):</b> Determines the mode that the primary channel is operating in. '0' corresponds to 'compatibility', '1' means PCI native. If this bit is set by SW, then the SNE bit must also be set by SW. While in theory these bits can be programmed separately, such a configuration is not supported by today's software and is not supported by this hardware.     |

### 23.1.1.5.2 Programming Interface when CC.SCC = "06h"

Table 23-8. Programming Interface when CC.SCC = "06h"

| Bit   | Type | Reset | Description   |
|-------|------|-------|---|
| 07:00 | RO   | 01h   | <b>Interface (IF)</b> : Indicates the SATA Controller is AHCI 1.0 compliant. Internally, under this condition, the SATA controller is in native mode and its I/O spaces are only accessible through the I/O BARs. |

### 23.1.1.6 Offset 0Ah: CC - Class Code Register

Table 23-9. Offset 0Ah: CC - Class Code Register

| Description: |               |  |        |                           |            |
|--------------|---------------|--|--------|---------------------------|------------|
| View:        | BAR:          | Bus:Device:Function:   |        | Offset Start: Offset End: |            |
| Size:        | Default:      |  |        | Power Well:               |            |
| Bit Range    | Bit Acronym   | Bit Description  | Sticky | Bit Reset Value           | Bit Access |
| PCI          | Configuration | 0:31:2   |        | 0Ah                       | 0Bh        |
| 16 bit       | Variable      |  |        | Core                      |            |
| 15 : 08      | BCC           | <b>Base Class Code (BCC)</b> : Indicates that this is a mass storage device.   |        | 01h                       | RO         |
| 07 : 00      | SCC           | <b>Sub Class Code (SCC)</b> : The value reported in this field is dependent on MAP.SMS, MAP.MV, . See the table in section 48.1.1.5. |        | Variable                  | RO         |

### 23.1.1.7 Offset 0Dh: MLT – Master Latency Timer Register

Table 23-10. Offset 0Dh: MLT – Master Latency Timer Register

| Description: |               |  |        |                           |            |
|--------------|---------------|--|--------|---------------------------|------------|
| View:        | BAR:          | Bus:Device:Function:   |        | Offset Start: Offset End: |            |
| Size:        | Default:      |  |        | Power Well:               |            |
| Bit Range    | Bit Acronym   | Bit Description  | Sticky | Bit Reset Value           | Bit Access |
| PCI          | Configuration | 0:31:2   |        | 0Dh                       | 0Dh        |
| 8 bit        | 00h           |  |        | Core                      |            |
| 07 : 00      | MLT           | <b>Master Latency Timer (MLT)</b> : This register has no meaning as the controller lives on NSI. |        | 00h                       | RO         |

### 23.1.1.8 Offset 10h: PCMDBA – Primary Command Block Base Address Register

This 8-byte I/O space is used in Native Mode for the Primary Controller's Command Block.

**Table 23-11. Offset 10h: PCMDBA – Primary Command Block Base Address Register**

|                     |                           |   |                                    |  |                   |
|---------------------|---------------------------|---|------------------------------------|--|-------------------|
| <b>Description:</b> |                           |   |                                    |  |                   |
| <b>View:</b> PCI    | <b>BAR:</b> Configuration |   | <b>Bus:Device:Function:</b> 0:31:2 | <b>Offset Start:</b> 10h<br><b>Offset End:</b> 13h |                   |

### 23.1.2 Additional SFF-8038i Configuration Registers

The following registers are necessary to implement as read/write bits in order to maintain software functionality for the SFF-8038i mode of operation (a.k.a. Bus Master IDE). They have no bearing on Serial ATA operation unless otherwise indicated, but are necessary to be read/write for legacy software capability.

The default values are defined with an h for hex, a bi for binary, or 00 for zero. If there is not a letter following the default value, assume it is a binary number.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

| Start | End | Symbol  | Name                             |
|-------|-----|---------|----------------------------------|
| 40    | 41  | PTIM    | Primary IDE Timing               |
| 42    | 43  | STIM    | Secondary IDE Timing             |
| 44    | 44  | D1TIM   | Slave IDE Timing                 |
| 48    | 48  | SYNCC   | Synchronous DMA Control Register |
| 4A    | 4B  | SYNCTIM | Synchronous DMA Timing Register  |
| 54    | 57  | IIOC    | IDE I/O Configuration            |

### 23.1.2.1 Offset 40h: PTIM – Primary Timing Register

This controls the timings driven on the parallel cable.

**Table 23-20. Offset 40h: PTIM – Primary Timing Register**

| Description: |                    |   |                             |                 |                                      |

**23.1.2.2 STIM – Secondary Timing Register**

See the above register description for Primary IDE Timing.

**23.1.2.3 Offset 44h: D1TIM – Device 1 IDE Timing Register**

The values in this register are only valid if the “Separate Timing Enable” bit is set in the timing registers. Bits 7:4 are used by device 1 on secondary if bit 14 of offset 42h is set, and bits 3:0 are used by device 1 on primary if bit 14 of offset 40h is set.

| 74    | 77  | PMCS   | PCI Power Management Control and Status |

#### 23.1.3.1 Offset 70h: PID – PCI Power Management Capability ID Register

The default values are defined with an h for hex, a bi for binary, or 00 for zero. If there is not a letter following the default value, assume it is a binary number.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

## 23.1.5 Additional Configuration Registers

The default values are defined with an h for hex, a bi for binary, or 00 for zero. If there is not a letter following the default value, assume it is a binary number.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

| Start | End | Symbol  | Name                             |

### 23.1.5.2 Offset 92h: PCS – Port Control and Status Register

This register is only used in systems that do not support AHCI. In AHCI enabled systems, bits[3:0] must always be set, and the status of the port is controlled through AHCI memory space.

Table 23-33. Offset 92h: PCS – Port Control and Status Register

| Description: |             |  |  |                             |                 |                                      |

| 23 : 16      | SID               | <b>Stepping Identifier (SID):</b> This field is incremented for each stepping of the part. Note that this field can be used by software to differentiate steppings when the Revision ID may not change.<br><b>Note:</b> 00h for A0 stepping<br><b>Note:</b> 01h for B0 stepping<br>The value read from this register is the same as that read from Device 31, Function 0, Offset F8h. |               | Variable        | RO          |
| 15 : 08      | MID               | <b>Manufacturer Identifier (MID):</b> 0Fh = Intel   |               | 0Fh             | RO          |
| 07 : 00      | PID               | <b>Process/Dot Identifier (PID):</b> Indicates the process as 1263h.  |               | 90h             | RO          |

## 23.2 SATA I/O Mapped Registers

All I/O registers are in the core well. When the Index/Data Pair is enabled these registers use 32 bytes of I/O space, allocated via the LBAR register (configuration offset 20h). When the Index/Data Pair is disabled these registers use 16 bytes of I/O space.

Registers 00-0Fh are only used for legacy operation. Software must not use these registers when running AHCI.

The default values are defined with an h for hex, a bi for binary, or 00 for zero. If there is not a letter following the default value, assume it is a binary number.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

| Start | End | Symbol | Name                       |
|-------|-----|--------|----------------------------|

## 23.2.1 Primary Devices

### 23.2.1.1 Offset 00h: PCMD – Primary Command Register

**Table 23-44. Offset 00h: PCMD – Primary Command Register**

| <b>Description:</b> |                                |  |                                    |  |            |
|---------------------|--------------------------------|--|------------------------------------|--|------------|
| <b>View:</b> PCI    | <b>Base Address:</b> LBAR (IO) |  | <b>Bus:Device:Function:</b> 0:31:2 | <b>Offset Start:</b> 00h<br><b>Offset End:</b> 00h |            |
| <b>Size:</b> 8 bit  | <b>Default:</b> 00h            |  | <b>Power Well:</b> Core            |  |            |
| Bit Range           | Bit Acronym                    | Bit Description  | Sticky                             | Bit Reset Value                                    | Bit Access |
| 07 : 04             | Reserved                       | Reserved   |                                    | 0h   | RO         |
| 03                  | RWC                            | <b>Read / Write Control (RWC):</b> Sets the direction of the bus master transfer: 0 = memory to device, 1 = device to memory. This bit must not be changed when the bus master function is active.   |                                    | 0h   | RW         |
| 02 : 01             | Reserved                       | Reserved   |                                    | 0h   | RO         |
| 00                  | START                          | <b>Start/Stop Bus Master (START):</b> Setting this bit enables bus master operation of the controller. Bus master operation does not actually start unless the Bus Master Enable bit in PCI configuration space is also set. Clearing it halts bus master operation.<br>All state information is lost when this bit is written to '0'; Master mode operation cannot be stopped and then resumed. If this bit is reset while bus master operation is still active and the device has not yet finished its data transfer, the bus master command is said to be aborted. If this bit is cleared to '0' prior to the DMA data transfer being initiated by the drive in a device to memory data transfer, then the ICH5 will not send DMAT to terminate the data transfer. SW intervention (e.g. sending SRST) is required to reset the interface in this condition.<br>This bit is intended to be cleared by software after the data transfer is completed, as indicated by either the ACT bit being cleared in the status register, or the I bit being set in the status register, or both. |                                    | 0h   | RW         |

### 23.2.1.2 Offset 02h: PSTS – Primary Status Register

Table 23-45. Offset 02h: PSTS – Primary Status Register

| Description: |                         |   |                             |                                      |            |

| 31 : 00             | DATA                     | <p><b>Data (DATA)</b>— R/W: This Data register is a “window” through which data is read or written to the AHCI memory mapped registers. A read or write to this Data register triggers a corresponding read or write to the memory mapped register pointed to by the Index register. The Index register must be setup prior to the read or write to this Data register.</p> <p>Note that a physical register is not actually implemented as the data is actually stored in the memory mapped registers.</p> <p>Since this is not a physical register, the “default” value is the same as the default value of the register pointed to by Index.</p> |                                    | Variable   | RW                |

## 23.3 SATA Memory Mapped Registers

The memory mapped registers within the SATA controller exist in non-cacheable memory space. Additionally, locked accesses are not supported. If software attempts to perform locked transactions to the registers, indeterminate results may occur. Register accesses shall have a maximum size of 64 bits. 64 bit accesses must not cross an 8 byte alignment boundary.

The registers are broken into 2 sections – global control registers and port control registers. All registers that start below address 100h are global and meant to apply to the entire HBA. The port control registers are the same for all ports, and there are as many registers banks as there are ports.

All registers not defined and all reserved bits within registers return ‘0’ when read.

| Start | End | Description                   |
|-------|-----|-------------------------------|
| 00    | 1F  | Generic Host Control          |
| 20    | 9F  | Reserved                      |
| A0    | FF  | Vendor Specific registers     |
| 100   | 17F | Port 0 port control registers |
| 180   | 1FF | Port 1 port control registers |
| 200   | 27F | Reserved                      |
| 280   | 2FF | Reserved                      |
| 300   | 3FF | Reserved                      |

| 04    | 07  | GHC    | Global Host Control |
| 08    | 0B  | IS     | Interrupt Status    |
| 0C    | 0F  | PI     | Ports Implemented   |
| 10    | 13  | VS     | Version             |

### 23.3.1.1 Offset 00h: HCAP – HBA Capabilities Register

This register indicates basic capabilities of the HBA to driver software. The RWO bits in this register are only cleared upon PLTRST#.

**Table 23-50. Offset 00h: HCAP – HBA Capabilities Register (Sheet 1 of 2)**

| Description: |                   |  |                             |                                      |            |
|--------------|-------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: ABAR         |  | Bus:Device:Function: 0:31:2 | Offset Start: 00h<br>Offset End: 03h |            |
| Size: 32 bit | Default: Variable |  |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 31           | S64A              | <b>Supports 64-bit Addressing (S64A):</b> Indicates the S-ATA controller can access 64-bit data structures. The 32-bit upper bits of the port DMA Descriptor, the PRD Base, and each PRD entry are read/write.   |                             | 1h                                   | RO         |
| 30           | SCQA              | <b>Supports Native Command Queuing Acceleration (SCQA):</b> Indicates the SATA controller supports Serial-ATA native command queuing. The HBA will handle DMA Setup FISes natively and will handle the auto-activate optimization through the FIS.   |                             | 1h                                   | RWO        |
| 29           | SSNTF             | <b>Supports SNotification Register (SSNTF):</b> The SATA controller supports the SNotification register.   |                             | 1h                                   | RWO        |
| 28           | SIS               | <b>Supports Interlock Switch (SIS):</b> Indicates whether the S-ATA controller supports interlock switches on its ports for use in hot plug operations. This value is loaded by platform BIOS prior to OS initialization.<br>If this bit is set, BIOS must also map the SATAGP pins to the S-ATA controller through GPIO space.              |                             | 1h                                   | RWO        |
| 27           | SSS               | <b>Supports Staggered Spin-up (SSS):</b> Indicates whether the S-ATA controller supports staggered spin-up on its ports, for use in balancing power spikes. This value is loaded by platform BIOS prior to OS initialization.  |                             | 1h                                   | RWO        |
| 26           | SALP              | <b>Supports Aggressive Link Power Management (SALP):</b> Indicates the S-ATA controller supports auto-generating link requests to the partial or slumber states when there are no commands to process.   |                             | 1h                                   | RWO        |
| 25           | SAL               | <b>Supports Activity LED (SAL):</b> Indicates the S-ATA controller supports a single output pin (SATALED#) which indicates activity.   |                             | 1h                                   | RO         |
| 24           | SCLO              | <b>Supports Command List Override (SCLO):</b> When set to '1', indicates that the HBA supports the PxCMD.CLO bit and it's associated function. When cleared to '0', The HBA is not capable of clearing the BSY and DRQ bits in the Status register in order to issue a software reset if these bits are still set from a previous operation. |                             | 1h                                   | RWO        |
| 23 : 20      | ISS               | <b>Interface Speed Support (ISS):</b> Indicates the maximum speed the S-ATA controller can support is 1.5 Gbps and 3 Gbps on its ports. Speed can be limited in each port by programming PxSCTL.DET to a lower value.  |                             | 2h                                   | RWO        |
| 19           | SNZO              | <b>Supports Non-Zero DMA Offsets (SNZO):</b> Reserved as per AHCI 1.0  |                             | 0h                                   | RO         |
| 18           | Reserved          | Reserved   |                             | 0h                                   | RO         |
| 17           | Reserved          | Reserved: BIOS must clear this bit.  |                             | 1h                                   | RWO        |
| 16           | Reserved          | Reserved   |                             | 0h                                   | RO         |
| 15           | PMD               | <b>PIO Multiple DRQ Block (PMD):</b> The SATA controller support PIO Multiple DRQ Command Block.   |                             | 1h                                   | RWO        |

Table 23-50. Offset 00h: HCAP – HBA Capabilities Register (Sheet 2 of 2)

| Description: |                   |   |                             |                                      |            |
|--------------|-------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: ABAR         |   | Bus:Device:Function: 0:31:2 | Offset Start: 00h<br>Offset End: 03h |            |
| Size: 32 bit | Default: Variable |   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym       | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 14           | SSC               | <b>Slumber State Capable (SSC):</b> The SATA controller supports the slumber state.   |                             | 1h                                   | RWO        |
| 13           | PSC               | <b>Partial State Capable (PSC):</b> The SATA controller supports the partial state.   |                             | 1h                                   | RWO        |
| 12 : 08      | NCS               | <b>Number of Command Slots (NCS):</b> This register field is read only = 1Fh indicating support for 32 slots.   |                             | 1Fh                                  | RO         |
| 07 : 06      | Reserved          | Reserved  |                             | 0h                                   | RO         |
| 05           | SXS               | Supports External SATA (SXS): When set to '1', indicates that the HBA has one or more Serial ATA ports that has a signal only connector that is externally accessible. If this bit is set, software may refer to the PxCMD.ESP bit to determine whether a specific port has its signal connector externally accessible as a signal only connector (i.e. power is not part of that connector). when the bit is cleared to '0', indicates that the HBA has no Serial ATA ports that have a signal only connector externally accessible. |                             | 0h                                   | RWO        |
| 04 : 00      | NDS               | <b>Number of Devices (NDS):</b> Indicates support for 2 devices.  |                             | 1h                                   | RO         |

### 23.3.1.2 Offset 04h: GHC – Global HBA Control Register

This register controls various global actions of the HBA.

**Table 23-51. Offset 04h: GHC – Global HBA Control Register**

| Description: |             |   |               |                 |            |
|--------------|-------------|---|---------------|-----------------|------------|
| View:        | BAR:        | Bus:Device:Function:  | Offset Start: | Offset End:     |            |
| PCI          | ABAR        | 0: 31: 2  | 04h           | 07h             |            |
| Size:        | Default:    |   | Power Well:   |                 |            |
| 32 bit       | 00000000h   |   | Core          |                 |            |
| Bit Range    | Bit Acronym | Bit Description   | Sticky        | Bit Reset Value | Bit Access |
| 31           | AE          | <p><b>AHCI Enable (AE):</b> When set, indicates that an AHCI driver is loaded and communication to the HBA shall be via AHCI mechanisms. This can be used by an HBA that supports both legacy mechanisms (such as SFF-8038i) and AHCI to know when the HBA is running under an AHCI driver.</p> <p>When set, software shall only talk to the HBA using AHCI. The HBA will not have to allow command processing via both AHCI and legacy mechanisms. When cleared, software will only communicate with the HBA using legacy mechanisms.</p> <p>Software shall set this bit to '1' before accessing other AHCI registers.</p> |               | 0h              | RW         |
| 30 : 02      | Reserved    | Reserved  |               | 0h              | RO         |
| 01           | IE          | <p><b>Interrupt Enable (IE):</b> This global bit enables interrupts from the HBA. When cleared (reset default), all interrupt sources from all ports are disabled. When set, interrupts are enabled.</p>  |               | 0h              | RW         |
| 00           | HR          | <p><b>HBA Reset (HR):</b> When set by SW, this bit causes an internal reset of the HBA. All state machines that relate to data transfers and queuing will return to an idle condition, and all ports will be re-initialized via COMRESET.</p> <p>When the HBA has performed the reset action, it will reset this bit to '0'. A software write of '0' will have no effect. For a description on which bits are reset when this bit is set, see the <i>AHCI specification</i>.</p>  |               | 0h              | RWS        |

### 23.3.1.3 Offset 08h: IS – Interrupt Status Register

This register indicates which of the ports within the controller have an interrupt pending and require service.

Table 23-52. Offset 08h: IS – Interrupt Status Register

| <b>Description:</b> |                           |   |                                    |  |            |

### 23.3.1.4 Offset 0Ch: PI – Ports Implemented Register

This register indicates which ports are exposed to the HBA. It is loaded by platform BIOS. It indicates which ports that the device supports are available for software to use. Any available port may not be implemented.

Table 23-53. Offset 0Ch: PI – Ports Implemented Register

| <b>Description:</b> |                           |  |                                    |  |            |

### 23.3.1.5 Offset 10h: VS – AHCI Version Register

This register indicates the major and minor version of the *AHCI specification*. It is BCD encoded. The upper two bytes represent the major version number, and the lower two bytes represent the minor version number. Example: Version 3.12 would be represented as 00030102h. The current version of the specification is 1.1 (00010100h).

**Table 23-54. Offset 10h: VS – AHCI Version Register**

|                     |                           |   |                                    |  |                   |

### 23.3.2 Vendor Specific Registers

This register contains the output bits associated with the two SATA drives and Vendor Specific Message when operating in the AHCI mode. The bits associated with the drives are intended to control LEDs (e.g., activity, fault, and locate LEDs). It is the responsibility of software to write data into this register. Three data bits are allocated per drive.

This bit shall be set even if the data transfer resulted in an error.   |                             | 0h   | RWC        |
| 00           | DHRS               | <b>Device to Host Register FIS Interrupt (DHRS):</b> A D2H register FIS has been received with the 'I' bit set, and has been copied into system memory.   |                             | 0h   | RWC        |

### 23.3.3.6 Offset 114h: PxIE[0-1] – Port [0-1] Interrupt Enable Register

This register enables and disables the reporting of the corresponding interrupt to system software. When a bit is set ('1') and the corresponding interrupt condition is active, then an interrupt is generated. Interrupt sources that are disabled ('0') are still reflected in the status registers. This register is symmetrical with the Port 0 Status register.

| 27                  | ASP                      | <b>Aggressive Slumber / Partial (ASP):</b> When set, and the ALPE bit is set, the HBA will aggressively enter the Slumber state when it clears the PxCI register and the PXSACT register is cleared. When cleared, and the ALPE bit is set, the HBA will aggressively enter the Partial state when it clears the PxCI register and the PXSACT register is cleared.  |   | 0h   | RW         |          |    |   |       |          |    |   |    |  |    |   |  |    |    |
| 26                  | ALPE                     | <b>Aggressive Link Power Management Enable (ALPE):</b> When set, the HBA will aggressively enter a lower link power state (Partial or Slumber) based upon the setting of the ASP bit.   |   | 0h   | RW         |          |    |   |       |          |    |   |    |  |    |   |  |    |    |
| 25                  | DLAE                     | <b>Drive LED on ATAPI Enable (DLAE):</b> When set, the HBA will drive the LED pin active for commands regardless of the state of PxCMD.ATAPI. When cleared, the HBA will only drive the LED pin active for commands if PxCMD.ATAPI is set to '0'.   |   | 0h   | RW         |          |    |   |       |          |    |   |    |  |    |   |  |    |    |

Table 23-62. Offset 118h: PxCMD[0-1] – Port [0-1] Command Register (Sheet 2 of 3)

| Description: |                   |   |                             |  |            |
|--------------|-------------------|---|-----------------------------|--|------------|
| View: PCI    | BAR: ABAR         |   | Bus:Device:Function: 0:31:2 | Offset Start: 118h, 198h<br>Offset End: 11Bh, 19Bh |            |
| Size: 32 bit | Default: Variable |   |                             | Power Well: Core                                   |            |
| Bit Range    | Bit Acronym       | Bit Description   | Sticky                      | Bit Reset Value                                    | Bit Access |
| 24           | ATAPI             | <b>Device is ATAPI (ATAPI):</b> When set, the connected device is an ATAPI device. This bit is used by the HBA to control whether or not to generate the desktop LED when commands are active.  |                             | 0h   | RW         |
| 23 : 22      | Reserved          | Reserved  |                             | 0h   | RO         |
| 21           | ESP               | <b>External SATA Port (ESP):</b> when set to '1', indicates that this port is routed externally and will be used with an external SATA device. When set to '1' HCAP.SXS must also be set to '1'. When cleared ('0'), indicates that this port is not routed externally and supports internal SATA devices only. ESP is mutually exclusive with the HPCP bit in this register  |                             | 0h   | RWO        |
| 20           | CPD               | <b>Cold Presence Detection (CPD):</b> The SATA controller does not support cold presence detect.  |                             | 0h   | RO         |
| 19           | ISP               | <b>Interlock Switch Attached to Port (ISP):</b> When interlock switches are supported in the platform (HCAP.SIS set), this indicates whether this particular port has an interlock switch attached. This bit can be used by system software to enable such features as aggressive power management, as disconnects can always be detected regardless of PHY state with an interlock switch. When this bit is set, it is expected that HPCP in this register is also set. The HBA takes no action on the state of this bit – it is for system software only. For example, if this bit is cleared, and an interlock switch toggles, the HBA shall still treat it as a proper interlock switch event.<br>Note that this bit is not reset on a HBA reset. |                             | 0h   | RWO        |
| 18           | HPCP              | <b>Hot Plug Capable Port (HPCP):</b> This indicates whether the this port is connected to a device which can be hot plugged. SATA by definition is hot-pluggable, but not all platforms are constructed to allow the device to be removed (it may be screwed into the chassis, for example). This bit can be used by system software to indicate a feature such as "eject device" to the end-user.<br>The HBA takes no action on the state of this bit – it is for system software only. For example, if this bit is cleared, and a hot plug event occurs, the HBA shall still treat it as a proper hot plug event.<br>Note that this bit is not reset on a HBA reset.  |                             | 0h   | RWO        |
| 17           | Reserved          | Reserved.   |                             | 0h   | RO         |
| 16           | Reserved          | Reserved  |                             | 0h   | RO         |
| 15           | CR                | <b>Command List Running (CR):</b> When this bit is set it indicates that the command list DMA engine for the port is running.   |                             | 0h   | RO         |
| 14           | FR                | <b>FIS Receive Running (FR):</b> When this bit is set it indicates that the FIS Receive DMA engine for the port is running.   |                             | 0h   | RO         |
| 13           | ISS               | <b>Interlock Switch State (ISS):</b> For HBAs that support interlock switches (HCAP.SIS=1), this bit indicates the current state of the interlock switch. A '0' indicates the switch is closed, and a '1' indicates the switch is opened. For HBAs that do not support interlock switches (HCAP.SIS=0), this bit reports '0'.<br>Software should only use this bit if both HCAP.SIS and PxCMD.ISP are set to '1'.   |                             | Variable   | RO         |

Table 23-62. Offset 118h: PxCMD[0-1] – Port [0-1] Command Register (Sheet 3 of 3)

| Description: |                   |   |                             |  |            |
|--------------|-------------------|---|-----------------------------|--|------------|
| View: PCI    | BAR: ABAR         |   | Bus:Device:Function: 0:31:2 | Offset Start: 118h, 198h<br>Offset End: 11Bh, 19Bh |            |
| Size: 32 bit | Default: Variable |   |                             | Power Well: Core                                   |            |
| Bit Range    | Bit Acronym       | Bit Description   | Sticky                      | Bit Reset Value                                    | Bit Access |
| 12 : 08      | CCS               | <b>Current Command Slot (CCS):</b> Indicates the current command slot the HBA is processing. This field is valid when the PxCMD.ST bit is set, and is constantly updated by the HBA. This field can be updated as soon as the HBA recognizes an active command slot, or at some point soon after when it begins processing the command. When PxCMD.ST transitions from a '1' to a '0', the HBA will reset this field to '0'. After PxCMD.ST transitions from '0' to '1', the highest priority slot to issue from next is command slot 0. After the first command has been issued, the highest priority slot to issue from next is PxCMD.CCS + 1. For example, after the HBA has issued its first command, if PxCMD.CCS = 0h and PxCi is set to 3h, the next command that will be issued is from command slot 1. |                             | 0h   | RO         |
| 07 : 05      | Reserved          | Reserved  |                             | 0h   | RO         |
| 04           | FRE               | <b>FIS Receive Enable (FRE):</b> When set, the HBA may post received FISes into the FIS receive area pointed to by PxFB and PxFBU. When cleared, received FISes are not accepted by the HBA, except for the first D2H register FIS after the initialization sequence.<br>System software must not set this bit until PxFB (PxFBU) have been programmed with a valid pointer to the FIS receive area. If software wishes to move the base, this bit must first be cleared, and software must wait for the PxCMD.FR bit to be cleared. Software must not clear this bit while PxCMD.ST is set to '1'.   |                             | 0h   | RW         |
| 03           | CLO               | <b>Command List Override (CLO):</b> Setting this bit to '1' causes PxTFD.STS.BSY and PxTFD.STS.DRQ to be cleared to '0'. This allows a software reset to be transmitted to the device regardless of whether the BSY and DRQ bits are still set in the PxTFD.STS register. The HBA sets this bit to '0' when PxTFD.STS.BSY and PxTFD.STS.DRQ have been cleared to '0'. A write to this register with a value of '0' shall have no effect.<br><br>This bit shall only be set to '1' immediately prior to setting the PxCMD.ST bit to '1' from a previous value of '0'. Setting this bit to '1' at any other time is not supported and will result in indeterminate behavior.  |                             | 0h   | RW         |
| 02           | POD               | <b>Power On Device (POD):</b> The SATA controller does not support cold presence detect.  |                             | 1h   | RO         |
| 01           | SUD               | <b>Spin-Up Device (SUD):</b> This bit is read/write and defaults to 0 for HBAs that support staggered spin-up via HCAP.SSS. This bit is read only '1' for HBAs that do not support staggered spin-up.<br>On an edge detect from '0' to '1', the HBA shall start a COMRESET initialization sequence to the device. Clearing this bit causes no action on the interface.  |                             | Variable   | RW/RO      |
| 00           | ST                | <b>Start (ST):</b> When set, the HBA may process the command list. When cleared, the HBA may not process the command list. Whenever this bit is changed from a '0' to a '1', the HBA starts processing the command list at entry '0'. Whenever this bit is changed from a '1' to a '0', the PxCi register is cleared by the HBA upon the HBA putting the controller into an idle state.<br><br>See section 10.2.1 of the AHCI spec for restrictions on when PxCMD.ST can be set to '1' and cleared to '0'.  |                             | 0h   | RW         |

### 23.3.4 Port Interface Registers (One Set Per Port)

These registers implement various functions of the interface with an SATA device, including the SATA superset registers of the *SATA specification*.

**Table 23-63. Port Interface Registers for Ports[1:0]**

| Start | End | Symbol | Description                    |
|-------|-----|--------|--------------------------------|

| 1B0   | 1B3 | P1SERR | Port 1 Serial ATA Error        |
| 1B4   | 1B7 | P1SACT | Port 1 Device Status           |
| 1B8   | 1BB | P1CI   | Port 1 Command Issue           |
| 1BC   | 1BF | P1SNTF | Port 1 Serial ATA Notification |

#### 23.3.4.1 Offset 120h: PxTFD[0-1] – Port [0-1] Task File Data Register

This is a 32-bit register that copies specific fields of the task file when FISes are received. The FISes that contain this information are:

- D2H Register FIS
- PIO Setup FIS
- Set Device Bits FIS (BSY and DRQ are not updated with this FIS)

### 23.3.4.2 Offset 124h: PxSIG[0-1] – Port [0-1] Signature Register

This is a 32-bit register which contains the initial signature of an attached device when the first D2H Register FIS is received from that device. It is updated once after a reset sequence.

Table 23-65. Offset 124h: PxSIG[0-1] – Port [0-1] Signature Register

### 23.3.4.3 Offset 128h: PxSSTS[0-1] – Port [0-1] Serial ATA Status Register

This is a 32-bit register that conveys the current state of the interface and host. The HBA updates it continuously and asynchronously. When the HBA transmits a COMRESET to the device, this register is updated to its reset values.

Table 23-66. Offset 128h: PxSSTS[0-1] – Port [0-1] Serial ATA Status Register

| Description: |                   |   |                             |  |            |

### 23.3.4.4 Offset 12Ch: PxSCTL[0-1] – Port [0-1] Serial ATA Control Register

This is a 32-bit read-write register by which software controls SATA capabilities. Writes to this register result in an action being taken by the host adapter or interface. Reads from the register return the last value written to it.

**Table 23-67. Offset 12Ch: PxSCTL[0-1] – Port [0-1] Serial ATA Control Register**

## 23.4 Overview

The SATA host controller contains two modes of operation – a legacy mode using I/O space, and an AHCI mode using memory space. The memory space bit GHC.AE, set by software, indicates to hardware that AHCI is being used. Software must not implement code which mixes the use of legacy mode and AHCI mode.

## 23.5 Legacy Operation

In this mode of operation, software is performing I/O operations to the controller and SATA devices. The SATA controller is using the shadow registers as described in the *SATA specification*, and performing master/slave operation on the ports. The EP80579 does not support slave operations.

Software must program the DEV bit in the task file as its first operation before programming the rest of the transfer or setting the bus master registers.

### 23.5.1 Transfer Examples

#### 23.5.1.1 Register FIS Only

If software only wishes to send a command to the SATA device, and does not wish for any ATAPI or data transfer to occur, it will perform PIO operations, setting up the required fields for the command, and either writing to the command register (1F7h for primary, 177h for secondary) or control register (3F6h for primary, 376h for secondary).

Hardware will send the register FIS with the appropriate field set for command or control block, and upon reception of the device-to-host register FIS indicating command completion, will update the shadow block.

### 23.5.1.2 Non-Queued DMA Data Transfers

The following sections describe a data transfer to and from a device using DMA as the command type. These transfers are all non-queued.

#### 23.5.1.2.1 ATA – Data from Memory to Device

##### Part I - Software Actions – Command Start

1. Software sets up a PRD table in memory, with one or more entries to accomplish the data transfer of the full command. Software places the address for this table PRD Base register.
2. Software writes to the task file to set up the command, with the final write being to the command register (1F7h, 177h).
3. Software sets the “start” bit in the SATA host controller. This step can be swapped with the previous step, since no action is taken until the data transfer is to begin.

##### Part II - Hardware Actions – Command Start

Upon seeing the command register written, hardware sends the register FIS to the device, and awaits reception of a PIO setup FIS, device-to-host register FIS, DMA Activate FIS, or DATA FIS.

##### Part III - Hardware Actions – Data Transfer

1. Since the direction of the transfer is from the host to the device (and the command was a DMA command), hardware will receive a DMA Activate FIS.
2. Upon reception, if the ‘start’ bit has been set, hardware begins fetching data from the locations specified in the PRD table. (Hardware could, and for performance reasons should, have started fetching data prior to seeing the device-to-host register FIS described in Part II).
3. Hardware formulates a DATA FIS and begins transmitting data to the device.
4. Hardware continues fetching PRDs as they become exhausted and fetching data from PRD locations, until the transfer is complete. If the transfer is small enough, this data may fall under a single DATA FIS. The SATA Host controller will send FISes of maximum size to minimize FIS overhead on the data transfer.

##### Part IV - Hardware Actions – Command Wrap-Up

1. After the last piece of data has been accepted by the device, hardware awaits a device-to-host register FIS.
2. When the register FIS is received, hardware updates its task file shadow block.

##### Part V - Software Actions – Command Wrap-Up

1. Reading device status and BMIDE status.
2. Complete request to OS.
3. Error handling may occur, including device reset & DMA engine re-initialization.

#### 23.5.1.2.2 ATA – Data from Device to Memory

The ATA Device-to-Memory command is exactly the same as the ATA Memory-to-Device command, except that in Part III, hardware is receiving DATA FISes and writing data to memory, instead of fetching data from memory and sending DATA FISes. The number of DATA FISes used is device specific. Additionally, a DMA Activate FIS will not be received – the device will simply start sending a DATA FIS.

### 23.5.1.2.3 ATAPI

ATAPI DMA transfers are a combination of a PIO write command for the packet command transfer, followed by a DMA command for the data transfer. See those sections for a detailed explanation.

PIO data transfers are covered below.

### 23.5.1.2.4 Write to Device

#### Part I - Software Actions – Command Start

Software writes to the task file to set up the command, with the final write being to the command register (1F7h, 177h).

#### Part II - Hardware Actions – Command Start

1. Upon seeing the command register written, hardware sends the register FIS to the device, and awaits reception of either a PIO setup FIS or a device-to-host register FIS.
2. Upon reception of the PIO setup FIS (since the command was a PIO command), hardware updates the shadow block with the contents of the FIS and the current status, and holds the E-Status in reserve. If the "I" bit was set, it generates an interrupt.

#### Part III - Hardware / Software Actions – Data Transfer

Software writes to the data port as 16-bit quantities. Hardware assembles these writes into its FIFO, and formulates a single DATA FIS to transmit the data. If software falls behind the data transmission rate of the interface (very likely), hardware will insert IDLE characters.

#### Part IV - Hardware Actions – Command Wrap-Up

After the last piece of data has been accepted by the device, hardware updates the shadow block's status register with the E-Status field.

#### Part V - Software Actions – Command Wrap-Up

1. Reading device status and BMIDE status
2. Complete request to OS
3. Error handling may occur, including device reset & DMA engine re-initialization.

### 23.5.1.2.5 Read from Device

The read ATA command is exactly the same as the write ATA command, except that in Part III, hardware is receiving the DATA FIS and writing data to memory, instead of fetching data from memory and sending a DATA FIS.

### 23.5.1.3 SW Assisted Queued DMA Transfer

In this mode of operation, SW supports queuing, the SATA device supports queuing, but the SATA host controller does not. There are two general flows, one for a device that does not support the DMA setup FIS, and one for a device that does support the DMA setup FIS:

In both cases, SW is doing the work to determine the tag of the transfer. No special hardware action is taken by the SATA host controller.

## 23.5.2 Error Handling

### 23.5.2.1 Errors on DMI

Errors on the memory interface will cause the following behavior:

| Cycle Type                           | Address/Cmd Parity Error  | Data Parity Error  | TAbort                                  | MAbort                                  |
|--------------------------------------|---|--|---|---|
| I/O, Config Write                    | Set DPE bit<br>Do not claim cycle   | Set DPE bit<br>Claim Cycle, data dropped<br>Return completion success  | NA                                      | NA                                      |
| I/O, Config Read                     | Set DPE bit<br>Do not claim cycle   | NA   | NA                                      | NA                                      |
| Memory Write (to HC)                 | Not supported   | NA   | NA                                      | NA                                      |

### 23.5.2.2 Errors on SATA Interface

There are several errors that can occur on the SATA interface which may interrupt a data transfer.

There are two aspects from the following tables that are important when.

- Errors that occur during DMA data in transfers (device sending data) that will result in data corruption will set the bus master error status bit (bit 1 of I/O offset 01h for primary, bit 1 of I/O offset 05h for secondary), while it may or may not set the bit during other cases. If the SATA device generates R\_ERR on DMA data out transfers (host sending data), the bus master error status bit will be set, while it may or may not be set on other transfers.
- Errors that occur in PIO or DMA data in transfers (device generating data) that will result in data corruption will cause the SATA host controller to generate R\_ERR on the SATA interface.

If the bus master error bit does get set for PIO transfers or non-data portions, it is acceptable.

Table 1448 breaks out conditions for the above rules. Additionally, other errors that may occur are listed for information purposes.

Table 23-72. Errors During Non-DATA FIS Reception

| Error Type   | Host Controller Behavior   |
|--|--|
| Received Disparity Error / Illegal Character (K28.3)             | Assume character is correct. Reset disparity counter. Do not set bus master error bit. Do not return R_ERR (still check for CRC errors). |
| Received Disparity Error / Illegal Character (D)                 | Return R_ERR at end of FIS. Do not set bus master error bit. (Device will retry)   |
| Calculated different CRC than received or malformed FIS received | Return R_ERR at end of FIS. Do not set bus master error bit. (Device will retry)   |
| Phyready dropping unexpectedly                                   | Send ALIGNs and return link FSM to IDLE. Do not set bus master error bit. (Device will retry)  |
| Illegal FIS length for corresponding FIS type <sup>2</sup>       | Return R_ERR at end of FIS. Do not set bus master error bit. (Device will retry).  |

Table 23-73. Errors During PIO Data FIS Reception

| Error Type  | Host Controller Behavior   |
|---|--|
| Received Disparity Error / Illegal character (K28.3)                | Assume character is correct. Reset disparity counter. Do not set bus master error bit. Do not return R_ERR (still check for CRC errors). |
| Received Disparity Error / Illegal Character (D)                    | Return R_ERR at end of FIS. Do not set bus master error bit. (Device will not retry)   |
| Calculated different CRC than received or malformed FIS received    | Return R_ERR at end of FIS. Do not set bus master error bit. (Device will not retry)   |
| Phyready dropping unexpectedly                                      | Send ALIGNs and return link FSM to IDLE. Do not set bus master error bit. (Device will not retry)  |
| Length of PIO Data FIS not matching transfer count in PIO_SETUP FIS | Return R_ERR at end of FIS. Do not set bus master error bit. (Device will not retry).  |

Table 23-74. Errors During DMA Data FIS Reception

| Error Type   | Host Controller Behavior   |
|--|--|
| Received Disparity Error / Illegal Character (K28.3)   | Assume character is correct. Reset disparity counter. Do not set bus master error bit. Do not return R_ERR (still check for CRC errors). |
| Received Disparity Error / Illegal Character (D)   | Return R_ERR at end of FIS. Set the bus master error bit. (Device will not retry)  |
| Calculated different CRC than received or malformed FIS received or internal buffer overflows (which could be caused by device violating HOLD-HOLDA latency) | Return R_ERR at end of FIS. Set the bus master error bit. (Device will not retry)  |
| Phyready dropping unexpectedly   | Send ALIGNs and return link FSM to IDLE. Set the bus master error bit. (Device will not retry)   |

Table 23-75. Errors during unknown FIS type<sup>3</sup> reception

| Error Type       | Host Controller Behavior  |
|------------------|---|
| Unknown FIS Type | The unknown FIS type is itself an error condition, and will result in bus master error bits being set and R_ERR being returned. |

Table 23-76. Errors during FIS transmission

| Error Type   | Host Controller Behavior                            |
|--|---|
| <b>Non-data FIS:</b> Received R_ERR (includes link protocol errors during transmission), or phyrdy dropping unexpectedly | Retry the FIS.                                      |
| <b>Data FIS:</b> Received R_ERR (includes link protocol errors during transmission), or phyrdy dropping unexpectedly     | Set the bus master error bit. Do not retry the FIS. |

**Notes:**

- Malformed FIS = FIS not constructed according to link layer protocols
- Illegal length for corresponding FIS type; For example the following FIS types and their corresponding lengths:  
D2H Dma\_Activate FIS length = 1DW  
D2H Register FIS = 5 DW  
D2H Pio\_Setup FIS = 5DW  
D2H Set-Device-Bits = 2DW  
D2H Bist FIS = 3DW
- Zero-length D2H Data FIS (i.e. Data FIS header immediately followed by CRC), and any D2H Data FIS following a D2H Dma\_Activate FIS are treated as unknown FIS types for all purposes.

### 23.5.3 Hot Plug Operation

Dynamic hot plug (such as surprise removal) is not supported in legacy mode. However, using the PCS register configuration bits, and power management flows, a device can be powered down by software, and the port can then be powered off, allowing removal and insertion of a new device.

### 23.5.4 48-Bit (“Large”) LBA Operation Requirements

The SATA host controller supports 48-bit LBA through the host-to-device register FIS when accesses are performed via writes to the task file. The SATA host controller will ensure that the correct data is put into the correct byte of the host-to-device FIS as follows: if only one write is performed, the data goes to the location specified; if a second write is performed, the data from the first write is shifted into the “upper” location, and the data from the second write goes to the location specified.

Suppose a sequence of writes occurred to the taskfile as follows:

- 1f2h (Sector Count) - 21h
- 1f2h (Sector Count) - 22h
- 1f3h (Sector Number - 31h
- 1f3h (Sector Number) - 32h
- 1f4h (Cylinder Low) - 41h
- 1f4h (Cylinder Low) - 42h
- 1f5h (Cylinder High) - 51h
- 1f5h (Cylinder High) - 52h

The resulting FIS when the command or control register is written will have the following values:

| DW |                |                    |   |                        |                      |
|----|----------------|--------------------|---|------------------------|----------------------|
| 0  | Features       | Command            | C | 0000000                | FIS Type (27h)       |
| 1  | Dev / Head     | Cyl High (52h)     |   | Cyl Low (42h)          | Sector Number (32h)  |
| 2  | Features (exp) | Cyl High Exp (51h) |   | Cyl Low Exp (41h)      | Sector Num Exp (31h) |
| 3  | Control        | Reserved (0)       |   | Sector Count Exp (21h) | Sector Count (22h)   |
| 4  | Reserved (0)   | Reserved (0)       |   | Reserved (0)           | Reserved (0)         |

The writes do not have to come in any specific order. All that is necessary is that the writes to these registers act as a FIFO – the second write moves data from the first write into a new location.

There are also special considerations when reading from the task file to support 48-bit LBA operation. Software may need to read all 16-bits. Since the registers are only 8-bits wide and act as a FIFO, a bit must be set in the device/control register, which is at offset 3f6h for primary and 376h for secondary (or their native counterparts).

If software clears bit 7 of the control register before performing a read, the last item written will be returned from the FIFO. If software sets bit 7 of the control register before performing a read, the first item written will be returned from the FIFO.

## 23.5.5 Power Management Operation

### 23.5.5.1 Introduction

Power management of the SATA Controller and ports will cover operations of the host controller and the SATA wire. This specification does not cover any power management that an SATA device may do internally that is transparent to the interface.

### 23.5.5.2 Power State Mappings

The *PCI specification* defines power management states for devices, which will be applied to the SATA host controller. They are:

- D0 – working (required).
- D1 – light sleep (not supported).
- D2 – deeper sleep (not supported).
- D3 – very deep sleep (required). This state is split into two sub-states, D3<sub>HOT</sub> (can respond to PCI configuration accesses) and D3<sub>COLD</sub> (cannot respond to PCI configuration accesses). These two sub-states are considered the same, where D3<sub>HOT</sub> has V<sub>CC</sub>, but D3<sub>COLD</sub> does not. This is the only state allowed for the host controller when the system is in an S1-S5 state.

SATA devices may also have multiple power states. From parallel ATA, three device states are supported through ACPI. They are:

- D0 – Device is working and instantly available.
- D1 – device enters when it receives a STANDBY IMMEDIATE command. Exit latency from this state is in seconds.
- D3 – from the SATA device's perspective, no different than a D1 state, in that it is entered via the STANDBY IMMEDIATE command. However, an ACPI method is also called which will reset the device and then cut its power through proprietary chipset methods. (In ICH, this included setting the tri-state bits of the interface, a GPIO which reset the device, and a GPIO to cut power to that device.)

Each of these device states are subsets of the host controller's D0 state. This is partially because host controllers (as integrated in Intel components) have not supported host-based power management, and also because the device must be put into one of the lower power states before power could be removed from the host.

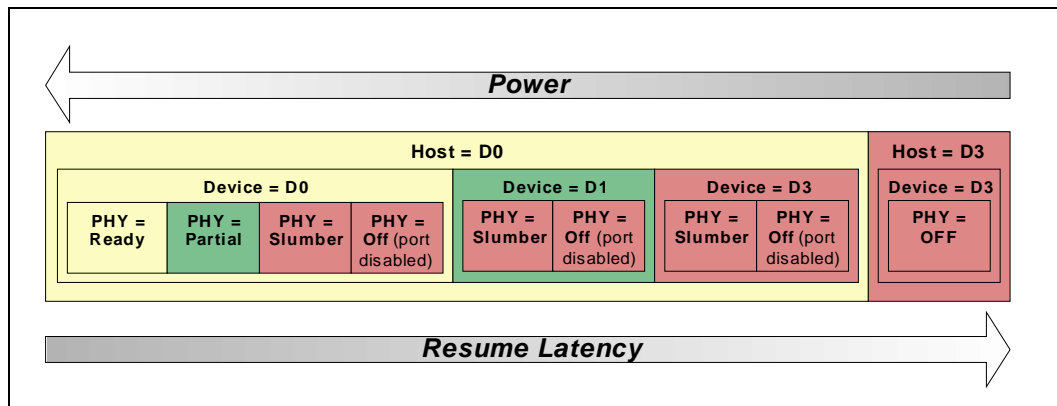

Finally, SATA defines three PHY layer power states, which have no equivalent mappings to parallel ATA. They are:

- PHY READY – PHY logic and PLL are both on and active.
- Partial – PHY logic is powered, but in a reduced state. Exit latency is no longer than 10µs.
- Slumber – PHY logic is powered, but in a reduced state. Exit latency can be up to 10ms.

Since these states have much lower exit latency than the ACPI D1 and D3 states, the SATA Controller defines these states as sub-states of the device D0 state.

Figure 23-1 is an hierarchical view of SATA power states.

**Figure 23-1. Legacy Mode Host Controller Power State Hierarchy**

### 23.5.5.3 Power State Transitions

Transitioning between various states is initiated by different levels of software and hardware.

#### 23.5.5.3.1 Partial and Slumber State Entry/Exit

The partial and slumber states are viewed as cheap and easy mechanism to save interface power when the interface is idle. The SATA Controller defines PHY layer power management (as performed via primitives) as a driver operation from the host side, and a device proprietary mechanism on the device side. The SATA Controller will accept device transition types, but will not issue any transitions as a host. All received requests from an SATA device will be ACKed.

When an operation is performed to the SATA Controller such that it needs to use the SATA cable, the controller must check whether the link is in the Partial or Slumber states, and if so, must issue a COM\_WAKE to bring the link back online. Similarly, the SATA device must perform the same action.

#### 23.5.5.3.2 Device D1, D3 States

These states are entered after some period of time when software has determined that no commands will be sent to this device for some time. The mechanism for putting a device in these states does not involve any work on the host controller, other than sending commands over the interface to the device. The command most likely to be used in ATA/ATAPI is the "STANDBY IMMEDIATE" command.

#### 23.5.5.3.3 Host Controller D3 state

After the interface and device have been put into a low power state, the host controller may be put into a low power state. This is performed via the PCI power management registers in configuration space.

There are two very important aspects to note when using PCI power management.

1. When the power state is D3, only accesses to configuration space are allowed. Any attempt to access the memory or I/O spaces must result in master abort.
2. When the power state is D3, no interrupts may be generated, even if they are enabled. If an interrupt status bit is pending when the controller transitions to D0, an interrupt may be generated.

When the controller is put into D3, it is assumed that software has properly shut down the device and disabled the ports. Therefore, there is no need to sustain any values on the port wires. The interface will be treated as if no device is present on the cable, and power will be minimized.

When returning from a D3 state, an internal reset will not be performed. When in legacy mode of operation, the SATA controller does not generate PME#. This includes attach events (since the port must be disabled), or interlock switch events (via the SATAGP pins).

#### 23.5.5.4 SMI Trapping (APM)

The ATC register in configuration space contains control for generating SMI# on accesses to the IDE I/O spaces. These bits map to the legacy ranges only (1f0h-1f7h, 3f4h-3f6h, 170h-177h, and 374h-376h). Trapping will not occur on the native IDE ranges defined by PCMDBA, PCTLBA, SCMDBA, SCTLBA, or LBAR. If the SATA controller is in legacy mode and is using these addresses, accesses to one of these ranges with the appropriate bit set will cause the cycle to not be forwarded to the SATA controller, and for SMI# to be generated.

SMI trapping is specifically supported in the following configurations:

- SATA controller in legacy addressing mode (non-combined).

Additionally, an ATS register bit will get set on an access to these ranges if the corresponding bit in the ATC register is set.

### 23.5.6 Interrupt Architecture

Table 23-77 summarizes interrupt behavior for MSI and wire-modes. In the table “bits” refers to the 4 possible interrupt bits in I/O space, which are: PSTS.PRDIS (offset 02h, bit 7), PSTS.I (offset 02h, bit 2), SSTS.PRDIS (offset 0Ah, bit 7), and SSTS.I (offset 0Ah, bit 2).

Table 23-77. MSI vs. PCI IRQ Actions

| Interrupt Register   | Wire-Mode Action | MSI Action   |
|--|------------------|--------------|
| All bits '0'   | Wire inactive    | No action    |
| One or more bits set to '1'  | Wire active      | Send message |
| One or more bits set to '1', new bit gets set to '1'                             | Wire active      | Send message |
| One or more bits set to '1', software clears some (but not all) bits             | Wire active      | Send message |
| One or more bits set to '1', software clears all bits                            | Wire inactive    | No action    |
| Software clears one or more bits, and one or more bits is set on the same clock. | Wire active      | Send message |

### 23.5.7 Staggered Spin-up

To support staggered spin-up with legacy software, the AHCI memory space register HCAP.SSS must be cleared, and the configuration register PCS is used to enable/disable the port.

### 23.5.8 HW/SW Operation for Detecting an SATA Device Presence

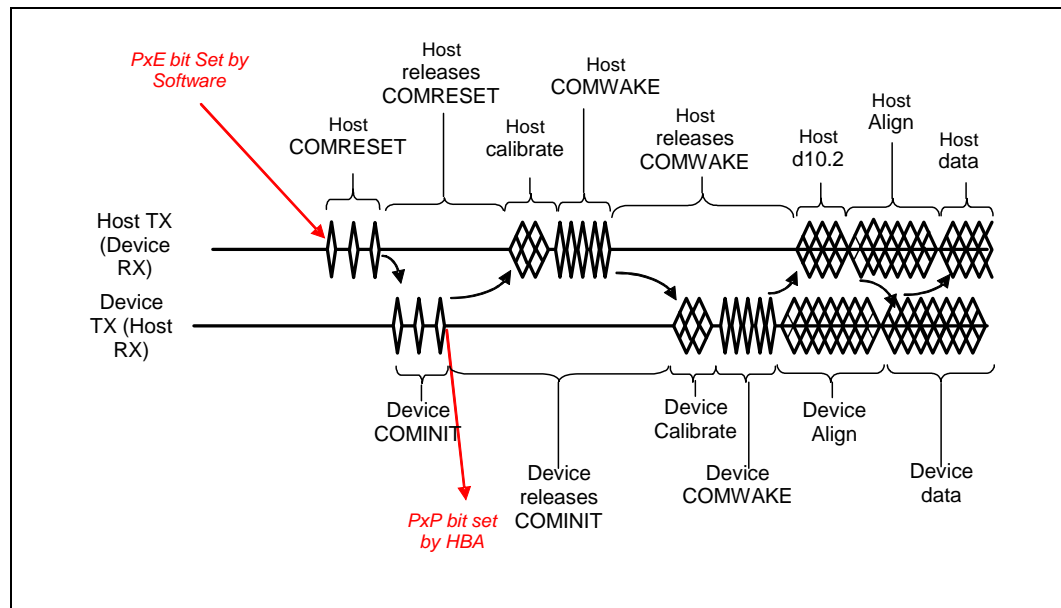

#### 23.5.8.1 Introduction

In legacy mode, the SATA controller does not generate interrupts based on hot plug/unplug events. However, the SATA PHY does know when a device is connected (if not in a partial or slumber state), and it is beneficial to communicate this information to host software as this will greatly reduce boot times and resume times.

#### 23.5.8.2 Hardware Flow

The flow for using these bits is shown in Table 23-2. The 'PxE' bit refers to PCS.P0E, and PCS.P1E bits, depending on the port being checked, and the 'PxP' bit refers to the PCS.P0P, and PCS.P1P bits, depending on the port being checked.

Figure 23-2. Hardware Flow for Port Enable/Device Present Bits

**Notes:**

1. The SATA host controller's COMRESET length will be 6 data bursts.

### 23.5.8.3 Software Flow

The software flow will be as follows:

- Sometime after power-on reset or resume from suspend, software will set the PCS.PxE bits, depending on which ports it wants to scan. They can both be set together.
- The *SATA specification* indicates that the COMRESET sequence to device detection is to be 880 us. For best results, software should wait some period longer than this, such as 10 ms.
- Software will read the PCS.PxP bits. If the bit is set, a device is present. If the bit is cleared, a device is not present.

If a port was disabled, software checks to see if a new device is connected by periodically re-enabling the port, and waiting 2-3ms to see if a device is present. If one is not, it can disable the port and check again later. If a port remains enabled, software can periodically poll PCS.PxP to see if a new device is connected.

### 23.5.9 SMI Generation

The SATA controller can generate SMIs on behalf of accesses to the task file. These SMIs are used to support legacy operating systems running APM (advanced power management). These SMIs are not used when the controller is an ACPI or PCI power managed device.

To support SMI generation, trap registers exist in power management space. These registers can be found at the PMBASE + 48h region. The register bits are:

D0\_TRP\_EN: Primary IDE master (port 0)

D1\_TRP\_EN: Primary IDE slave (port 1)

These bits, when set, affect the legacy IDE ranges 1F0h – 17Fh, 3F6h, 170h – 17Fh, 376h, and the range pointed to by the LBAR register in configuration space. If native IDE is enabled, trapping will not be performed. If AHCI is enabled, trapping will not be performed.

### 23.5.10 LED

The LED must be driven whenever the BSY bit is set in either port. The LED output will go directly to SATALED#, an active-low open-collector output. When SATALED# is low, the LED is active. When SATALED# is tri-stated, the LED is inactive.

## 23.6 AHCI Operation

### 23.6.1 System Memory Structures

The serial ATA controller supports 2 ports, and each port supports 32 commands. The command list and received FIS may live in 64-bit space

Figure 23-3. Port System Memory Structure

## 23.6.2 Error Reporting and Recovery

### Error Reporting and Recovery

All errors within an HBA occur within ports. There are no errors that apply to the entire host controller.

### 23.6.2.1 Error Types

#### 23.6.2.1.1 System Memory Errors

System memory errors such as target abort, master abort, and parity may cause the host to stop processing the currently running command. These are serious errors that cannot be recovered from without software intervention.

A master/target abort error occurs when system software has given a pointer to the HBA that does not exist in physical memory. When this occurs, the HBA aborts the transfer (if necessary). When this is complete, the HBA sets PxIS.HBFS. If PxIE.HBFE and GHC.IE are set, the HBA shall also generate an interrupt.

A data error (such as CRC or parity), may or may not be transient. If the error occurred on a fetch of a CFIS, PRD entry or command list, the HBA shall stop. If the error occurred on a data FIS or the ACMD field, the HBA is allowed to stop, but may also continue. When a data error occurs, the HBA aborts the transfer (if necessary). When this is complete, the HBA sets PxIS.HBDS. If PxIE.HBDE and GHC.IE are set, the HBA shall also generate an interrupt.

If the HBA continue after a data error on a data or ACMD field, it shall poison the CRC of the Data FIS it transfers to the device.

#### 23.6.2.1.2 Interface Errors

Interface errors are errors that occur due to electrical issues on the interface, or protocol miscommunication between the device and HBA. Depending on the type of error, different bits in the PxSERR register are set. When these bits are set, either PxIS.IFS (fatal) or PxIS.INFS (non-fatal) shall be set, and if enabled, the HBA shall generate an interrupt.

Conditions that cause PxIS.IFS/PxIS.INFS to be set are:

- In the PxSERR.ERR field, the P bit is set to '1'
- In the PxSERR.DIAG field, the C or H bit is set to '1'
- PhyRdy drops unexpectedly

Examples of these types of errors are below, with the corresponding PxSERR bit that is set if appropriate.

The only difference between PxIS.IFS and PxIS.INFS being set is the type of FIS that is being transmitted/received when the error occurs. If the error occurred during a non-Data FIS, the FIS must be retransmitted, so the error is non-fatal and PxIS.INFS is set. If the error occurred during a Data FIS, the transfer shall stop, so the error is fatal and PxIS.IFS is set.

In the case of a non-Data FIS error, between seeing a non-Data FIS fail and the attempt to re-transmit, the HBA may receive other FISes from the device (this will most likely happen when performing native command queuing commands). When this occurs, the HBA must accept the FIS, perform the correct actions, and then retry the failed FIS.

If the HBA was transmitting a Data FIS it does not retry the FIS and waits for software to clear the PxCMD.ST bit to '0'. The HBA shall retransmit a non-Data FIS continuously after a failure until either the transfer succeeds or system software stops the controller by clearing PxCMD.ST to '0'.

- Received Disparity Error / Illegal Character (K28.3): When a disparity error is encountered, the HBA assumes the disparity of this character is correct and resets the running disparity counter in the 8b/10b decoder. No error bits are set.
- Received Disparity Error / Illegal Character (D): When this occurs, the HBA returns R\_ERR at the end of the FIS. It sets PxSERR.DIAG.B. Note that PxIS.IFS/PxIS.INFS shall not be set; the CRC error that is likely to occur due to this event will set the appropriate bit. If there is an illegal character outside the FIS boundaries, the HBA may ignore the event and is not required to set PxSERR.DIAG.B.
- PhyRdy Dropping Unexpectedly: When this occurs, the HBA returns to idle. If the PhyRdy signal dropped during the middle of a command, the HBA may have to be restarted. If the PhyRdy signal dropped outside of a FIS, neither the PxIS.IFS nor the PxIS.INFS bits shall be set.
- Calculated Different CRC than Received: When this occurs, the HBA returns R\_ERR and returns to idle. It sets PxSERR.DIAG.C
- Incorrect FIS or FIS with Illegal Length for Corresponding FIS Type Received: When this occurs, the HBA returns R\_ERR at end of the FIS, shall not post the FIS to memory, and returns to idle. It sets PxSERR.ERR.P. This can only be done for supported FIS types. An unknown FIS is not considered an illegal FIS, unless the length received is more than 64 bytes. If an unknown FIS arrives with length <= 64 bytes, it is posted and the HBA continues normal operation.
- Internal Buffer Overflow: This occurs when the HBA sends a HOLD, but a HOLDA was not received quickly enough by the HBA, and the HBA's internal data FIFOs overflow. The HBA returns R\_ERR at the end of the FIS. It sets PxSERR.ERR.P.
- HBA Receives R\_ERR: If the HBA receives an R\_ERR to a FIS it was transmitting, it sets PxSERR.DIAG.H.
- FIS received from a device, where both BSY and DRQ are to be updated in the Status register and both PxTFD.STS.BSY and PxTFD.STS.DRQ are cleared: When this occurs, the HBA returns R\_OK, does not set any error bits, and does not update any registers or the received FIS area based on the received FIS (i.e. the FIS is ignored).
- It is system software's responsibility to check the PxSERR register periodically to determine if the interface is operating cleanly, and take appropriate actions (such as going down to Generation1 speed if operating at a higher speed or notifying the user) when interface errors occur.

### 23.6.2.1.3 Device Errors

When a FIS arrives that updates the taskfile, the HBA checks to see if PxTFD.STS.ERR is set. If it is, and PxIE.TFEE is set, the HBA shall generate an interrupt and stop processing any more commands.

### 23.6.2.1.4 Command List Overflow

Command list overflow is defined as software building a command table that has fewer total bytes than the transaction given to the device. On device writes, the HBA will run out of data, and on reads, there will be no room to put the data.

For an overflow on data read, either PIO or DMA, the HBA shall set PxIS.OFS, and if enabled via PxIE.OFE and GHC.IE, generate an interrupt. When this condition occurs on data reads, the HBA shall make a best effort to continue, however the HBA may not be able to recover without software intervention. Overflow is a serious error, thus software should perform a fatal error recovery procedure to ensure that the HBA is brought back to a known condition before continuing. For an overflow on writes, the HBA may transmit HOLDs to the device since it does not have any data to satisfy the request size; a COMRESET is required by software to clean up from this serious error.

For an overflow on data writes with DMA, the HBA does not know there is more data until it receives the next DMA Activate. When this occurs, it may optionally set PxIS.OFS and attempt to terminate the transfer. However, this is a fatal condition, and an HBA is allowed to hang on the transfer. For PIO writes, the HBA receives the PIO Setup FIS and therefore knows the length, and therefore may optionally set PxIS.OFS. However, by not satisfying the length, the transfer shall end in an error, and software must recover. Therefore setting PxIS.OFS is optional for both DMA and PIO data write conditions. Detecting overflow and setting PxIS.OFS on native command queuing commands is optional.

#### 23.6.2.1.5 Command List Underflow

Command list underflow is defined as software building a command table that has more total bytes than the transaction given to the device.

For data writes, both PIO and DMA, the device shall detect an error and end the transfer. These errors are most likely going to be fatal errors that will cause the port to be restarted. For data reads, the HBA shall update its PRD byte count with the total number of bytes received from the last FIS, and may be able to continue normally, but is not required to.

The HBA is not required to detect underflow conditions for native command queuing commands.

#### 23.6.2.1.6 Native Command Queuing Tag Errors

The HBA does not actively check incoming DMA Setup FISes to ensure that the PxSACT register bit for that slot is set.

The reason for this is if the device gives an incorrect tag, it could just as likely be for a tag that is active. In this case, the HBA would see no error, although the data transfer that occurs is incorrect. Therefore, there is little benefit in the HBA checking for inactive tags. Just as in the wrong active tag case, the data transfer that occurs will be incorrect.

Existing error mechanisms, such as host bus failure, or bad protocol, are used to recover from this case.

#### 23.6.2.1.7 PIO Data Transfer Errors

In accordance with Serial ATA 1.0a, Data FISes prior to the final Data FIS must be an integral number of Dwords. If the HBA receives an intermediate Data FIS transfer request that is not an integral number of Dwords, the HBA shall set PxSERR.ERR.P to '1', set PxIS.IFS to '1' and stop running until software restarts the port.

The HBA shall ensure that the size of the Data FIS received during a PIO command matches the size in the Transfer Count field of the preceding PIO Setup FIS. If the Data FIS size does not match the Transfer Count field in the preceding PIO Setup, the HBA shall respond with R\_ERR to the Data FIS, set PxSERR.ERR.P to '1', set PxIS.IFS to '1', and then stop running until software restarts the port.

### 23.6.2.2 Error Recovery

#### 23.6.2.2.1 HBA Aborting a Transfer

When the HBA detects an error that it cannot recover from, it may need to end the transfer on the SATA interface.

To do this, the HBA asserts SYNC Escape to stop the bad FIS, and when the device is quiescent, returns to idle. The SATA device should send a D2H Register FIS at this point, with the ERR bit set to indicate an error in the transfer.

When aborting a transfer, the HBA does not wait for the D2H Register FIS before proceeding with error recovery (such as setting interrupt status bits and generating interrupts). This is because a device may be in a hung condition and cannot generate the D2H Register FIS.

#### 23.6.2.2.2 Software Error Recovery

When an interrupt is generated due to an error condition, software will attempt to recover. Fatal errors (signified by the setting of PxIS.HBFS, PxIS.HBDS, PxIS.IFS, or PxIS.TFES) will cause the HBA to enter the ERR:Fatal state, and clear PxCMD.CR. In this state, the HBA shall not issue any new commands nor acknowledge DMA Setup FISes to process any native command queuing commands. To recover, the port must be restarted; the port is restarted by clearing PxCMD.ST to '0' and then setting PxCMD.ST to '1'. For non-fatal errors (signified by the setting of PxIS.INFS or PxIS.OFS) the HBA continues to operate.

If the transfer was aborted, the device is expected to send a D2H Register FIS with PxTFD.STS.ERR set to '1' and both PxTFD.STS.BSY and PxTFD.STS.DRQ cleared to '0'. Under this scenario, system software knows that the device is in a stable state and transfers may be restarted without issuing a COMRESET to the device. No FIS will be posted and no register updates will be done based on FISes received after a fatal error has occurred. Received FISes will not be acted on until a COMRESET or a new command is sent to the device, after the error is recovered from appropriately including clearing the PxCMD.ST bit.

For fatal errors, software must determine which commands were not processed and either re-issue them or notify higher level software that the command failed.

To detect an error that requires software recovery actions to be performed, software should check whether any of the following status bits are set on an interrupt: PxIS.HBFS, PxIS.HBDS, PxIS.IFS, and PxIS.TFES. If any of these bits are set, software should perform the appropriate error recovery actions based on whether non-queued commands were being issued or native command queuing commands were being issued.

### 23.6.3 Hot Plug Operation

If HCAP.SIS is set, the SATA controller uses the SATAGP[3:0] pins as interlock switches.

The EP80579 supports Hot Plug Surprise Removal Notification. However Hot Plug Surprise Removal Notification (without an interlock switch) is **mutually exclusive** with the PARTIAL and SLUMBER power management states.

## 23.6.4 Power Management Operation

### 23.6.4.1 Introduction

This section covers power management of the HBA and the Serial ATA interface. This specification does not cover any power management that a Serial ATA device may do internally that is transparent to the interface.

### 23.6.4.2 Power State Mappings

The *PCI specification* defines power management states for devices, which shall be applied to the HBA. They are:

- D0 - Working (required).
- D1 - Not defined for storage HBAs.
- D2 - Not defined for storage HBAs.
- D3 - Very deep sleep (required). This state is split into two sub-states, D3HOT (can respond to PCI configuration accesses) and D3COLD (cannot respond to PCI configuration accesses). These two sub-states are considered the same, where D3HOT has VCC, but D3COLD does not. PxCMD.ST must be cleared to '0' before entering the D3 power state.

Serial ATA devices may also have multiple power states. Each of these device states are subsets of the HBA's D0 state. They are:

- D0 - Device is working and instantly available.
- D1 - Device enters when it receives a STANDBY IMMEDIATE command. Exit latency from this state is in seconds.
- D2 - Not currently defined for Serial ATA devices.
- D3 - Device enters when it receives a SLEEP command. Exit latency from this state is in seconds.

Finally, Serial ATA defines three Phy layer (or interface) power states. They are:

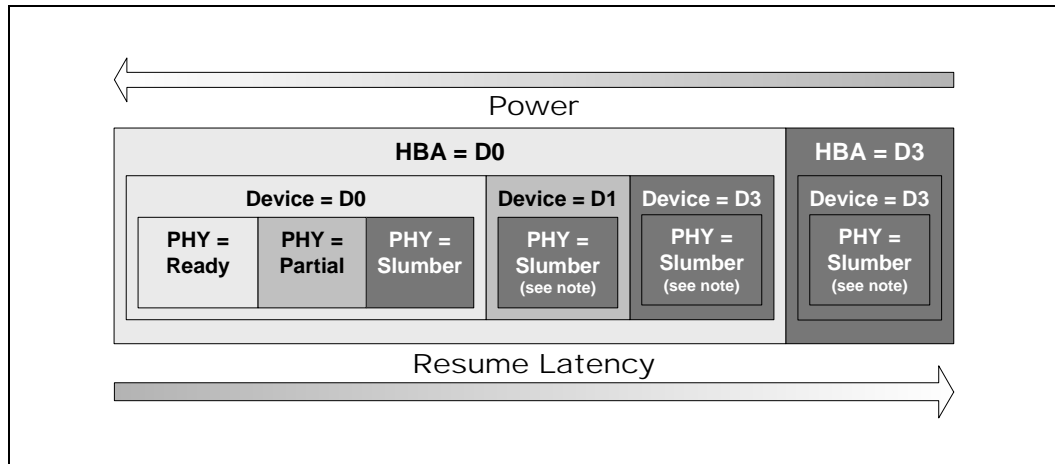

- Phy Ready - Phy logic and PLL are both on and active.
- Partial - Phy logic is powered, but in a reduced state. Exit latency is no longer than 10 $\mu$ s.
- Slumber - Phy logic is powered, but in a reduced state. Exit latency can be up to 10ms.

Since these states have much lower exit latency than the D1 and D3 states, AHCI defines these states as sub-states of the device D0 state.

The following picture gives a hierarchical view of power states of Serial ATA.

Figure 23-4. Power State Hierarchy

**Note:** The Phy is not required to be in a Slumber state when the device is in a D1 or D3 state, nor is it required to be in a Slumber state when the HBA is in a D3 state. While this may be the likely condition of the interface when the devices connected to the interface are in a low power state, it is not a requirement, and the interface shall break out of these states on a power management event.

### 23.6.4.3 Power State Transitions

#### 23.6.4.3.1 Interface Power Management

The *Serial ATA 1.0a Specification* defines two lower power interface power management states, Partial and Slumber, in order to save power on the Serial ATA link in power sensitive systems. The Partial and Slumber interface power management states can be initiated by software, the HBA itself, or by the device. The interface power management state is negotiated between the host and the device on the interface using Serial ATA primitives. Any request can be accepted (using the PMACK primitive) or rejected (using PMNACK primitives) based upon current conditions and settings in the device and HBA. The current interface power management state is reflected to software in PxSSTS.IPM.

#### Device Initiated

By default, a device that supports initiating interface power management states has the capability disabled. To enable this feature, the appropriate SET FEATURES command may be issued to the device. The HBA shall respond to device initiated power management requests as specified by PxSCTL.IPM. A request from the device to enter an interface power management state may be rejected by the HBA if the HBA needs to transmit a FIS to the device.

#### System Software Initiated

PxCMD.ICC is used by system software to initiate interface power management state transitions. The request to transition to a different interface power management state shall only be acted on by the HBA if the Link layer is currently in the L\_IDLE state. If the HBA's Link layer is not in the L\_IDLE state when the PxCMD.ICC field is written, the request shall be ignored. The HBA shall not perform a transition directly from Partial to Slumber or from Slumber to Partial based on a new value being written to PxCMD.ICC. If the link is currently in a Partial or Slumber interface power management state, it is software's responsibility to bring the link to the active state before requesting a

transition to a different interface power management state. The time from the request written to PxCMD.ICC until the link is active is bounded by the maximum recovery times from Partial or Slumber as outlined in the *Serial ATA 1.0a Specification*.

### HBA Initiated

The HBA may implement aggressive power management, as indicated in HCAP.SALP. Aggressive power management allows the HBA to initiate an interface power management state as soon as there are no commands outstanding to the device. This enables immediate entry into the low power interface state without waiting for software in power sensitive systems. The PxCMD.ALPE bit defines whether the feature is enabled and the PxCMD.ASP field controls whether Partial or Slumber is initiated by the HBA when enabled.

When PxCMD.ALPE is set to '1', if the HBA recognizes that there are no commands to process, the HBA shall initiate a transition to Partial or Slumber interface power management state based upon the setting of PxCMD.ASP. The HBA recognizes no commands to transmit as either:

- PxSACT is set to 0h, and the HBA updates PxCI from a non-zero value to 0h.
- PxCI is set to 0h, and a Set Device Bits FIS is received that updates PxSACT from a non-zero value to 0h.

If the PxSACT and PxCI registers are both cleared to 0h, and the interface is in an active state, the HBA shall not initiate placing the interface into a lower power state, unless PxCMD.ICC is written with an appropriate value.

Before performing a FIS transmission, the HBA must ensure the link is in the active state. If the link is in the Partial or Slumber interface power management state, a COMWAKE must be issued, and the HBA must wait until the link is active before proceeding with transmission of the FIS.

#### 23.6.4.3.2 Software Requirements and Precedence

Software must check HCAP.SSC (Slumber capable) and HCAP.PSC (Partial capable) to determine if the HBA supports interface power management transitions as an initiator or a target. If an interface power management state is not supported, then software shall not write the PxCMD.ICC field nor set the aggressive power management capability to initiate a transition to that state. Software must set the PxSCTL.IPM field to disable transition to any unsupported interface power management state. If HCAP.SSC or HCAP.PSC is cleared to '0', software should disable device-initiated power management by issuing the appropriate SET FEATURES command to the device.

HBA initiated interface power management requests are higher priority than software initiated requests. Thus if the HBA and software request transitions to different states at the same time, the HBA's request shall take precedence over the software request.

#### 23.6.4.3.3 Device D1, D3 States

The D1 and D3 device states are entered when system software has determined that no commands will be sent to the device for some time. To enter these states, software may perform two actions. The first is to issue a command to the device to enter the low power state (STANDY IMMEDIATE for D1, SLEEP for D3), and the second step is to put the interface into a Slumber power management state (by setting PxCMD.ICC to 6h).

Note: It is recommended that the device initiate a Slumber power management state when it receives a command to enter the D1 or D3 state.

#### 23.6.4.3.4 HBA D3 state

After the interface and device have been put into a low power state, the HBA may be put into a low power state. This is performed via the PCI power management registers in configuration space. AHCI only supports the D3 state.

There are two very important aspects to note when using PCI power management.

- When the power state is D3, only accesses to configuration space are allowed. Any attempt to access the register memory space must result in master abort.
- When the power state is D3, no interrupts may be generated, even if they are enabled. If an interrupt status bit is pending when the controller transitions to D0, an interrupt may be generated.

Software must disable interrupts (GHC.IE must be cleared to '0') prior to requesting a transition of the HBA to the D3 state. This precaution by software avoids an interrupt storm if an interrupt occurs during the transition to the D3 state.

PxCMD.ST must be cleared to '0' before entry into the D3 power state.

#### 23.6.4.4 PME

When the HBA is in the D3 state, it may optionally wake based on a change in the device state.

PME must be generated when the HBA is in the D3 state under the following conditions:

- PxIS.PCS is set to '1' due to a native hot plug insertion.
- PxIS.DIS set, indicating an interlock switch has been opened or closed.
- PxIS.CPDS set, indicating cold presence detect state change.
- Set Device Bits FIS received on the interface with the T bit set to '1' and the Notification ('N') bit also set to '1'.

If any of these bits are set, regardless of the setting of the enables in PxIE and GHC.IE, the HBA shall generate PME#.

For the I<sup>2</sup>C approach, the SGPIO Control Register is made visible in the SMBus slave register space. SGPIO control register is mapped to SMBus slave registers at offset 9h, Ah and Bh. The SM Link interface is externally connected to an unused SMBus on the BMC. BMC will read the data, encapsulate it in the IPMI format and drive that data through another SMBus or I<sup>2</sup>C bus to the GEM controller. GEM controller then updates the LED drivers with the updated status.

## 23.7 Additional Information

### 23.7.1 Mode Switching

Software mode could change from one to another by manipulating the MAP register. There are some specific requirements for the register:

- MAP.SMS and MAP.MV shall only be programmed to values that would result in legal CC.SCC, DID and PI values (See Section 48.1.5.1). If MAP.SMS and MAP.MV are not programmed correctly, hardware shall default the mode back to IDE.
- MAP register must survive across D3hot to D0 power state transitions.
- MAP.SMS shall not be manipulated during runtime operation; i.e. the OS will not do this. However, the BIOS may choose to change it during POST to switch to other software mode.

When switching from one mode to another (via MAP.SMS), the BIOS should ensure that LBAR and ABAR configuration register at offset 20h and 24h are cleared correctly. The BIOS should also ensure that the function disable bits are set or cleared correctly.

Note that when CC.SCC is not 01h, software could also 'change mode' from IDE to AHCI or vice versa by writing to the AE bit of GHC register. This change of software mode during run-time (by using AHCI device driver) is not the kind of mode switching described in this section.

### 23.7.1.1 AHCI Mode

AHCI mode has the following requirements/characteristics:

For AHCI:

- Default CC.SCC = 06h
- Default PI = 01h
- Has a unique Device ID
- BAR0 to BAR4 (i.e. PCMDBA, PCTLBA, SCMDBA, SCTLBA and LBAR) are functional.
- BAR5 (i.e. ABAR) is functional as a memory BAR.
- MSI is supported.
- MAP.SMS is 01b for AHCI mode.
- MAP.SMS is not applicable when MAP.MV is 10b, indicating combined-mode, in mobile SKUs.
- BIOS should program MAP.MV, then only program MAP.SMS to the desired but legal value.

### 23.7.1.2 IDE Mode

- IDE mode has the following requirements/characteristics:
- D31F2 shall have CC.SCC = 01h
- D31F2 shall support both native and legacy I/O access, indicating by a PI register default value of 8Ah.
- MSI is not supported.
- BAR0 to BAR4 (i.e. PCMDBA, PCTLBA, SCMDBA, SCTLBA and LBAR) are functional.
- BAR5 is functional as an I/O BAR that implements an index/data pair mechanism for accessing SControl, SError and SStatus registers.
- MAP.SMS must be 00b for IDE mode.
- BIOS should program MAP.MV, then only program MAP.SMS to the desired but legal value.

## 24.0 SMBus Controller Functional Description: Bus 0, Device 31, Function 3

### 24.1 Overview

CMI's IICH contains an SMBus Host interface that allows the processor to communicate with SMBus slaves.

Table 24-1 lists the SMBus signals and the actions taken during various power events

**Table 24-1. SMBus signals**

| Signal Name | Power Plane | During Reset               | After Reset | S3     | S5     | Alt Driver  |
|-------------|-------------|----------------------------|-------------|--------|--------|-------------|
| SMBDATA     | Resume      | See note                   |             | High-Z | High-Z | Peripherals |
| SMBCLK      | Resume      |                            |             | High-Z | High-Z | Peripherals |
| SMBALERT#   | Resume      | Can be driven high or low. |             |        |        | Peripherals |

**Note:** SMBDATA and SMBCLK might go active if other devices are using the bus.

Unless specified, all of SMBus logic and registers in this chapter are reset by either CF9 reset or RSMRST#.

#### 24.1.1 Host Controller

The CMI provides a *System Management Bus (SMBus) Specification, Version 2.0*-compliant host controller. The host controller provides a mechanism for the processor to initiate communications with SMB peripherals (slaves). The CMI is also capable of operating in a mode in which it can communicate with I<sup>2</sup>C compatible devices.

The CMI can perform SMBus messages with either PEC enabled or disabled. The actual PEC calculation and checking is performed in software. The SMBus Host Controller logic can automatically append the CRC byte if configured to do so.

The CMI SMBus logic exists in Device 31, Function 3 configuration space, and consists of a transmit data path and host controller. The transmit data path provides the data flow logic needed to implement the seven different SMB command protocols and is controlled by the host controller. The logic is clocked by the RTC clock.

The SMBus Address Resolution Protocol (ARP) is supported through software by using the existing host controller commands, except for the new Host Notify command (which is actually a received message).

The programming model of the host controller is combined into two portions: A PCI configuration portion and a system I/O mapped portion. All static configuration, such as the I/O base address, is done via the PCI configuration space. Real-time programming of the host interface is done in system I/O space.

The Host Controller needs to check for parity errors as a target. If it sees an error, it must set the detected parity error bit (bit 15 of status). If bit 6 and bit 8 of the command register are set, it needs to generate SERR#, and set the signalled SERR# bit in the status register (bit 14).

### 24.1.2 Slave Interface

The slave interface allows an external master to write or read. The write cycles can be used to cause certain events or pass messages, and the read cycles can be used to determine the state of various status bits. The internal Host Controller cannot access the internal Slave Interface.

## 24.2 SMBus Controller PCI Configuration Register Details

Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values and are read-only. Writes to reserved locations may cause system failure and unpredictable behavior.

Reserved bits are read only.

**Table 24-2. Bus 0, Device 31, Function 3: Summary of SMBus Controller PCI Configuration Registers**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|
| 00h          | 01h        | "Offset 00h: VID: Vendor ID Register" on page 897                | 8086h         |

### 24.2.1.9 Offset 20h: SM\_BASE: SMB Base Address Register

SM\_BASE sets the base address in I/O space for the SMBus I/O registers (see Section 24.3, “SMBus Controller I/O-Mapped Configuration Register Details” on page 905). These registers can be mapped anywhere in the I/O space on 32-byte boundaries.

**Table 24-11. Offset 20h: SM\_BASE: SMB Base Address Register**

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:31:3 | Offset Start: 20h<br>Offset End: 23h |            |
| Size: 32 bit | Default:           | 00000001h  |                             | Power Well: Resume                   |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |

| 00           | IOSI               | <b>I/O Space Indicator:</b> This read-only bit always is 1, indicating that the SMB logic is I/O mapped. |                             | 1                                    | RO         |

### 24.2.1.10 Offset 2Ch: SVID: SVID Register

BIOS sets the value in this register to identify the Subsystem Vendor ID. The SMBus SVID register, in combination with the SMBus Subsystem ID register, enables the operating system to distinguish each subsystem from the others.

*Note:* The software can write to this register only once per core well reset. Writes must be done as a single 16-bit cycle.

**Table 24-12. Offset 2Ch: SVID: SVID Register**

| Description: |                    |  |                             |                                      |            |

| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 15 : 00      | SVID               | Subsystem Vendor ID: The SVID register, in combination with the Subsystem ID (SID) register, enables the operating system (OS) to distinguish subsystems from each other.<br><b>Note:</b> Software can write to this register only once per core well reset. Writes must be done as a single 16-bit cycle. |                             | 00h                                  | RWO        |

### 24.2.1.11 Offset 2Eh: SID: Subsystem Identification Register

BIOS sets the value in this register to identify the Subsystem ID. The SMBus SID register, in combination with the SMBus SVID register, enables the operating system to distinguish each subsystem from the others.

*Note:* The software can write to this register only once per core well reset. Writes must be done as a single 16-bit cycle.

### 24.3.1 SMBus Controller I/O-Mapped Configuration Register Descriptions

The SMBus Controller I/O-mapped configuration registers are mapped into I/O space using register SM\_BASE (see Section 24.2.1.9, “Offset 20h: SM\_BASE: SMB Base Address Register” on page 901).

#### 24.3.1.1 Offset 00h: HSTS: Host Status Register

All status bits are set by hardware and cleared by the software writing a one to the particular bit position. Writing a zero to any bit position has no effect.

Table 24-19. Offset 00h: HSTS: Host Status Register (Sheet 1 of 2)

| Description: |                   |   |                             |                                      |            |
|--------------|-------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: SM_BASE (IO) |   | Bus:Device:Function: 0:31:3 | Offset Start: 00h<br>Offset End: 00h |            |
| Size: 8 bit  | Default: 00h      |   |                             | Power Well: Resume                   |            |
| Bit Range    | Bit Acronym       | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 07           | BDS               | <p><b>BYTE_DONE_STS:</b><br/>           0 = Software can clear this by writing a 1<br/>           1 = Host controller received a byte (for Block Read commands) or if it has completed transmission of a byte (for Block Write commands) when the 32-byte buffer is not being used. This bit is set, even on the last byte of the transfer. This bit is not set when transmission is due to the LAN interface heartbeat.</p> <p>This bit has no meaning for block transfers when the 32-byte buffer is enabled.</p> <p>When the last byte of a block message is received, the host controller sets this bit. However, it does not immediately set the INTR bit (bit 1 in this register). When the interrupt handler clears the BYTE_DONE_STS bit, the message is considered complete, and the host controller will then set the INTR bit (and generate another interrupt). Thus, for a block message of n bytes, n+1 interrupts will be generated. The interrupt handler needs to be implemented to handle these cases.</p> |                             | 0h                                   | RWC        |
| 06           | IUS               | <p><b>In Use Status:</b><br/>           0 = After a full PCI reset, a read to this bit returns a 0.<br/>           1 = After the first read, subsequent reads return a 1. A write of a 1 to this bit resets the next read value to 0. Writing a 0 to this bit has no effect. Software can poll this bit until it reads a 0, and then own the usage of the host controller.</p> <p>This bit has no other effect on the hardware, and is only used as semaphore among various independent software threads that may need to use the SMBus logic.</p>  |                             | 0h                                   | RW         |
| 05           | SMBALERT_STS      | <p><b>System Bus Alert Status:</b><br/>           0 = Interrupt or SMI# was not generated by SMBALERT#. Software clears this bit by writing a 1 to it.<br/>           1 = The source of the interrupt or SMI# was the SMBALERT# signal. This bit is only cleared by software writing a 1 to the bit position or by CF9 RESET or RSMRST# going low (but not PLTRST#).</p> <p>If the signal is programmed as a GPI, then this bit is never set.</p>   |                             | 0h                                   | RWC        |

| 05           | LAST_BYTE         | <p>Used for I<sup>2</sup>C Read commands as an indication that the next byte is the last one to be received for that block. The algorithm and usage model for this bit is as follows (assume a message of n bytes):</p> <ol style="list-style-type: none"> <li>1. When the software sees the BYTE_DONE_STS bit set (bit 7 in the SMBus Host Status Register) for each of bytes 1 through n-2 of the message, the software should then read the Block Data Byte Register to get the byte that was just received.</li> <li>2. After reading each of bytes 1 to n-2 of the message, the software will then clear the BYTE_DONE_STS bit.</li> <li>3. After receiving byte n-1 of the message, the software will then set the "LAST BYTE" bit. The software will then clear the BYTE_DONE_STS bit.</li> <li>4. The CMI then receives the last byte of the message (byte n). However, the state machine sees the LAST BYTE bit set, and instead of sending an ACK after receiving the last byte, it instead sends a NAK.</li> <li>5. After receiving the last byte (byte n), the software still clears the BYTE_DONE_STS bit. However, the LAST_BYTE bit is irrelevant at that point.</li> </ol> <p><b>Notes:</b></p> <ol style="list-style-type: none"> <li>1. This bit may be set when the TCO timer causes the SECOND_TO_STS bit to be set. See section <a href="#">Section 18.2.2.6</a>, bit 1 for more details on that bit. The SMBus device driver should clear the LAST_BYTE bit (if it is set) before starting any new command.</li> <li>2. In addition to I2C Read Commands, the LAST_BYTE bit also causes Block Read/Write cycles to stop prematurely (at the end of the next byte).</li> </ol> |                             | 0h                                   | RW         |

### 24.3.1.7 Offset 07h: HBD: Host Block Data Register

Table 24-25. Offset 07h: HBD: Host Block Data Register

| Description: |                   |  |                             |                                      |            |
|--------------|-------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: SM_BASE (IO) |  | Bus:Device:Function: 0:31:3 | Offset Start: 07h<br>Offset End: 07h |            |
| Size: 8 bit  | Default: 00h      |  |                             | Power Well: Resume                   |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 07 : 00      | BDTA              | <p><b>Block Data:</b> This is either a register, or a pointer into a 32-byte block array, depending upon whether the E32B bit is set in the Auxiliary Control register. When the E32B bit is cleared, this is a register containing a byte of data to be sent on a block write or read from on a block read.</p> <p>When the E32B bit is set, reads and writes to this register are used to access the 32-byte block data storage array. An internal index pointer is used to address the array, which is reset to 0 by reading the HCTL register (offset 02h). The index pointer then increments automatically upon each access to this register. The transfer of block data into (read) or out of (write) this storage array during an SMBus transaction always starts at index address 0.</p> <p>When the E2B bit is set, for writes, software will write up to 32-bytes to this register as part of the setup for the command. After the Host Controller has sent the Address, Command, and Byte Count fields, it will send the bytes in the SRAM pointed to by this register. When the E2B bit is cleared for writes, software will place a single byte in this register. After the host controller has sent the address, command, and byte count fields, it will send the byte in this register. If there is more data to send, software will write the next series of bytes to the SRAM pointed to by this register and clear the DONE_STS bit. The controller will then send the next byte. During the time between the last byte being transmitted to the next byte being transmitted, the controller will insert wait-states on the interface.</p> <p>When the E2B bit is set for reads, after receiving the byte count into the Data0 register, the first series of data bytes go into the SRAM pointed to by this register. If the byte count has been exhausted or the 32-byte SRAM has been filled, the controller will generate an SMI# or interrupt (depending on configuration) and set the DONE_STS bit. Software will then read the data. During the time between when the last byte is read from the SRAM to when the DONE_STS bit is cleared, the controller will insert wait-states on the interface. This eight bit register is transmitted in the DATA1 field of the SMB protocol during the execution of any command.</p> |                             | 00h                                  | RW         |

### 24.3.1.8 Offset 08h: PEC: Packet Error Check Data Register

This register contains the 8-bit CRC value that is used as the Packet Error Check on SMBus. For writes, this register is written by software prior to running the command. For reads, this register is read by software after the read command is completed on SMBus.

**Table 24-26. Offset 08h: PEC: Packet Error Check Data Register**

| Description: |                   |   |                             |                                      |            |

## 24.4 Host Controller

### 24.4.1 Overview

The SMB Host Controller is used to send commands to other SMB slave devices. Software sets up the host controller with an address, command, and for writes, data and optionally PEC; and then tells the controller to start. When the controller has finished transmitting data on writes, or receiving data on reads, it generates an SMI# or interrupt, if enabled.

The host controller supports eight command protocols of the SMB interface (see the *System Management Bus (SMBus) Specification, Version 2.0*): Quick Command, Send Byte, Receive Byte, Write Byte/Word, Read Byte/Word, Process Call, Block Read, Block Write and Block write-block read process call.

The SMB Host Controller requires that the various data and command fields be setup for the type of command to be sent. When software sets the START bit, the SMB Host Controller performs the requested transaction and interrupt the processor (or generate an SMI#) when its finished. Once a START command has been issued, the values of the "active registers" (Host Control, Host Command, Transmit Slave Address, Data0, Data1) should not be changed or read until the interrupt status bit (INTR) has been set (indicating the completion of the command). Any register values needed for computation purposes should be saved prior to issuing of a new command, as the SMB Host Controller will update all registers while completing the new command.

The CMI supports slave functionality, including the Host Notify protocol, on the SMLink pins when in TCO compatible mode. Therefore, in order to be fully compliant with the *SMBus Specification* (which requires the Host Notify cycle), the SMLink and SMBus signals must be tied together externally.

Using the SMB Host Controller to send commands to the SMB slave port is not supported.

### 24.4.2 Command Protocols

In all of the following commands, the Host Status Register (offset 00h) is used to determine the progress of the command. While the command is in operation, the HOST\_BUSY bit is set. If the command completes successfully, the INTR bit is set in the Host Status Register. If the device does not respond with an acknowledge, and the transaction times out, the DEV\_ERR bit is set. If software sets the KILL bit in the Host Control Register while the command is running, the transaction stops and the FAILED bit is set after the CMI forces a timeout. In addition, if the KILL bit is set during the CRC cycle, both the CRCE and DEV\_ERR bits are also set. When the KILL bit is set, the CMI aborts current transaction by asserting SMBCLK low for greater than the timeout period, asserts a STOP condition and then releases SMBCLK and SMBDATA. However, setting the KILL bit does not affect SMLINK or TCO transactions or causes the CMI to force a timeout if it is not performing a transaction.

#### 24.4.2.1 Quick Command

When programmed for a quick command, the Transmit Slave Address Register is sent. [Table 24-31](#) shows the order. The PEC byte is never appended to the Quick Protocol. Software must force the PEC\_EN bit to '0' when performing the Quick Command for possible future enhancements. Also, Quick Command with I2C\_EN set produces undefined results. Software must force the I2C\_EN bit to 0 when running this command.

Table 24-31. Quick Protocol

| Bit | Description            |
|-----|------------------------|
| 1   | Start Condition        |
| 2–8 | Slave Address - 7 bits |
| 9   | Read / Write Direction |
| 10  | Acknowledge from slave |
| 11  | Stop                   |

#### 24.4.2.2 Send Byte/Receive Byte

For the send byte command, the Transmit Slave Address and Device Command Registers are sent.

The Receive Byte is similar to a Send Byte, the only difference is the direction of data transfer. When programmed for the receive byte command, the Transmit Slave Address Register is sent. The data received is stored in the DATA0 register. The order sent/received without PEC is shown in Table 24-32. Send Byte/Receive Byte command with I2C\_EN set produces undefined results. Software must force the I2C\_EN bit to 0 when running this command.

Table 24-32. Send/Receive Byte Protocol without PEC

| Send Byte Protocol |                        | Receive Byte Protocol |                        |
|--------------------|------------------------|-----------------------|------------------------|
| Bit                | Description            | Bit                   | Description            |
| 1                  | Start                  | 1                     | Start                  |
| 2 – 8              | Slave Address - 7 bits | 2 – 8                 | Slave Address - 7 bits |
| 9                  | Write                  | 9                     | Read                   |
| 10                 | Acknowledge from slave | 10                    | Acknowledge from slave |
| 11 – 18            | Command code - 8 bits  | 11 – 18               | Data byte from slave   |
| 19                 | Acknowledge from slave | 19                    | NOT Acknowledge        |
| 20                 | Stop                   | 20                    | Stop                   |

The order sent/received, with PEC, is shown in Table 24-33.

Table 24-33. PEC Send/Receive Order

| Send Byte Protocol |                        | Receive Byte Protocol |                        |
|--------------------|------------------------|-----------------------|------------------------|
| Bit                | Description            | Bit                   | Description            |
| 1                  | Start                  | 1                     | Start                  |
| 2 – 8              | Slave Address - 7 bits | 2 – 8                 | Slave Address - 7 bits |
| 9                  | Write                  | 9                     | Read                   |
| 10                 | Acknowledge from slave | 10                    | Acknowledge from slave |
| 11 – 18            | Command code - 8 bits  | 11 – 18               | Data byte from slave   |
| 19                 | Acknowledge from slave | 19                    | Acknowledge            |
| 20 – 27            | PEC                    | 20 – 27               | PEC from slave         |
| 28                 | Acknowledge from slave | 28                    | Not Acknowledge        |
| 29                 | Stop                   | 29                    | Stop                   |

### 24.4.2.3 Write Byte/Word

The first byte of a write byte/word access is the command code. The next one or two bytes are the data to be written. When programmed for a write byte/word command, the Transmit Slave Address, device command, and Data0 Registers are sent. In addition, the Data1 Register is sent on a write word command. The order of bits without PEC is shown in Table 24-34. Issuing a write byte/word command with I2C\_EN set produces undefined results. Software must force the I2C\_EN bit to 0 when running this command.

The order of bits with PEC is shown in Table 24-35.

**Table 24-34. Write Byte/Word Protocol Without PEC**

| Write Byte Protocol |                        | Write Word Protocol |                         |
|---------------------|------------------------|---------------------|-------------------------|
| Bit                 | Description            | Bit                 | Description             |
| 1                   | Start                  | 1                   | Start                   |
| 2 – 8               | Slave Address - 7 bits | 2 – 8               | Slave Address - 7 bits  |
| 9                   | Write                  | 9                   | Write                   |
| 10                  | Acknowledge from slave | 10                  | Acknowledge from slave  |
| 11 – 18             | Command code - 8 bits  | 11 – 18             | Command code - 8 bits   |
| 19                  | Acknowledge from slave | 19                  | Acknowledge from slave  |
| 20 – 27             | Data Byte - 8 bits     | 20 – 27             | Data Byte Low - 8 bits  |
| 28                  | Acknowledge from Slave | 28                  | Acknowledge from Slave  |
| 29                  | Stop                   | 29 – 36             | Data Byte High - 8 bits |
|                     |                        | 37                  | Acknowledge from slave  |
|                     |                        | 38                  | Stop                    |

**Table 24-35. PEC Bit Order**

| Write Byte Protocol |                        | Write Word Protocol |                         |
|---------------------|------------------------|---------------------|-------------------------|
| Bit                 | Description            | Bit                 | Description             |
| 1                   | Start                  | 1                   | Start                   |
| 2 – 8               | Slave Address - 7 bits | 2 – 8               | Slave Address - 7 bits  |
| 9                   | Write                  | 9                   | Write                   |
| 10                  | Acknowledge from slave | 10                  | Acknowledge from slave  |
| 11 – 18             | Command code - 8 bits  | 11 – 18             | Command code - 8 bits   |
| 19                  | Acknowledge from slave | 19                  | Acknowledge from slave  |
| 20 – 27             | Data Byte - 8 bits     | 20 – 27             | Data Byte Low - 8 bits  |
| 28                  | Acknowledge from Slave | 28                  | Acknowledge from Slave  |
| 29 – 36             | PEC                    | 29 – 36             | Data Byte High - 8 bits |
| 37                  | Acknowledge from Slave | 37                  | Acknowledge from slave  |
| 38                  | Stop                   | 38 – 45             | PEC                     |
|                     |                        | 46                  | Acknowledge from slave  |
|                     |                        | 47                  | Stop                    |

#### 24.4.2.4 Read Byte/Word

Reading data is slightly more complicated than writing data. First a command to the slave device must be written. Then it must follow that command with a repeated start condition to denote a read from that device's address. The slave then returns one or two bytes of data.

When programmed for the read byte/word command, the transmit slave address and device command registers are sent. Data is received into the DATA0 on the read byte, and the DAT0 and DATA1 registers on the read word. The order sent and received with PEC disabled is shown in [Table 24-36](#).

Read byte/word command with I2C\_EN set produces undefined results. Software must force the I2C\_EN bit to 0 when running this command.

**Table 24-36. Read Byte/Word Protocol without PEC**

| Read Byte Protocol |                          | Read Word Protocol |                                    |
|--------------------|--------------------------|--------------------|------------------------------------|
| Bit                | Description              | Bit                | Description                        |
| 1                  | Start                    | 1                  | Start                              |
| 2 – 8              | Slave Address - 7 bits   | 2 – 8              | Slave Address - 7 bits             |
| 9                  | Write                    | 9                  | Write                              |
| 10                 | Acknowledge from slave   | 10                 | Acknowledge from slave             |
| 11 – 18            | Command code - 8 bits    | 11 – 18            | Command code - 8 bits              |
| 19                 | Acknowledge from slave   | 19                 | Acknowledge from slave             |
| 20                 | Repeated Start           | 20                 | Repeated Start                     |
| 21 – 27            | Slave Address - 7 bits   | 21 – 27            | Slave Address - 7 bits             |
| 28                 | Read                     | 28                 | Read                               |
| 29                 | Acknowledge from slave   | 29                 | Acknowledge from slave             |
| 30 – 37            | Data from slave - 8 bits | 30 – 37            | Data Byte Low from slave - 8 bits  |
| 38                 | NOT acknowledge          | 38                 | Acknowledge                        |
| 39                 | Stop                     | 39 – 46            | Data Byte High from slave - 8 bits |
|                    |                          | 47                 | NOT acknowledge                    |
|                    |                          | 48                 | Stop                               |

The order sent and received with PEC enabled is shown in [Table 24-37](#).

**Table 24-37. Read Byte/Word Protocol with PEC**

| Read Byte Protocol |                        | Read Word Protocol |                        |
|--------------------|------------------------|--------------------|------------------------|
| Bit                | Description            | Bit                | Description            |
| 1                  | Start                  | 1                  | Start                  |
| 2 – 8              | Slave Address - 7 bits | 2 – 8              | Slave Address - 7 bits |
| 9                  | Write                  | 9                  | Write                  |
| 10                 | Acknowledge from slave | 10                 | Acknowledge from slave |
| 11 – 18            | Command code - 8 bits  | 11 – 18            | Command code - 8 bits  |
| 19                 | Acknowledge from slave | 19                 | Acknowledge from slave |
| 20                 | Repeated Start         | 20                 | Repeated Start         |
| 21 – 27            | Slave Address - 7 bits | 21 – 27            | Slave Address - 7 bits |

Table 24-37. Read Byte/Word Protocol with PEC

|         |                          |         |                                    |
|---------|--------------------------|---------|------------------------------------|
| 28      | Read                     | 28      | Read                               |
| 29      | Acknowledge from slave   | 29      | Acknowledge from slave             |
| 30 – 37 | Data from slave - 8 bits | 30 – 37 | Data Byte Low from slave - 8 bits  |
| 38      | Acknowledge              | 38      | Acknowledge                        |
| 39 – 46 | PEC from slave           | 39 – 46 | Data Byte High from slave - 8 bits |
| 47      | NOT acknowledge          | 47      | Acknowledge                        |
| 48      | Stop                     | 48 – 55 | PEC from slave                     |
|         |                          | 56      | NOT acknowledge                    |
|         |                          | 57      | Stop                               |

#### 24.4.2.5 Process Call

The process call is named because a command sends data and waits for the slave to return a value dependent on that data. The protocol is simply a write word followed by a read word, but without a second command or stop condition.

When programmed for the process call command, the CMI transmits the transmit address, device command, and DATA0 and DATA1 registers. Data received from the device is stored in the DATA0 and DATA1 registers. The value written into bit 0 of the Transmit Slave Address Register (SMBus Offset 04h) needs to be programmed to 0.

*Note:*

If the I2C\_EN bit is set, then the command field is not sent.

The order sent with PEC disabled is shown in Table 24-38. The process call command with I2C\_EN set and either the PEC\_EN or AAC bit set produces undefined results. Software must either force the I2C\_EN bit or both PEC\_EN and AAC bits to 0 when running this command.

Table 24-38. Process Call Protocol without PEC

| Bit     | Description                                    |
|---------|--|
| 1       | Start  |
| 2 – 8   | Slave Address - 7 bits                         |
| 9       | Write  |
| 10      | Acknowledge from Slave                         |
| 11 – 18 | Command code - 8 bits (Skip if I2C_EN is set)  |
| 19      | Acknowledge from slave (Skip if I2C_EN is set) |
| 20 – 27 | Data byte Low - 8 bits                         |
| 28      | Acknowledge from Slave                         |
| 29 – 36 | Data Byte High - 8 bits                        |
| 37      | Acknowledge from slave                         |
| 38      | Repeated Start                                 |
| 39 – 45 | Slave Address - 7 bits                         |
| 46      | Read   |
| 47      | Acknowledge from slave                         |
| 48 – 55 | Data Byte Low from slave - 8 bits              |
| 56      | Acknowledge                                    |

**Table 24-38. Process Call Protocol without PEC**

|         |                                    |
|---------|------------------------------------|
| 57 – 64 | Data Byte High from slave - 8 bits |
| 65      | NOT acknowledge                    |
| 66      | Stop                               |

The order sent with PEC enabled is shown in [Table 24-39](#).

**Table 24-39. Process Call Protocol with PEC**

| Bit     | Description                        |
|---------|------------------------------------|
| 1       | Start                              |
| 2 – 8   | Slave Address - 7 bits             |
| 9       | Write                              |
| 10      | Acknowledge from Slave             |
| 11 – 18 | Command code - 8 bits              |
| 19      | Acknowledge from slave             |
| 20 – 27 | Data byte Low - 8 bits             |
| 28      | Acknowledge from Slave             |
| 29 – 36 | Data Byte High - 8 bits            |
| 37      | Acknowledge from slave             |
| 38      | Repeated Start                     |
| 39 – 45 | Slave Address - 7 bits             |
| 46      | Read                               |
| 47      | Acknowledge from slave             |
| 48 – 55 | Data Byte Low from slave - 8 bits  |
| 56      | Acknowledge                        |
| 57 – 64 | Data Byte High from slave - 8 bits |
| 65      | Acknowledge                        |
| 66 – 73 | PEC from slave                     |
| 74      | NOT acknowledge                    |
| 75      | Stop                               |

#### 24.4.2.6 Block Read/Write

The CMI contains a 32-byte buffer for read and write data which can be enabled by setting bit '1' of the Auxiliary Control register at offset 0Dh in I/O space, as opposed to a single byte of buffering. This 32-byte buffer is filled with write data before transmission and filled with read data on reception. In the CMI, the interrupt is generated only after a transmission or reception of 32 bytes, or when the entire byte count has been transmitted/received.

The block write command with I2C\_EN set and either the PEC\_EN or AAC bit set produces undefined results. Software must either force the I2C\_EN bit or both PEC\_EN and AAC bits to 0 when running this command.

**24.4.2.6.1 SM Bus Mode**

The block write begins with a slave address and a write condition. After the command code the CMI issues a byte count describing how many more bytes will follow in the message. If a slave had 20 bytes to send, the first byte would be the number 20 (14h), followed by 20 bytes of data. The byte count may not be 0. A block read or write is allowed to transfer a maximum of 32 data bytes.

When programmed for a block write command, the transmit slave address, device command, and Data0 (count) registers are sent. Data is then sent from the Block Data Byte register; the total data sent being the value stored in the Data0 Register. On block read commands, the first byte received is stored in the Data0 register, and the remaining bytes are stored in the Block Data Byte register.

**24.4.2.6.2 I<sup>2</sup>C Mode**

The format of the command changes slightly for block commands if the I2C\_EN bit is set. The CMI still sends the number of bytes (on writes) or receive the number of bytes (on reads) indicated in the DATA0 register. However, it does not send the contents of the DATA0 register as part of the message.

The format of the command changes slightly for a block write if the I2C\_EN bit is set. The CMI still sends the number of bytes indicated in the DATA0 register. However, it does not send the contents of the DATA0 register as part of the message.

The protocol for the block write and block read without PEC is shown in [Table 24-40](#).

**Table 24-40. Block Read/Write Protocol without PEC (Sheet 1 of 2)**

| Block Write Protocol |   | Block Read Protocol |                                   |
|----------------------|---|---------------------|-----------------------------------|
| Bit                  | Description   | Bit                 | Description                       |
| 1                    | Start   | 1                   | Start                             |
| 2 – 8                | Slave Address - 7 bits                                    | 2 – 8               | Slave Address - 7 bits            |
| 9                    | Write   | 9                   | Write                             |
| 10                   | Acknowledge from slave                                    | 10                  | Acknowledge from slave            |
| 11 – 18              | Command code - 8 bits                                     | 11 – 18             | Command code - 8 bits             |
| 19                   | Acknowledge from slave                                    | 19                  | Acknowledge from slave            |
| 20 – 27              | Byte Count - 8 bits (skip this step if I2C_EN bit set)    | 20                  | Repeated Start                    |
| 28                   | Acknowledge from Slave (skip this step if I2C_EN bit set) | 21 – 27             | Slave Address - 7 bits            |
| 29 – 36              | Data Byte 1 - 8 bits                                      | 28                  | Read                              |
| 37                   | Acknowledge from Slave                                    | 29                  | Acknowledge from slave            |
| 38 – 45              | Data Byte 2 - 8 bits                                      | 30 – 37             | Byte Count from slave - 8 bits    |
| 46                   | Acknowledge from slave                                    | 38                  | Acknowledge                       |
| ...                  | Data Bytes / Slave Acknowledges...                        | 39 – 46             | Data Byte 1 from slave - 8 bits   |
| ...                  | Data Byte N - 8 bits                                      | 47                  | Acknowledge                       |
| ...                  | Acknowledge from Slave                                    | 48 – 55             | Data Byte 2 from slave - 8 bits   |
| ...                  | Stop  | 56                  | Acknowledge                       |
|                      |   | ...                 | Data Bytes from slave/Acknowledge |

**Table 24-40. Block Read/Write Protocol without PEC (Sheet 2 of 2)**

|  |  |     |                                 |
|--|--|-----|---------------------------------|
|  |  | ... | Data Byte N from slave - 8 bits |
|  |  | ... | NOT Acknowledge                 |
|  |  | ... | Stop                            |

The protocol for the block write and block read with PEC is shown in [Table 24-41](#).

The block write command with I2C\_EN set and the PEC\_EN bit set produces undefined results. Software must force the PEC\_EN bit to 0 when running this command.

**Table 24-41. Block Read/Write Protocol with PEC**

| Block Write Protocol |                                    | Block Read Protocol |                                   |
|----------------------|------------------------------------|---------------------|-----------------------------------|
| Bit                  | Description                        | Bit                 | Description                       |
| 1                    | Start                              | 1                   | Start                             |
| 2 – 8                | Slave Address - 7 bits             | 2 – 8               | Slave Address - 7 bits            |
| 9                    | Write                              | 9                   | Write                             |
| 10                   | Acknowledge from slave             | 10                  | Acknowledge from slave            |
| 11 – 18              | Command code - 8 bits              | 11 – 18             | Command code - 8 bits             |

| ...                  | Data Byte N - 8 bits               | 47                  | Acknowledge                       |
| ...                  | Acknowledge from Slave             | 48 – 55             | Data Byte 2 from slave - 8 bits   |
| ...                  | PEC – 8 bits                       | 56                  | Acknowledge                       |
| ...                  | Acknowledge from Slave             | ...                 | Data Bytes from slave/Acknowledge |
| ...                  | Stop                               | ...                 | Data Byte N from slave - 8 bits   |
|                      |                                    | ...                 | Acknowledge                       |
|                      |                                    | ...                 | PEC from slave – 8 bits           |
|                      |                                    | ...                 | NOT Acknowledge                   |
|                      |                                    | ...                 | Stop                              |

**24.4.2.7 I<sup>2</sup>C Read**

This command allows the CMI to perform block reads to certain I2C devices, such as serial E2PROMs. The SMBus Block Read supports the 7-bit addressing mode only. However this doesn't allow access to devices that need to use the I<sup>2</sup>C "Combined Format" that has data bytes after the address. Typically these data bytes correspond to an offset (address) within the serial memory chips.

The I<sup>2</sup>C Read command with either PEC\_EN or AAC bit set produces undefined results. Software must force both PEC\_EN and AAC bits to 0 when running this command.

To support these devices, the CMI implements an I<sup>2</sup>C Read command with the following format:

| Bit     | Description                       |
|---------|-----------------------------------|
| 1       | Start                             |
| 2 – 8   | Slave Address - 7 bits            |
| 9       | Write                             |
| 10      | Acknowledge from slave            |
| 11 – 18 | Send DATA1 register               |
| 19      | Acknowledge from slave            |
| 20      | Repeated Start                    |
| 21 – 27 | Slave Address - 7 bits            |
| 28      | Read                              |
| 29      | Acknowledge from slave            |
| 30 – 37 | Data Byte 1 from slave - 8 bits   |
| 38      | Acknowledge                       |
| 39 – 46 | Data Byte 2 from slave - 8 bits   |
| 47      | Acknowledge                       |
| ...     | Data Bytes from slave/Acknowledge |
| ...     | Data Byte N from slave - 8 bits   |
| ...     | NOT Acknowledge                   |
| ...     | Stop                              |

The CMI continues reading data from the peripheral until the NAK is received.

*Note:* This new command is supported independent of the setting of the I2C\_EN bit.

*Note:* The value written into bit 0 of the Transmit Slave Address register (SMBus Offset 04h) must be 0.

#### 24.4.2.8 Block Write-Block Read Process Call

The block write-block read process call is a two-part message. The call begins with a slave address and a write condition. After the command code the host issues a write byte count (M) that describes how many more bytes will be written in the first part of the message. If a master has six bytes to send, the byte count field will have the value 6 (0000 0110b), followed by the six bytes of data. The write byte count (M) cannot be zero.

The second part of the message is a block of read data beginning with a repeated start condition followed by the slave address and a read bit. The next byte is the read byte count (N), which may differ from the write byte count (M). The read byte count (N) cannot be zero.

The combined data payload must not exceed 32 bytes. The byte length restrictions of this process call are summarized as follows:

- $M \geq 1$  byte
- $N \geq 1$  byte
- $M + N \leq 32$  bytes

The read byte count does not include the PEC byte. The PEC is computed on the total message beginning with the first slave address and using the normal PEC computational rules. It is highly recommended that a PEC byte be used with the block write-block read process call. Software must do a read to the command register (offset 2h) to reset the 32 byte buffer pointer prior to reading the block data register.

*Note:* There is no STOP condition before the repeated START condition, and that a NACK signifies the end of the read transfer.

*Note:* E32B in the Auxiliary Control register must be set when using this protocol.

**Table 24-42. Block Write-Block Read Process Call Protocol with/without PEC**

| Bit     | Description                              |
|---------|--|
| 1       | Start                                    |
| 2 – 8   | Slave Address - 7 bits                   |
| 9       | Write                                    |
| 10      | Acknowledge from Slave                   |
| 11 – 18 | Command code - 8 bits                    |
| 19      | Acknowledge from slave                   |
| 20 – 27 | Data Byte Count (M) - 8 bits             |
| 28      | Acknowledge from Slave                   |
| 29 – 36 | Data Byte (1) - 8 bits                   |
| 37      | Acknowledge from slave                   |
| 38 – 45 | Data Byte (2) - 8 bits                   |
| 46      | Acknowledge from slave                   |
| ...     | ...                                      |
|         | Data Byte (M) - 8 bits                   |
|         | Acknowledge from slave                   |
|         | Repeated Start                           |
|         | Slave Address - 7 bits                   |
|         | Read                                     |
|         | Acknowledge from slave                   |
|         | Data Byte Count (N) from slave – 8 bits  |
|         | Acknowledge from master                  |
|         | Data Byte (1) from slave – 8 bits        |
|         | Acknowledge from master                  |
|         | Data Byte (2) from slave – 8 bits        |
|         | Acknowledge from master                  |
| ...     | ...                                      |
|         | Data Byte Count (N) from slave – 8 bits  |
|         | Acknowledge from master (Skip if no PEC) |
|         | PEC from slave (Skip if no PEC)          |
|         | NOT acknowledge                          |
|         | Stop                                     |

### 24.4.3 I<sup>2</sup>C Behavior

When the I2C\_EN bit is set, the CMI SMBus logic is set to communicate with I<sup>2</sup>C devices. This forces the following changes:

1. The Process Call command skips the command code (and its associated acknowledge)
2. The Block Write command skips sending the byte count (DATA0)

In addition, the CMI supports the I<sup>2</sup>C Read command. This is independent of the I2C\_EN bit. When operating in I<sup>2</sup>C mode, (I2C\_EN bit set), the CMI never uses the 32-byte buffer for any block commands.

### 24.4.4 Heartbeat for Use with External LAN

This method allows the CMI to send messages to an External LAN controller when the processor is otherwise unable to do so. It uses the SMLink Interface between the CMI and external LAN controller in TCO compatible mode. The actual heartbeat message is a block write. Only eight bytes are sent.

See [Chapter 18.0, "System Management,"](#) for more details on the heartbeat packet format, and the specific bits sent in the packet.

## 24.5 Bus Arbitration

Several masters may attempt to get on the bus at the same time by driving the SMBDATA line low to signal a start condition. The CMI continuously monitors the SMBDATA line. When the CMI is attempting to drive the bus to a '1' by letting go of the SMBDATA line, and it samples SMBDATA low, then some other master is driving the bus and the CMI stops transferring data.

If the CMI detects loss of arbitration, the condition is called a collision. The CMI sets the BUS\_ERR bit in the Host Status register, and if enabled, generates an interrupt or SMI#. The processor is responsible for restarting the transaction.

## 24.6 Bus Timings

The SM Bus runs at between 10 – 100 kHz. Most of the timings associated with the SM Bus are microseconds in length. The SM Bus runs off of a divide by two of the RTC clock internally and employs counters of various length off of the RTC clock to drive the SM Bus.

When the CMI is a SM Bus master, it drives the clock. When the CMI is sending address or command as an SM Bus master, or data bytes as a master on writes, it will drive data relative to the clock it is also driving. It does not start toggling the clock until the start or stop condition meets proper setup and hold. The CMI also guarantees minimum time between SM Bus transactions as a master.

### 24.6.1 Clock Stretching

Some devices may not be able to handle their clock toggling at the rate that the CMI as an SM Bus master would like. They have the capability of stretching the low time of the clock. When the CMI attempts to release the clock (allowing the clock to go high), the clock remains low for an extended period of time.

The CMI monitors the SM Bus clock line after it releases the bus to determine whether to enable the counter for the high time of the clock. While the bus is still low, the high time counter must not be enabled. Similarly, the low period of the clock can be stretched by an SM Bus master if it is not ready to send or receive data.

## 24.6.2 Bus Time Out (CMI as SMB Master)

If there is an error in the transaction, such that an SMBus device does not signal an acknowledge, or holds the clock lower than the allowed time-out time, the transaction will time out. The CMI discards the cycle, and set the DEV\_ERR bit. The time out minimum is 25 ms. The time-out counter inside the CMI starts when the first bit of data is transferred by the CMI. The time-out minimum is 25 ms (800 RTC clocks).

The 25 ms timeout counter does not count under the following conditions:

1. BYTE\_DONE\_STATUS bit (SMBus I/O Offset 00h, bit 7) is set, and
2. The SECOND\_TO\_STS bit (TCO I/O Offset 06h, bit 1) is not set (this indicates that the system has not locked up).

## 24.7 Interrupts/SMI #

The CMI SM Bus controller uses PIRQB# as its interrupt pin. However, the system can alternatively be set up to generate SMI# instead of an interrupt, by setting the SMBUS\_SMI\_EN bit (Device 31, Function 0, Offset 40h, bit 1).

The following tables specify how the various enable bits in the SMBus function control the generation of the interrupt, Host and Slave SMI, and Wake internal signals. The rows in the tables are additive, which means that if more than one row is true for a particular scenario then the results for all of the activated rows occurs.

**Table 24-43. Summary of Enables for SMBALERT#**

| Event  | INTREN (Host Control I/O Register, Offset 02h, Bit 0) | SMB_SMI_EN (Host Configuration Register, D31, F3, Offset 40h, Bit 1) | SMBALERT_DIS (Slave Command I/O Register, Offset 11h, Bit 2) | Result                               |
|--|---|--|--|--------------------------------------|
| SMBALERT# asserted low (always reported in SMBALERT_STS-Host Status Register, bit 5) | X   | X  | X  | Wake generated                       |
|  | X   | 1  | 0  | Slave SMI# generated (SMBUS_SMI_STS) |
|  | 1   | 0  | 0  | Interrupt generated                  |

**Table 24-44. Summary of Enables for SMBus Slave Write, and SMBus Host Events**

| Event  | INTREN (Host Control I/O Register, Offset 02h, Bit 0) | SMB_SMI_EN (Host Configuration Register, D31, F3, Offset 40h, Bit 1) | Result  |
|--|---|--|---|
| Slave Write to Wake/SMI# command                         | X   | X  | Wake generated when asleep<br>Slave SMI# generated when awake (SMBUS_SMI_STS) |
| Slave Write to SMLINK_SLAVE_SMI command                  | X   | X  | Slave SMI# generated when in the S0 state (SMBUS_SMI_STS)                     |
| Any combination of Host Status Register [04:01] asserted | 0   | X  | None  |
|  | 1   | 0  | Interrupt generated   |
|  | 1   | 1  | Host SMI# generated   |

Table 24-45. Summary of Enables for the Host Notify Command

| HOST_NOTIFY_INTREN<br>(Slave Control I/O Register,<br>Offset 11h, bit 0) | SMB_SMI_EN (Host<br>Configuration Register,<br>D31, F3, Off40h, Bit 1) | HOST_NOTIFY_WKEN<br>(Slave Control I/O Register,<br>Offset 11h, bit 1) | Result                                  |
|--|--|--|---|
| 0  | X  | 0  | None                                    |
| X  | X  | 1  | Wake generated                          |
| 1  | 0  | X  | Interrupt generated                     |
| 1  | 1  | X  | Slave SMI# generated<br>(SMBUS_SMI_STS) |

## 24.8 CRC Generation and Checking

If the AAC bit is set in the Auxiliary Control register, the CMI automatically calculates and drives CRC at the end of the transmitted packet for write cycles, and checks the CRC for read cycles. It does not transmit the contents of the PEC register for CRC. The PEC bit must not be set in the Host Control register if this bit is set, or unspecified behavior results.

If the read cycle results in a CRC error, the DEV\_ERR bit and the CRCE bit in the Auxiliary Status register at offset 0Ch is set.

### 24.8.1 Slave Interface I/O Space

The following registers are used by the SMBus Slave logic. Refer to [Section 24.3](#) for the complete list of SMB I/O Registers.

Table 24-46. Bus 0, Device 31, Function 3, Slave PCI Registers Mapped Through SM\_Base (IO)

| Offset Start | Offset End | Register ID - Description                                      | Default Value |

| 17h          | 17h        | "Offset 17h: NDHB: Notify Data High Byte Register" on page 934 | 00h           |

## 24.8.2 Register Details

### 24.8.2.1 Offset 09h: RSA: Receive Slave Address Register

Table 24-47. Offset 09h: RSA: Receive Slave Address Register

| Description: |                   |   |                             |                                      |            |
|--------------|-------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: SM_BASE (IO) |   | Bus:Device:Function: 0:31:3 | Offset Start: 09h<br>Offset End: 09h |            |
| Size: 8 bit  | Default: 44h      |   |                             | Power Well: Resume                   |            |
| Bit Range    | Bit Acronym       | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 07           | Reserved          | Reserved  |                             | 0b                                   |            |
| 06 : 00      | RSA               | <b>SLAVE_ADDR[06:00]</b> : This field is the slave address that is decoded for read and write cycles. The default is not 0 so that it can respond even before the processor comes up (or if the processor is dead). This register is reset by CF9 RESET or RSMRST#, but not by PLTRST#. |                             | 1000100b                             | RW         |

### 24.8.2.2 Offset 0Ah: SD: Slave Data Register

Table 24-48. Offset 0Ah: SD: Slave Data Register

| Description: |                   |  |                             |                                      |            |
|--------------|-------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: SM_BASE (IO) |  | Bus:Device:Function: 0:31:3 | Offset Start: 0Ah<br>Offset End: 0Bh |            |
| Size: 16 bit | Default: 0000h    |  |                             | Power Well: Resume                   |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 15 : 00      | SD                | <b>SLAVE_DATA[15:00]</b> : This field is the 16-bit data value written by the external SMBus master. The processor can then read the value from this register. This register is reset by CF9 RESET or RSMRST#, but not by PLTRST#. SLAVE_DATA[07:00] corresponds to the Data Message Byte 0 (see Section 24.8.2.1) at Slave Write Register 4 in the table. SLAVE_[15:08] corresponds to the Data Message Byte 1 (see Section 24.8.2.1) at Slave Write Register 5 in the table. |                             | 0h                                   | RO         |

### 24.8.2.3 Offset 10h: SSTS: Slave Status Register

Table 24-49. Offset 10h: SSTS: Slave Status Register

| Description: |                   |  |                             |                                      |            |
|--------------|-------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: SM_BASE (IO) |  | Bus:Device:Function: 0:31:3 | Offset Start: 10h<br>Offset End: 10h |            |
| Size: 8 bit  | Default: 00h      |  |                             | Power Well: Resume <sup>a</sup>      |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 07 : 01      | Reserved          | Reserved   |                             | 0h                                   |            |
| 00           | HOST_NOTIFY_STS   | Software reads this bit to determine that the source of the interrupt or SMI# was the reception of the Host Notify Command. Software clears this bit after reading any information needed from the notify address and data registers by writing a 1 to this bit. The CMI allows the notify address and data registers to be overwritten once this bit has been cleared. When this bit is 1, the CMI will NACK the first byte (host address) of any new "Host Notify" commands on the SMLink. Writing a 0 to this bit has no effect<br>0 = Bit is clear, allows the notify address and data registers to be overwritten.<br>1 = This bit is set when the CMI has completely received a successful Host Notify Command on the SMLink pins. |                             | 0h                                   | RWC        |

a. This register is in the resume well and is reset by CF9 RESET or RSMRST#. All bits in this register are implemented in the 64 kHz clock domain. Therefore, software must poll the register until a write takes effect before assuming that a write has completed internally.

### 24.8.2.4 Offset 11h: SCMD: Slave Command Register

Table 24-50. Offset 11h: SCMD: Slave Command Register (Sheet 1 of 2)

| Description: |                   |  |                             |                                      |            |
|--------------|-------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: SM_BASE (IO) |  | Bus:Device:Function: 0:31:3 | Offset Start: 11h<br>Offset End: 11h |            |
| Size: 8 bit  | Default: 00h      |  |                             | Power Well: Resume <sup>a</sup>      |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 07 : 03      | Reserved          | Reserved   |                             | 00h                                  |            |
| 02           | SMBALERT_DIS      | 0 = Allows the generation of interrupt or SMI#.<br>1 = Software sets this bit to 1 to block the generation of the interrupt or SMI# due to the SMBALERT# source. This bit is logically inverted and ANDed with the SMBALERT_STS bit. The resulting signal is distributed to the SMI# and/or interrupt generation logic. This bit does not effect the wake logic. |                             | 0h                                   | RW         |
| 01           | HOST_NOTIFY_WKEN  | Software sets this bit to 1 to enable the reception of a Host Notify command as a wake event. When enabled this event is Ored with the other SMBus wake events and is reflected in the SMB_WAK_STS bit of the General Purpose Event 0 Status register.<br>0 = Disable<br>1 = Enable  |                             | 0h                                   | RW         |

Table 24-50. Offset 11h: SCMD: Slave Command Register (Sheet 2 of 2)

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: SM_BASE (IO)  |  | Bus:Device:Function: 0:31:3 | Offset Start: 11h<br>Offset End: 11h |            |
| Size: 8 bit  | Default: 00h       |  |                             | Power Well: Resume <sup>a</sup>      |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 00           | HOST_NOTIFY_INTREN | Software sets this bit to 1 to enable the generation of interrupt or SMI# when HOST_NOTIFY_STS is 1. This enable does not affect the setting of the HOST_NOTIFY_STS bit. When the interrupt is generated, either PIROB or SMI# is generated, depending on the value of the SMB_SMI_EN bit (D31, F3, Off40h, B1). If the HOST_NOTIFY_STS bit is set when this bit is written to a 1, then the interrupt (or SMI#) will be generated. The interrupt (or SMI#) is logically generated by ANDing the STS and INTREN bits.<br>0 = Disable<br>1 = Enable |                             | 0h                                   | RW         |

a. This register is in the resume well and is reset by CF9 RESET or RSMRST#. All bits in this register are implemented in the 64 kHz clock domain. Therefore, software must poll the register until a write takes effect before assuming that a write has completed internally.

#### 24.8.2.5 Offset 14h: NDA: Notify Device Address Register

This register is in the resume well and is reset by CF9 RESET or RSMRST#.

Table 24-51. Offset 14h: NDA: Notify Device Address Register

| Description: |                   |  |                             |                                      |            |
|--------------|-------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: SM_BASE (IO) |  | Bus:Device:Function: 0:31:3 | Offset Start: 14h<br>Offset End: 14h |            |

| 07 : 00            | DATA_HIGH_BYTE           | This field contains the second (high) byte of data received during the Host Notify protocol of the <i>SMBus Specification</i> . Software should only consider this field valid when the HOST_NOTIFY_STS bit is set to 1. |                                    | 00h  | RO         |

a. Reset by CF9 RESET or RSMRST#.

## 24.9 Slave Interface Behavioral Description

The SMBus slave logic does not generate or handle receiving the PEC byte. There is no ASF support.

The slave interface allows the CMI to decode cycles on SMLink in TCO compatible mode, and allows an external microcontroller to perform specific actions. Key features and capabilities:

- Supports decode of three types of messages: byte write, byte read, and host notify
- Register for the receive slave address. This is the address that the CMI decodes. A default value is provided so that the slave interface can be used without the processor having to program this register.
- Receive Slave Data register in the SMBus I/O space that includes the data written by the external microcontroller
- Registers that the external microcontroller can read to get the state
- Status bits to indicate that the SMLink/SMBus slave logic caused an interrupt or SMI#
  - Bit 0 of the slave status register for the host notify command
  - Bit 16 of the SMI Status Register for all others

**Note:** The external microcontroller should not attempt to access the SMBus slave logic until one second after both: RTEST# is high and RSMRST# is high.

If a master leaves the clock and data bits of the SMLink or SMBus interface at '1' for 50  $\mu$ s or more in the middle of a cycle, the slave logic's behavior is undefined. This is interpreted as an unexpected idle and should be avoided when performing management activities to the slave logic.

### 24.9.1 Format of Slave Write Cycle

The external master performs byte write commands to the SMBus Slave Interface. The Command field (bits 11 – 18) indicate which register is being accessed. The Data field (bits 20 – 27) indicate the value that should be written to that register.

The write cycle format is shown below in [Table 24-54](#). [Table 24-55](#) has the values associated with the registers.

**Table 24-54. Slave Write Cycle Format**

| Bit     | Description            | Driven By                | Comment  |
|---------|------------------------|--------------------------|--|
| 1       | Start Condition        | External Microcontroller |  |
| 2 – 8   | Slave Address - 7 bits | External Microcontroller | Must match value in Receive Slave Address register   |
| 9       | Write                  | External Microcontroller | Hardwired to 0   |
| 10      | ACK                    | CMI                      |  |
| 11 – 18 | Command                | External Microcontroller | This field indicates which register will be accessed. See <a href="#">Table 24-55</a> for the register definitions |
| 19      | ACK                    | CMI                      |  |
| 20 – 27 | Register Data          | External Microcontroller | See <a href="#">Table 24-55</a> for the register definitions   |
| 28      | ACK                    | CMI                      |  |
| 29      | Stop                   | External Microcontroller |  |

Table 24-55. Slave Write Registers

| Register | Function:  |
|----------|--|
| 0        | Command Register. See Table 24-56 for legal values written to this register. |
| 1 – 3    | Reserved   |
| 4        | Data Message Byte 0  |
| 5        | Data Message Byte 1  |
| 6 – 7    | Reserved   |
| 8        | Reserved   |
| 9 – FFh  | Reserved   |

**Note:** The external microcontroller is responsible to make sure that it does not update the contents of the data byte registers until they have been read by the system processor. The CMI overwrites the old value with any new value received. A race condition is possible where the new value is being written to the register just at the time it is being read. The CMI does not attempt to cover this race condition (i.e., unpredictable results in this case).

Table 24-56. Command Types

| Command Type | Description  |
|--------------|--|
| 0            | Reserved   |
| 1            | <b>WAKE/SMI#:</b> Wake system if it is not already awake. If system is already awake, then an SMI# is generated.   |
| 2            | <b>Unconditional Powerdown:</b> This command should set the PWRBTNOR_STS bit, and have the same effect as the power button override occurring.   |
| 3            | <b>HARD RESET Without Power Cycling SYSTEM:</b> The causes a soft reset of the system (does not include cycling of the power supply). This is equivalent to a write to the CF9h register with bits 02:01 set to 1, but bit 03 set to 0.  |
| 4            | <b>HARD RESET SYSTEM:</b> The causes a hard reset of the system (including cycling of the power supply). This is equivalent to a write to the CF9h register with bits 03:01 set to 1.  |
| 5            | <b>Disable the TCO Messages.</b> This command disables the IICH from sending Heartbeat and Event messages. Once this command has been done, there is no method to reenables the Heartbeat and Event messages, until CF9 RESET or RSMRST# goes low and then high.   |
| 6            | <b>WD RELOAD:</b> Reload watchdog timer.   |
| 7            | Reserved   |
| 8            | <b>SMLINK_SLAVE_SMI:</b> When the CMI detects this command type while in the S0 state, it will set the SMLINK_SLAVE_SMI_STS bit. This command should only be used if the system is in an S0 state. If the message is received during S3 or S5 states, it is acknowledged by the CMI but the SMLINK_SLAVE_SMI_STS bit is not set.<br><b>Note:</b> It is possible that the system transitions out of the S0 state at the same time that the SMLINK_SLAVE_SMI command is received. In this case, the SMLINK_SLAVE_SMI_STS bit may get set but not serviced before the system goes to sleep. Once the system returns to S0, the SMI associated with this bit would then be generated. Software must be able to handle this scenario. |
| 9 – FFh      | Reserved   |

### 24.9.2 Format of Read Command

The external master performs byte read commands to the SMBus Slave Interface. The Command field (bits 11-18) indicate which register is being accessed. The Data field (bits 30-37) indicate the value that should be read from that register. Table 24-57 shows the read cycle format. Table 24-58 shows the register mapping for the data byte.

Table 24-57. Slave Read Cycle Format

| Bit     | Description            | Driven by:               | Comment:   |
|---------|------------------------|--------------------------|--|
| 1       | Start                  | External Microcontroller |  |
| 2 – 8   | Slave Address - 7 bits | External Microcontroller | Must match value in Receive Slave Address register   |
| 9       | Write                  | External Microcontroller | Hardwired to 0   |
| 10      | ACK                    | CMI                      |  |
| 11 – 18 | Command code - 8 bits  | External Microcontroller | Indicates which register is being accessed. See Table 24-58 for list of implemented registers. |
| 19      | ACK                    | CMI                      |  |
| 20      | Repeated Start         | External Microcontroller |  |
| 21 – 27 | Slave Address - 7 bits | External Microcontroller | Must match value in Receive Slave Address register   |
| 28      | Read                   | External Microcontroller | Hardwired to 1   |
| 29      | ACK                    | CMI                      |  |
| 30 – 37 | Data Byte              | CMI                      | Value depends on register being accessed. See Table 24-58 for list of implemented registers.   |
| 38      | NOT ACK                | External Microcontroller |  |
| 39      | Stop                   | External Microcontroller |  |

Table 24-58. Data Values for Slave Read Registers (Sheet 1 of 2)

| Register | Bits  | Description  |
|----------|-------|--|
| 0        | 07:00 | Reserved for capabilities indication. Should always return 00h. Future chips may return another value to indicate different capabilities.                                    |
| 1        | 02:00 | System Power State<br>000 = S0<br>001 = Reserved<br>010 = Reserved<br>011 = S3<br>100 = Reserved<br>101 = S5<br>110 = Reserved<br>111 = Reserved                             |
|          | 07:03 | Reserved   |
| 2        | 03:00 | Reserved   |
|          | 07:04 | Reserved   |
| 3        | 05:00 | Watchdog Timer current value. Watchdog Timer has 10 bits, but this field is only 6 bits. If the current value is greater than 3Fh, the CMI always reports 3Fh in this field. |
|          | 07:06 | Reserved   |

Table 24-58. Data Values for Slave Read Registers (Sheet 2 of 2)

| Register | Bits  | Description   |
|----------|-------|---|
| 4        | 00    | 1 = The Intruder Detect (INTRD_DET) bit is set. This indicates that the system cover has been opened.   |
|          | 01    | 1 = BTI Temperature Event occurred. This bit is set if the CMI's PROCHOT# input signal is active. Need to take after polarity control.  |
|          | 02    | DOA processor Status. This bit is 1 to indicate that the processor is dead.   |
|          | 03    | 1 = SECOND_TO_STS bit set. This bit is set after the second timeout (SECOND_TO_STS bit) of the Watchdog Timer occurs.   |
|          | 06:04 | Reserved. Will always be 0, but software should ignore.   |
|          | 07    | Reflects the value of the GPI[11]/SMBALERT# pin (and is dependent upon the value of the GPI_INV[11] bit. If the GPI_INV[11] bit is 1, then the value in this bit equals the level of the GPI[11]/SMBALERT# pin (high = 1, low = 0). If the GPI_INV[11] bit is 0, then the value of this bit equals the inverse of the level of the GPI[11]/SMBALERT# pin (high = 0, low = 1). |
| 5        | 00    | FWH bad bit. This bit is 1 to indicate that the FWH read returned FFh, which indicates that it is probably blank.   |
|          | 01    | Battery Low Status. '1' if the BATLOW# pin is a '0'.  |
|          | 02    | CPU Power Failure Status: '1' if the CPUPWR_FLR bit in the GEN_PMCON_2 register is set.   |
|          | 07:01 | Reserved  |
| 6        | 07:00 | Contents of the Message 1 register. See <a href="#">Section 18.2.2.8</a> for details.   |
| 7        | 07:00 | Contents of the Message 2 register. See <a href="#">Section 18.2.2.8</a> for details.   |
| 8        | 07:00 | Contents of the WDSTATUS register. See <a href="#">Section 18.2.2.9</a> for details.  |
| 9        | 07:00 | Contents of the SATA SGPIO Control Register (bits 07:00). See <a href="#">Section 48.3.3.1</a> for details.   |
| A        | 07:00 | Contents of the SATA SGPIO Control Register (bits 15:08). See <a href="#">Section 48.3.3.1</a> for details.   |
| B        | 07:00 | Contents of the SATA SGPIO Control Register (bits 23:16). See <a href="#">Section 48.3.3.1</a> for details.   |
| C – FFh  | 07:00 | Reserved  |

**Warning:** The external microcontroller is responsible to make sure that it does not read the contents of the various message registers until they have been written by the system processor. The CMI overwrites the old value with any new value received. A race condition is possible where the new value is being written to the register just at the time it is being read. The CMI does not attempt to cover this race condition (i.e., unpredictable results in this case).

#### Behavioral Notes:

The SMBus protocol always has either start bit-address-write bit or repeated start bit-address-read bit. The CMI is implemented such that the read/write bit in the repeated start phase is ignored with an assumption that the protocol always followed. In other words, if start-address-read occurs (which is illegal for SMBus byte read protocol), the CMI still grabs the cycle. In another case, if a repeated start-address-write sequence occurs, then the cycle continues as a slave read.

### 24.9.3 Format of the Host Notify Command

The CMI tracks and responds to the standard Host Notify command as specified in the *SMBus Specification*. The host address for this command is fixed to 0001000b. If the CMI already has data for a previously-received host notify command which has not been serviced yet by the host software (as indicated by the HOST\_NOTIFY\_STS bit), then it will NACK following the host address byte of the protocol. This allows the host to communicate non-acceptance to the master and retain the host notify address and data values for the previous cycle until host software completely services the interrupt.

**Note:** Host software must always clear the HOST\_NOTIFY\_STS bit *after* completing any necessary reads of the address and data registers.

Table 24-59 shows the host notify protocol.

**Table 24-59. Host Notify Protocol**

| Bit     | Description             | Driven by:      | Comment:   |
|---------|-------------------------|-----------------|--|
| 1       | Start                   | External Master |  |
| 2 – 8   | SMB Host Addr - 7 bits  | External Master | Always 0001_000  |
| 9       | Write                   | External Master | Hardwired to 0   |
| 10      | ACK (or NACK)           | CMI             | The CMI NACKs if HOST_NOTIFY_STS is 1  |
| 11 – 17 | Device Address - 7 bits | External Master | Indicates the address of the master; loaded in to the Notify Device Address Register |
| 18      | Unused- Hardwired to 0  | External Master | 7-bit-only address; this bit is inserted to complete the byte                        |
| 19      | ACK                     | CMI             |  |
| 20 – 27 | Data Byte Low           | External Master | Loaded in to the Notify Data Low Byte Register                                       |
| 28      | ACK                     | CMI             |  |
| 29 – 36 | Data Byte High          | External Master | Loaded in to the Notify Data High Byte Register                                      |
| 37      | ACK                     | CMI             |  |
| 38      | Stop                    | External Master |  |

## 25.0 USB (1.1) Controller: Bus 0, Device 29, Function 0

### 25.1 USB (1.1) Controller Configuration Register Details

**Note:** Reserved bits are read only.

**Warning:** Address locations that are not listed are considered reserved register locations and are read only. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure and unpredictable results.

**Table 25-1. Bus 0, Device 29, Functions 0, Summary of USB (1.1) Controller PCI Configuration Registers**

| Offset Start | Offset End | Register ID - Description   | Default Value |

**25.1.1.4 RID - Revision ID Register**

The value reported in this register depends on the value written to the Revision ID in Device 31, Function 0, Offset 08h.

**Table 25-5. RID - Revision ID Register**

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:29:0 | Offset Start: 08h<br>Offset End: 08h |            |
| Size: 8 bit  | Default:           | Variable   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 07 : 00      | REVID              | <b>Revision ID:</b> 8-bit value that indicates the revision number of the USB1.1 interface. The value reported in this register depends on the value written to the Revision ID in Device 31, Function 0, Offset 08h. This register follows the ICH revision ID scheme as defined in Section 19.2.1.4, "Offset 08h: RID - Revision ID Register" on page 736. |                             | Variable                             | RO         |

### 25.1.1.5 SUBC - Sub Class Code Register

A value of 03h indicates that this is a Universal Serial Bus Host Controller.

**Table 25-6. SUBC - Sub Class Code Register**

| Description: |             |   |                      |                           |                 |            |
|--------------|-------------|---|----------------------|---------------------------|-----------------|------------|
| View:        | BAR:        |   | Bus:Device:Function: | Offset Start: Offset End: |                 |            |
| Size:        | Default:    |   |                      | Power Well:               |                 |            |
| Bit Range    | Bit Acronym | Bit Description   |                      | Sticky                    | Bit Reset Value | Bit Access |
| 07 : 00      | SCC         | <b>Sub-Class Code:</b> Indicates the device is a USB1.1 device. |                      |                           | 03h             | RO         |

### 25.1.1.6 BCC - Base Class Code Register

A value of 0Ch indicates that this is a Serial Bus controller.

**Table 25-7. BCC - Base Class Code Register**

| Description: |             |   |                      |                           |                 |            |
|--------------|-------------|---|----------------------|---------------------------|-----------------|------------|
| View:        | BAR:        |   | Bus:Device:Function: | Offset Start: Offset End: |                 |            |
| Size:        | Default:    |   |                      | Power Well:               |                 |            |
| Bit Range    | Bit Acronym | Bit Description   |                      | Sticky                    | Bit Reset Value | Bit Access |
| 07 : 00      | BCC         | <b>Base Class Code:</b> Indicates the device is a USB device. |                      |                           | 0Ch             | RO         |

### 25.1.1.7 MLT - Master Latency Timer Register

Because the USB controller is internally implemented with arbitration on the CMI, it does not need a master latency timer. The bits are hardwired to 0.

**Table 25-8. MLT - Master Latency Timer Register**

| Description: |             |  |                      |                           |                 |            |
|--------------|-------------|--|----------------------|---------------------------|-----------------|------------|
| View:        | BAR:        |  | Bus:Device:Function: | Offset Start: Offset End: |                 |            |
| Size:        | Default:    |  |                      | Power Well:               |                 |            |
| Bit Range    | Bit Acronym | Bit Description                              |                      | Sticky                    | Bit Reset Value | Bit Access |
| 07 : 00      | MLC         | <b>Master Latency Count:</b> Hardwired to 0. |                      |                           | 0h              | RO         |

### 25.1.1.8 HDR - Header Type Register

For function 0, bit 7 is determined by the values in the USB Function Disable bits (11:8 of the Function Disable register in Memory-mapped configuration space).

Table 25-9. HDR - Header Type Register

| Description: |             |  |                      |        |                                      |            |
|--------------|-------------|--|----------------------|--------|--------------------------------------|------------|
| View:        | BAR:        | Configuration  | Bus:Device:Function: | 0:29:0 | Offset Start: 0Eh<br>Offset End: 0Eh |            |

| 00           | RTE         | <b>Resource Type Indicator:</b> This bit is hardwired to 1 indicating that the base address field in this register maps to I/O space      |                      |        | 1                                    | RO         |

### 25.1.1.10 USBx\_SVID - USB Subsystem Vendor ID Register

*Note:* x indicates the USB controller number.

BIOS sets the value in this register to identify the Subsystem Vendor ID. The USB\_SVID register, in combination with the USB Subsystem ID register, enables the operating system to distinguish each subsystem from the others.

*Note:* Software can write to this register only once per core well reset. Writes must be done as a single 16-bit cycle.

**Table 25-11. USBx\_SVID - USB Subsystem Vendor ID Register**

| Description: |                    |   |                             |                                      |            |
|--------------|--------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:29:0 | Offset Start: 2Ch<br>Offset End: 2Dh |            |
| Size: 16 bit | Default:           | 0000h   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 15 : 00      | SVID               | <b>Subsystem Vendor ID:</b> BIOS sets the value in this register to identify the Subsystem Vendor ID. The USB_SVID register, in combination with the USB Subsystem ID register, enables the operating system to distinguish each subsystem from the others. |                             | 0000h                                | RWO        |

### 25.1.1.11 USBx\_SID - USB Subsystem ID Register

*Note:* x indicates the USB controller number.

BIOS sets the value in this register to identify the Subsystem ID. The SID register, in combination with the SVID register, enables the operating system to distinguish each subsystem from other(s).

*Note:* The software can write to this register only once per core well reset. Writes must be done as a single 16-bit cycle.

**Table 25-12. USBx\_SID - USB Subsystem ID Register**

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:29:0 | Offset Start: 2Eh<br>Offset End: 2Fh |            |

| Bit Range    | Bit Acronym        | Bit Description  |                             | Sticky                               | Bit Reset Value | Bit Access |
| 07 : 00      | INTL               | <b>Interrupt line:</b> This data is not used. This data is used to communicate to software which interrupt line the interrupt pin is connected to. |                             |                                      | 00h             | RW         |

### 25.1.1.13 INTP - Interrupt Pin Register

Table 25-14. INTP - Interrupt Pin Register

| Description: |                    |   |                             |                                      |                 |            |
|--------------|--------------------|---|-----------------------------|--------------------------------------|-----------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:29:0 | Offset Start: 3Dh<br>Offset End: 3Dh |                 |            |
| Size: 8 bit  | Default:           | Variable  |                             | Power Well: Core                     |                 |            |
| Bit Range    | Bit Acronym        | Bit Description   |                             | Sticky                               | Bit Reset Value | Bit Access |
| 07 : 00      | INTPN              | <b>Interrupt Pin:</b> This read-only value tells the software which interrupt pin each USB host controller uses. The upper 4 bits are hardwired to 0000b; the lower 4 bits are determine by the Interrupt Pin default values that are programmed in the memory-mapped configuration space as follows:<br>Function 0 D29IP.U0P<br><b>Note:</b> This does not determine the mapping to the PIRO pins. |                             |                                      | Variable        | RO         |

### 25.1.1.14 SBRN - Serial Bus Release Number Register

A value of 10h indicates that this is controller follows USB release 1.1.

Table 25-15. SBRN - Serial Bus Release Number Register

| Description: |                    |   |                             |                                      |                 |            |
|--------------|--------------------|---|-----------------------------|--------------------------------------|-----------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:29:0 | Offset Start: 60h<br>Offset End: 60h |                 |            |
| Size: 8 bit  | Default:           | 10h   |                             | Power Well: Core                     |                 |            |
| Bit Range    | Bit Acronym        | Bit Description   |                             | Sticky                               | Bit Reset Value | Bit Access |
| 07 : 00      | SBN                | Indicates that this controller follows USB release 1.0. |                             |                                      | 10h             | RO         |

### 25.1.1.15 USBLKMCR - USB Legacy Keyboard/Mouse Control Register

This register is implemented separately in each of the USB1.1 functions. However, the enable and status bits for the trapping logic are ORed and shared, respectively, since their functionality is not specific to any one host controller.

**Table 25-16. USBLKMCR - USB Legacy Keyboard/Mouse Control Register (Sheet 1 of 2)**

| Description: |                    |   |                             |                                      |            |
|--------------|--------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:29:0 | Offset Start: C0h<br>Offset End: C1h |            |
| Size: 16 bit | Default:           | 2000h   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 15           | SMIBYENDPS         | <b>SMI Caused by End of Pass-through:</b> Indicates if the event occurred. Even if the corresponding enable bit is not set in the Bit 7, then this bit will still be active. It is up to the SMM code to use the enable bit to determine the exact cause of the SMI#.<br>0 = No event occurred.<br>1 = Event occurred.<br><b>Note:</b> Writing a 1 to this bit (in any of the controllers) will clear the latch.  |                             | 0h                                   | RWC        |
| 14           | Reserved           | Reserved  |                             | 0h                                   |            |
| 13           | USBPIRQEN          | <b>PCI Interrupt Enable:</b> Used to prevent the USB controller from generating an interrupt due to transactions on its ports. When disabled, that it will probably be configured to generate an SMI using bit 4 of this register. Defaults to 1 for compatibility with older USB software.<br>0 = Disable<br>1 = Enable  |                             | 1                                    | RW         |
| 12           | SMIBYUSB           | <b>SMI Caused by USB Interrupt:</b> This bit indicates if an interrupt event occurred from this classic controller. The interrupts from the classic USB controller is taken before the enable in bit 13 has any effect to create this read-only bit. Even if the corresponding enable bit is not set in the Bit 4, then this bit may still be active. It is up to the SMM code to use the enable bit to determine the exact cause of the SMI#.<br>0 = No event occurred<br>1 = Event occurred.<br><b>Note:</b> Writing a 1 to this bit will have no effect. The software must clear the interrupts via the USB controllers. |                             | 0h                                   | RO         |
| 11           | TRAPBY64W          | <b>SMI Caused by Port 64 Write:</b> Indicates if the event occurred. Even if the corresponding enable bit is not set in the Bit 3, then this bit will still be active. It is up to the SMM code to use the enable bit to determine the exact cause of the SMI#. Writing a 1 to this bit (in any of the controllers) will clear the bit. The A20Gate Pass-Through Logic allows specific port 64h Writes to complete without setting this bit.<br>0 = No event occurred.<br>1 = Event Occurred.<br><b>Note:</b> Software clears this bit by writing a 1 to the bit location in any of the controllers                         |                             | 0h                                   | RWC        |
| 10           | TRAPBY64R          | <b>SMI Caused by Port 64 Read:</b> Indicates if the event occurs. Even if the corresponding enable bit is not set in the Bit 2, then this bit will still be active. It is up to the SMM code to use the enable bit to determine the exact cause of the SMI#. Writing a 1 to this bit (in any of the controllers) will clear the bit.<br>0 = No event occurred.<br>1 = Event Occurred.<br><b>Note:</b> Software clears this bit by writing a 1 to the bit location in any of the controllers   |                             | 0h                                   | RWC        |

Table 25-16. USBLKMCR - USB Legacy Keyboard/Mouse Control Register (Sheet 2 of 2)

| Description: |                    |  |                             |                                      |            |

## 25.2 USB (1.1) Controller I/O-Mapped Register Details

Some of the read/write register bits which deal with changing the state of the USB hub ports function such that on read back they reflect the current state of the port and not necessarily the state of the last write to the register. This allows the software to poll the state of the port and wait until it is in the proper state before proceeding. A Host controller reset, global reset, or port reset will immediately terminate a transfer on the affected ports and disable the port. This affects the USBCMD register, bit [4] and the PORTSC registers, bits [12,6,2]. See individual bit descriptions for more detail.

Base address for these I/O registers is set by the USBIOBAR register, see [Section 25.1.1.9, "USBIOBAR - Base Address Register" on page 946](#).

### 25.2.1 Register Details

#### 25.2.1.1 USBCMD: USB Command Register

The Command Register indicates the command to be executed by the serial bus host controller. Writing to the register causes a command to be executed. [Table 25-22](#) provides additional information on the operation of the Run/Stop and Debug bits.

Table 25-21. USB\_CMD: USB Command Register (Sheet 1 of 2)

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: USBIOBAR (IO) |  | Bus:Device:Function: 0:29:0 | Offset Start: 00h<br>Offset End: 01h |            |
| Size: 16 bit | Default: 0000h     |  |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 15 : 09      | Reserved           | Reserved.  |                             | 0h                                   |            |
| 08           | Reserved           | 1 = Reserved   |                             | 0h                                   | RW         |
| 07           | MAXP               | <p><b>Max Packet:</b><br/>0 = 32 bytes.<br/>1 = 64 bytes.</p> <p>This bit selects the maximum packet size that can be used for full speed bandwidth reclamation at the end of a frame. This value is used by the Host Controller to determine whether it should initiate another transaction based on the time remaining in the SOF counter. Use of reclamation packets larger than the programmed size will cause a Babble error if executed during the critical window at frame end. The Babble error results in the offending endpoint being stalled. Software is responsible for ensuring that any packet which could be executed under bandwidth reclamation be within this size limit.</p> |                             | 0h                                   | RW         |
| 06           | CF                 | <p><b>Configure Flag:</b><br/>0 = Indicates that software has not completed host controller configuration.<br/>1 = HCD software sets this bit as the last action in its process of configuring the host controller.</p> <p>This bit has no effect on the hardware. It is provided only as a semaphore service for software.</p>  |                             | 0h                                   | RW         |
| 05           | SWDBG              | <p><b>Software Debug:</b><br/>0 = Normal Mode.<br/>1 = Debug mode. In software Debug mode, the Host Controller clears the Run/Stop bit after the completion of each USB transaction. The next transaction is executed when software sets the Run/Stop bit back to 1.</p> <p>The SWDBG bit must only be manipulated when the controller is in the stopped state. This can be determined by checking the HCHalted bit in the USBSTS register.</p>  |                             | 0h                                   | RW         |
| 04           | FGR                | <p><b>Force Global Resume:</b><br/>0 = Software sets this bit to 0 after 20 ms has elapsed to stop sending the Global Resume signal. At that time all USB devices must be ready for bus activity.<br/>1 = Host Controller sends the Global Resume signal on the USB. The Host Controller sets this bit to 1 when a resume event (connect, disconnect, or K-state) is detected while in global suspend mode. The 1 to 0 transition causes the port to send a low speed EOP signal. This bit will remain a 1 until the EOP has completed.</p>  |                             | 0h                                   | RW         |

Table 25-21. USBCMD: USB Command Register (Sheet 2 of 2)

| Description: |                    |   |                             |                                      |            |
|--------------|--------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: USBIOBAR (IO) |   | Bus:Device:Function: 0:29:0 | Offset Start: 00h<br>Offset End: 01h |            |
| Size: 16 bit | Default: 0000h     |   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 03           | EGSM               | <p><b>Enter Global Suspend Mode:</b></p> <p>0 = Software resets this bit to 0 to come out of Global Suspend mode. Software writes this bit to 0 at the same time that Force Global Resume (bit 4) is written to 0 or after writing bit 4 to 0.</p> <p>1 = Host Controller enters the Global Suspend mode. No USB transactions occurs during this time. The Host Controller is able to receive resume signals from USB and interrupt the system. Software must ensure that the Run/Stop bit (bit 0) is cleared prior to setting this bit.</p>  |                             | 0h                                   | RW         |
| 02           | GRESET             | <p><b>Global Reset:</b></p> <p>0 = This bit is reset by the software after a minimum of 10 ms has elapsed as specified in the <i>Universal Serial Bus (USB) Specification, Rev. 2.0</i>.</p> <p>1 = Global Reset. The host controller sends the global reset signal on the USB and then resets all its logic. Chip Hardware Reset has the same effect as Global Reset (bit 2), except that the host controller does not send the Global Reset on USB.</p>   |                             | 0h                                   | RW         |
| 01           | HCRESET            | <p><b>Host Controller Reset:</b> The HCRESET effects on hub registers are slightly different from Chip Hardware Reset and Global USB Reset. The HCRESET affects bits [8,3:0] of the Port Status and Control Register (PORTSC) of each port. HCRESET resets the state machines of the Host Controller including the Connect/Disconnect state machine (one for each port). When the Connect/Disconnect state machine is reset, the output that signals connect/disconnect are negated to 0, effectively signaling a disconnect, even if a device is attached to the port. This virtual disconnect causes the port to be disabled. This disconnect and disabling of the port causes bit 1 (connect status change) and bit 3 (port enable/disable change) of the PORTSC to get set. The disconnect also causes bit 8 of PORTSC to reset. About 64 bit times after HCRESET goes to 0, the connect and low-speed detect will take place and bits 0 and 8 of the PORTSC will change accordingly.</p> <p>0 = Reset by the host controller when the reset process is complete.</p> <p>1 = Reset. When this bit is set, the host controller module resets its internal timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated.</p> |                             | 0h                                   | RW         |
| 00           | RS                 | <p><b>Run/Stop:</b></p> <p>0 = Stop. Completes the current transaction on the USB and then halts. The HC Halted bit in the status register indicates when the Host Controller has finished the transaction and has entered the stopped state. The Host Controller clears this bit when the following fatal errors occur: consistency check failure, Memory access errors.</p> <p>1 = Run. Proceeds with execution of the schedule and continues execution as long as this bit is set.</p>   |                             | 0h                                   | RW         |

Table 25-22. Run/Stop, Debug Bit Interaction SWDBG (Bit 5), Run/Stop (Bit 0) Operation

| SWDBG (Bit 5) | Run/Stop (Bit 0) | Description  |
|---------------|------------------|--|
| 0             | 0                | If executing a command, the Host Controller completes the command and then stops. The 1.0 ms frame counter is reset and command list execution resumes from start of frame using the frame list pointer selected by the current value in the FRNUM register. (While Run/Stop=0, the FRNUM register can be reprogrammed).                                       |
| 0             | 1                | Execution of the command list resumes from Start Of Frame using the frame list pointer selected by the current value in the FRNUM register. The Host Controller remains running until the Run/Stop bit is cleared (by Software or Hardware).   |
| 1             | 0                | If executing a command, the Host Controller completes the command and then stops and the 1.0 ms frame counter is frozen at its current value. All status are preserved. The Host Controller begins execution of the command list from where it left off when the Run/Stop bit is set.  |
| 1             | 1                | Execution of the command list resumes from where the previous execution stopped. The Run/Stop bit is set to 0 by the Host Controller when a TD is being fetched. This causes the Host Controller to stop again after the execution of the TD (single step). When the Host Controller has completed execution, the HC Halted bit in the Status Register is set. |

When the USB Host Controller is in Software Debug Mode (USBCMD Register bit 5=1), the single stepping software debug operation is as follows:

To Enter Software Debug Mode:

1. HCD puts Host Controller in Stop state by setting the Run/Stop bit to 0.
2. HCD puts Host Controller in Debug Mode by setting the SWDBG bit to 1.
3. HCD sets up the correct command list and Start Of Frame value for starting point in the Frame List Single Step Loop:
4. HCD sets Run/Stop bit to 1.
5. Host Controller executes next active TD, sets Run/Stop bit to 0, and stops.
6. HCD reads the USBCMD register to check if the single step execution is completed (HCHalted=1).
7. HCD checks results of TD execution. Go to step 4 to execute next TD or step 8 to end Software Debug mode.
8. HCD ends Software Debug mode by setting SWDBG bit to 0.
9. HCD sets up normal command list and Frame List table.
10. HCD sets Run/Stop bit to 1 to resume normal schedule execution.

In Software Debug mode, when the Run/Stop bit is set, the Host Controller starts. When a valid TD is found, the Run/Stop bit is reset. When the TD is finished, the HCHalted bit in the USBSTS register (bit 5) is set.

The software Debug mode skips over inactive TDs and only halts after an active TD has been executed. When the last active TD in a frame has been executed, the Host Controller waits until the next SOF is sent and then fetches the first TD of the next frame before halting.

This HCHalted bit can also be used outside of Software Debug mode to indicate when the Host Controller has detected the Run/Stop bit and has completed the current transaction. Outside of the Software Debug mode, setting the Run/Stop bit to 0 always resets the SOF counter so that when the Run/Stop bit is set the Host Controller starts over again from the frame list location pointed to by the Frame List Index (see FRNUM Register description) rather than continuing where it stopped.

### 25.2.1.2 USBSTS: USB Status Register

This register indicates pending interrupts and various states of the Host Controller. The status resulting from a transaction on the serial bus is not indicated in this register. Software sets a bit to 0 in this register by writing a 1 to it. See Section 4, “Interrupts,” of the *Universal Host Controller Interface (UHCI) Specification, Rev. 1.1*, for additional information concerning USB interrupt conditions.

**Table 25-23. USBSTS: USB Status Register (Sheet 1 of 2)**

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: USBIOBAR (IO) |  | Bus:Device:Function: 0:29:0 | Offset Start: 02h<br>Offset End: 03h |            |
| Size: 16 bit | Default: 0020h     |  |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 15 : 06      | Reserved           | Reserved   |                             | 0h                                   | RO         |
| 05           | HCH                | <b>HCHalted:</b><br>0 = The host controller is running.<br>1 = The host controller has stopped executing as a result of the Run/Stop bit being set to 0, either by software or by the host controller hardware (debug mode or an internal error). Default.<br>Software clears this bit by writing a 1 to it.   |                             | 1                                    | RWC        |
| 04           | HCPE               | <b>Host Controller Process Error:</b><br>0 = No error.<br>1 = The host controller has detected a fatal error. This indicates that the Host Controller suffered a consistency check failure while processing a Transfer Descriptor. An example of a consistency check failure would be finding an illegal PID field while processing the packet header portion of the TD. When this error occurs, the Host Controller clears the Run/Stop bit in the Command register to prevent further schedule execution. A hardware interrupt is generated to the system.<br>Software clears this bit by writing a 1 to it. |                             | 0h                                   | RWC        |
| 03           | HSE                | <b>Host System Error:</b><br>0 = No error occurred.<br>1 = A serious error occurs during a host system access involving the Host Controller module. Conditions that set this bit to 1 include Parity error, Master Abort, and Target Abort. When this error occurs, the Host Controller clears the Run/Stop bit in the Command register to prevent further execution of the scheduled TDs. A hardware interrupt is generated to the system.<br>Software clears this bit by writing a 1 to it.  |                             | 0h                                   | RWC        |

The Host Controller also sets this bit to 1 when a short packet is detected (actual length field in TD is less than maximum length field in TD), and short packet detection is enabled in that TD.<br>Software clears this bit by writing a 1 to it.  |                             | 0h                                   | RWC        |

### 25.2.1.3 USBINTR: USB Interrupt Enable Register

This register enables and disables reporting of the corresponding interrupt to the software. When a bit is set and the corresponding interrupt is active, an interrupt is generated to the host. Fatal errors (Host Controller Processor Error-bit 4, USBSTS Register) cannot be disabled by the host controller. Interrupt sources that are disabled in this register still appear in the Status Register to allow the software to poll for events.

Table 25-24. USBINTR: USB Interrupt Enable Register

| Description: |                    |   |                             |                                      |            |

#### 25.2.1.4 FRNUM: Frame Number Register

Bits [10:0] of this register contain the current frame number which is included in the frame SOF packet. This register reflects the count value of the internal frame number counter. Bits [9:0] are used to select a particular entry in the Frame List during schedule execution. This register is updated at the end of each frame time.

This register must be written as a word. Byte writes are not supported. This register cannot be written unless the Host Controller is in the STOPPED state as indicated by the HCHalted bit (USBSTS register). A write to this register while the Run/Stop bit is set (USBCMD register) is ignored.

Table 25-25. FRNUM: Frame Number Register

| Description: |                    |   |                             |                                      |            |
|--------------|--------------------|---|-----------------------------|--------------------------------------|------------|

| 10 : 00      | FLCIFN             | <b>Frame List Current Index/Frame Number:</b> Bits [10:0] provide the frame number in the SOF Frame. The value in this register increments at the end of each time frame (approximately every 1 ms). In addition, bits [9:0] are used for the Frame List current index and correspond to memory address signals [11:2]. |                             | 0h                                   | RW         |

### 25.2.1.5 FRBASEADD: Frame List Base Address Register

This 32-bit register contains the beginning address of the Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. When written, only the upper 20 bits are used. The lower 12 bits are written as zero (4 Kbyte alignment). The contents of this register are combined with the frame number counter to enable the Host Controller to step through the Frame List in sequence. The two least significant bits are always 00. This requires DWORD alignment for all list entries. This configuration supports 1024 Frame List entries.

**Table 25-26. FRBASEADD: Frame List Base Address Register**

| Description: |                    |   |                             |                                      |            |

### 25.2.1.6 SOFMOD: Start of Frame Modify Register

This 1-byte register is used to modify the value used in the generation of SOF timing on the USB. Only the 7 least significant bits are used. When a new value is written into the these 7 bits, the SOF timing of the next frame will be adjusted. This feature can be used to adjust out any offset from the clock source that generates the clock that drives the SOF counter. This register can also be used to maintain real time synchronization with the rest of the system so that all devices have the same sense of real time. Using this register, the frame length can be adjusted across the full range required by the *USB Specification*. Its initial programmed value is system dependent based on the accuracy of hardware USB clock and is initialized by system BIOS. It may be reprogrammed by USB system software at any time. Its value will take effect from the beginning of the next frame. This register is reset upon a Host Controller Reset or Global Reset. Software must maintain a copy of its value for reprogramming if necessary.

**Table 25-27. SOFMOD: Start of Frame Modify Register**

## 25.3 Data Transfers to/from Main Memory

The *Universal Host Controller Interface (UHCI) Specification, Rev. 1.1* describes the details on how HCD and CMI communicate via the Schedule data structures.

## 25.4 Data Structures in Main Memory

The *UHCI Specification* details the data structures used to communicate control, status, and data between software and CMI.

## 25.5 Data Transfers To/From Main Memory

The following sections describe the details on how HCD and CMI communicate via the Schedule data structures. The discussion is organized in a top-down manner, beginning with the basics of walking the Frame List, followed by a description of generic processing steps common to all transfer descriptors, and finally a discussion on Transfer Queuing.

During data transfers to and from main memory, the UHCI DMA engine must provide an indication to the processor power management logic that it is busy. Therefore, the memory accesses may actually be “cache accesses”. The indication to the power management logic will be referred to as “UHCI Bus Master Status”.

The UHCI controllers offer two different policies for the generation of the UHCI Bus Master Status: static and dynamic.

The static policy requires that the UHCI Bus Master Status signal is asserted when the HCHalted bit is 0. This policy prevents C3/C4 entry whenever the DMA engine is enabled.

The dynamic policy requires that the UHCI Bus Master Status signal deasserts after completely traversing the schedule for a particular Frame unless the Frame bit counter indicates that the next Frame begins in less than ~100 usecs. Specifically the UHCI Bus Master Status signal must deassert in any of the following:

1. After reading the Frame List Pointer and detecting that the Terminate bit is set and the next Frame is greater than ~100 usecs in the future.
2. After servicing a Queue Head in which the Terminate bit is set in the Queue Head Link Pointer and the next Frame is greater than ~100 usecs in the future.
3. The RUN bit is 0 and the HCHalted bit is 1
4. After servicing a Transfer Descriptor which is not in the context of a Queue and it's Terminate bit is set and the next Frame is greater than ~100 us in the future

The UHCI Bus Master Status signal must assert in either of the following cases:

1. The RUN bit transitions from 0 to 1
2. The Frame bit counter indicates that the next Frame begins in less than ~100  $\mu$ s

The value of 100  $\mu$ s is somewhat arbitrary. This is based on the assumption that a “reasonable worst case” exit time is approximately 100  $\mu$ s. Even if the exit latency is greater than this, it does not mean that there will be a USB functional failure. It only means that the USB traffic will begin later in the upcoming Frame than it normally would have. In order to specify numbers for checking in validation, the ~100  $\mu$ s time must fall within the range 97  $\mu$ s to 110  $\mu$ s.

The UHCI BM\_STS Static Policy Enable configuration bit (D31.F0.A9h.5) selects between the dynamic and static policies.

### 25.5.1 Executing the Schedule

Software programs the starting address of the Frame List and the Frame List index, then causes CMI to execute the schedule by setting the Run/Stop bit in the Control register to Run. The CMI processes the schedule one entry at a time: the next element in the frame list is not fetched until the current element in the frame list is retired.

Schedule execution proceeds in the following fashion:

- The CMI first fetches an entry from the Frame List. This entry has three fields. Bit 0 indicates whether the address pointer field is valid. Bit 1 indicates whether the address points to a Transfer Descriptor or to a queue head. The third field is the pointer itself.
- If the Frame List entry indicates that it points to a Transfer Descriptor, the CMI fetches the entry and begins the operations necessary to initiate a transaction on USB. Each TD contains a link field that points to the next entry, as well as indicating whether it is a TD or a QH.
- If the Frame List entry contains a pointer to a QH, the CMI processes the information from the QH to determine the address of the next data object that it must process.
- The TD/QH process continues until the millisecond allotted to the current frame expires. At this point, the CMI fetches the next entry from the Frame List. If the CMI is not able to process all of the transfer descriptors during a given frame, those descriptors are retired by software without having been executed.

### 25.5.2 Processing Transfer Descriptors

The CMI executes a TD using the following, generalized algorithm. These basic steps are common across all modes of TDs. Subsequent sections present processing steps unique to each TD mode.

1. The CMI Fetches TD or QH from the current Link Pointer.
2. If a QH, go to 1 to fetch from the Queue Element Link Pointer. If inactive, go to 12
3. Build Token, actual bits are in TD Token.
4. If (Host-to-Function) then  
     [*Memory Access*] issue request for data, (referenced through TD.BufferPointer)  
     wait for first chunk data arrival  
     end if
5. [*Begin USB Transaction*] Issue Token (from token built in 2, above) and begin data transfer.  
     if (Host-to-Function) then Go to 6  
     else Go to 7  
     end if
6. Fetch data from memory (via TD BufferPointer) and transfer over USB until TD Maximum-Length bytes have been read and transferred. [*Concurrent system memory and USB Accesses*]. Go to 8.
7. Wait for data to arrive (from USB). Write incoming bytes into memory beginning at TD BufferPointer. Internal HC buffer must signal end of data packet. Number of bytes received must be  $\leq$  TD Maximum-Length; The length of the memory area referenced by TD BufferPointer must be  $\geq$  TD Maximum-Length. [*Concurrent system memory and USB Accesses*].
8. Issue handshake based on status of data received (Ack or Time-out). Go to 10.
9. Wait for handshake, if required [*End of USB Transaction*].
10. Update Status [*Memory Access*] (TD.Status and TD.ActualLength).  
     If the TD completed successfully, mark the TD inactive. Go to 11.

If not successful, and the error count has not been reached, leave the TD active. If the error count has been reached, mark the TD inactive. Go to 12.

11. Write the link pointer from the current TD into the element pointer field of the QH structure. If the Vf bit is set in the link pointer, go to 2.
12. Proceed to next entry.

### 25.5.3 Command Register, Status Register, and TD Status Bit Interaction

| Condition  | USB Status Register Actions   | TD Status Register Actions                                   |
|--|---|--|
| CRC/Time Out Error                               | Set USB Error Int bit <sup>1</sup> , Clear HC Halted bit  | Clear Active bit <sup>1</sup> and set Stall bit <sup>1</sup> |
| Illegal PID, PID Error, Maximum Length (illegal) | Clear Run/Stop bit in command register<br>Set HC Process Error and HC Halted bits   |  |
| Master/Target Abort on memory accesses           | Clear Run/Stop bit in command register<br>Set Host System Error and HC Halted bits  |  |
| Suspend Mode                                     | Clear Run/Stop bit in command register <sup>2</sup><br>Set HC Halted bit  |  |
| Resume Received<br>Suspend Mode = 1              | Set Resume received bit   |  |
| Run/Stop = 0                                     | Clear Run/Stop bit in command register<br>Set HC Halted bit   |  |
| Configuration Flag Set                           | Set Configuration Flag in command register  |  |
| HC Reset/Global Reset                            | Clear Run/Stop and configuration Flag in command register<br>Clear USB Int, USB Error Int, Resume received, Host System Error, HC Process Error, and HC Halted bits |  |
| IOC = 1 in TD Status                             | Set USB Int bit   |  |
| Stall  | Set USB Error Int bit   | Clear Active bit <sup>1</sup> and set Stall bit              |
| Bit Stuff/Data Buffer Error                      | Set USB Error Int bit <sup>1</sup>  | Clear Active bit <sup>1</sup> and set Stall bit <sup>1</sup> |
| Short Packet Detect                              | Set USB Int bit   | Clear Active bit   |

**Notes:**

1. Only If error counter counted down from 1 to 0.
2. Suspend mode can be entered only when Run/Stop bit is 0.

*Note:* If a NAK or STALL response is received from a SETUP transaction, a Time Out Error will be reported. This will cause the Error counter to decrement and the CRC/Time-out Error status bit to be set within the TD Control and Status Dword during write back. If the Error counter changes from 1 to 0, the Active bit will be reset to 0 and Stalled bit to 1 as normal.

### 25.5.4 Transfer Queuing

Transfer Queues are used to implement a guaranteed data delivery stream to a USB Endpoint. Transfer Queues are composed of two parts: a Queue Header (QH) and a linked list. The linked list of TDs and QHs has an indeterminate length (0 to n).

The QH contains two link pointers and is organized as two contiguous DWords. The first DWord is a horizontal pointer (Queue Head Link Pointer), used to link a single transfer queue with either another transfer queue, or a TD (target data structure depends on Q bit). If the T bit is set, this QH represents the last data structure in the current Frame. The T bit informs the CMI that no further processing is required until the beginning of the next frame. The second DWord is a vertical pointer (Queue Element Link Pointer) to the first data structure (TD or QH) being managed by this QH. If the T bit is set, the queue is empty. This pointer may reference a TD or another QH.

Figure 25-1 illustrates four example queue conditions. The first QH (on far left) is an example of an “empty” queue; the termination bit (T Bit), in the vertical link pointer field, is set to 1. The horizontal link pointer references another QH. The next queue is the expected typical configuration. The horizontal link pointer references another QH, and the vertical link pointer references a valid TD.

Typically, the vertical pointer in a QH points to a TD. However, as shown in Figure 25-1 (third example from left side of figure) the vertical pointer could point to another QH. When this occurs, a new Q Context is entered and the Q Context just exited is NULL (The CMI will not update the vertical pointer field).

The far right QH is an example of a frame ‘termination’ node. Since its horizontal link pointer has its termination bit set, the CMI assumes there is no more work to complete for the current Frame.

Figure 25-1. Example Queue Conditions

Transfer Queues are based on the following characteristics:

- A QH’s vertical link pointer (Queue Element Link Pointer) references the ‘Top’ queue member. A QH’s horizontal link pointer (Queue Head Link Pointer) references the “next” work element in the Frame.
- Each queue member’s link pointer references the next element within the queue.

In the simplest model, the CMI follows vertical link point to a queue element, then executes the element. If the completion status of the TD satisfies the advance criteria as shown in Table 25-29, the CMI advances the queue by writing the just-executed TD’s link pointer back into the QH’s Queue Element link pointer. The next time the queue head is traversed, the next queue element will be the Top element.

The traversal has two options: Breadth first, or Depth first. A flag bit in each TD (Vf - Vertical Traversal Flag) controls whether traversal is Breadth or Depth first. The default mode of traversal is Breadth-First. For Breadth-First, the CMI only executes the top element from each queue. The execution path is:

QH (Queue Element Link Pointer)→ TD

- Write-Back to QH (Queue Element Link Pointer)
- QH (Queue Head Link pointer).

Breadth-First is also performed for every transaction execution that fails the advance criteria. This means that if a queued TD fails, the queue does not advance, and the CMI traverses the QH's Queue Head Link Pointer.

In a Depth-first traversal, the top queue element must complete successfully to satisfy the *advance criteria* for the queue. If the CMI is currently processing a queue, and the advance criteria are met, and the Vf bit is set, the CMI follows the TD's link pointer to the next schedule work item.

Regardless of traversal model, when the advance criteria are met, the successful TD's link pointer is written back to the QH's Queue Element link pointer.

When the CMI encounters a QH, it caches the QH internally, and sets internal state to indicate it is in a Q-context. It needs this state to update the correct QH (for auto advancement) and also to make the correct decisions on how to traverse the Frame List.

Restricting the advancement of queues to advancement criteria implements a guaranteed data delivery stream.

A queue is **never** advanced on an error completion status (even in the event the error count was exhausted).

Table 25-29 lists the general queue advance criteria, which are based on the execution status of the TD at the 'Top' of a currently 'active' queue.

**Table 25-29. Queue Advance Criteria**

| Function-to-Host (IN) |           |                 | Host-to-Function (OUT) |           |                 |
|-----------------------|-----------|-----------------|------------------------|-----------|-----------------|
| Non-NULL              | NULL      | Error/NAK       | Non-NULL               | NULL      | Error/NAK       |
| Advance Q             | Advance Q | Retry Q Element | Advance Q              | Advance Q | Retry Q Element |

Table 25-30 is a decision table illustrating the valid combinations of link pointer bits and the valid actions taken when advancement criteria for a queued transfer descriptor are met. The column headings for the link pointer fields are encoded, based on the following list:

Table 25-30. USB Schedule List Traversal Decision Table

| Q Context | QH.Q | QH.T | QE.Q | QE.T | TD.Vf | TD.Q | TD.T | Description  |

## 25.6 USB Buffer Management

The USB controller contains a 64 byte FIFO, which operate in a ping/pong fashion. This buffer is not aligned to any memory boundary. Upon each new transfer descriptor (TD), the buffer resets its pointer to the top.

When transmitting to a USB port, if the length field from the TD is greater than 32 bytes, meaning the internal FIFO boundary will be crossed, the host controller will read both ping and pong together. When ping has been transferred to USB, and the total TD length has not been fetched, the USB host controller will fetch another 32 bytes.

When receiving from a USB port, it is not known how many bytes will be received. Therefore, the CMI will flush each buffer to memory as it becomes full.

## 25.7 Data Encoding and Bit Stuffing

The CMI USB employs NRZI data encoding (Non-Return to Zero Inverted) when transmitting packets. Full details on this implementation are given in the *USB Specification, Rev. 2.0*.

The USB employs NRZI data encoding when transmitting packets. In NRZI encoding, a 1 is represented by no change in level and a 0 is represented by a change in level. A string of zeros causes the NRZI data to toggle each bit time. A string of ones causes long periods with no transitions in the data. In order to ensure adequate signal transitions, bit stuffing is employed by the transmitting device when sending a packet on the USB. A 0 is inserted after every six consecutive 1s in the data stream before the data is NRZI encoded to force a transition in the NRZI data stream. This gives the receiver logic a data transition at least once every seven bit times to guarantee the data and clock lock. A waveform of the data encoding is shown in [Figure 25-2](#).

Figure 25-2. USB Data Encoding

Bit stuffing is enabled beginning with the Sync Pattern and throughout the entire transmission. The data “one” that ends the Sync Pattern is counted as the first one in a sequence. Bit stuffing is always enforced, without exception. If required by the bit stuffing rules, a zero bit will be inserted even if it is the last bit before the end-of-packet (EOP) signal.

## 25.8 Bus Protocol

### 25.8.1 Bit Ordering

Bits are sent out onto the bus least significant bit (LSb) first, followed by next LSB, the most significant bit (MSb) last.

### 25.8.2 SYNC Field

All packets begin with a synchronization (SYNC) field, which is a coded sequence that generates a maximum edge transition density. The SYNC field appears on the bus as IDLE followed by the binary string “KJKJKJKK,” in its NRZI encoding. It is used by the input circuitry to align incoming data with the local clock and is defined to be eight bits in length. SYNC serves only as a synchronization mechanism and is not shown in the following packet diagrams in [Section 25.8.3](#). The last two bits in the SYNC field are a marker that is used to identify the first bit of the PID. All subsequent bits in the packet must be indexed from this point.

### 25.8.3 Packet Field Formats

All packets have distinct start and end of packet delimiters. Full details are given in the *USB Specification*.

### 25.8.3.1 Packet Identifier Field

A packet identifier (PID) immediately follows the SYNC field of every USB packet. A PID consists of a four bit packet type field followed by a four-bit check field. The PID indicates the type of packet and, by inference, the format of the packet and the type of error detection applied to the packet. The four-bit check field of the PID insures reliable decoding of the PID so that the remainder of the packet is interpreted correctly. The PID check field is generated by performing a ones complement of the packet type field.

Any PID received with a failed check field or which decodes to a non-defined value is assumed to be corrupted and it, as well as the remainder of the packet, is ignored by the receiver.

PIDs are divided into four coding groups: token, data, handshake, and special, with the first two transmitted PID bits (PID<1:0>) indicating which group. This accounts for the distribution of PID codes.

## 25.8.4 Address Fields

Function endpoints are addressed using two fields: the function address field and the endpoint field. Full details on this are given in the *USB Specification*.

### 25.8.4.1 Address Field

The function address (ADDR) field specifies the function, via its address, that is either the source or destination of a data packet, depending on the value of the token PID. A total of 128 addresses are specified as ADDR[6:0]. The ADDR field is specified for IN, SETUP, and OUT tokens.

### 25.8.4.2 Endpoint Field

An additional four-bit endpoint (ENDP) field, permits more flexible addressing of functions in which more than one sub-channel is required. Endpoint numbers are function specific. The endpoint field is defined for IN, SETUP, and OUT token PIDs only.

## 25.8.5 Frame Number Field

The frame number field is an 11-bit field that increments by the host on a per frame basis. The frame number field rolls over upon reaching its maximum value of x7FF, and is sent only for SOF tokens at the start of each frame.

## 25.8.6 Data Field

The data field may range from 0 to 1023 bytes and must be an integral numbers of bytes. [Table 25-31](#) lists the format for multiple bytes. Data bits within each byte are shifted out LSB first.

**Table 25-31. Data Field**

| Bit   | Data Sent      |
|-------|----------------|
| x - 1 | Byte N - 1, D7 |
| x     | Byte N, D0     |
| x + 1 | Byte N, D1     |
| x + 2 | Byte N, D2     |
| x + 3 | Byte N, D3     |
| x + 4 | Byte N, D4     |

Table 25-31. Data Field

|       |               |
|-------|---------------|
| x + 5 | Byte N, D5    |
| x + 6 | Byte N, D6    |
| x + 7 | Byte N, D7    |
| x + 8 | Byte N+1, D 0 |

### 25.8.7 Cyclic Redundancy Check (CRC)

CRC is used to protect the all non-PID fields in token and data packets. In this context, these fields are considered to be protected fields. Full details on this are given in the *USB Specification*.

## 25.9 Packet Formats

The USB protocol calls out several packet types: token, data, and handshake packets. Full details on this are given in the *USB Specification*.

## 25.10 USB Interrupts

### 25.10.1 Overview

There are two general groups of USB interrupt sources, those resulting from execution of transactions in the schedule, and those resulting from a CMI operation error. All transaction-based sources can be masked by software through the Interrupt Enable register. Additionally, individual transfer descriptors can be marked to generate an interrupt on completion.

When the CMI drives an interrupt for USB, it internally drives the PIRQA# pin for USB function #0 (see [Chapter 26.0, "USB 2.0 Host Controller: Bus 0, Device 29, Function 7"](#)) until all sources of the interrupt are cleared. In order to accommodate some operating systems, the Interrupt Pin register must contain a different value for each function of this multi-function device.

### 25.10.2 Transaction-Based Interrupts

These interrupts are not signaled until after the status for the last complete transaction in the frame has been written back to host memory. This guarantees that software can safely process through (Frame List Current Index -1) when it is servicing an interrupt.

#### 25.10.2.1 CRC Error/Time-out

A CRC/Time-out error occurs when a packet transmitted from the CMI to a USB device or a packet transmitted from a USB device to the CMI generates a CRC error. The CMI is informed of this event by a time out from the USB device or by the CMI's CRC checker generating an error on reception of the packet. Additionally, a USB bus time-out occurs when USB devices do not respond to a transaction phase within 19 bit times of an EOP. Either of these conditions will cause the C\_ERR field of the TD to be decremented.

When the C\_ERR field decrements to zero, the following occurs:

- The Active bit in the TD is cleared
- The Stalled bit in the TD is set
- The CRC/Time-out bit in the TD is set.

- At the end of the frame, the USB Error Interrupt bit is set in the HC status register.

If the CRC/Time out interrupt is enabled in the Interrupt Enable register, a hardware interrupt will be signaled to the system.

### 25.10.2.2 Interrupt on Completion

Transfer Descriptors contain a bit that can be set to cause an interrupt on their completion. The completion of the transaction associated with that block causes the USB Interrupt bit in the HC Status Register to be set at the end of the frame in which the transfer completed. When a TD is encountered with the IOC bit set to 1, the IOC bit in the HC Status register is set to 1 at the end of the frame if the active bit in the TD is set to 0 (even if it was set to 0 when initially read).

If the IOC Enable bit of Interrupt Enable register (bit 2 of I/O offset 04h) is set, a hardware interrupt is signaled to the system. This status bit is set whether the TD completes successfully, or because of errors. If the completion is because of errors, the USB Error bit in the HC status register is also set.

### 25.10.2.3 Short Packet Detect

A transfer set is a collection of data which requires more than 1 USB transaction to completely move the data across the USB. An example might be a large print file which requires numerous TDs in multiple frames to completely transfer the data. Reception of a data packet that is less than the endpoint's Maximum Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer set, even if there are active TDs remaining for this transfer set. Setting the SPD bit in a TD indicates to the HC to set the USB Interrupt bit in the HC status register at the end of the frame in which this event occurs. This feature streamlines the processing of input on these transfer types. If the Short Packet Interrupt Enable bit in the Interrupt Enable register is set, a hardware interrupt is signaled to the system at the end of the frame where the event occurred.

### 25.10.2.4 Serial Bus Babble

When a device transmits on the USB for a time greater than its assigned Maximum Length, it is said to be babbling. This error results in the Active bit in the TD being cleared to 0 and the Stalled and Babble bits being set to one. The C\_ERR field is not decremented for a babble. The USB Error Interrupt bit in the HC Status register is set to 1 at the end of the frame. A hardware interrupt is signaled to the system.

If an EOF babble was caused by the CMI (due to incorrect schedule for instance), the CMI will force a bit stuff error followed by an EOP and the start of the next frame.

### 25.10.2.5 Stalled

This event indicates that a device/endpoint returned a STALL handshake during a transaction or that the transaction ended in an error condition. The TDs Stalled bit is set and the Active bit is cleared. Reception of a STALL does not decrement the error counter. A hardware interrupt is signaled to the system.

### 25.10.2.6 Data Buffer Error

This event indicates that an overrun of incoming data or a under-run of outgoing data has occurred for this transaction. This would generally be caused by the CMI not being able to access required data buffers in memory within necessary latency requirements. Either of these conditions will cause the C\_ERR field of the TD to be decremented.

When C\_ERR decrements to zero, the Active bit in the TD is cleared, the Stalled bit is set, the USB Error Interrupt bit in the HC Status register is set to 1 at the end of the frame and a hardware interrupt is signaled to the system.

#### 25.10.2.7 Bit Stuff Error

A bit stuff error results from the detection of a sequence of more than six 1s in a row within the incoming data stream. This will cause the C\_ERR field of the TD to be decremented. When the C\_ERR field decrements to 0, the Active bit in the TD is cleared to 0, the Stalled bit is set to 1, the USB Error Interrupt bit in the HC Status register is set to 1 at the end of the frame and a hardware interrupt is signaled to the system.

### 25.10.3 Non-Transaction Based Interrupts

If a CMI process error or system error occur, the CMI halts and immediately issues a hardware interrupt to the system.

#### 25.10.3.1 Resume Received

This event indicates that the CMI received a RESUME signal from a device on the USB bus during a global suspend. If this interrupt is enabled in the Interrupt Enable register, a hardware interrupt will be signaled to the system allowing the USB to be brought out of the suspend state and returned to normal operation.

#### 25.10.3.2 Process Error

The HC monitors certain critical fields during operation to ensure that it does not process corrupted data structures. These include checking for a valid PID and verifying that the MaxLength field is less than 1280. If it detects a condition that would indicate that it is processing corrupted data structures, it immediately halts processing, sets the HC Process Error bit in the HC Status register and signals a hardware interrupt to the system.

This interrupt cannot be disabled through the Interrupt Enable register.

#### 25.10.3.3 Host System Error

The CMI sets this bit to 1 when a Parity Error, Master Abort, or Target Abort occurs on memory accesses. When this error occurs, the CMI clears the Run/Stop bit in the Command register to prevent further execution of the scheduled TDs. This interrupt cannot be disabled through the Interrupt Enable register.

#### 25.10.3.4 Implementation Notes

1. If a bad PID is found, but the packet will not be run because there is not enough time left in the frame due to the size of the transfer or the packet time out, an error will not be flagged.
2. "If a bad PID is found, but the packet will not be run because the TD's active bit is off, the host controller will not halt, and an error will not be flagged."

## 25.11 USB Power Management

The Host Controller can be put into a suspended state and its power can be removed. This requires that certain bits of information are retained in the resume power plane of the CMI so that a device on a port may wake the system. Such a device may be a fax-modem, which will wake up the machine to receive a fax or take a voice message.

The following bits in I/O space are to be maintained when the CMI enters a low power state:

**Table 25-32. Bits Maintained in Low Power States**

| Register                | Offset      | Bit | Description                      |
|-------------------------|-------------|-----|----------------------------------|
| Command                 | 00h         | 3   | Enter Global Suspend Mode (EGSM) |
| Status                  | 02h         | 2   | Resume Detect                    |
| Port Status and Control | 10h and 12h | 2   | Port Enabled/Disabled            |
|                         |             | 6   | Resume Detect                    |
|                         |             | 8   | Low-speed Device Attached        |
|                         |             | 12  | Suspend                          |

When the CMI detects a resume event on any of its ports, it sets the corresponding USB\_STS bit in ACPI space. If USB is enabled as a wake/break event, the system will wake up and an SCI will be generated.

## 25.12 USB Legacy Keyboard Operation

When a USB keyboard is plugged into the system, and a standard keyboard is not, the system may not boot, and DOS legacy software will not run, because the keyboard will not be identified. The CMI implements a series of trapping operations which will snoop accesses that go to the keyboard controller, and put the expected data from the USB keyboard into the keyboard controller.

The following table summarizes the implementation of the bits in the USB Legacy Keyboard/Mouse Control Registers.

**Table 25-33. USB Legacy Keyboard/Mouse Control Register Bit Implementation (Sheet 1 of 2)**

| Bit # | Bit Name                          | Summary                             | Details   |
|-------|-----------------------------------|-------------------------------------|---|
| 15    | SMI Caused by End of Pass-Through | Logically 1 bit for all controllers | This bit in all host controllers will be set at the same time and cleared at the same time. It is cleared whenever software writes a 1 to this bit in any of the classic USB host controllers. This bit may either be implemented separately for each controller or shared and aliased. |
| 13    | PCI Interrupt Enable              | Independent enable                  | Each bit provides individual host control   |
| 12    | SMI Caused by USB Interrupt       | Independent status                  | Individual status bits for each controller  |
| 11    | SMI Caused by Port 64 Write       | Logically 1 bit for all controllers | This bit in all host controllers will be set at the same time and cleared at the same time. It is cleared whenever software writes a 1 to this bit in any of the classic USB host controllers. This bit may either be implemented separately for each controller or shared and aliased. |
| 10    | SMI Caused by Port 64 Read        | Logically 1 bit for all controllers | This bit in all host controllers will be set at the same time and cleared at the same time. It is cleared whenever software writes a 1 to this bit in any of the classic USB host controllers. This bit may either be implemented separately for each controller or shared and aliased. |
| 9     | SMI Caused by Port 60 Write       | Logically 1 bit for all controllers | This bit in all host controllers will be set at the same time and cleared at the same time. It is cleared whenever software writes a 1 to this bit in any of the classic USB host controllers. This bit may either be implemented separately for each controller or shared and aliased. |

Table 25-33. USB Legacy Keyboard/Mouse Control Register Bit Implementation (Sheet 2 of 2)

| Bit # | Bit Name                          | Summary   | Details   |
|-------|-----------------------------------|---|---|
| 8     | SMI Caused by Port 60 Read        | Logically 1 bit for all controllers                 | This bit in all host controllers will be set at the same time and cleared at the same time. It is cleared whenever software writes a 1 to this bit in any of the classic USB host controllers. This bit may either be implemented separately for each controller or shared and aliased. |
| 7     | SMI at End of Pass-Through Enable | Separate enables ORed together                      | This bit enables the generation of the SMI based on bit 15 within the same function. If bit 15 is implemented as a shared/aliased bit across all functions, then the bit 7s from all classic USB controllers are ORed together and used to enable the SMI based on bit 15.              |
| 6     | Pass Through State                | Logically 1 bit for all controllers                 | This bit in all host controllers reflects the state of the Pass-Through state machine. Software can force this bit to 0 by clearing the A20Gate Pass-Through Enable (bit 5) in <i>all</i> of the host controllers.  |
| 5     | A20Gate Pass-Through Enable       | ORed together to enable the pass-thru state machine | If any of these bits in the classic USB host controllers is set, then the IICH will enable the Legacy Keyboard A20Gate Pass-through sequence. This prevents the SMI status bits (11:8) from asserting in all controllers when the specific sequence of I/O cycles is observed.          |
| 4     | SMI on USB IRQ                    | Independent Enable                                  | Each bit provides individual host control   |
| 3     | SMI on Port 64 Writes Enable      | Separate enables ORed together                      | Each bit enables SMI generation if the corresponding bit 11 is set. If bit 11 is implemented as a shared/aliased bit across all functions, then the bit 3s from all classic USB controllers are ORed together and used to enable the SMI based on bit 11.                               |
| 2     | SMI on Port 64 Reads Enable       | Separate enables ORed together                      | Each bit enables SMI generation if the corresponding bit 10 is set. If bit 10 is implemented as a shared/aliased bit across all functions, then the bit 2s from all classic USB controllers are ORed together and used to enable the SMI based on bit 10.                               |
| 1     | SMI on Port 60 Writes Enable      | Separate enables ORed together                      | Each bit enables SMI generation if the corresponding bit 9 is set. If bit 9 is implemented as a shared/aliased bit across all functions, then the bit 1s from all classic USB controllers are ORed together and used to enable the SMI based on bit 9.                                  |
| 0     | SMI on Port 60 Reads Enable       | Separate enables ORed together                      | Each bit enables SMI generation if the corresponding bit 8 is set. If bit 8 is implemented as a shared/aliased bit across all functions, then the bit 0s from all classic USB controllers are ORed together and used to enable the SMI based on bit 8.                                  |

**Note:** The scheme described below assumes that the keyboard controller (8042 or equivalent) is on the LPC bus.

This legacy operation is performed through SMM space. The latched SMI source (60R, 60W, 64R, 64W) is available in the Status Register. Because the enable is after the latch, it is possible to check for other events that didn't necessarily cause an SMI. It is the software's responsibility to logically AND the value with the appropriate enable bits.

**Note:** SMI is generated before the LPC cycle completes on the IMCH/IICH interface to ensure that the processor doesn't complete the cycle before the SMI is observed. The logic will also need to block the accesses to the 8042.

If there is an external 8042, then this is accomplished by not activating the 8042 CS. This is done by logically ANDing the four enables (60R, 60W, 64R, 64W) with the 4 types of accesses to determine if 8042 CS should go active. An additional term is required for the "pass-through" case.

## 26.0 USB 2.0 Host Controller: Bus 0, Device 29, Function 7

---

### 26.1 Overview

This section focuses on CMI-specific implementation details of the *Universal Serial Bus (USB) Specification, Revision 2.0* and *Enhanced Host Controller Interface (EHCI) Specification* for Universal Serial Bus specifications.

Register address locations not shown in [Section 26.2](#) must be treated as Reserved.

**Note:** All configuration registers in this section are in the Core Well and reset by a Core Well reset and the D3-to-D0 warm reset, except as noted.

CMI contains an Enhanced Host Controller Interface (EHCI) compliant host controller which supports up to two *USB Rev. 2.0 Specification*-compliant root ports. USB 2.0 allows data transfers up to 480 Mbits/s using the same pins as the two USB1 ports. CMI contains port-routing logic that determines whether a USB port is controlled by one of the UHCI controllers or by the EHCI controller. A USB 2.0-based Debug Port is also implemented in CMI. A summary of the key architectural differences between the USB 1.1 UHCI host controllers and the USB 2.0 EHCI host controller is shown in the table below:

**Table 26-1. USB 1.1 and USB 2.0 Comparison**

|                                | USB 1.1 UHCI       | USB 2.0 EHCI                                    |
|--------------------------------|--------------------|---|
| Accessible by                  | I/O space          | Memory Space                                    |
| Memory Data Structure          | Single linked list | Separated in to Periodic and Asynchronous lists |
| Differential Signaling Voltage | 3.3 V              | 400 mV  |
| Controllers                    | 1                  | 1   |
| Ports per Controller           | 2                  | 2   |

## 26.2 USB 2.0 PCI Configuration Registers

The default values are defined with an h for hex, a b for binary, or 00 for zero. If there is not a letter following the default value, assume it is a binary number.

**Warning:** Address locations that are not listed are considered reserved registers locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

**Table 26-2. Bus 0, Device 29, Function 7: Summary of USB (2.0) Controller PCI Configuration Registers (Sheet 1 of 2)**

| Offset Start | Offset End | Register ID - Description   | Default Value |
|--------------|------------|---|---------------|

| 07 : 00                                    | PM_NEXT                   | This register defaults to 58h, which indicates that the next capability registers begin at configuration offset 58h. This register is writable when the WRT_RDONLY bit is set. This allows BIOS to effectively hide the Debug Port capability registers, if necessary. This register must only be written during system initialization before the plug-and-play software has enabled any master-initiated traffic. Only values of 58h (Debug Port visible) and 00h (Debug Port invisible) are expected to be programmed in this register. |                                    | 58h  | RW                |

### 26.2.1.18 Offset 52h: PM\_CAP - Power Management Capabilities Register

Normally, this register is read-only to report capabilities to the power management software. In order to report different power management capabilities depending on the system in which CMI is used, bits 15:11 and 08:06 in this register are writable when the WRT\_RDONLY bit in [Table 26-32, “Offset 80h: AC - Access Control Register”](#) on [page 999](#) is set. The value written to this register does not affect the hardware other than changing the value returned during a read.

Reset: core well, but not D3-to-D0.

### 26.2.1.24 Offset 61h: FLA - Frame Length Adjustment Register

This feature is used to adjust any offset from the clock source that generates the clock that drives the SOF counter. When a new value is written into these six bits, the length of the frame is adjusted. Its initial programmed value is system dependent based on the accuracy of hardware USB clock and is initialized by system BIOS. This register must only be modified when the *HChalted* bit in the USBSTS register is a one. Changing value of this register while the host controller is operating yields undefined results. It must not be reprogrammed by USB system software unless the default or BIOS programmed values are incorrect, or the system is restoring the register while returning from a suspended state.

Table 26-26. Offset 61h: FLA - Frame Length Adjustment Register

| Description: Reset: Suspend well, not D3-to-D0 nor core well reset |                    |  |                             |                                      |            |

The SOF cycle time (number of SOF counter clock periods to generate a SOF microframe length) is equal to 59488 + value in this field. The default value is decimal 32 (20h), which gives a SOF cycle time of 60000.</p> <p><b>Frame Length</b><br/>           (# High Speed bit times)FLADJ Value<br/>           (decimal) (decimal)<br/>           59488 0 (00h)<br/>           59504 1 (01h)<br/>           59520 2 (02h)<br/>           ...<br/>           59984 31 (1Fh)<br/>           60000 32 (20h)<br/>           ...<br/>           60480 62(3Eh)<br/>           60496 63 (3Fh)</p> |                             | 100000b                              | RW         |

### 26.2.1.25 Offset 62h: PWC - Port Wake Capability Register

This register is in the suspend power well. The intended use of this register is to establish a policy about which ports are to be used for wake events. Bit positions 1-8 in the mask correspond to a physical port implemented on the current EHCI controller. A one in a bit position indicates that a device connected below the port can be enabled as a wake-up device and the port may be enabled for disconnect/connect or overcurrent events as wake-up events. This is an information-only mask register. The bits in this register DO NOT affect the actual operation of the EHCI host controller. The system-specific policy can be established by BIOS initializing this register to a system-specific value. System software uses the information in this register when enabling devices and ports for remote wake-up.

*Note:* There is no support for wake from USB when in S3/S4/S5.

**Table 26-27. Offset 62h: PWC - Port Wake Capability Register**

### 26.2.1.26 Offset 64h: CUO - Classic USB Override Register

This 16-bit register provides a bit corresponding to each of the ports on the EHCI host controller (The *EHCI Specification* supports up to 16 ports). When a bit is set to '1', the corresponding USB port is routed to the classic (UHCI) host controller and will only operate using the classic signaling rates. The feature is implemented with the following requirements:

- The associated Port Owner bit does *not* reflect the value in this Override register. This guarantees compatibility with EHCI drivers.
- BIOS must only write to this register during initialization (while the Configured Flag is '0').
- The register is implemented in the Suspend well to maintain port routing when the core power goes down.

- When a '1' is present in the Override register, then the classic controller operates the port regardless of the EHCI port routing logic. The corresponding EHCI port will always appear disconnected in this mode.

*Note:* EHCI test modes will not work on a port that has been overridden by this register.

- Port 0 must never be programmed to the Classic USB Override mode. This is because the Debug Port is used on Port 0 and the two modes conflict with each other.

### 26.2.1.29 Offset 70h: ISU2SMI - Intel Specific USB 2.0 SMI Register

This register provides a mechanism for BIOS to provide USB 2.0 related bug fixes and workarounds. Writing a '1' to that bit location clears bits that are marked as Read/Write/Clear (RW/C). Software must clear all SMI status bits prior to setting the global SMI enable bit and individual SMI enable bit to prevent spurious SMI when returning from a power down.

**Table 26-31. Offset 70h: ISU2SMI - Intel Specific USB 2.0 SMI Register (Sheet 1 of 3)**

## 26.3 USB 2.0 Memory-Mapped I/O Registers

The USB 2.0 EHCI memory-mapped I/O space is composed of two sets of registers: Capability Registers and Operational Registers. The base address of the address space that these registers materialize in is set by the MBAR BAR in the PCI configuration header (see Section 26.2.1.10, “Offset 10h: MBAR - Memory Base Address Register” on page 985).

The EHCI controller does not support as a target memory transactions that are locked transactions. Attempting to access the EHCI controller Memory-Mapped I/O space using locked memory transactions will result in undefined behavior.

*Note:* When the USB 2.0 function is in the D3 PCI power state, accesses to the USB 2.0 memory range are ignored and will result in a master abort. Similarly, if the Memory Space Enable (MSE) bit is not set in the Command register in configuration space, the memory range will not be decoded by the Enhanced Host Controller (EHC). If the MSE bit is not set, then CMI must default to allowing any memory accesses for the range specified in the BAR to go to LPC. This is because the range may not be valid and, therefore, the cycle must be made available to any other targets that may be currently using that range.

### 26.3.1 Host Controller Capability Register Details

These registers specify the limits, restrictions and capabilities of the host controller implementation.

Within the Host Controller Capability Registers, only the Structural Parameters register is writable. This register is implemented in the Suspend well and is only reset by the standard suspend-well hardware reset, not by HCRESET or the D3-to-D0 reset.

#### 26.3.1.1 Offset 00h: CAPLENGTH - Capability Length Register

This register is used as an offset to add to the Memory Base Register to find the beginning of the Operational Register Space. This is fixed at 20h, indicating that the Operation Registers begin at offset 20h.

**Table 26-35. Offset 00h: CAPLENGTH - Capability Length Register**

| Description: |              |  |                             |                                      |            |
|--------------|--------------|--|-----------------------------|--------------------------------------|------------|

This field is hardwired to 20h indicating that the Operation Registers begin at offset 20h. |                             | 20h                                  | RO         |

### 26.3.1.2 Offset 02h: HCIVERSION - Host Controller Interface Version Number Register

This is a 2-byte register containing a BCD encoding of the version number of interface to which this host controller interface conforms.

**Table 26-36. Offset 02h: HCIVERSION - Host Controller Interface Version Number Register**

| Description: |                |   |                               |                                      |            |

### 26.3.1.3 Offset 04h: HCSPARAMS - Host Controller Structural Parameters Register

This is a set of fields that are structural parameters: Number of downstream ports, etc. Some fields in this register are writable when the WRT\_RDONLY bit is set. Fields that are described as “hardwired” are never writable. This register is implemented in the suspend well to avoid having to reload the parameters following a system sleep state in which the core power is removed.

**Table 26-37. Offset 04h: HCSPARAMS - Host Controller Structural Parameters Register (Sheet 1 of 2)**

| Description: Reset: Suspend well reset, but not D3-to-D0 reset or HCRESET. |                    |   |                               |                                      |            |

Values for this field have the following interpretation:<br>0 = Data structures using 32-bit address memory pointers<br>1 = Data structures using 64-bit address memory pointers<br><br>Only 64-bit addressing is supported. This bit is read-only '1'.<br><br>Only 44 bits of addressing is supported. Bits 63:44 will always be 0 on cycles generated to memory.  |                               | 1h                                   | RO         |

### 26.3.2 Host Controller Operational Register Details

This section defines the enhanced host controller operational registers. These registers are located after the capabilities registers. The operational register base must be DWord aligned and is calculated by adding the value in the first capabilities register to the base address of the enhanced host controller register address space. In the following text, the offset is relative to the Memory Base Register. All registers are 32 bits in length. Software must read and write these registers using only Dword accesses.

These registers are divided into two sets. The first set at offsets 20h to 3Fh are implemented in the core power well. Unless otherwise noted, the core-well registers are reset by the assertion of any of the following:

- core well hardware reset
- HCRESET
- D3-to-D0 reset

The second set at offsets 60h to the end of the implemented register space are implemented in the Suspend power well. Unless otherwise noted, the core-well registers are reset by the assertion of either of the following:

- suspend well hardware reset
- HCRESET

The default values are defined with an h for hex, a b for binary, or 00 for zero. If there is not a letter following the default value, assume it is a binary number.

**Warning:** Address locations that are not listed are considered reserved registers locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

**Table 26-39. Host Controller Operational Register Details Summary Table**

| MEM_BASE + Offset |     | Symbol           | Register Name/Function   | Default   | Special Notes | Access  |

| 01           | HCRESET            | <b>Host Controller Reset:</b> This control bit used by software to reset the host controller. The effects of this on Root Hub registers are similar to a Chip Hardware Reset (i.e., RSMRST# assertion and PWROK deassertion).<br>When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports.<br>PCI Configuration registers and Host Controller Capability Registers are not affected by this reset.<br>All operational registers, including port registers and port state machines are set to their initial values. Port ownership reverts to the companion host controller(s), with the side effects described in the <i>EHCI Specification</i> . Software must reinitialize the host controller in order to return the host controller to an operational state.<br>This bit is set to zero by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register.<br>Software must not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior.  |                             | 0h                                   | RW             |   |   |                                   |   |   |                |   |   |                 |   |   |   |  |    |    |
| 00           | RS                 | <b>Run/Stop:</b> Default 0b. 1=Run. 0=Stop.<br>1 = The Host Controller proceeds with execution of the schedule. The Host Controller continues execution as long as this bit is set to a 1.<br>0 = The Host Controller completes the current and any actively pipelined transactions on the USB and then halts. The Host Controller must halt within 16 microframes after software clears the Run bit. The HC Halted bit in the status register indicates when the Host Controller has finished its pending pipelined transactions and has entered the stopped state.<br>Software must not write a 1 to this field unless the host controller is in the Halted state (i.e., HCHalted in the USBSTS register is a one).<br>The following table explains how the different combinations of Run and Halted must be interpreted:<br><table border="1" style="margin-left: 20px;"> <thead> <tr> <th>Run/Stop</th> <th>Halted</th> <th>Interpretation</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>Valid - in the process of halting</td> </tr> <tr> <td>0</td> <td>1</td> <td>Valid - halted</td> </tr> <tr> <td>1</td> <td>0</td> <td>Valid - running</td> </tr> <tr> <td>1</td> <td>1</td> <td>Invalid - the HCHalted bit clears immediately</td> </tr> </tbody> </table><br>Memory read cycles initiated by the EHC that receive any status other than Successful will result in this bit being cleared (and also affect the Host Error bit). | Run/Stop                    | Halted                               | Interpretation | 0 | 0 | Valid - in the process of halting | 0 | 1 | Valid - halted | 1 | 0 | Valid - running | 1 | 1 | Invalid - the HCHalted bit clears immediately |  | 0h | RW |

### 26.3.2.2 Offset 24h: USB2STS - USB 2.0 Status Register

This register indicates pending interrupts and various states of the Host Controller. The status resulting from a transaction on the serial bus is not indicated in this register. Software sets a bit to 0 in this register by writing a 1 to it. See the Interrupts description in section 4 of the *EHCI Specification* for additional information concerning USB 2.0 interrupt conditions.

### 26.3.2.3 Offset 28h: USB2INTR - USB 2.0 Interrupt Enable Register

This register enables and disables reporting of the corresponding interrupt to the software. When a bit is set and the corresponding interrupt is active, an interrupt is generated to the host. Interrupt sources that are disabled in this register still appear in the Status Register to allow the software to poll for events.

Each interrupt enable bit description indicates whether it is dependent on the interrupt threshold mechanism (see Section 4 of the *EHCI Specification*).

Table 26-42. Offset 28h: USB2INTR - USB 2.0 Interrupt Enable Register

**Note:** For all enable register bits, 1= Enabled, 0= Disabled

### 26.3.2.4 Offset 2Ch: FRINDEX - Frame Index Register

This register is used by the host controller to index into the periodic frame list. The register updates every 125 microseconds (once each microframe). Bits [12:3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index is fixed at 10 since only 1024-entry frame lists are supported. This register must be written as a DWord. Word and byte writes produce undefined results. This register cannot be written unless the Host Controller is in the Halted state as indicated by the *HCHalted* bit (USB 2.0STS register). A write to this register while the Run/Stop bit is set to a one (USB 2.0CMD register) produces undefined results. Writes to this register also affect the SOF value. See Section 4 of the *EHCI Specification* for details.

| 13 : 00      | FLCI               | <b>Frame List Current Index/Frame Number:</b> The value in this register increments at the end of each time frame (e.g., microframe). Bits [12:3] are used for the Frame List current index. This means that each location of the frame list is accessed eight times (frames or microframes) before moving to the next index. |                               | 0h                                   | RW         |

The SOF frame number value for the bus SOF token is derived or alternatively managed from this register. Please refer to Section 4 of the *EHCI Specification* for a detailed explanation of the SOF value management requirements on the host controller. The value of FRINDEX must be 125  $\mu$ s (1 microframe) ahead of the SOF token value. The SOF value may be implemented as an 11-bit shadow register. For this discussion, this shadow register is 11 bits and is named SOFV. SOFV updates every 8 microframes. (1 ms). An example implementation to achieve this behavior is to increment SOFV each time the FRINDEX[2:0] increments from a zero to a one.

Software must use the value of FRINDEX to derive the current microframe number and to provide the *get* microframe number function required for client drivers. Therefore, the value of FRINDEX and the value of SOFV must be kept consistent if chip is reset or software writes to FRINDEX. Writes to FRINDEX must also *write-through* FRINDEX[13:3] to SOFV[10:0]. In order to keep the update as simple as possible, software must never write a FRINDEX value where the three least significant bits are 111b or 000b.

### 26.3.2.5 Offset 30h: CTRLDSSEGMENT - Control Data Structure Segment Register

This 32-bit register corresponds to the most significant address bits [63:32] for all EHCI data structures. Since the 64-bit Addressing Capability field is hardwired in HCCPARAMS to one, then this register is used with the link pointers to construct 64-bit addresses to EHCI control data structures. This register is concatenated with the link pointer from either the PERIODICLISTBASE, ASYNCLISTADDR, or any control data structure link field to construct a 64-bit address. This register allows the host software to locate all control data structures within the same 4 GByte memory segment.

**Note:** CMI has 44-bit addressing internally for both control and data structures. Address bits 63:44 [31:12] are hardwired to zero independent of the setting of this register. The lower 12 address bits 43:32 [11:0] are fully read/write capable for software compatibility and specification compliance.

**Table 26-44. Offset 30h: CTRLDSSEGMENT - Control Data Structure Segment Register**

**26.3.2.6 Offset 34h: PERIODICLISTBASE - Periodic Frame List Base Address Register**

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. Since the host controller operates in 64-bit mode (as indicated by the one in the 64-bit Addressing Capability field in the HCCSPARAMS register) (offset 08h, bit 0), then the most significant 32 bits of every control data structure address comes from the CTRLDSSEGMENT register. System software loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4 Kbyte aligned. The contents of this register are combined with the Frame Index Register (FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

**Table 26-45. Offset 34h: PERIODICLISTBASE - Periodic Frame List Base Address Register**

| Description:        |                           |   |                                    |  |            |

### 26.3.2.7 Offset 38h: ASYNCLISTADDR - Current Asynchronous List Address Register

This 32-bit register contains the address of the next asynchronous queue head to be executed. Since the host controller operates in 64-bit mode (as indicated by a one in 64-bit Addressing Capability field in the HCCPARAMS register), then the most significant 32 bits of every control data structure address comes from the CTRLDSSEGMENT register. Bits [4:0] of this register cannot be modified by system software and will always return zeros when read. The memory structure referenced by this physical memory pointer is assumed to be 32-byte aligned.

**Table 26-46. Offset 38h: ASYNCLISTADDR - Current Asynchronous List Address Register**

| Description: |                    |   |                             |                                      |            |

### 26.3.2.8 Offset 60h: CONFIGFLAG - Configure Flag Register

This register is in the suspend power well. It is only reset by hardware when the suspend power is initially applied or in response to a host controller reset. This 32-bit register contains the address of the next asynchronous queue head to be executed. Since the host controller operates in 64-bit mode (as indicated by a 1 in 64-bit Addressing Capability field in the HCCPARAMS register), then the most significant 32 bits of every control data structure address comes from the CTRLDSSEGMENT register (offset 08h). Bits [4:0] of this register cannot be modified by system software and will always return 0's when read. The memory structure referenced by this physical memory pointer is assumed to be 32-byte aligned.

**Table 26-47. Offset 60h: CONFIGFLAG - Configure Flag Register**

| Description: |                    |  |                             |                                      |            |

This bit controls the default port-routing control logic. Bit values and side effects are listed below. See section 4 of the <i>EHCI Specification</i> for operation details.<br>0 = Port routing control logic default-routes each port to the classic host controllers.<br>1 = Port routing control logic default-routes all ports to this host controller. |                             | 0h                                   | RW         |

### 26.3.2.9 Offset 64h: PORTSC - Port N Status and Control Register

A host controller must implement one or more port registers. Software uses the N\_Port information from the Structural Parameters Register to determine how many ports need to be serviced. All ports have the structure defined below. Software must not write to unreported Port Status and Control Registers.

This register is in the suspend power well. It is only reset by hardware when the suspend power is initially applied or in response to a host controller reset. The initial conditions of a port are:

- No device connected
- Port disabled

**Note:** When a device is attached, the port state transitions to the connected state and system software will process this as with any status change notification. Refer to Section 4 of the *EHCI Specification* for operational requirements for how change events interact with port suspend mode.

**Note:** If a port is being used as the Debug Port, then the port may report device connected and enabled when the Configured Flag is a zero.

**Note:** There is no support for wake from USB when in S3/S4/S5.

**Table 26-48. Offset 64h: PORTSC - Port N Status and Control Register (Sheet 1 of 5)**

| 08  | PR                 | <p><b>Port Reset:</b><br/>0 = Port is not in Reset (default).<br/>1 = Port is in Reset.</p> <p>When software writes a one to this bit (from a zero), the bus reset sequence as defined in the <i>USB Rev. 2.0 Specification</i> is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the <i>USB Rev. 2.0 Specification</i>, completes.</p> <p><b>Note:</b> When software writes this bit to a one, it must also write a zero to the <i>Port Enable</i> bit.</p> <p><b>Note:</b> When software writes a zero to this bit, there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g., set the <i>Port Enable</i> bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 ms of software transitioning this bit from a one to a zero. For example, if the port detects that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2 ms of software writing this bit to a zero.</p> <p>The HCHalted bit in the USB2STS register must be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one.</p> <p>The <i>Run/Stop</i> bit in the Command Register must be set in order for the <i>Port Reset</i> bit to be cleared.</p> |                                      | 0h              | RW             |     |     |  |     |         |  |     |         |   |     |           |  |  |    |    |

| 10  | Enable             |   |  |                 |            |         |    |        |    |         |  |    |    |
| 11  | Suspend            |   |  |                 |            |         |    |        |    |         |  |    |    |
| 06  | FPR                | <p><b>Force Port Resume:</b><br/>                     0 = No resume (K-state) detected/driven on port (default).<br/>                     1 = Resume detected/driven on port.</p> <p>This functionality defined for manipulating this bit depends on the value of the <i>Suspend</i> bit. For example, if the port is not suspended (<i>Suspend</i> and <i>Enabled</i> bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined.</p> <p>Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the <i>Port Change Detect</i> bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the <i>Port Change Detect</i> bit.</p> <p>When the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the <i>USB Rev. 2.0 Specification</i>. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.</p> |  | 0h              | RW         |         |    |        |    |         |  |    |    |

The functionality of this bit is not dependent upon the port owner.<br/>           CMI automatically disables the port when the overcurrent active bit is '1'.</p>  |                                      | 0h              | RO         |
| 03  | PEDC               | <p><b>Port Enable/Disable Change:</b><br/>           0 = No change (default).<br/>           1 = Port enabled/disabled status has changed.<br/>           For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the <i>USB Specification</i> for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.</p>  |                                      | 0h              | RWC        |
| 02  | PENDIS             | <p><b>Port Enabled/Disabled:</b><br/>           0 = Disable (default).<br/>           1 = Enable.<br/>           As described in the <i>EHCI Specification</i>, ports are enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. The host controller will only set this bit to a one when the reset sequence determines that the attached device is a high-speed device.</p>   |                                      | 0h              | RW         |
| 01  | CSC                | <p><b>Connect Status Change:</b><br/>           0 = No change (default).<br/>           1 = Change in Current Connect Status.<br/>           Indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be "setting" an already-set bit (i.e., the bit will remain set). Software sets this bit to 0 by writing a 1 to it.</p> |                                      | 0h              | RWC        |
| 00  | CCS                | <p><b>Current Connect Status:</b><br/>           0 = No device is present (default).<br/>           1 = Device is present on port.<br/>           This value reflects the current state of the port and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set.</p>   |                                      | 0h              | RO         |

## 26.4 EHC Initialization

The following describes the expected EHC initialization sequence in chronological order, beginning with a complete power cycle in which the suspend well and core well have been off.

### 26.4.1 Power On

The suspend well is a “deeper” power plane than the core well, which means that the suspend well is always functional when the core well is functional but the core well may not be functional when the suspend well is. Therefore, the suspend well reset pin (RSMRST#) deasserts before the core well reset pin (PWROK) rises.

1. The suspend well reset deasserts, leaving all registers and logic in the suspend well in the default state. However, it is not possible to read any registers until after the core well reset deasserts.
2. The core well reset deasserts, leaving all registers and logic in the core well in the default state. The EHC configuration space is accessible at this point. The core well reset can (and typically does) occur without the suspend well reset asserting. This means that all of the Configure Flag and Port Status and Control bits (and any other suspend-well logic) may be in any valid state at this time.

### 26.4.2 Driver Initialization

See Chapter 4 of the *EHCI Specification, Rev. 1.0*.

### 26.4.3 EHC Resets

In addition to the standard hardware resets, portions of the EHC are reset by the HCRESET bit and the transition from the D3hot device power management state to the D0 state. The effect of each of these resets are:

**Table 26-49. HCRESET Bit Summary**

| Reset   | Does Reset   | Does Not Reset  | Comments   |
|---|--|---|--|
| HCRESET bit set   | Memory space registers except Structural Parameters (which is written by BIOS) | Configuration Registers                                     | The HCRESET must only affect registers that the EHCI driver controls. PCI Configuration space and BIOS-programmed parameters must not be reset.  |
| Software writes the Device Power State from D3hot (11b) to D0 (00b) | Core-well registers (except BIOS-programmed registers)                         | Suspend-well registers; BIOS-programmed Core-well Registers | The D3-to-D0 transition must not cause wake information (suspend well) to be lost. It also must not clear BIOS-programmed registers because BIOS may not be invoked following the D3-to-D0 transition. |

If the detailed register descriptions give exceptions to these rules, those exceptions override these rules. This summary is provided to help explain the reasons for the reset policies.

## 26.5 Data Structures in Main Memory

See Section 3 and Appendix B of the *EHCI Specification, Rev. 1.0* for details.

## 26.6 USB 2.0 Enhanced Host Controller DMA

The USB 2.0 enhanced host controller implements three sources of USB packets. They are, in order of priority on USB during each microframe,

1. the USB 2.0 Debug Port (see [Section 26.13](#)),
2. the Periodic DMA engine, and
3. the Asynchronous DMA engine.

CMI always performs any currently-pending debug port transaction at the beginning of a microframe, followed by any pending periodic traffic for the current microframe. If there is time left in the microframe, then the EHC performs any pending asynchronous traffic at the end of the microframe (EOF1). The debug port traffic is only presented on one port (Port #0), while the other ports are idle during this time.

The following subsections describe the policies of the periodic and asynchronous DMA engines.

### 26.6.1 Periodic List Execution

The Periodic DMA engine contains buffering for two control structures (two transactions). By implementing two entries, the EHC is able to pipeline the memory accesses for the next transaction while executing the current transaction on the USB ports. A multiple-packet, high-bandwidth transaction occupies one of these buffer entries, which means that up to six 1 Kbyte data packets may be associated with the two buffered control structures.

In order to simplify the pipelined implementation that is optimized for normal execution, the EHC does not implement immediate retries on High Bandwidth Interrupt transactions that encounter transaction errors (for ins and outs) or a Data Toggle mismatch (for Interrupt In). This is an optional implementation, but not recommended, by the *USB Specification* and the *USB Specification, Revision 0.95*. The EHC will reattempt the transaction when that qTD is encountered again in the periodic schedule. If successful when reattempted, then the EHC will continue with the multiple packets allowed by the high-bandwidth endpoint during that same microframe.

#### 26.6.1.1 Read Policies for Periodic DMA

The Periodic DMA engine performs memory reads for the following structures:

**Table 26-50. Periodic DMA Engine Memory Reads**

| Memory Structure          | Size (DWORDS) | Comments   |
|---------------------------|---------------|--|
| Periodic Frame List entry | 1             | The EHC reads the entry for each microframe. The frame list is not internally cached across microframes. |
| Frame Span Traversal Node | 2             |  |
| iTD                       | 23            | Only the 64-bit addressing format is supported.  |
| siTD                      | 9             | Only the 64-bit addressing format is supported.  |

Table 26-50. Periodic DMA Engine Memory Reads

|            |           |   |
|------------|-----------|---|
| qTD        | 13        | Only the 64-bit addressing format is supported.   |
| Queue Head | 17        | Only the 64-bit addressing format is supported.   |
| Out Data   | Up to 257 | Large read requests are broken down into smaller aligned read requests based on the setting of the Read Request Maximum Length field. |

Periodic DMA read policies:

1. The EHC Periodic DMA Engine (PDE) does not generate accesses to main memory unless all three of the following conditions are met:
  - a. The HCHalted bit is 0 (memory space, offset 24h, bit 12). Software clears this bit indirectly by setting the RUN/STOP bit to 1.
  - b. The Periodic Schedule Status bit is 1 (memory space, offset 24h, bit 14). Software sets this bit indirectly by setting the Periodic Schedule Enable Bit to 1.
  - c. The Bus Master Enable bit is 1 (configuration space, offset 04h, bit 2).
2. Once the above conditions are met, the PDE waits until the frame index counter rolls over from the end of microframe 6 to the beginning of microframe 7 to begin prefetching for microframe 0 of the next frame. This means the initial memory access may be delayed up to 1 ms after the DMA-enabled conditions are met. Further delays within the arbitration and datapath are also possible before the first read request is presented on the IMCH/IICH link.
3. The Periodic Frame List Entry is always read from memory before any data structures associated with the new microframe are accessed.
4. Prefetching is limited to the current and next microframes only. If prefetching is disabled, the periodic DMA engine will perform transactions serially (no pipelining) and will read structures for the current microframe only.
5. The PDE fetches structures in the periodic list until all information (including data) is available to run one USB transaction before beginning to fetch the structures for a pipelined transaction. For High-Bandwidth Out transactions, all of the data may not fit into the Data FIFO; in those cases, the next pipelined control structure fetches will be delayed until some data is delivered to USB.
6. The PDE does not refetch the control structure between "Multi" packets of a High Bandwidth endpoint.
7. The PDE will not generate any control structure reads (including the frame list index) if both of the transaction buffers are occupied. Data reads are the only read requests that will be generated by the PDE in this case.
8. The PDE will not pipeline fetch a control structure (iTd, siTD, or QH) if the other transaction slot contains that control structure already. This is to avoid executing based on stale fields in the control structure since a status write (or overlay) is expected to occur following execution of the pending transaction. The PDE will traverse the schedule (periodic frame list entry and any inactive control structures for the microframe) before encountering the Link Pointer to the stale structure. At that point the fetching pauses until the pending transaction is completed. *The iTD could be refetched since a separate status is maintained for each microframe; the PDE will not attempt this optimization.*
9. Once the PDE checks the length of a periodic packet against the remaining time in the microframe (late-start check) and decides that there is not enough time to run it on the wire, then the EHC switches over to run asynchronous traffic. The EHC does not attempt to look for any shorter packets in the remainder of the periodic schedule that might be able to fit in the current microframe.

10. The PDE implements a “Gross Late-Start” check which determines whether any more control or data structure reads will be initiated for transactions associated with the current microframe. The threshold for this check is determined by the Gross Late Start Cut-Off field in configuration register offset 84h.
11. An entry in the 2-deep command FIFO becomes available for a new transaction fetch when any of the following events occur:
  - a. The final transaction results are posted in write buffers to memory.
  - b. Either of the late-start checks fail for this transaction (or the preceding transaction in the same microframe).
  - c. A High-Bandwidth Interrupt transaction times out. For High-Bandwidth Interrupt transactions that time out, the CMI does not immediately retry the transaction as recommended by the *USB Specification* (Section 5.9.1). Instead, all control and data structures are flushed and the transaction is reattempted the next time that endpoint is scheduled.

*Note:* When a host error occurs, the commands are kept in the PDE. The EHCI software driver must assert the HCRESET in order to clear the pending transactions before reenabling the PDE.

12. Data fetches are not initiated unless there is room in the Out Data FIFO to consume the amount of data requested.
13. Read requests are broken up and throttled based on the Read Request Maximum Length field and the Request Rate Throttle fields in the configuration register at offset FCh. Control or Data structures that cross a Maximum Length-aligned boundary in memory are broken into multiple requests. This allows other packets from within the IICH to be interleaved on the IMCH/IICH link and through the memory controller to avoid temporary starvation of those functions. When generating the multiple read requests, the EHC will naturally-align the requests (i.e., 64-byte requests will not fetch across 64-byte address boundaries in memory). This guarantees that, as cache-line sizes increase, the back-to-back requests do not cause double-snoops on specific cache lines. Unlike control structure read requests, only reads for data will be subject to the Request Rate Throttle.
14. Asynchronous DMA memory accesses may be interleaved at any point with the periodic DMA memory accesses on the IMCH/IICH link.

### 26.6.1.2 Write Policies for Periodic DMA

The Periodic DMA engine performs writes to the following data structures:

Periodic DMA write policies:

1. The Periodic DMA Engine (PDE) will only generate writes after a transaction is executed on USB. Some important notes associated with this rule are:
  - a. If either of the late-start checks fails before the transaction is run on the USB ports, then none of the writes normally associated with that transaction will occur. High-Bandwidth Exception: If the late-start check fails after the first packet of a High-Bandwidth (multi) transaction is executed but before the last packet, then the PDE must write the status for any completed transfers to memory.
  - b. The Queue Head Overlay write occurs after the first transaction for a qTD is completed on the USB interface.
2. Status writes are always performed after In Data writes for the same transaction.
3. When writing the status back to the two siTDs associated with a backpointer, the PDE first writes to the siTD which was referenced by the backpointer and secondly writes to the siTD which contains the backpointer.

4. Asynchronous DMA memory accesses may be interleaved at any point with the periodic DMA memory accesses on the IMCH/IICH link.
5. When writing back the qTD information after clearing the *Active* bit, the *EHCI Specification* does not require that the *C\_Page* field is written. However, due to byte-granular write control, the EHC does write to this field, and the value is not necessarily the final or incremented *C\_Page* value.

## 26.6.2 Asynchronous List Execution

The Asynchronous DMA engine contains buffering for two control structures (two transactions). By implementing two entries, the EHC is able to pipeline the memory accesses for the next transaction while executing the current transaction on the USB ports.

### 26.6.2.1 Read Policies for Asynchronous DMA

The Asynchronous DMA engine performs reads for the following structures:

**Table 26-51. Asynchronous DMA Engine Reads**

| Memory Structure | Size (DWORDS) | Comments   |
|------------------|---------------|--|
| qTD              | 13            | Only the 64-bit addressing format is supported.  |
| Queue Head       | 17            | Only the 64-bit addressing format is supported.  |
| Out Data         | Up to 129     | Large read requests are broken down in to smaller aligned read requests based on the setting of the Read Request Maximum Length field. |

Asynchronous DMA read policies:

1. The EHC Asynchronous DMA Engine (ADE) does not generate accesses to main memory unless all four of the following conditions are met. (The ADE may be active when the periodic schedule is actively executed, unlike the description in the *EHCI Specification*; since the EHC contains independent DMA engines, the ADE may perform memory accesses interleaved with the PDE accesses.)
  - a. The HCHalted bit is 0 (memory space, offset 24h, bit 12). Software clears this bit indirectly by setting the RUN/STOP bit to 1.
  - b. The Asynchronous Schedule Status bit is 1 (memory space, offset 24h, bit 14). Software sets this bit indirectly by setting the Asynchronous Schedule Enable Bit to 1.
  - c. The Bus Master Enable bit is 1 (configuration space, offset 04h, bit 2).
  - d. The ADE is not sleeping due to the detection of an empty schedule. There is not one single bit that indicates this state. However, the sleeping state is entered when the Queue Head with the H bit set is encountered when the Reclamation bit in the USB 2.0 Status register is 0.
2. Once the above conditions are met, the ADE immediately begins reading the Queue Head to which the Current Asynchronous List Address Register points. Delays within the arbitration and datapath are possible before the first read request is presented on the IMCH/IICH link.
3. If prefetching is disabled, the ADE will perform transactions serially (no pipelining).
4. The ADE fetches structures in the asynchronous list until all information (including data) is available to run one USB transaction before beginning to fetch the structures for a pipelined transaction.
5. The ADE will not generate any control structure reads if both of the transaction buffers are occupied. Data reads are the only read requests that will be generated by the ADE in this case.

6. The ADE does not fetch data when a QH is encountered in the Ping state. An Ack handshake in response to the Ping results in the ADE writing the QH to the Out state, which results in the fetching and delivery of the Out Data on the next iteration through the asynchronous list.
7. The ADE will not pipeline fetch a Queue Head if the other transaction slot contains that Queue Head already (i.e., only one active QH). This is to avoid executing based on stale fields in the Queue Head since a status write (or overlay) is expected to occur following execution of the pending transaction. The ADE will traverse the schedule (any inactive Queue Heads) before encountering the Link Pointer to the stale structure. At that point the fetching pauses until the pending transaction is completed.
8. Once the ADE checks the length of an asynchronous packet against the remaining time in the microframe (late-start check) and decides that there is not enough time to run it on the wire, then the EHC stops all activity on the USB ports for the remainder of that microframe. The EHC does not attempt to look for any shorter packets in the remainder of the asynchronous schedule that might be able to fit in the current microframe. Unlike the PDE, the ADE keeps the transaction internally for executing in the next microframe without refetching from memory.
9. An entry in the 2-deep command FIFO becomes available for a new transaction fetch when any of the following events occur:
  - a. The final transaction results are posted in write buffers to memory.
  - b. A host error causes an unexpected halt. Any unexecuted transactions in the command FIFO are flushed.
10. Once the ADE detects an "empty" asynchronous schedule as described in the *EHC1 Specification*, it implements a waking mechanism like the one in the example. The amount of time that the ADE "sleeps" is  $10 \mu\text{s} \pm 30 \text{ ns}$ .
11. Data fetches are not initiated unless there is room in the Out Data FIFO for the amount of data requested.
12. Read requests are broken up and throttled based on the Read Request Maximum Length field and the Request Rate Throttle fields in the configuration register at offset FCh. Control or Data structures that cross a Maximum Length-aligned boundary in memory are broken into multiple requests. This allows other packets from within the IICH to be interleaved on the IMCH/IICH link and through the memory controller to avoid temporary starvation of those functions. When generating the multiple read requests, the EHC will naturally-align the requests (i.e., 64-byte requests will not fetch across 64-byte address boundaries in memory). This guarantees that, as cache-line sizes increase, the back-to-back requests do not cause double-snoops on specific cache lines. Unlike control structure read requests, only reads for data will be subject to the Request Rate Throttle.
13. Periodic DMA memory accesses may be interleaved at any point with the asynchronous DMA memory accesses on IMCH/IICH link.

### 26.6.2.2 Write Policies for Asynchronous DMA

The Asynchronous DMA engine performs writes to the following memory structures:

**Table 26-52. Asynchronous DMA Engine Writes**

| Memory Structure                     | Size (DWORDS) | Comments   |
|--------------------------------------|---------------|--|
| Asynchronous Queue Head Overlay      | 14            | Only the 64-bit addressing format is supported. Dwords 0Ch through 43h are written.  |
| Asynchronous Queue Head Status Write | 3             | Dwords 14h through 1Fh are written.  |
| Asynchronous qTD Status Write        | 3             | Dwords 04h through 0Fh are written. PID Code, IOC, Buffer Pointer (page 0), and Alt. Next qTD Pointer are rewritten with the original value. |
| In Data                              | Up to 129     | Data writes are broken down into 16 Dword-aligned chunks.  |

Asynchronous DMA write policies:

1. The Asynchronous DMA Engine (ADE) will only generate writes after a transaction is executed on USB. Some important notes associated with this rule are:
  - a. If the late-start check fails before the transaction is run on the USB ports, then the USB transaction and the writes are delayed until the next opportunity to run the asynchronous traffic.
  - b. The Queue Head Overlay write occurs after the first transaction for a qTD is completed on the USB interface.
2. Status writes are always performed after In Data writes for the same transaction.
3. Periodic DMA memory accesses may be interleaved at any point with the Asynchronous DMA memory accesses on IMCH/IICH link.
4. When writing back the qTD information after clearing the *Active* bit, the *EHCI Specification* does not require that the *C\_Page* field is written. However, due to byte-granular write control, the EHC does write to this field, and the value is not necessarily the final or incremented *C\_Page* value.

## 26.7 Data Encoding and Bit Stuffing

See the *USB Rev. 2.0 Specification*.

## 26.8 Packet Formats

See the *USB Rev. 2.0 Specification*.

## 26.9 USB 2.0 Interrupts and Error Conditions

The *EHCI Specification* goes into detail on the EHC interrupts and the error conditions that cause them. All error conditions that the EHC detects can be reported through the EHCI Interrupt status bits. Only CMI-specific interrupt and error-reporting behavior is documented in this section. The EHCI Interrupts Section (in the *EHCI Specification*) must be read first, followed by this section, to fully comprehend the EHC interrupt and error-reporting functionality.

- Based on the EHC's Buffer sizes and buffer management policies, the Data Buffer Error can never occur.
- Master Abort and Target Abort responses from the system interface on EHC-initiated read packets will be treated as Fatal Host Errors. The EHC halts when these conditions are encountered.

- CMI may assert the interrupts that are based on the interrupt threshold as soon as the status for the last complete transaction in the interrupt interval has been posted in the internal write buffers. The requirement in the *EHCI Specification* (that the status is written to memory) is met internally, even though the write may not be seen on the IMCH/IICH interface before the interrupt is asserted.
- Since CMI only supports the 1024-element Frame List size, the Frame List Rollover interrupt occurs every 1024 milliseconds.
- CMI delivers interrupts using PIRQ#[A].
- CMI does not modify the CERR count on an Interrupt IN when the “Do Complete-Split” execution criteria are not met.
- For complete-split transactions in the Periodic list, the “Missed Microframe” bit does not get set on a control-structure-fetch that fails the late-start test. If subsequent accesses to that control structure do not fail the late-start test, then the “Missed Microframe” bit will get set and written back.

### 26.9.1 Aborts on USB 2.0-Initiated Memory Reads

If a read initiated by the EHC receives any status other than “Successful” in the completion packet, the EHC treats it as a fatal host error. The following actions are taken when this occurs:

- The Host System Error status bit is set
- The DMA engines are halted, the Run/Stop bit is cleared, and the HCHalted bit is set, after completing up to one more transaction on the USB interface
- If enabled (by the Host System Error Enable), then an interrupt is generated
- If the status is Master Abort, then the Received Master Abort bit in configuration space is set
- If the status is Target Abort, then the Received Target Abort bit in configuration space is set
- If enabled (by the SERR Enable bit and the SERR on Abort Enable bit in the function’s configuration space), then the Signaled System Error bit in configuration bit is set and the internal SERR signal is asserted

### 26.9.2 Host Interface Parity Errors

In the event of parity errors on the host-side interface, the EHC is required to respond as shown in the following table.

The EHC is accessible as a target after the parity errors are detected (assuming that

**Table 26-53. Host Interface Parity Errors (Sheet 1 of 2)**

| Input Scenario                         |                   |                                | Resulting Behavior         |                                  |                                |  |

|   | 1   | 0                              | 1                          | 1                                | 1                              | Cycle is taken.<br>Halt the Host Controller, if currently not halted.<br>Do not forward data to the USB ports.<br>No SERR# generated.<br>(No PERR# on the IMCH/IICH link)<br>Software can only determine that the error occurred through the Host Error interrupt or by polling. |
|   | 1   | 1                              | 1                          | 1                                | 1                              | Cycle is taken.<br>Halt the Host Controller, if currently not halted.<br>Do not forward data to the USB ports.<br>SERR# generated.<br>(No PERR# on the IMCH/IICH link)   |

the system instability has not caused a deadlock in some way).

All of the above description is required behavior. The following text describes the CMI-specific implementation details:

There are three general forms of parity errors that the EHC may detect on its system interface:

- Command/Address (on cycles from the host side)
  - C/A parity error on Host-initiated cycles, or
  - Command parity error on Completion packets to CMI

- Host-Initiated Write Data
- Read Completion Data to the EHC

When any of these three errors are detected and the Parity Error Response bit is set in the USB 2.0 function, the EHC immediately sets the Host Error bit to '1' and clears the Run/Stop bit to '0'. At most, one more packet completes on the high-speed USB ports after this occurs (this packet will not contain, or be based upon, the data containing the host error). When that packet is completed, the HCHalted bit is set to a '1'. Once the Host Error bit has been set, the Run/Stop bit can not be set by software until after the HCRESET is generated by software and completed by the EHC, which lasts for multiple milliseconds. The EHC will still accept host-initiated cycles as a target after the HCHalted bit has been set.

It is recommended that software reboot in the event of a parity error because the error could be an indication of other system hardware problems.

## 26.10 USB 2.0 Power Management

### 26.10.1 Pause Feature

This feature allows platforms to dynamically enter low-power states during brief periods when the system is idle (i.e., between keystrokes). This is useful for enabling power management features like Enhanced Intel SpeedStep Technology (EIST). The policies for entering these states typically are based on the recent history of system bus activity to incrementally enter deeper power management states. Normally, when the EHC is enabled, it regularly accesses main memory while traversing the DMA schedules looking for work to do; this activity is viewed by the power management software as a non-idle system, thus preventing the power managed states to be entered. Suspending all of the enabled ports can prevent the memory accesses from occurring, but there is an inherent latency overhead with entering and exiting the suspended state on the USB ports that makes this unacceptable for the purpose of dynamic power management. As a result, the EHCI software drivers are allowed to pause the EHC's DMA engines when it knows that the traffic patterns of the attached devices can afford the delay. The pause only prevents the EHC from generating memory accesses; the SOF packets continue to be generated on the USB ports (unlike the suspended state).

The expected sequence of events for the Pause Feature is:

1. When starting the DMA engines for the first time, the enable bits are set at the same time as, or after, the Run bit is set. However, the EHC should be capable of handling the Run bit set to 0 while one or both of the enable bits are 1; this may happen, for example, when the hardware halts the DMA due to an error. The enable bits may be set to 1 by different writes to the Command Register. The EHC takes the following actions when the enable bits are set by software:
  - a. The corresponding Asynch/Periodic Schedule Status bit(s) is (are) immediately set to 1.
  - b. If the Asynch Enable bit is set, the first queue head in the asynchronous schedule is immediately fetched (if the Bus Master Enable bit in Configuration space is set).
  - c. If the Periodic Enable bit is set, then the periodic frame list entry is fetched (if the Bus Master Enable bit in Configuration space is set) on the next internal trigger point, which may be up to 1 ms later.
2. Before clearing a Schedule Enable bit, software reads the USB 2.0 Status register to make sure that the corresponding Schedule Status bit has been set.

3. When system software determines that it should pause the EHC schedule, one or both of the Schedule Enable bits are written to 0. When this happens, the EHC responds as follows:
  - a. The schedule disables are handled independently. In other words, the asynchronous and periodic disables may take effect in any order and vary greatly in latency.
  - b. If the Periodic Schedule Enable is cleared, up to two more periodic transactions may be seen on the USB ports. Reads associated with the periodic schedule cease when the first fetch for a new transaction would normally be initiated; any reads required to execute an already partially-fetched transaction will continue to be generated. Writes associated with the periodic schedule may continue until all pending transactions in the periodic DMA engine's transaction queue are completed. The Periodic Schedule Status bit is cleared when the memory reads have completed and the memory writes have been internally posted.

*Note:* Multiple high-bandwidth packets are considered one transaction.

- c. If the Asynchronous Schedule Enable is cleared, up to two more asynchronous transactions may be seen on the USB ports. Reads associated with the asynchronous schedule cease when the first fetch for a new transaction would normally be initiated; any reads required to execute an already partially-fetched transaction will continue to be generated. Writes associated with the asynchronous schedule will continue until all pending transactions in the asynchronous DMA engine's transaction queue are completed. The Asynchronous Schedule Status bit is cleared when the memory reads have completed and the memory writes have been internally posted.
4. Before setting a Schedule Enable bit, software reads the USB 2.0 Status register to make sure that the corresponding Schedule Status bit is cleared.
5. When system software determines that it should reenables the EHC, one or both of the Schedule Enable are written to 1. When this happens, the EHC responds as described in the initial start-up case above.

The CMI does *not* implement a similar pause mechanism in the classic host controllers, which conflicts with the recommendation in the *EHCI Specification*.

## 26.10.2 Suspend Feature

The *EHCI Specification* describes the details of Port Suspend and Resume.

## 26.10.3 ACPI Device States

The USB 2.0 function only supports the D0 and D3 PCI Power Management states. Notes regarding implementation of the Device States:

1. The EHC hardware does not inherently consume any more power when it is in the D0 state than it does in the D3 state. However, software is required to suspend or disable all ports prior to entering the D3 state such that the maximum power consumption is reduced.
2. In the D0 state, all implemented EHC features are enabled.
3. In the D3 state, accesses to the EHC memory-mapped I/O range will master abort. Since the Debug Port uses the same memory range, the Debug Port is only operational when the EHC is in the D0 state.
4. In the D3 state, the EHC interrupt must never assert for any reason. The internal PME# signal is used to signal wake events, etc.
5. When the Device PowerState field is written to D0 from D3, an internal reset is generated. See [Section 26.4.3](#) for general rules on the effects of this reset.

6. Attempts to write any other value into the Device PowerState field other than 00b (D0 state) and 11b (D3 state) will complete normally without changing the current value in this field.

Software performs the following sequence to put the EHC in the D3 state:

1. Software selectively suspends any enabled EHC ports.
2. Software reads back the selectively suspended ports to make sure the EHC has completed the suspend request.
3. Software clears the Run bit.
4. Software reads back the USB 2.0 Status Register to verify that the EHC is halted.
5. Software reads and saves the contents of the PCI configuration registers for restoring the context after transitioning back to the D0 state.
6. Software writes the Device PowerState field to the D3 state.

#### 26.10.4 ACPI System States

The EHC behavior as it relates to other power management states in the system is summarized in the following list:

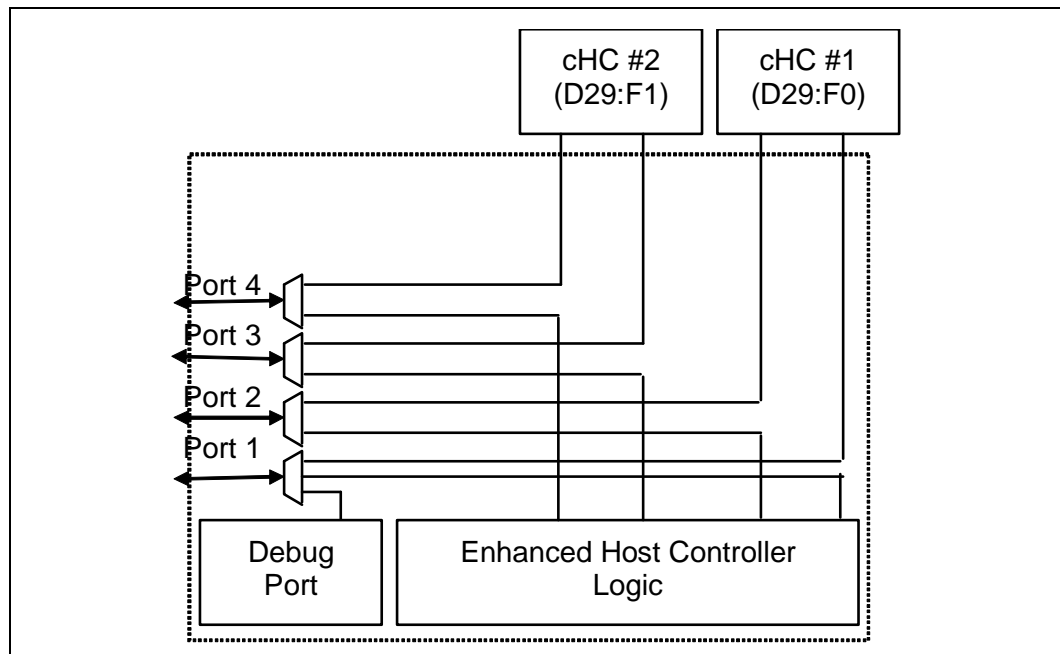

- The System is always in the S0 state when the EHC is in the D0 state. However, when the EHC is in the D3 state, the system may be in any power management state (including S0).
- When in D0, the Pause feature (described above) enables dynamic CPU low-power states to be entered.
- The PLL in the EHC is disabled when entering the S3-Cold/S4/S5 states (core power turns off).
- All core-well logic is reset in the S3/S4/S5 states.

#### 26.11 Interaction with Classic Host Controllers

The Enhanced Host Controller shares the two USB ports with two UHCI Classic Host Controllers (cHCs). The cHC at Device 29: Function 0 shares ports 1 and 2 with the EHC. There is very little interaction between the Enhanced and Classic controllers other than the muxing control that is provided as part of the EHC.

Figure 26-1 depicts the USB Port Connections at a conceptual level. The dashed rectangle indicates all of the logic that is part of the Enhanced Host Controller cluster.

Figure 26-1. USB Port Connections

### 26.11.1 Port-Routing Logic

Integrated into the EHC functionality is “port-routing logic,” which performs the muxing between the classic and enhanced Host Controllers. CMI conceptually implements this logic as described in the *EHCI Specification, Rev. 1.0*. If a device is connected that is not capable of USB 2.0’s high-speed signaling protocol or if the EHCI software drivers are not present as indicated by the Configured Flag, then the cHC owns the port. Owning the port means that the differential output is driven by the owner and the input stream is only visible to the owner. The HC that is not the owner of the port internally sees a disconnected port.

*Note:* The port-routing logic is the only block of logic that observes the physical (real) connect/disconnect information. The port status logic inside each of the host controllers observes the electrical (artificial) connect/disconnect information that is generated by the port-routing logic.

Only the differential signal pairs are muxed/demuxed between the classic and enhanced host controllers. The other USB functional signals are handled as follows:

- The Overcurrent inputs (OC#[3:0]) are directly routed to both controllers. An overcurrent event is recorded in both controllers’ status registers.
- The Port Routing logic is implemented in the Suspend power well so that reenumeration and remapping of the USB ports is not required following entering and exiting a system sleep state in which the core power is turned off.
- CMI also allows the USB Debug Port traffic to be routed in and out of Port #0. When in this mode, the Enhanced Host Controller is the owner of Port #0.

### 26.11.2 Device Connects

The *EHCI Specification, Rev. 1.0* describes the details of handling Device Connects. There are four general scenarios that are summarized below.

1. Configure Flag = 0 and a Classic-only Device is connected  
In this case, the classic Host Controller is the owner of the port both before and after the connect occurs; the EHC (except for the port-routing logic) never sees the connect occur. The UHCI driver handles the connection and initialization process.
2. Configure Flag = 0 and an Enhanced-capable Device is connected  
In this case, the classic Host Controller is the owner of the port both before and after the connect occurs; the EHC (except for the port-routing logic) never sees the connect occur. The UHCI driver handles the connection and initialization process. Since the classic Host Controller does not perform the high-speed chirp handshake, the device operates in compatible mode.
3. Configure Flag = 1 and a Classic-only Device is connected  
In this case, the enhanced Host Controller is the owner of the port before the connect occurs. The EHCI driver checks the Line Status bits to determine if a low-speed device is connected. If so, then the Port Owner bit is written to a 1 and the UHCI driver handles the reset sequence. If a low-speed device is not detected through the Line Status bits, the EHCI driver handles the connection and performs the port reset. After the reset process completes, the EHC hardware has cleared (not set) the Port Enable bit in the EHC's PORTSC register. The EHCI driver then writes a 1 to the Port Owner bit in the same register, causing the classic Host Controller to see a connect event and the EHC to see an "electrical" disconnect event. The UHCI driver and hardware handle the connection and initialization process from that point on. The EHCI driver and hardware handle the perceived disconnect.
4. Configure Flag = 1 and an Enhanced-capable Device is connected  
In this case, the enhanced Host Controller is the owner of the port before, and remains the owner after, the connect occurs. The EHCI driver handles the connection and performs the port reset. After the reset process completes, the EHC hardware has set the Port Enable bit in the EHC's PORTSC register. The port is functional at this point. The classic Host Controller continues to see an unconnected port.

### 26.11.3 Device Disconnects

The *EHCI Specification, Rev. 1.0* describes the details of handling Device Connects. There are three general scenarios that are summarized below.

1. Configure Flag = 0 and the device is disconnected  
In this case, the classic Host Controller is the owner of the port both before and after the disconnect occurs; the EHC (except for the port-routing logic) never sees a device attached. The UHCI driver handles disconnection process.
2. Configure Flag = 1 and a Classic Device is disconnected  
In this case, the classic Host Controller is the owner of the port before the disconnect occurs. The disconnect is reported by the classic Host Controller and serviced by the associated UHCI driver. The port-routing logic in the EHC cluster forces the Port Owner bit to 0, indicating that the EHC owns the unconnected port.
3. Configure Flag = 1 and an Enhanced Device is disconnected  
In this case, the enhanced Host Controller is the owner of the port before, and remains the owner after, the disconnect occurs. The EHCI hardware and driver handle the disconnection process. The classic Host Controller never sees a device attached.

### 26.11.4 Effect of Resets on Port-Routing Logic

As mentioned above, the Port Routing logic is implemented in the Suspend power well so that reenumeration and remapping of the USB ports is not required following entering and exiting a system sleep state in which the core power is turned off.

Table 26-54. Effect of Resets on Port-Routing Logic

| Reset Event        | Effect on Configure Flag | Effect on Port Owner Bits |
|--------------------|--------------------------|---------------------------|
| Suspend Well Reset | cleared (0)              | set (1)                   |
| Core Well Reset    | no effect                | no effect                 |
| D3-to-D0 Reset     | no effect                | no effect                 |
| HCRESET            | cleared (0)              | set (1)                   |

## 26.12 USB 2.0 Legacy Keyboard Operation

CMI must support the possibility of a keyboard downstream from either a USB1 (low-speed or full-speed) or a USB 2.0 (high-speed) port. See [Section 25.12, “USB Legacy Keyboard Operation”](#) for the description of the legacy keyboard support.

The EHC provides the basic ability to generate SMIs on an interrupt event, along with more sophisticated control of the generation of SMIs, as documented in [Section 26.2.1.27, “Offset 68h: ULSEC - USB 2.0 Legacy Support Extended Capability Register”](#).

## 26.13 USB 2.0 Based Debug Port

CMI supports the elimination of the legacy COM ports by providing the ability for new debugger software to interact with devices on a USB 2.0 port.

High-level restrictions and features:

- Must be operational before USB 2.0 drivers are loaded.
  - Must work even when the port is disabled.
  - Must work even though non-configured port is default-routed to the classic controller.

*Note:* The Debug Port cannot be used to debug an issue that requires a classic USB device on Port #0 using the UHCI drivers.

- Must allow normal system USB 2.0 traffic in a system that may only have one USB port.
- Debug Port device (DPD) must be High-Speed capable and connect to a High-Speed port on CMI systems.
- Debug Port FIFO must always make forward progress (a bad status on USB is simply presented back to software).

The Debug Port FIFO is only given one USB access per microframe.

### 26.13.1 USB 2.0 Based Debug Port Overview

The Debug port facilitates OS and device driver debug. It allows the software to communicate with an external console using a USB 2.0 connection. Because the interface to this link does not go through the normal USB 2.0 stack, it allows communication with the external console during cases where the OS is not loaded, the USB 2.0 software is broken, or where the USB 2.0 software is being debugged.

Specific features of this implementation of a debug port are:

- Only works with an external USB 2.0 debug device (console)

- Implemented for a specific port on the host controller
- Operational anytime the port is not suspended AND the host controller is in D0 power state.
- Capability is interrupted when port is driving USB RESET

### 26.13.2 Debug Port Register Details

The Debug port's registers are located in the same memory range as the standard EHCI registers, which are defined by the Base Address Register (BAR). The base offset for these registers (A0h) is declared in the Debug Port Base Offset Capability Register at Configuration offset 5Ah. The specific EHCI port that supports this debug capability is indicated by a four-bit field (bits 20-23) in the HCSPARAMS register of an EHCI controller.

Behavioral Rules:

1. All of these registers are implemented in the core well and reset by EHC HCRESET, EHC D3-to-D0 state transition, and PLTRST#.
2. The hardware associated with this register provides no checks to ensure that software programs the interface correctly. How the hardware behaves when programmed illegally is undefined.

The default values are defined with an h for hex, a b for binary, or 00 for zero. If there is not a letter following the default value, assume it is a binary number.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

#### 26.13.2.1 Offset A0h: CNTL\_STS - Control/Status Register

Software must do Read-Modify-Write operations to this register to preserve the contents of bits not being modified. This include Reserved bits.

In order to preserve the usage of RESERVED bits in the future, software must always write the same value read from the bit until it is defined. Reserved bits will always return 0 when read.

Table 26-55. Offset A0h: CNTL\_STS - Control/Status Register (Sheet 1 of 2)

| Description: |                    |  |                               |                                      |            |
|--------------|--------------------|--|-------------------------------|--------------------------------------|------------|
| View: PCI    | BAR: MBAR          |  | Bus:Device:Function: 0: 29: 7 | Offset Start: A0h<br>Offset End: A3h |            |
| Size: 32 bit | Default: 00000000h |  |                               | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                        | Bit Reset Value                      | Bit Access |
| 31           | Reserved           | Reserved   |                               | 0h                                   |            |
| 30           | OWNER_CNT          | 0 = Ownership of the debug port is NOT forced to the EHCI controller. (Default)<br>1 = Ownership of the debug port is forced to the EHCI controller (i.e., immediately taken away from the companion Classic USB Host controller). If the port was already owned by the EHCI controller, then setting this bit has no effect. This bit overrides all of the ownership-related bits in the standard EHCI registers.<br><br>The value in this bit does not affect the value reported in the PORTSC Port Owner bit.   |                               | 0h                                   | RW         |
| 29           | Reserved           | Reserved   |                               | 0h                                   |            |
| 28           | ENABLED_CNT        | 0 = Software can clear this by writing a 0 to it. The hardware clears this bit for the same conditions where the Port Enable/Disable Change bit (in the PORTSC register) is set. (Default)<br>1 = Debug port is enabled for operation. Software can directly set this bit if the port is already enabled in the associated PORTSC register (this is enforced by the hardware).   |                               | 0h                                   | RW         |

| Bit Range    | Bit Acronym        | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 06           | ERROR_GOOD_N_STS   | 0 = The hardware clears this bit to 0 upon the proper completion of a read or write.<br>1 = The hardware sets this bit to indicate that an error has occurred. Details on the nature of the error are provided in the Exception field. Reset default = 0.   |                             | 0h                                   | RO         |
| 05           | GO_CNT             | Software sets this bit to cause the hardware to perform a read or write request. Writing a 0 to this bit has no effect. Writing a 1 to this bit when it is already set may result in undefined behavior. When set, the hardware clears this bit when the hardware sets the DONE_STS bit.<br>Reset default = 0.  |                             | 0h                                   | RW         |
| 04           | WRITE_READ_N_CNT   | Software sets this bit to indicate that the current request is a write. Software clears this bit to indicate that the current request is a read.<br>Reset default = 0.  |                             | 0h                                   | RW         |
| 03 :00       | DATA_LEN_CNT       | This field is used to indicate the size of the data to be transferred. For write operations, this field is set by software to indicate to the hardware how many bytes of data in Data Buffer are to be transferred to the console. A value of 0h indicates that a zero-length packet must be sent. A value of 1-8 indicates 1-8 bytes are to be transferred. Values 9-Fh are illegal and how hardware behaves if used is undefined.<br>For read operations, this field is set by hardware to indicate to software how many bytes in Data Buffer are valid in response to a read operation. A value of 0h indicates that a zero length packet was returned and the state of Data Buffer is not defined. A value of 1-8 indicates 1-8 bytes were received. Hardware is not allowed to return values 9-Fh.<br>The transferring of data always starts with byte 0 in the data area and moves toward byte 7 until the transfer size is reached.<br>Reset default = 0h. |                             | 0h                                   | RW         |

### 26.13.2.2 Offset A4h: USBPID - USB PIDs Register

This Dword register is used to communicate PID information between the USB debug driver and the USB debug port. The debug port uses some of these fields to generate USB packets, and uses other fields to return PID information to the USB debug driver.

**Table 26-56. Offset A4h: USBPID - USB PIDs Register**

| Description: |                    |   |                               |                                      |            |
|--------------|--------------------|---|-------------------------------|--------------------------------------|------------|
| View: PCI    | BAR: MBAR          |   | Bus:Device:Function: 0: 29: 7 | Offset Start: A4h<br>Offset End: A4h |            |
| Size: 32 bit | Default: 00000000h |   |                               | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                        | Bit Reset Value                      | Bit Access |
| 31 :24       | Reserved           | Reserved.   |                               | 0h                                   |            |
| 23 :16       | RECEIVED_PID_STS   | The hardware updates this field with the received PID for transactions in either direction. When the controller is writing data, this field is updated with the handshake PID that is received from the device. When the host controller is reading data, this field is updated with the data packet PID (if the device sent data), or the handshake PID (if the device NAKs the request). This field is valid when the hardware clears the GO_DONE#_CNT bit. |                               | 0h                                   | RO         |
| 15 :08       | SEND_PID_CNT       | The hardware sends this PID to begin the data packet when sending data to USB (i.e., WRITE_READ#_CNT is asserted). Software will typically set this field to either DATA0 or DATA1 PID values.  |                               | 0h                                   | RW         |
| 07 :00       | TOKEN_PID_CN_T     | The hardware sends this PID as the Token PID for each USB transaction. Software will typically set this field to either IN, OUT or SETUP PID values.  |                               | 0h                                   | RW         |

### 26.13.2.3 Offset A8h: DATABUF - Data Buffer Bytes 7:0

*Note:* This register can be accessed as eight separate 8-bit registers or two separate 32-bit registers.

**Table 26-57. Offset A8h: DATABUF - Data Buffer Bytes 7:0**

| Description: |                            |   |                               |                                      |            |
|--------------|----------------------------|---|-------------------------------|--------------------------------------|------------|
| View: PCI    | BAR: MBAR                  |   | Bus:Device:Function: 0: 29: 7 | Offset Start: A8h<br>Offset End: AFh |            |
| Size: 64 bit | Default: 0000000000000000h |   |                               | Power Well: Core                     |            |
| Bit Range    | Bit Acronym                | Bit Description   | Sticky                        | Bit Reset Value                      | Bit Access |
| 63 :00       | DATABUFFER                 | These are the 8 bytes of the data buffer. Bits 7:0 correspond to least significant byte (byte 0). Bits 63:56 correspond to the most significant byte (byte 7).<br>The bytes in the Data Buffer must be written with data before software initiates a write request. For a read request, the Data Buffer contains valid data when DONE_STS is set by the hardware, ERROR_GOOD#_STS is cleared by the hardware, and the DATA_LENGTH_CNT field indicates the number of bytes that are valid. |                               | 0h                                   | RW         |

## 26.13.2.4 Offset B0h: CONFIG - Configuration Register

**Table 26-58. Offset B0h: CONFIG - Configuration Register**

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: MBAR          |  | Bus:Device:Function: 0:29:7 | Offset Start: B0h<br>Offset End: B0h |            |
| Size: 32 bit | Default: 00007F01h |  |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 31 :15       | Reserved           | Reserved   |                             | 0h                                   |            |
| 14 :08       | USB_ADDRESS_CNF    | 7-bit field that identifies the USB device address used by the controller for all Token PID generation. This is a RW field that is set to 7Fh after reset. |                             | 7Fh                                  | RW         |
| 07 :04       | Reserved           | Reserved   |                             | 0h                                   |            |
| 03 :00       | USB_ENDPOINT_CNF   | This 4-bit field identifies the endpoint used by the controller for all Token PID generation. This is a RW field that is set to 01h after reset.           |                             | 1h                                   | RW         |

## 26.13.3 USB 2.0 Based Debug Port Theory of Operation

There are two operational modes for the USB debug port:

1. Mode 1 is when the Enhanced USB Host Controller is in a disabled state from the viewpoint of a standard EHCI driver (i.e., Host Controller's *Run/Stop* bit is 0). In Mode 1, the Debug Port controller is required to generate 'keepalive' packets less than 2 milliseconds apart to keep the attached debug device from suspending. The keepalive packet must be a standalone 32-bit SYNC field.
2. Mode 2 is when the host controller is running (i.e., Host controller's *Run/Stop#* bit is 1). In Mode 2, the normal transmission of SOF packets (or SYNC keepalives if the port is functionally disabled) will keep the debug device from suspending.

### 26.13.3.1 Behavioral Rules

3. In both modes 1 and 2, the Debug Port controller must check for software requested debug transactions at least every 125 microseconds. If the debug port is enabled by the debug driver, and the standard host controller driver resets the USB port, USB debug transactions are held off for the duration of the reset and until after the first SOF is sent.
4. If the standard host controller driver suspends the USB port, then USB debug transactions are held off for the duration of the suspend/resume sequence and until after the first SOF is sent.
5. The ENABLED\_CNT bit in the debug register space is independent of the similar port control bit in the associated Port Status and Control register.

Table 26-59 shows the debug port behavior related to the state of bits in the debug registers as well as bits in the associated Port Status and Control register.

Table 26-59. Debug Port Behavior

| Debug bits |             | EHCI bits   |            |         | Debug port behavior  |
|------------|-------------|-------------|------------|---------|--|
| OWNER_CNT  | ENABLED_CNT | Port Enable | Run/ Stop# | Suspend |  |
| 0          | X           | X           | X          | X       | Debug port is not being used. Normal operation.  |
| 1          | 0           | X           | X          | X       | Debug port is not being used. Normal operation.  |
| 1          | 1           | 0           | 0          | X       | Debug port in Mode 1. SYNC keepalives sent plus debug traffic  |
| 1          | 1           | 0           | 1          | X       | Debug port in Mode 2. SYNC keepalives or SOF packets may be sent plus debug traffic. CMI generates SYNC keepalives, not SOF packets. No other normal traffic is sent out this port, because the port is not enabled. |
| 1          | 1           | 1           | 0          | 0       | Illegal. Host controller driver must never put the controller into this state (enabled, not running and not suspended).  |
| 1          | 1           | 1           | 0          | 1       | Port is suspended. No debug traffic sent.  |
| 1          | 1           | 1           | 1          | 0       | Debug port in Mode 2. Debug traffic is interspersed with normal traffic.   |
| 1          | 1           | 1           | 1          | 1       | Port is suspended. No debug traffic sent.  |

### 26.13.3.2 OUT Transactions

An OUT Transaction sends data to the debug device. It can occur only when the following are true:

- The debug port is enabled
- The debug software sets the GO\_CNT bit
- The WRITE\_READ#\_CNT bit is set

The sequence of the transaction is:

1. Software sets the appropriate values in the following bits:

USB\_ADDRESS\_CNF  
 USB\_ENDPOINT\_CNF  
 DATA\_BUFFER[63:0]  
 TOKEN\_PID\_CNT[7:0]  
 SEND\_PID\_CNT[15:8]  
 DATA\_LEN\_CNT  
 WRITE\_READ#\_CNT (note: this will always be 1 for OUT transactions)  
 GO\_CNT (Note: this will always be 1 to initiate the transaction)

2. The debug port controller sends a token packet consisting of:

- A. SYNC
- B. TOKEN\_PID\_CNT field
- C. USB\_ADDRESS\_CNF field
- D. USB\_ENDPOINT\_CNF field
- E. 5-bit CRC field

3. After sending the token packet, the debug port controller sends a data packet consisting of:

- F. SYNC

- G. SEND\_PID\_CNT field
- H. The number of data bytes indicated in DATA\_LEN\_CNT from the DATA\_BUFFER
- I. 16-bit CRC

*Note:* A DATA\_LEN\_CNT value of zero is valid in which case no data bytes would be included in the packet.

4. After sending the data packet, the controller waits for a handshake response from the debug device.

- If a handshake is received, the debug port controller:

J. Places the received PID in the RECEIVED\_PID\_STS field

K. Resets the ERROR\_GOOD#\_STS bit

L. Sets the DONE\_STS bit

- If no handshake PID is received, the debug port controller:

J. Sets the EXCEPTION\_STS field to 001b

K. Sets the ERROR\_GOOD#\_STS bit

L. Sets the DONE\_STS bit

### 26.13.3.3 IN Transactions

An IN transaction receives data from the debug device. It can occur only when the following are true:

- The debug port is enabled
- The debug software sets the GO\_CNT bit
- The WRITE\_READ#\_CNT bit is reset

The sequence of the transaction is:

1. Software sets the appropriate values in the following bits:

USB\_ADDRESS\_CNF

USB\_ENDPOINT\_CNF

TOKEN\_PID\_CNT[7:0]

DATA\_LEN\_CNT

WRITE\_READ#\_CNT (note: this will always be 0 for IN transactions)

GO\_CNT (note: this will always be 1 to initiate the transaction)

The debug port controller sends a token packet consisting of:

- SYNC
- TOKEN\_PID\_CNT field
- USB\_ADDRESS\_CNT field
- USB\_ENDPOINT\_CNT field
- 5-bit CRC field.

2. After sending the token packet, the debug port controller waits for a response from the debug device.

If a response is received:

The received PID is placed into the RECEIVED\_PID\_STS field

- Any subsequent bytes are placed into the DATA\_BUFFER
- The DATA\_LEN\_CNT field is updated to show the number of bytes that were received after the PID.

3. If a valid packet was received from the device that was one byte in length (indicating it was a handshake packet), then the debug port controller:

- Resets the ERROR\_GOOD#\_STS bit
  - Sets the DONE\_STS bit
4. If a valid packet was received from the device that was more than one byte in length (indicating it was a data packet), then the debug port controller:
- Transmits an ACK handshake packet
  - Resets the ERROR\_GOOD#\_STS bit
  - Sets the DONE\_STS bit
5. If no valid packet is received, then the debug port controller:
- Sets the EXCEPTION\_STS field to 001b
  - Sets the ERROR\_GOOD#\_STS bit,
  - Sets the DONE\_STS bit.

### 26.13.3.4 Debug Software

#### 26.13.3.4.1 Enabling the Debug Port

There are two mutually exclusive conditions that debug software must address as part of its startup processing:

- The EHCI has been initialized by system software.
- The EHCI has not been initialized by system software.

Debug software can determine the current 'initialized' state of the EHCI by examining the *Configure Flag* in the EHCI USB 2.0 Command Register. If this flag is set, then system software has initialized the EHCI. Otherwise, the EHCI must not be considered initialized. Debug software will initialize the debug port registers depending on the state of the EHCI. However, before this can be accomplished, debug software must determine which root USB port is designated as the debug port.

#### 26.13.3.4.2 Determining the Debug Port

Debug software can easily determine which USB root port has been designated as the debug port by examining bits 20:23 of the EHCI Host Controller Structural Parameters register. This 4-bit field represents the numeric value assigned to the debug port (i.e., 0000 == port 0, 0001 == port 1, 0010 == port 2 ..... 1111 == port 15). This value is 0000 (port 0).

#### 26.13.3.4.3 Debug Software Startup with Non-Initialized EHCI

Debug software can attempt to use the debug port if, after setting the *OWNER\_CNT* bit, the *Current Connect Status* bit in the appropriate (See [Section 26.13.3.4.2, "Determining the Debug Port"](#)) *PORTSC* register is set. If the *Current Connect Status* bit is not set, then debug software may choose to terminate, or it may choose to wait until a device is connected.

If a device is connected to the port, then debug software must reset/enable the port. Debug software does this by setting and then clearing the *Port Reset* bit in the *PORTSC* register. Software must set the *Run/Stop* bit in the EHCI Command Register before clearing the *Port Reset* bit in order to complete the reset and to enable the port. To guarantee a successful reset, debug software must also keep the *Port Reset* bit set for at least 50 ms. Due to possible delays, this bit may not change to zero immediately; reset is complete when this bit reads as zero. Software must not continue until this bit reads zero.

If a high-speed device is attached, the EHCI will automatically set the *Port Enabled/Disabled* bit in the PORTSC register and the debug software can proceed. Debug software must set the *ENABLED\_CNT* bit in the Debug Port Control/Status register, and then reset (clear) the *Port Enabled/Disabled* bit in the PORTSC register and the *Run/Stop* bit in the EHCI Command Register. The EHCI bits are cleared in order to present the proper default idle conditions to the EHCI driver as it loads.

#### 26.13.3.4.4 Debug Software Startup with Initialized EHCI

Debug software can attempt to use the debug port if the *Current Connect Status* bit in the appropriate (See [Section 26.13.3.4.2, "Determining the Debug Port"](#)) PORTSC register is set. If the *Current Connect Status* bit is not set, then debug software may terminate or it may wait until a device is connected.

If a device is connected, then debug software must set the *OWNER\_CNT* bit and then the *ENABLED\_CNT* bit in the Debug Port Control/Status register.

#### 26.13.3.4.5 Determining Debug Peripheral Presence

After enabling the debug port functionality, debug software can determine if a debug peripheral is attached by attempting to send data to the debug peripheral. If all attempts result in an error (*Exception* bits in the Debug Port Control/Status register indicates a Transaction Error), then the attached device is not a debug peripheral. If the debug port peripheral is not present, then debug software may terminate or it may wait until a debug peripheral is connected.

§ §

## 27.0 Power Management

---

### 27.1 Features

- ACPI Power and Thermal Management Support.
  - Processor THRMTRIP# emergency shutdown.
  - ACPI 24-Bit Timer.
  - Software initiated throttling of processor performance for Thermal and Power Reduction.
  - SCI and SMI# Generation.
- PCI PME# Signal for Wake Up from Low-Power states.
- SYS\_Reset# input to eliminate external glue logic.
- System Clock Control.
  - ACPI C0 state Full On: Processor operating. Individual devices may be shut to save power.
  - ACPI C1 state Auto-Halt: Processor has executed a AutoHalt instruction and is not executing code. The processor snoops the bus and maintains cache coherency.
  - ACPI C2 state Stop-Grant state (using STPCLK# signal) halts processor's instruction stream.
- System Sleeping State Control.
  - ACPI S0 state – All power planes active (awake).
  - ACPI S3 state – Suspend to RAM (STR).
  - Supports S3-Cold state.
  - ACPI S4 state – Suspend-to-Disk (STD).
  - ACPI S5 state – Soft Off (SOFF).
  - Power Failure Detection and Recovery.
- Streamlined Legacy Power Management Support for APM-Based Systems.

## 27.2 IMCH-IICH Messages

NSI messaging protocol is supported. Messages associated with power management and state transitions are summarized in Table 27-1. The Legacy Protocol messages are shown only for reference. NSI messages that are not associated with power management are not shown.

Table 27-1. IMCH-IICH Messages

| Legacy Message | New Message         | Direction  | Description/Comment:  |
|----------------|---------------------|------------|---|
| ---            | Reset-Warn          | IICH→IMCH  | Warning from the IICH to the IMCH that the IICH is about to assert the PLTRST# signal. The IMCH is expected to acknowledge this with the Reset-Warn-Ack. However, if the IMCH fails to do this within the timeout period, the IICH will assert the reset.   |
| ---            | Reset-Warn-Ack      | IMCH→IICH  | Acknowledge from the IMCH that it has seen the Reset-Warn message is now ready for the IICH to cause the reset.   |
| Stop-Grant     | Stop-Grant (REQ-C2) | IMCH→IICH  | If the processor is in C0 - indication that the processor has issued last Stop-Grant cycle. The IMCH may receive more than one Stop-Grant cycle from the processor(s). It is the IMCH's responsibility to only send the last Stop-Grant.  |
| Go-C0          | Go-C0               | IICH→IMCH  | Indication that system is going back to C0 state.   |
| --             | Ack-C0              | IMCH→IICH  | Acknowledge that IMCH observed the Go-C0 message and is ready to proceed.   |
| --             | Go-C2               | IICH→IMCH  | This is an indication that the processor has been put into Stop-Grant state. When coming from C0, this tells the IMCH that it is safe to assert SLP#.   |
| --             | Ack-C2              | IMCH→IICH  | IMCH indicates it observed the Go-C2 message and is now ready to proceed. If going toward C0, the IICH is free to deassert STPCLK#.   |
| Go-C3          | Go-S3               | IICH→IMCH  | Indication that the IICH is getting ready to put the system into S3, S4 or S5 state.  |
| Ack-C3         | Ack-S3              | IMCH→IICH  | Indication that the IMCH observed the Go-S3 message and is ready to proceed.  |
| --             | REQ-C0 (Break-Ind)  | IMCH →IICH | This is an indication from the IMCH to the IICH that the IMCH thinks the processor must be brought to a C0 state. This would be sent for several cases:<br>1. If the IMCH had received a "Pending Break Event" indication from the processor. This is needed when PBE# is not muxed with FERR# and is instead muxed with some pin that goes only to the IMCH.<br>2. The IMCH has some internal device or link to external device that can cause a break event that is not associated with an interrupt.<br><b>Note:</b> The IMCH is not required to implement this message. |

## 27.3 Power Management Register Details

This section shows the power management registers. The power management registers are distributed within the PCI Device 31: Function 0 space, as well as a separate I/O range. Each register is described below. Unless otherwise indicated, bits are in the main (core) power well.

Bits not explicitly defined in each register are assumed to be reserved.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return on-zero values are read only. Writes to reserved locations may cause system failure and unpredictable behavior.

**Note:** Reserved bits are read only.

### 27.3.1 Power Management PCI Configuration Registers

**Note:** For more information on the format of the register description tables that follow in this chapter, see Section 7.1.1, "Register Description Tables" on page 183).

**Table 27-2. Bus 0, Device 31, Function 0: Summary of LPC Interface Power Management PCI Configuration Registers**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|
| A0h          | A0h        | "Offset A0h: GEN_PMCON_1 - General PM Configuration 1 Register" on page 1048 | 0200h         |

| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 02           | MAWVS              | <p><b>Minimum SLP_S4# Assertion Width Violation Status:</b><br/>           0 = Software clears this bit by writing a 1 to it.<br/>           1 = Hardware sets this bit when the SLP_S4# assertion width is less than the time programmed in the SLP_S4# Minimum Assertion Width field (D31.F0.A4h.5:4). When exiting G3, the timer begins when the RSMRST# input deasserts.</p> <p><b>Note:</b> This bit is functional regardless of the value in the SLP_S4# Assertion Stretch Enable. This bit is reset by the assertion of the RSMRST# pin, but can be set in some cases before the default value is readable.</p> |                             | 0h                                   | RWC        |
| 01           | CPUPWR_FLR         | <p><b>CPU Power Failure:</b><br/>           0 = Software (typically) BIOS clears this bit by writing a 0 to it.<br/>           1 = Indicates that the VRMPWRGD input signal (A) from the processor's VRM went low.</p> <p><b>Note:</b> VRMPWRGD is sampled using the RTC clock. Therefore, low times that are less than one RTC clock period may not be detected.</p>  |                             | 0h                                   | RW         |
| 00           | PWROK_FLR          | <p><b>Power OK Failure:</b><br/>           0 = Software clears this bit by writing a 1 to it, or when the system goes into a G3 state.<br/>           1 = This bit will be set any time PWROK goes low, when the system was in S0, or S1 state. The bit will be cleared only by software by writing a 1 to this bit or when the system goes to a G3 state.</p> <p>See Section 27.6.3 for more details about the PWROK pin functionality.</p> <p><b>Note:</b> In the case of true PWROK failure, PWROK will go low first before the VRMPWRGD.</p>   |                             | 0h                                   | RWC        |

### 27.3.1.3 Offset A4h: GEN\_PMCON\_3 - General PM Configuration 3 Register

Table 27-5. Offset A4h: GEN\_PMCON\_3 - General PM Configuration 3 Register (Sheet 1 of 2)

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: 0:31:0 | Offset Start: A4h<br>Offset End: A4h |            |
| Size: 8 bit  | Default: 00h       |  |                             | Power Well: RTC                      |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 07 : 06      | SWSMI_RATE_SEL     | <p>This 2-bit value indicates when the SWSMI timer will time out. Valid values are:</p> <ul style="list-style-type: none"> <li>• 00 1.5 ms +/- 0.6 ms</li> <li>• 01 16 ms +/- 4 ms</li> <li>• 10 32 ms +/- 4 ms</li> <li>• 11 64 ms +/- 4 ms</li> </ul> <p>These bits are not cleared by any type of reset except RTEST#.</p>  |                             | 00h                                  | RW         |
| 05 : 04      | SMAW               | <p><b>SLP_S4# Minimum Assertion Width:</b> This 2-bit value indicates the minimum assertion width of the SLP_S4# signal to guarantee that the DRAMs have been safely power-cycled. This value may be modified per platform depending on DRAM types, power supply capacitance, etc. Valid values are:</p> <ul style="list-style-type: none"> <li>• 11 1 to 2 seconds</li> <li>• 10 2 to 3 seconds</li> <li>• 01 3 to 4 seconds</li> <li>• 00 4 to 5 seconds</li> </ul> <p>This value is used in two ways:</p> <ol style="list-style-type: none"> <li>1. If the SLP_S4# assertion width is ever shorter than this time, a status bit (D31.F0.A2h.2) is set for BIOS to read when S0 is entered</li> <li>2. If enabled by bit 3 in this register, the hardware will prevent the SLP_S4# signal from deasserting within this minimum time period after asserting</li> </ol> <p><b>Note:</b> The logic that measures this time is in the suspend power well. Therefore, when leaving the G3 state, the minimum time is measured from the deassertion of RSMRST#.</p> <p>RTEST# forces this field to the conservative default state (00b).</p> |                             | 00h                                  |            |
| 03           | SASE               | <p><b>SLP_S4# Assertion Stretch Enable:</b></p> <p>0 = The SLP_S4# minimum assertion time is 1 to 2 RTCCCLK.</p> <p>1 = The SLP_S4# signal will minimally assert for the time specified in bits 5:4 of this register.</p> <p>This bit is cleared by RTEST#.</p>  |                             | 0h                                   | RW         |

Exception: If the system is in S5 state due to a powerbutton override, then the GPIs will not cause wake events.</p> <p><b>Note:</b> Core well GPIs are not capable of waking the system from sleep states where the core well is not powered.</p> |                             | 00h                                  | RW         |

### 27.3.2 APM Power Management I/O-Mapped Registers

Table 27-7 shows the I/O registers associated with APM support. This register space is enabled in the PCI Device 31: Function 0 space (APMC\_EN), and cannot be moved (fixed I/O location).

*Note:* For more information on the format of the register description tables that follow in this chapter, see Section 7.1.1, "Register Description Tables" on page 183).

Table 27-7. Summary of APM Registers Mapped in I/O Space

### 27.3.2.1 Offset B2h: APM\_CNT - Advanced Power Management Control Port Register

Used to pass an APM command between the OS and the SMI handler. Writes to this port not only store data in the APMC register, but also generates an SMI# when the APMC\_EN bit is set.

Table 27-8. Offset B2h: APM\_CNT - Advanced Power Management Control Port Register

| Description: |                          |   |        |                   |                 |

### 27.3.2.2 Offset B3h: APM\_STS - Advanced Power Management Status Port Register

Used to pass data between the OS and the SMI handler. Basically, this is a scratchpad register and is not effected by any other register or function (other than a PCI reset).

Table 27-9. Offset B3h: APM\_STS - Advanced Power Management Status Port Register

| Description: |                          |   |        |                   |                 |

| Bit Range    | Bit Acronym              | Bit Description   | Sticky | Bit Reset Value   | Bit Access      |
| 07 : 00      | APM_STS                  | Used to pass data between the OS and the SMI handler. Basically, this is a scratchpad register and is not affected by any other register or function (other than a platform reset). |        | 00h               | RW              |

### 27.3.3 General Power Management I/O-Mapped Registers

Table 27-10 shows the registers associated with ACPI and Legacy power management support. These registers are enabled in the PCI Device 31: Function 0 space (ACPI Enable in Section 19.2.2), and can be moved to any I/O location (128-byte aligned) determined by ABASE in Section 19.2.2.1 (referenced in this chapter by PMBASE). The registers are defined to be compliant with the *Advanced Configuration and Power Interface (ACPI) Specification, Rev. 2.0*, and generally use the same bit names. All reserved bits and registers will always return 0 when read, and will have no effect when written.

*Note:* For more information on the format of the register description tables that follow in this chapter, see Section 7.1.1, “Register Description Tables” on page 183).

Table 27-11. Offset 00h: PM1\_STS – Power Management 1 Status Register (Sheet 2 of 2)

| Description: |                  |   |                             |                                      |            |
|--------------|------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: PMBASE (IO) |   | Bus:Device:Function: 0:31:0 | Offset Start: 00h<br>Offset End: 00h |            |
| Size: 16 bit | Default: 0000h   |   |                             | Power Well: Core <sup>a</sup>        |            |
| Bit Range    | Bit Acronym      | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 08           | PWRBTN_STS       | <p>This bit is set when the PWRBTN# signal is asserted (low), independent of any other enable bit. See PWRBTN_EN for the effect when PWRBTN_STS goes active. PWRBTN_STS is always a wake event. This bit is only set by hardware and can be cleared by software writing a one to this bit position. This bit is not affected by hard resets caused by a CF9 write, but is reset by RSMRST#.</p> <p>If the PWRBTN# signal is held low for more than 4 seconds, CMI clears the PWRBTN_STS bit, sets the PWRBTNOR_STS bit, the system transitions to the S5 state, and only PWRBTN# is enabled as a wake event.</p> <p>If PWRBTN_STS bit is cleared by software while the PWRBTN# pin is still held low, this will not cause the PWRBTN_STS bit to be set. The PWRBTN# signal must go inactive and active again to set the PWRBTN_STS bit.</p> <p><b>Note:</b> The SMBus Unconditional Power down message, the CPU Thermal Trip and the Internal Thermal Sensors' Catastrophic Condition result in behavior matching the Powerbutton Override, which includes clearing this bit.</p> |                             | 0h                                   | RWC        |
| 07 : 06      | Reserved         | Reserved  |                             | 0h                                   |            |
| 05           | GBL_STS          | <p>0 = The SCI handler must then clear this bit by writing a 1 to the bit location.</p> <p>1 = Set when an SCI is generated due to BIOS wanting the attention of the SCI handler. BIOS has a corresponding bit, BIOS_RLS, which will cause an SCI and set this bit.</p> <p>This bit will not cause wake events or SMI#. This bit is not effected by SCI_EN.</p> <p><b>Note:</b> GBL_STS being set will cause an SCI, even if the SCI_EN bit is not set. Software must take great care not to set the BIOS_RLS bit (which causes GBL_STS to be set) if the SCI handler is not in place.</p>  |                             | 0h                                   | RWC        |
| 04 01        | Reserved         | Reserved  |                             | 000h                                 |            |
| 00           | TMROF_STS        | <p>0 = The SCI or SMI# handler clears this bit by writing a 1 to the bit location.</p> <p>1 = This bit gets set any time bit 22 of the 24-bit timer goes low (bits are numbered from 0 to 23). This will occur every 2.3435 seconds. Hence, it is highly likely that a read to this register after reset will yield a 1 in this field. When the TMROF_EN bit (PMBASE + 02h, bit 0) is set, then the setting of the TMROF_STS bit will additionally generate an SCI or SMI# (depending on the SCI_EN).</p>   |                             | 0h                                   | RWC        |

### 27.3.3.4 Offset 08h: PM1\_TMR - Power Management 1 Timer Register

Table 27-14. Offset 08h: PM1\_TMR - Power Management 1 Timer Register

| Description: |                    |   |                             |                                      |            |
|--------------|--------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: PMBASE (IO)   |   | Bus:Device:Function: 0:31:0 | Offset Start: 08h<br>Offset End: B8h |            |
| Size: 32 bit | Default: 00000000h |   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 31 : 24      | Reserved           | Reserved. Will always read as 0.  |                             | 00h                                  |            |
| 23 : 00      | TMR_VAL            | This read-only field returns the running count of the PM timer. This counter runs off a 3.579545 MHz clock (derived from 14.31818 MHz divided by 4). It is reset (to 0) during a PCI reset, and then continues counting as long as the system is in the S0 state. Hence, it is highly likely that a read to this register after reset will yield a non-zero value. After an S1 state, the counter will not be reset (it will continue counting from the last value in S0 state).<br>Anytime bit 22 of the timer goes HIGH to LOW (bits referenced from 0 to 23), the TMR_OF_STS bit is set. The High-to-Low transition will occur every 2.3435 seconds. Writes to this register have no effect. |                             | 00h                                  | RO         |

### 27.3.3.6 Offset 14h: LV2 - Level 2 Register

Reads to this register return all zeros, writes to this register have no effect. Reads to this register generate a “enter a level 2 power state” (C2) to the clock control logic. This will cause the STPCLK# signal to go active, and stay active until a break event occurs. Throttling (due to THTL\_EN or FORCE\_THTL) will be ignored.

*Note:* This register must not be used by systems with more than 1 logical processor, unless appropriate semaphoring software has been put in place to ensure that all threads/processors are ready for the C2 state when the read to this register occurs.

**Table 27-16. Offset 14h: LV2 - Level 2 Register**

### 27.3.3.7 Offset 28h: GPE0\_STS - General Purpose Event 0 Status Register

*Note:* This register is symmetrical to the General Purpose Event 0 Enable Register. Unless indicated otherwise below, if the corresponding \_EN bit is set, then when the STS bit is set, a Wake Event is generated. Once back in an S0 state (or if already in an S0 state when the event occurs), CMI will also generate an SCI if the SCIEN (PMBASE + 04h, bit 0) bit is set, or an SMI# if the SCIEN bit is not set. Bits 31:16 are reset by a CF9h write; bits 15:0 are not be reset by CF9 write. Bits 31:0 are reset by RSMRST#.

| View: PCI    | BAR: PMBASE (IO)   |   | Bus:Device:Function: 0:31:0 | Offset Start: 28h<br>Offset End: 28h |            |
| Size: 32 bit | Default: 00000000h |   |                             | Power Well: Resume                   |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 13           | PME_B0_STS         | <b>Note:</b> This bit will be set to 1 when any internal device with PCI Power Management capabilities on bus 0 asserts the equivalent of the PME# signal. Additionally, if the PME_B0_EN bit is set, and the system is in an S0 state, then the setting of the PME_B0_STS bit will generate an SCI (or SMI# if SCI_EN is not set). If the PME_B0_STS bit is set, and the system is in an S1/S3/S4 state (or S5 state due to SLP_TYP and SLP_EN), then the setting of the PME_B0_STS bit will generate a wake event, and an SCI (or SMI# if SCI_EN is not set) will be generated. If the system is in an S5 state due to power button override, then the PME_B0_STS bit will not cause a wake event or SCI. The default for this bit is 0. Writing a 1 to this bit position clears this bit |                             | 0h                                   | RWC        |
| 12           | Reserved           | Reserved  |                             | 0h                                   |            |
| 11           | PME_STS            | This bit will be set to 1 by hardware when the PME# signal goes active. [Note CMI might be the cause of PME# going active in some cases]. Additionally, if the PME_EN bit is set, and system is in an S0 state, then the setting of the PME_STS bit will generate an SCI (or SMI# if SCI_EN is not set). If the PME_EN bit is set, and the system is in an S1/S3/S4 state (or S5 state due to SLP_TYP and SLP_EN), then the setting of the PME_STS bit will generate a wake event, and an SCI (or SMI# if SMI_EN is not set) will be generated. If the system is in an S5 state due to power button override, then PME_STS will not cause a wake event or SCI. This bit is cleared by writing a 1 to this bit position.   |                             | 0h                                   | RWC        |

**27.3.3.8 Offset 2Ch: PMBASE\_GPE0\_EN - General Purpose Event 0 Enables Register**

*Note:* This register is symmetrical to the General Purpose Event 0 Status Register. All the bits in this register must be cleared to 0 based on a Power Button Override-CPU Thermal Trip event, or internal thermal sensor catastrophic condition. Unless otherwise noted, all bits are in the resume well. The Resume well bits are all cleared by RSMRST# and RTC well bits are cleared by RTEST#.

| Description: |                    |   |                             |                                      |            |
|--------------|--------------------|---|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: PMBASE (IO)   |   | Bus:Device:Function: 0:31:0 | Offset Start: 30h<br>Offset End: 30h |            |
| Size: 32 bit | Default: 00000000h |   |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                      | Bit Reset Value                      | Bit Access |
| 04           | SMI_ON_SLP_EN      | 0 = Disables the generation of SMI# on SLP_EN. Note that this bit must be 0 before the software attempts to transition the system into a sleep state by writing a 1 to the SLP_EN bit.<br>1 = A write of 1 to the SLP_EN bit (bit 13 in PM1_CNT register) will generate an SMI#, and the system will not transition to the sleep state based on that write to the SLP_EN bit.<br><br>This allows the SMI# handler work around chip-level bugs. It is expected that the SMI# handler will turn off the SMI_ON_SLP_EN bit before actually setting the SLP_EN bit.   |                             | 0h                                   | RW         |
| 03           | LEGACY_USB_EN      | 0 = Disables legacy USB circuit<br>1 = Enables legacy USB circuit to cause SMI#.  |                             | 0h                                   | RW         |
| 02           | BIOS_EN            | 0 = Disables the generation of SMI# when ACPI software writes a 1 to the GBL_RLS bit.<br>1 = Enables the generation of SMI# when ACPI software writes a 1 to the GBL_RLS bit.   |                             | 0h                                   | RW         |
| 01           | EOS                | End of SMI. This bit controls the arbitration of the SMI signal to the processor. This bit must be set in order to assert SMI# low to the processor after SMI# has been asserted previously.<br>0 = Once SMI# low is asserted, the EOS bit is automatically cleared.<br>1 = In the SMI handler, the processor must clear all pending SMIs (by servicing them and then clearing their respective status bits), set the EOS bit, and exit SMM. This will allow the SMI arbiter to reassert SMI upon detection of an SMI event and the setting of a SMI status bit. The SMI# signal will go inactive for 4 PCI clocks. |                             | 0h                                   | RW         |
| 00           | GBL_SMI_EN         | 0 = No SMI# will be generated.<br>1 = Enables the generation of SMIs in the system upon any enabled SMI event. This bit is reset by a PCI reset event.<br><b>Note:</b> When the SMI_LOCK bit is set, this bit cannot be changed.  |                             | 0h                                   | RW         |

27.3.3.10 Offset 34h: SMI\_STS - SMI Status Register

Note: If the corresponding \_EN bit is set when the \_STS bit is set, CMI will cause an SMI# (except bits 8-10, which do not cause SMI#.)

Table 27-20. Offset 34h: SMI\_STS - SMI Status Register (Sheet 1 of 3)

| Description: |                    |  |                             |                                      |            |

| 19           | Reserved           | Reserved   |                             | 0h                                   |            |
| 18           | INTEL_USB2_STS     | This non-sticky read-only bit is a logical OR of each of the SMI status bits in the Intel-Specific USB 2.0 SMI Status Register ANDed with the corresponding enable bits. This bit will not be active if the enable bits are not set. Writes to this bit will have no effect.   |                             | 0h                                   | RO         |
| 17           | LEGACY_USB2_STS    | This non-sticky read-only bit is a logical OR of each of the SMI status bits in the USB 2.0 Legacy Support Register ANDed with the corresponding enable bits. This bit will not be active if the enable bits are not set. Writes to this bit will have no effect.  |                             | 0h                                   | RO         |
| 16           | SMBUS_SMI_STS      | This bit is set to 1 to indicate that the SMI# was caused by:<br>A. The SMBus Slave receiving a message that an SMI# must be caused.<br>B. The SMBALERT# signal goes active and the SMB_SMI_EN bit is set and the SMBALERT_DIS bit is cleared.<br>C. The SMBus Slave receiving a HOST_NOTIFY message and the HOST_NOTIFY_INTREN and the SMB_SMI_EN bits are set.<br>D. The SMBus Slave receiving a "SMI in S0" message. This bit is sticky. It is cleared by writing a 1 to this bit position.<br><b>Note:</b> This bit is set from the 64 KHz clock domain used by the SMBus. Software must wait at least 15.63 μs (= 1/64 kHz) after the initial assertion of this bit before clearing it. |                             | 0h                                   | RWC        |
| 15           | SERIRQ_SMI_STS     | 0 = SMI# not caused by SERIRQ decoder.<br>1 = Indicates the SMI# was caused by the SERIRQ decoder.<br><b>Note:</b> This bit is <b>not</b> sticky. Writes to this bit will have no effect.  |                             | 0h                                   | RO         |
| 14           | PERIODIC_STS       | This bit will be set at the rate determined by the PER_SMI_SEL bits. If the PERIODIC_EN bit is also set, an SMI# is generated. This bit is cleared by writing a 1 to this bit position.  |                             | 0h                                   | RWC        |
| 13           | TCO_STS            | 0 = SMI not caused by TCO logic.<br>1 = Indicates SMI was caused by the TCO logic. The reset value of this bit may be overwritten soon after reset by the TCO counter. Hence, it is possible that a read to this register after reset will yield a 1 in this field.<br><b>Note:</b> Will not cause wake event. This bit is cleared by writing a 1 to this bit position.  |                             | 0h                                   | RWC        |

Table 27-20. Offset 34h: SMI\_STS - SMI Status Register (Sheet 2 of 3)

| Description: |                    |  |                             |                                      |            |
|--------------|--------------------|--|-----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: PMBASE (IO)   |  | Bus:Device:Function: 0:31:0 | Offset Start: 34h<br>Offset End: 34h |            |
| Size: 32 bit | Default: 00000000h |  |                             | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                      | Bit Reset Value                      | Bit Access |
| 12           | DEVMON_STS         | This read-only bit is set when bit 0 in the DEVTRAP_STS register is set. It is not sticky, so writes to this bit will have no effect.<br>See Section 27.3.1.3.]  |                             | 0h                                   | RO         |
| 11           | MCSMI_STS          | 0 = Indicates that there has been no access to the power management microcontroller range (62h or 66h).<br>1 = Set if there has been an access to the power management microcontroller range (62h or 66h) and the Microcontroller Decode Enable #1 bit in the LPC Bridge I/O Enables configuration register is 1. Note that this implementation assumes that the Microcontroller is on LPC, if this changes in the future (i.e. PCI e-based SIO), then the implementation will need to remove the LPC Decode Enable dependency. If this bit is set, and the MCSMI_EN bit is also set, CMI will generate an SMI#.<br><br>This bit is set by hardware and cleared by software writing a 1 to its bit position. |                             | 0h                                   | RWC        |
| 10           | GPE1_STS           | This bit is a logical OR of the bits in the ALT_GPI_SMI_STS register that are also set up to cause an SMI# (as indicated by the GPI_ROUT registers) and have the corresponding bit set in the ALT_GPI_SMI_EN register.<br>0 = SMI# was not generated by a GPI assertion.<br>1 = SMI# was generated by a GPI assertion.<br><br>Bits that are not routed to cause an SMI# will have no effect on this bit. This bit is NOT sticky. Writes to this bit will have no effect.   |                             | 0h                                   | RO         |
| 09           | GPE0_STS           | This bit is a logical OR of bits 13, 11, 8:6, 4:3 and 0 in the GPE0_STS register (PMBASE + 28h) that also have the corresponding bit set in the GPE0_EN register (PMBASE + 2Ch). This bit is NOT sticky.<br>0 = SMI# was not generated by a GPE0 event.<br>1 = SMI# was generated by a GPE0 event.<br><b>Note:</b> Writes to this bit will have no effect. The setting of this bit does not cause the SMI#<br><b>Note:</b> Bits 31:16 of the GPE0_STS register are not capable of generating SMIs; therefore, they do not set this SMI status bit.   |                             | 0h                                   | RO         |
| 08           | PM1_STS_REG        | This is an OR of the bits (except for bits 5 and 4) in the ACPI PM1 Status Reg. (offset PMBASE+00h). Not sticky. Writes to this bit have no effect.<br>0 = SMI# was not generated by a PM1_STS event.<br>1 = SMI# was generated by a PM1_STS event.<br><br>This bit gets set when PM1_STS.TMROF_STS gets set. Hence, it is highly likely that a read to this register after reset will yield a 1 in this field.<br><b>Note:</b> The setting of this bit does not cause the SMI#.   |                             | 0h                                   | RO         |

| 15 : 00      | ALT_GPI_SMI_STS  | These bits report the status of the corresponding GPIs. 1 = active, -0 = inactive. These bits are sticky. If the following conditions are true, then an SMI# will be generated and the ALT_GPI_SMI_STS bit set:<br>1. The corresponding bit in the ALT_GPI_SMI_EN register is set<br>2. The corresponding GPI must be routed in the GPI_ROUT register to cause an SMI.<br>3. The corresponding GPIO must be implemented.<br>All bits are in the resume well. Default for these bits are dependent on the state of the GPI pins. |                             | 0000h                                | RWC        |

27.3.3.13 Offset 44h: DEVTRAP\_STS - DEVTRAP\_STS Register

Each bit indicates if an access has occurred to the corresponding devices trap range, or for bits 6:9 if the corresponding PCI interrupt is active. Write 1 to the same bit position to clear it. This register is used by APM power management software to see if there has been system activity. The periodic SMI# timer indicates if it is the right time to read the DEVTRAP\_STS register (PMBASE + 44h).

Table 27-23. Offset 44h: DEVTRAP\_STS - DEVTRAP\_STS Register (Sheet 1 of 2)

## 27.4 SMI #/SCI Generation

Upon any SMI# event taking place, IICH will assert SMI# to the processor, which will cause it to enter SMM space. SMI# remains active until the EOS bit is set. When the EOS bit is set, SMI# will go inactive for a minimum of 4 PCICLK. If another SMI event occurs, SMI# will be driven active again.

The SCI is a level-mode interrupt that is typically handled by an ACPI-aware operating system. In non-APIC systems (which is the default), the SCI IRQ is routed to one of the 8259 interrupts (IRQ9, 10, or 11). The 8259 interrupt controller must be programmed to level mode for that interrupt.

In systems using the APIC, the SCI can be routed to interrupts 9, 10, 11, 20, 21, 22, or 23. The interrupt polarity changes depending on whether it is on an interrupt shareable with a PIRQ or not; see Section 27.3.1 for details. The interrupt will remain asserted until all SCI sources are removed.

Table 27-24 shows which events can cause an SCI and Table 27-26 shows the causes of an SMI#.

*Note:* Some events can be programmed to cause either an SMI# or SCI. The usage of the event for SCI (instead of SMI#) is typically associated with an ACPI-based system.

**Table 27-24. Causes of SCI**

| Cause                              | Additional Enables (See Note 1)   | Where Reported |
|------------------------------------|-----------------------------------|----------------|
| PME#                               | PME_EN = 1                        | PME_STS        |
| Internal EHCI wake (PME_B0)        | PME_B0_EN = 1                     | PME_B0_STS     |
| Power Button Press                 | PWRBTN_EN = 1                     | PWRBTN_STS     |
| RTC Alarm                          | RTC_EN = 1                        | RTC_STS        |
| Ring Indicate                      | RI_EN = 1                         | RI_STS         |
| USB #1 wakes                       | USB1_EN = 1                       | USB1_STS       |
| PROCHOT# pin active                |                                   |                |

Table 27-26. Causes of SMI# (Sheet 2 of 2)

| Cause                                     | Additional Enables | Where Reported    | Synch |
|---|--------------------|-------------------|-------|
| Access to Microcontroller Range (62h/66h) | MCSMI_EN           | MCSMI_STS         | X     |
| SLP_EN bit written to 1                   | SMI_ON_SLP_EN = 1  | SMI_ON_SLP_EN_STS | X     |

- Notes:** Causes of SMI#:
1. GBL\_SMI\_EN must be 1 to enable SMI
  2. EOS must be written to 1 to reenble SMI for the next one
  3. Some SMI#s are considered "synchronous", in that the processor must recognize the SMI# prior to completing the instruction (I/O read, I/O write, Memory read, or Memory write) that must cause the SMI#. This is accomplished by having the SMI# signal go active to the processor prior to the processor observing the RDY# signal that terminates the cycle. SMI#s marked with X in the Synch column are treated as Synchronous.
  4. NMI2SMI\_STS isn't gated by TCO\_EN.
  5. An SMI# must be fully enabled when CMI is also enabled to trap cycles. If SMI# is not enabled in conjunction with the trap enabling, then hardware behavior is undefined. [Note: added as per SUN# 47], part 3.

Table 27-27. Causes of TCO SMI#

| Cause                                    | Additional Enables | Where Reported |
|--|--------------------|----------------|
| Year 2000 Rollover                       | None               | NEWCENTURY_STS |
| TCO TIMEROUT                             | None               | TIMEOUT        |
| OS writes to TCO_DAT_IN register         | None               | OS_TCO_SMI     |
| NMI occurred (and NMIs mapped to SMI)    | NMI2SMI_EN = 1     | NMI2SMI_STS    |
| Note: NMI2SMI_STS isn't gated by TCO_EN. |                    |                |
| INTRUDER# signal goes active             | INTRD_SEL = 10     | INTRD_DET      |
| Changes of the BIOSWP bit from 0 to 1    | BLD = 1            | BIOSWR_STS     |
| Message from IMCH                        |                    | IMCHSMI_STS    |
| Write attempted to BIOS                  | BIOSWP = 1         | BIOSWR_STS     |

See Chapter 32.0, "High Precision Event Timers" for details on the TCO SMI# causes.

### 27.4.0.1 PCI Express\* SCI

PCI Express\* ports and the IMCH (via NSI) have the ability to cause PME using messages. When a PME message is received, the PCI\_EXP\_STS bit is set. If the PCI\_EXP\_EN bit is also set, CMI can cause an SCI via the GPE1\_STS register.

## 27.5 Dynamic Processor Clock Control

### 27.5.1 Overview

CMI has primary control for dynamically starting and stopping system clocks. The clock control is used for the transitions among the various S0/Cx states (i.e., IA 32 core throttling). Each dynamic clock control method is described in this section. The various Sleep states may also perform types of non-dynamic clock control, and are described in [Section 27.4](#).

CMI supports the ACPI C0, C1 and C2 states

The Dynamic Clock control is handled using the following signals:

- STPCLK# - Used to halt the IA 32 core instruction stream

The C1 state is entered based on the IA 32 core performing an autohalt instruction.

The C2 state is entered based on the IA 32 core reading the Level 2 register.

The C1, and C2 states end due to a Break event. Based on the break event, CMI returns the system to a C0 state. [Table 27-28](#) lists the possible break events from the C2, states.

**Table 27-28. Break Events**

| Event   | Breaks From | Comment   |
|---|-------------|---|
| Any unmasked interrupt goes active                    | C2          | IRQ[0:15] when using the 8259s, IRQ[0:23] for I/O (x) APIC. Since SCI is an interrupt, any SCI will also be a break event.                        |
| Any internal event that will cause an NMI or SMI#     | C2          | Many possible sources   |
| Any internal event that will cause INIT# to go active | C2          | Could be indicated by the keyboard controller via the RCIN input signal.  |
| RTC Interrupt Pending                                 | C2          | Only available if the RTC Interrupt (IRQ8) is enabled as a break event (See RTC Interrupt Break Enable bit in <a href="#">Section 29.3.1.1</a> ). |
| CPU Pending Break Event Indication                    | C2          | Only available if FERR# is enabled for break event indication (See FERR# MUX Enable bit in <a href="#">Section 29.3.1.1</a> )                     |
| REQ-C0 message from IMCH                              | C2          | Can be sent at any time after the Ack-C2 message and before the Ack-C0 message (i.e., any time not in C0 state).                                  |

The Pending Break Event (PBE) indication from the IA 32 core is supported using the FERR# signal. The following rules apply:

1. When STPCLK# is detected active by the IA 32 core, the FERR# signal from the IA 32 core will be redefined to indicate whether an interrupt is pending. The signal is active low (i.e., FERR# will be low to indicate a pending interrupt).
2. When the STPCLK# asserts, it will latch the current state of the FERR# signal and continue to present this state to the FERR# state machine (independent of what the FERR# pin does after the latching).
3. When the Stop-Grant cycle is detected, it will start looking at the FERR# signal as a break event indication. If FERR# is sampled low, a break event is indicated. This will force a transition to the C0 state.
4. When the IA 32 core detects the deassertion of STPCLK#, the IA 32 core will start driving the FERR# signal with the natural value (i.e., the value it would do if the pin

was not muxed). The time from STPCLK# inactive to the FERR# signal transitioning back to the native function must be less than 120 ns.

5. At least 180 ns passes after deasserting STPCLK# and then starts using the FERR# signal for an indication of a floating point error. The maximum time that may pass is bounded such that it must have a chance to look at the FERR# signal before reasserting STPCLK#. Based on current implementation, that maximum time would be 240 ns (8 PCI clocks). Since the IA 32 core has 120 ns to revert to the proper FERR# function, there are 60 ns of margin inherent in the timings.

The break event associated with this mechanism does not need to set any particular status bit, since the pending interrupt will be serviced by the processor after returning to the C0 state.

## 27.5.2 Transition Rules Among S0/Cx and Sx States

The following priority rules and assumptions apply among the various S0/Cx and throttling states:

- Entry to any S0/Cx state is mutually exclusive with entry to S1, S3, S4 or S5 state. This is because the processor can only perform one register access at a time and Sleep states have higher priority than thermal throttling.
- ..When the SLP\_EN bit is set (system going to a S1, S3, S4 or S5 sleep state), the THTL\_EN and FORCE\_THTL bits can be internally treated as being disabled (no throttling while going to sleep state).
- If the THTL\_EN or FORCE\_THTL bits are set, and a Level 2 read then occurs, the system must immediately go and stay in a C2 state until a break event occurs. A Level 2 read has higher priority than the software initiated throttling.
- After an exit from a C2 state (due to a Break event), and if the THTL\_EN or FORCE\_THTL bits are still set, the system will continue to throttle STPCLK#. The first transition on STPCLK# active can be delayed by up to one PROCHOT period (1024 PCI clocks = 30.72  $\mu$ s), depending on the time of the break event.
- The IMCH (or equivalent) must post Stop-Grant cycles in such a way that the processor gets an indication of the end of the special cycle prior to CMI observing the Stop-Grant cycle. This ensures that the STPCLK# signal stays active for a sufficient period after the processor observes the response phase.
- If in the C1 state and the STPCLK# signal goes active, the processor will generate a Stop-Grant cycle, and the system must go to the C2-like state. When STPCLK# goes inactive, it must return to the C1 state.

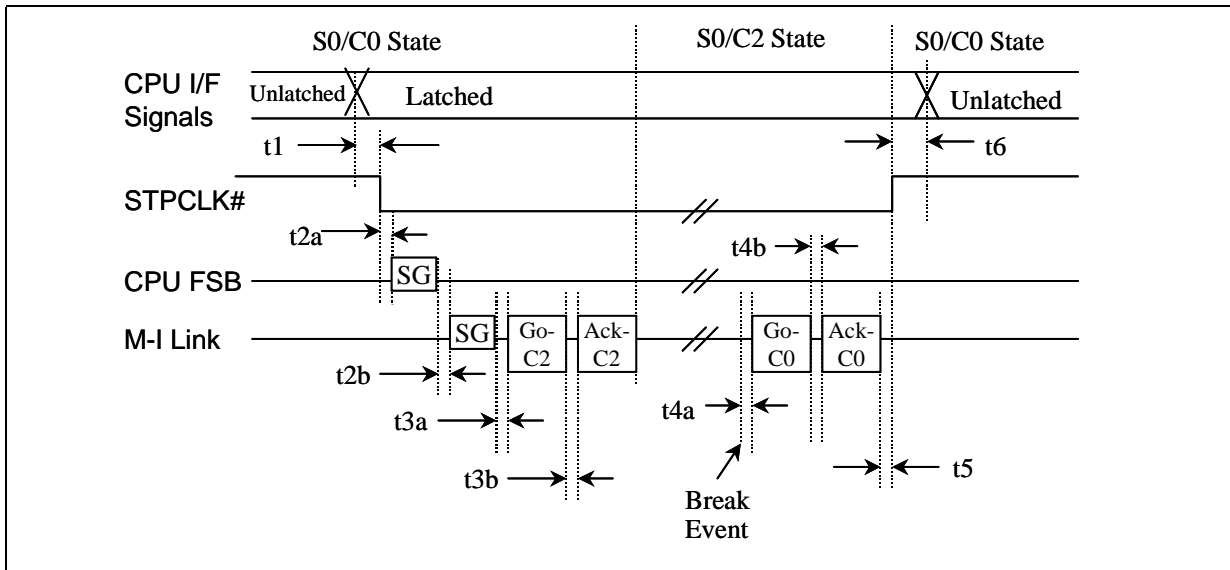

### 27.5.3 S0/C0, S0/C2, Entry/Exit Timings and Sequences

The timings associated with the C0-C2-C0 sequences are shown in the following figures and tables.

#### 27.5.3.1 C0→C2→C0 Timings and Diagram

Figure 27-1. C0→C2→C0 Entry/Exit Timings

Note: In Figure 27-1, the M-I Link must be labeled as "NSI" and the "SG" message on NSI must be "Req-C2"

## 27.5.3.2 C0→C2 Entry Sequence

Table 27-29. C0→C2→C0 Timings

| Sym | Min | Max    | Units   | Description  |
|-----|-----|--------|---------|--|
| T1  | 0   | Note 1 |         | CPU Interface Signals Latched prior to STPCLK# active. Note that this does not apply for synchronous SMI's. Changed as per DCN #014, part 1.   |
| T2a | 0   | Note 2 |         | STPCLK# active to Stop-Grant cycle on processor front-side bus (can wait forever)  |
| T2b | 0   | Note 3 |         | Stop-Grant on FSB to Stop-Grant on NSI.<br><b>Note:</b> This is according to an IMCH specification.  |
| T3a | 0   | Note 1 |         | Stop-Grant on NSI to Go-C2 message. This must be as short as feasible.   |
| T3b | 128 | Note 3 | BCLK    | Go C-2 message to Ack-C2 message. Note that this is according to an IMCH specification and is only required if the IMCH has the CPUSLP# signal. It is needed to enforce the Stop-Grant to CPUSLP# timing requirements. If the IMCH does not have the CPUSLP# signal, then this can be 0. |
| T4a | 0   | 8      | PCI CLK | Break Event to when GO_C0 message is ready to be sent. The actual message may be delayed if NSI is busy with other traffic.  |
| T4b | 0   | Note 3 |         | Go-C0 message to Ack-C0 message. Note that this is an IMCH specification. This must be as short as feasible.   |
| T5  | 0   | Note 1 |         | End of Ack_C0 message to STPCLK# high  |
| T6  | 8   | 9      | PCI CLK | STPCLK# high to processor interface signals unlatched.   |

1. This value must be small (a few PCI clocks). For messages, it may be difficult to determine the maximum time, since power management messages may have to wait for other traffic on NSI.
2. This is a processor specification that is unbounded.
3. This is an IMCH specification. The maximum is presently not specified. CMI should not be dependent on this specific value.

The processor goes from a C0 to a C2 state because all of the threads in the processor are idle and have nothing to do. The decision to go to the C2 state is made by software.

The following timings are shown in [Figure 27-1](#).

1. The processor reads the Level 2 register.
2. t1 prior to asserting STPCLK#, CMI will latch the processor interface signals, except SMI# activation due to a synchronous SMI event. Changed as per DCN #014, part 3.
3. t2a later, in response to observing STPCLK# active, the processor(s) performs one or more Stop-Grant cycles on the front-side bus.
4. t2b later, IMCH forwards the last Stop-Grant cycle to CMI via NSI. This will be called "REQ-C2."
5. The processor is now in C2 state. There are some additional steps below that must complete between the IICH and IMCH to keep them in synchronization.
6. t3a after receiving the Stop-Grant from the IMCH, the IICH sends a Go-C2 message to the IMCH
7. t3b after receiving the Go-C2 message, the IMCH sends an Ack-C2 message. At this point, the IMCH is permitted to send the REQ-C0 (Break-Ind) message.

### 27.5.3.3 C2→C0 Break Sequence

CMI returns the processor to a C0 state in order to execute code. This is due to a break event. See [Table 27-28](#) for the various break event causes.

The following timings are shown in [Figure 27-1](#).

1. A Break event is detected
2. t4a later, CMI sends GO\_C0 message to the IMCH.
3. t4b after receiving the Go-C0 message, then IMCH sends an Ack-C0 to the IICH. At this point, the IMCH is not permitted to send the REQ-C0 (Break Ind) Message.
4. t5 after receiving the Ack-C0 message, CMI deasserts STPCLK# to the processor (this enables processor instruction stream)
5. The processor is now back in a C0 state
6. t6 after deasserting STPCLK#, CMI unlatches the processor interface signals, except SMI#, which was not latched for synchronous SMI events. Changed as per DCN #014, part 4.

## 27.6 Sleep States

### 27.6.1 Sleep State Overview

CMI directly supports different sleep states (S1, S3, S4 or S5), which are entered by setting the SLP\_EN bit, or due to a Power Button press. The entry to the Sleep states are based on several assumptions:

- Entry to a Cx state is mutually exclusive with entry to a Sleep state. This is because the processor can only perform one register access at a time. A request to Sleep always has higher priority than throttling.
- Prior to setting the SLP\_EN bit, the software turns off processor-controlled throttling. Thermal throttling cannot be disabled, but setting the SLP\_EN bit disables thermal throttling (since S1, S3, S4 or S5 sleep states have higher priority).
- The G3 state cannot be entered via any software mechanism. The G3 state indicates a complete loss of power.

[Table 27-30](#) shows the differences in the sleeping states with regard to the listed output signals:

### 27.6.2 Initiating Sleep States

**Table 27-30. Sleep State Output Conditions**

| State | STPCLK# | CPUSLP#           | SLP_S3#  | SLP_S4#  | SLP_S5#  |
|-------|---------|-------------------|----------|----------|----------|
| S1    | Active  | Optionally Active | Inactive | Inactive | Inactive |
| S3    | Active  | Plane off         | Active   | Inactive | Inactive |
| S4    | Active  | Plane off         | Active   | Active   | Inactive |
| S5    | Active  | Plane off         | Active   | Active   | Active   |

Entry to Sleep states (S1, S3, S4 or S5) are initiated by any of the following methods:

1. Masking interrupts, turning off all bus master enable bits, setting the desired type in the SLP\_TYP field and setting the SLP\_EN bit. The hardware will then put the system into the corresponding Sleep state.
2. Pressing the PWRBTN# signal for more than four seconds to cause a Power Button Override event. In this case the transition to the S5 state will be less graceful, since there will be no dependencies on observing Stop-Grant cycles from the processor or on clocks other than the RTC clock.

Other Assumptions:

- Entry to a Cx state is mutually exclusive with entry to a Sleep state. This is because the processor can only perform one register access at a time. A request to Sleep always has higher priority than throttling.
- Setting the SLP\_EN bit will disable all throttling (since S1, S3, S4 or S5 sleep states have higher priority).
- The G3 state cannot be entered via any software mechanism. The G3 state indicates a complete loss of power.
- Before entering sleep state, an ACPI OS will mask all interrupts and will turn off all bus master enable bits. For non-ACPI systems, the BIOS will mask interrupts and turn off all bus master enable bits. Interrupts might not be masked at the I/O subsystem. Some Operating Systems have been observed to only mask interrupts inside the processor.

Table 27-31. Sleep Types

| Sleep Type | Comment   |
|------------|---|
| S1         | CMI asserts the STPCLK# signal. It also has the option to assert CPUSLP# signal. This lowers the processor's power consumption. No snooping is possible in this state.                    |
| S3         | CMI asserts SLP_S3#. The SLP_S3# signal controls the power to non-critical circuits. Power is only retained to devices needed to wake from this sleeping state, as well as to the memory. |
| S4         | CMI asserts SLP_S3# and SLP_S4#. The SLP_S4# signal shuts off the power to the memory subsystem. Only devices needed to wake from this state should be powered.                           |
| S5         | The SLP_S5# signal shuts off the power to the memory subsystem. Only devices needed to wake from this state must be powered. CMI asserts SLP_S3#, SLP_S4# and SLP_S5#.                    |

### 27.6.3 Exiting Sleep States

Sleep states (S1, S3, S4 or S5) are exited based on Wake events. The Wake events will force the system to a full on state (S0), although some non-critical subsystems might still be shut and have to be brought back manually. For example, the hard disk may be shut during a sleep state, and have to be enabled via an I/O pin before it can be used.

*Note:* Upon exit from CMI-controlled Sleep states, the WAK\_STS bit will be set. To enable Wake Events, the possible causes of wake events (and their restrictions) are shown in [Table 27-32](#).

There is no support for wake from USB when in S3/S4/S5.

Table 27-32. Causes of Wake Events

| Cause                              | States can wake from:                           | How Enabled   |
|------------------------------------|---|---|
| RTC Alarm                          | S1,S3,S4,S5                                     | Set RTC_EN bit in PM1_EN Register   |
| Power Button                       | S1,S3,S4,S5                                     | Always enabled as Wake event  |
| GPI[0:15]                          | S1,S3,S4,S5                                     | GPE0_EN register (after having gone to S5 via SLP_EN, but not after a power failure.) GPIs that are in the core well are not capable of waking the system from sleep states where the core well is not powered. |
| Classic USB                        | S1  | Set USB1_EN bits in GPE0_EN Register  |
| RI                                 | S1,S3,S4,S5                                     | Set RI_EN bit in GPE0_EN Register   |
| Primary PME#                       | S1,S3,S4,S5 (Note 2)                            | PME_BO_EN bit in GPE0_EN register   |
| Secondary PME# (pin)               | S1,S3,S4,S5 (Note 2)                            | PME_EN bit in GPE0_EN register.   |
| SMBus ALERT# Signal                | S1,S3,S4,S5                                     | Always Enabled as a Wake Event  |
| SMBus Slave Message                | S1,S3,S4,S5, including S5-Power Button Override | Three SMBus commands always enabled as Wake events. These commands (see Note 1. below) can wake from S5 due to Power Button.  |
| SMBus Host Notify message received | S1,S3,S4,S5                                     | HOST_NOTIFY_WKEN bit SMBus Slave Command register. Reported in the SMB_WAK_STS bit in GPE0_STS register.  |

**Notes:**

1. If in the S5 state due to a powerbutton override or THRMTRIP#, the only wake events are Power Button, Wake SMBus Slave Message (01h), and Hard Reset SMBus Slave Messages (03h, 04h).
2. PME#, RTC, GPI[0:n], and RI# will be wake events from S5 only if it was entered via software setting the SLP\_EN and SLP\_TYP bits, or if there is a power failure.
3. GbE wake-up capability (Wake on LAN) is described in Section 37.5.10, "Wake on LAN" on page 1402
4. There is no support for wake from USB when in S3/S4/S5.

Table 27-33. GPI Wake Events

| GPI              | Power Well | Wake From   | Notes          |
|------------------|------------|-------------|----------------|
| GPI[12, 11, 7:0] | Core       | S1          | ACPI Compliant |
| GPI[8]           | Resume     | S1,S3,S4,S5 | ACPI Compliant |

The latency to exit the various sleep states varies greatly and is heavily dependent on power supply design, so much so that the exit latencies due to CMI are insignificant.

## 27.6.4 Sx-G3-Sx, Handling Power Failures

In systems, power failures can occur if the AC power is cut (a real power failure) or if the system is unplugged. In either case, PWROK and RSMRST# are assumed to go low.

Depending on when the power failure occurs and how the system is designed, different transitions could occur due to a power failure. The AFTER\_G3 bit provides the ability to program whether or not the system should boot once power returns after a power loss event. If the policy is to not boot, the system remains in an S5 state. There are only three possible events that will wake the system after a power failure.

1. **PWRBTN#**: PWRBTN# is always enabled as a wake event. When RSMRST# is low (G3 state), the PWRBTN\_STS bit is reset. When CMI exits G3 after power returns

(RSMRST# goes high), the PWRBTN# signal is already high (because V<sub>CC</sub>-standby goes high before RSMRST# goes high) and the PWRBTN\_STS bit is 0.

2. **RI#:** RI# does not have an internal pull-up. Therefore, if this signal is enabled as a wake event, it is important to keep this signal powered during the power loss event. If this signal goes low (active), when power returns the RI\_STS bit is set and the system interprets that as a wake event.
3. **RTC Alarm:** The RTC\_EN bit is in the RTC well and is preserved after a power loss. Like PWRBTN\_STS the RTC\_STS bit is cleared when RSMRST# goes low.

CMI monitors both PWROK and RSMRST# to detect for power failures. If PWROK goes low, the PWROK\_FLR bit is set. If RSMRST# goes low, PWR\_FLR is set. Software can clear PWR\_FLR by writing a 1 to that bit

Although PME\_EN is in the RTC well, this signal cannot wake the system after a power loss. PME\_EN is cleared by RTEST#, and PME\_STS is cleared by RSMRST#.

Table 27-34. Transitions Due To Power Failure

| State at Power Failure | AFTERG3_EN bit | Transition When Power Returns |
|------------------------|----------------|-------------------------------|
| S0, S1, S3             | 1<br>0         | S5<br>S0                      |
| S4                     | 1<br>0         | S4<br>S0                      |
| S5                     | 1<br>0         | S5<br>S0                      |

The power failure bit (PWR\_FLR) is set after any power failure. Software can clear it by writing a 1 to that bit.

The CPUPWR\_FLR bit separately reports power failures that result in VRMPWRGD going inactive.

## 27.7 Processor Thermal Management

CMI has several mechanisms to assist with managing thermal problems in the system.

### 27.7.1 PROCHOT# Signal for SMI# or SCI

The PROCHOT# signal is used as a status input from a thermal sensor. The sensor could be inside the processor or in a separate component near the processor. CMI follows these behaviors with regard to the PROCHOT# signal:

1. Based on the PROCHOT# signal going active, CMI generates an SMI# or SCI (depending on SCI\_EN).
2. If the PROCHOT\_POL bit is set low, when PROCHOT# goes low, the PROCHOT\_STS bit will be set. This is an indicator that the thermal threshold has been exceeded. If the PROCHOT\_EN bit is set, then when PROCHOT\_STS goes active, either an SMI# or SCI# will be generated (depending on the SCI\_EN bit being set). The power management software (BIOS or ACPI) can then take measures to start reducing the temperature. Examples include shutting unneeded subsystems, or halting the processor.
3. By setting the PROCHOT\_POL bit to high, another SMI# or SCI# can optionally be generated when the PROCHOT# signal goes back high. This allows the software (BIOS or ACPI) to turn off the cooling methods.

**Note:** PROCHOT# assertion does not cause a TCO event message in S3 or S4. The level of the signal is not reported in the heartbeat message.

### 27.7.2 Processor Passive Cooling

The FORCE\_THTL bit allows the BIOS to force passive cooling independent of the ACPI software (which uses the THTL\_EN and THTL\_DTY bits). It has the following behavior:

1. If this bit is set, CMI will start throttling using the ratio in the PROCHOT\_DTY field.
2. If this bit is turned off, (cleared) CMI will stop throttling, unless the THTL\_EN bit is set (indicating that ACPI software is attempting throttling).

If both the THTL\_EN and FORCE\_THTL bits are both set, then the IICH must use the duty cycle defined by the PROCHOT\_DTY field, not the THTL\_DTY field. (i.e., PROCHOT\_DTY has higher priority).

### 27.7.3 On-Demand Passive Cooling

This is a method to cool the system by throttling the processor. The mode is initiated by software setting the THTL\_EN or THTL\_DTY bits.

#### Behavioral Description:

1. Software sets the THTL\_DTY bits to select throttle ratio and the THTL\_EN bit to enable the throttling.
2. Throttling results in STOPCLK# active for a minimum time of 12.5% and a maximum of 87.5%. The period is 1024 PCI clocks. Thus, the STOPCLK# signal can be active for as little as 128 PCI clocks or as much as 896 PCI clocks. The actual slowdown (and cooling) of the processor will depend on the instruction stream, because the processor is allowed to finish the current instruction. Furthermore, CMI waits for the STOP-GRANT cycle before starting the count of the time the STOPCLK# signal is active.
3. CMI will perform the Go-C2/Ack-C2 and Go-C0/Ack-C0 messages for throttling, just as if it were making transitions to/from a C2 state.

### 27.7.4 Active Cooling

Active cooling involves fans. The GPIO signals from CMI can be used to turn on/off a fan.

## 27.8 Event Input Signals, Messages and Their Usage

CMI has various input signals that trigger specific events. This section describes those signals and how they should be used.

### 27.8.1 PWRBTN# – Power Button

CMI PWRBTN# signal operates as a “Fixed Power Button” as described in the *ACPI Specification*. PWRBTN# signal has a 16 ms debounce on the input. The state transition descriptions are included in [Table 27-35](#). The transitions start as soon as the PWRBTN# is pressed (but after the debounce logic), and does not depend on when the Power Button is released. A power button override will force a transition to S5, even if PWROK is not active.

**Table 27-35. Transitions Due to Power Button**

| Present State | Event   | Transition/Action                           | Comment   |
|---------------|---|---|---|
| S0/Cx         | PWRBTN# goes low                                    | SMI# or SCI generated (depending on SCI_EN) | Software will typically initiate a Sleep state.                                 |
| S1-S5         | PWRBTN# goes low                                    | Wake Event. Transitions to S0 state.        | Standard wakeup<br><b>Note:</b> Could be impacted by SLP_S4# minimum assertion. |
| G3            | PWRBTN# pressed                                     | None  | No effect since no power. Not latched nor detected.                             |
| S0 -S4        | PWRBTN# held low for at least 4 consecutive seconds | Unconditional transition to S5 state.       | No dependence on processor (such as Stop-Grant cycles) or any other subsystem.  |

### 27.8.1.1 Power Button Override Function

If PWRBTN# is observed active for at least 4 consecutive seconds, then the state machine must unconditionally transition to the G2/S5 state, regardless of present state (S0-,S4) even if PWROK is not active. In this case, the transition to the G2/S5 state must not depend on any particular response from the processor (such as a Stop-Grant cycle), nor any similar dependency from any other subsystem.

*Note:* The 4-second PWRBTN# assertion must only be used if a system lock-up has occurred. The 4-second timer starts counting when CMI is in a S0 state. If the PWRBTN# signal is asserted and held active when the system is in a suspend state (S1,S5), the assertion causes a wake event. Once the system has resumed to the S0 state, the 4-second timer starts. The PWRBTN# status is readable to check if the button is currently being pressed or has been released. The status is taken after the debounce, and is readable via the PWRBTN\_LVL bit.

*Note:* During the time that the SLP\_S4# signal is stretched for the minimum assertion width (if enabled by D31:F0:A4h bit 3), the Power Button is not a wake event. As a result, it is conceivable that the user will press and continue to hold the Power Button waiting for the system to awake. Since a 4-second press of the Power Button is already defined as an Unconditional Power down, the power button timer will be forced to inactive while the power-cycle timer is in progress. Once the power-cycle timer has expired, the Power Button awakes the system. Once the minimum SLP\_S4# power cycle expires, the Power Button must be pressed for another 4 to 5 seconds to create the Override condition to S5.

### 27.8.1.2 Sleep Button

The *Advanced Configuration and Power Interface (ACPI) Specification, Rev. 2.0b* defines an optional Sleep button. It differs from the power button in that it only is a request to go from S0 to S1-S4 (not S5). Also, in an S5 state, the Power Button can wake the system, but the Sleep Button cannot.

Although CMI does not include a specific signal designated as a Sleep Button, one of the GPIO signals can be used to create a “Control Method” Sleep Button See the *ACPI Specification* for implementation details.

## 27.8.2 RI# – Ring Indicate Signal

The Ring Indicator can cause a wake event (if enabled) from the S1, S3, S4 or S5 states. Table 27-36 shows when the wake event is generated or ignored in different states. If in the G0/S0/Cx states, CMI generates an interrupt based on RI# active, and the interrupt will be set up as a Break event.

*Note:* There is no filtering on the RI# signal. Any debounce filtering must be done externally.

**Table 27-36. Transitions Due to RI# Signal**

| Present State  | Event      | RI_EN | Event      |
|----------------|------------|-------|------------|
| S0             | RI# Active | X     | Ignored    |
| S1, S3, S4, S5 | RI# Active | 0     | Ignored    |
|                |            | 1     | Wake Event |

## 27.8.3 PME# – PCI Power Management Event

The PME# signal comes from a PCI device to request that the system be restarted. The PME# signal can generate an SMI, SCI, or optionally a Wake event. The event occurs when the PME# signal goes from high to low. No event is caused when it goes from low to high.

## 27.8.4 SYS\_RESET# Button

When the SYS\_RESET# button is detected as active after the debounce logic (100 ms debounce on the input, same as PWRBTN#), CMI will attempt to perform a “graceful” reset, by waiting up to 25 ms, +/- 2ms for SM Bus to go idle. If SM Bus is idle when the button is detected active, the reset will occur immediately, otherwise the counter will start. If at any point during the count SM Bus goes idle, the counter will be reset and the full system reset will occur. If, however, the counter expires and SM Bus is still active, a full system reset will be forced upon the system even though SMBus activity is still occurring.

Once the reset is asserted, it will remain asserted for approximately 1 ms, regardless of whether the SYS\_RESET# input remains asserted or not. It cannot occur again until SYS\_RESET# has been detected inactive after the debounce logic, and the system is back to a full S0 state with PLTRST# inactive.

*Note:* If bit 3 of the CF9h I/O register is set then SYS\_RESET# will result in a full power cycle reset.

## 27.8.5 Processor Thermal Trip

If THRMTRIP# goes active, the processor is indicating an overheat condition, and will immediately transition to an S5 state. However, since the processor has overheated, it will not respond to the STPCLK# pin with a stop grant special cycle. Therefore, CMI will not wait for one. Immediately upon seeing THRMTRIP# low, CMI will initiate a transition to the S5 state, drive signals SLP\_S3#, SLP\_S4#, SLP\_S5# low, and set the CTS bit. The transition will generally look like a power button override.

When a THRMTRIP# event occurs, CMI will power down immediately without following the normal S0 -> S5 path.

If the processor is running extremely hot and is heating up, it is possible (although very unlikely) that components around it, such as the IICH, are no longer executing cycles properly. Therefore, if THRMTRIP# goes active, and IICH is relying on state machine logic to perform the power down, the state machine may not be working, and the system will not power down.

CMI will follow this flow for THRMTRIP#.

1. At boot (PLTRST# low), THRMTRIP# ignored.
2. After power-up (PLTRST# high), if THRMTRIP# sampled active, SLP\_S3#, SLP\_S4#, and SLP\_S5# fire, and normal sequence of sleep machine starts.
3. Until sleep machine enters the S5 state, SLP\_S3#, SLP\_S4#, and SLP\_S5# stay active, even if THRMTRIP# is now inactive. This is the equivalent of "latching" the thermal trip event.
4. When S5 state reached, go to step #1, otherwise stay here. If CMI never gets to S5, CMI does not reboot until power is cycled.

During boot, THRMTRIP# is ignored until SLP\_S3#, PWROK, VRMPWRGD, and PLTRST# are all '1'. During entry into a powered-down state (due to S3, S4, S5 entry, power cycle reset, etc.) THRMTRIP# is ignored until either SLP\_S3# = 0, or PWROK = 0, or VRMPWRGD = 0.

*Note:* A processor thermal trip event will

1. Set the AFTERG3\_EN bit
2. Clear the PWRBTN\_STS bit
3. Clear all the GPE0\_EN register bits
4. Clear the SMB\_WAK\_STS bit only if SMB\_WAK\_STS was set due to SMBus slave receiving message and not set due to SMBAlert.

*Note:* The THRMTRIP# pin must be glitch free.

## 27.8.6 SATA SCI

The SATA logic can cause an SCI, but not an SMI or wake event. When the SATA logic causes an SCI, the SATA\_SCI\_STS bit will be set. The SCI handler enables the SCI and clears the SCI via bits in the SATA unit.

## 27.8.7 PCI Express\* PME Event Message

PCI Express\* ports and the IMCH have the ability to cause PME using messages. When a PME message is received, CMI will set the PCI-EXP\_STS bit.

## 27.9 Alternate (ALT) Access Mode

Before entering a low power state, several registers from powered down parts may need to be saved. In the majority of cases, this is not an issue, as registers have read and write paths. However, several of the ISA (legacy) compatible registers are either read-only or write-only. To get data out of write-only registers, and to restore data into read-only registers, the IICH implements an alternate access mode.

If the ALT access mode is entered and exited after reading the registers of IICH timer (8254), the timer starts counting faster (13.5 ms). The following steps listed below can cause problems:

1. BIOS enters ALT access mode for reading the IICH timer related registers.
2. BIOS exits ALT access mode.
3. BIOS continues through the execution of other needed steps and passes control to the operating system.

After getting control in step #3, if the operating system does not reprogram the system timer again, the timer ticks may be happening faster than expected. For example DOS and its associated software assume that the system timer is running at 54.6 ms and as a result the time-outs in the software may be happening faster than expected.

Operating systems (e.g., Microsoft Windows\* 98, Windows\* 2000, and Windows NT\*) reprogram the system timer and therefore do not encounter this problem.

For some other loss (e.g., Microsoft MS-DOS\*) the BIOS must restore the timer back to 54.6 ms before passing control to the operating system. If the BIOS is entering ALT access mode before entering the suspend state it is not necessary to restore the timer contents after the exit from ALT access mode.

### 27.9.1 Write Only Registers with Read Paths in Alternate Access Mode

The registers described in [Table 27-37](#) have read paths in alternate access mode. The access number field in the table indicates which register will be returned per access to that port.

Table 27-37. Write-Only Registers with Read Paths in Alternate Access Mode (Sheet 1 of 2)

| Restore Data |            |        |                                    |          |                                    | Restore Data |  |
|--------------|------------|--------|------------------------------------|----------|------------------------------------|--------------|--|
| I/O Addr     | # of Reads | Access | Data                               | I/O Addr | # of Reads                         | Access       | Data   |
| 00h          | 2          | 1      | DMA Chan 0 base address low byte   | 40h      | 7                                  | 1            | Timer Counter 0 status, bits [5:0]           |
|              |            | 2      | DMA Chan 0 base address high byte  |          |                                    | 2            | Timer Counter 0 base count low byte          |
| 01h          | 2          | 1      | DMA Chan 0 base count low byte     |          |                                    | 3            | Timer Counter 0 base count high byte         |
|              |            | 2      | DMA Chan 0 base count high byte    |          |                                    | 4            | Timer Counter 1 base count low byte          |
| 02h          | 2          | 1      | DMA Chan 1 base address low byte   |          |                                    | 5            | Timer Counter 1 base count high byte         |
|              |            | 2      | DMA Chan 1 base address high byte  |          |                                    | 6            | Timer Counter 2 base count low byte          |
| 03h          | 2          | 1      | DMA Chan 1 base count low byte     |          |                                    | 7            | Timer Counter 2 base count high byte         |
|              |            | 2      | DMA Chan 1 base count high byte    |          | Timer Counter 1 status, bits [5:0] |              |  |
| 04h          | 2          | 1      | DMA Chan 2 base address low byte   | 42h      | 1                                  |              | Timer Counter 2 status, bits [5:0]           |
|              |            | 2      | DMA Chan 2 base address high byte  | 70h      | 1                                  |              | Bit 7 = NMI Enable, Bits [6:0] = RTC Address |
| 05h          | 2          | 1      | DMA Chan 2 base count low byte     | C4h      | 2                                  | 1            | DMA Chan 5 base address low byte             |
|              |            | 2      | DMA Chan 2 base count high byte    |          |                                    | 2            | DMA Chan 5 base address high byte            |
| 06h          | 2          | 1      | DMA Chan 3 base address low byte   | C6h      | 2                                  | 1            | DMA Chan 5 base count low byte               |
|              |            | 2      | DMA Chan 3 base address high byte  |          |                                    | 2            | DMA Chan 5 base count high byte              |
| 07h          | 2          | 1      | DMA Chan 3 base count low byte     | C8h      | 2                                  | 1            | DMA Chan 6 base address low byte             |
|              |            | 2      | DMA Chan 3 base count high byte    |          |                                    | 2            | DMA Chan 6 base address high byte            |
| 08h          | 6          | 1      | DMA Chan 0-3 Command <sup>2</sup>  | CAh      | 2                                  | 1            | DMA Chan 6 base count low byte               |
|              |            | 2      | DMA Chan 0-3 Request               |          |                                    | 2            | DMA Chan 6 base count high byte              |
|              |            | 3      | DMA Chan 0 Mode: Bits(1:0) = "00"  | CCh      | 2                                  | 1            | DMA Chan 7 base address low byte             |
|              |            | 4      | DMA Chan 1 Mode: Bits(1:0) = "01"  |          |                                    | 2            | DMA Chan 7 base address high byte            |
|              |            | 5      | DMA Chan 2 Mode: Bits(1:0) = "10"  | CEh      | 2                                  | 1            | DMA Chan 7 base count low byte               |
|              |            | 6      | DMA Chan 3 Mode: Bits(1:0) = "11". |          |                                    | 2            | DMA Chan 7 base count high byte              |

**Notes:**

1. The OCW1 register must be read before entering Alternate Access Mode.
2. Bits 5, 3, 1, and 0 return 0.
3. The additional write-only registers are described in their respective sections.

**Table 27-37. Write-Only Registers with Read Paths in Alternate Access Mode (Sheet 2 of 2)**

| Restore Data |            |        |  |          |            | Restore Data |                                    |  |
|--------------|------------|--------|--|----------|------------|--------------|------------------------------------|--|
| I/O Addr     | # of Reads | Access | Data                                       | I/O Addr | # of Reads | Access       | Data                               |  |
| 20h          | 12         | 1      | PIC ICW2 of Master controller              | D0h      | 6          | 1            | DMA Chan 4-7 Command <sup>2</sup>  |  |

|              |            | 8      | PIC ICW3 of Slave controller               |          |            |              |                                    |  |
|              |            | 9      | PIC ICW4 of Slave controller               |          |            |              |                                    |  |
|              |            | 10     | PIC OCW1 of Slave controller <sup>1</sup>  |          |            |              |                                    |  |
|              |            | 11     | PIC OCW2 of Slave controller               |          |            |              |                                    |  |
|              |            | 12     | PIC OCW3 of Slave controller               |          |            |              |                                    |  |

**Notes:**

1. The OCW1 register must be read before entering Alternate Access Mode.
2. Bits 5, 3, 1, and 0 return 0.
3. The additional write-only registers are described in their respective sections.

**27.9.2 PIC Reserved Bits**

Many bits within the PIC are reserved, and must have certain values written in order for the PIC to operate properly. Therefore, there is no need to return these values in alternate (ALT) access mode. When reading PIC registers from 20h and A0h, the reserved bits shall return the values listed in [Table 27-38](#).

**Table 27-38. PIC Reserved Bits Return Values**

| PIC Reserved Bits | Value Returned |
|-------------------|----------------|
| ICW2(2:0)         | 000            |
| ICW4(7:5)         | 000            |
| ICW4(3:2)         | 00             |
| ICW4(0)           | 0              |
| OCW2(4:3)         | 00             |
| OCW3(7)           | 0              |
| OCW3(5)           | Reflects bit 6 |
| OCW3(4:3)         | 01             |

### 27.9.3 Read-Only Registers with Write Paths in ALT Access Mode

The registers described in Table 27-39 have write paths to them in ALT access mode. Software will restore these values after returning from a powered down state. These registers must be handled special by software. When in normal mode, writing to the base address/count register also writes to the current address/count register. Therefore, the base address/count must be written first, then the part is put into alternate access mode and the current address/count register is written.

Only bits 3:0 of the DMA Status Registers listed below are writable.

Table 27-39. Register Write Accesses in Alternate Access Mode

| I/O Address | Register Write Value                  |
|-------------|---------------------------------------|
| 08h         | DMA Status Register for channels 0-3. |
| D0h         | DMA Status Register for channels 4-7. |

## 27.10 System Power Supplies, Planes, and Signals

### 27.10.1 Power Plane Control with SLP\_S3#, SLP\_S4# and SLP\_S5#

The usage of SLP\_S3# and SLP\_S4# depend on whether the platform is configured for S3-Cold.

- S3-Cold — The SLP\_S3# output signal can be used to cut power to the system core supply, since it will only go active for the STR state (typically mapped to ACPI S3). Power must be maintained to system memory, CMI Resume Well, and to any other circuits that need to generate Wake signals from the STR state.

Cutting power to the core may be done via the power supply, or by external FETs to the motherboard.

The SLP\_S4# and SLP\_S5# output signal can be used to cut power to the system core supply, as well as power to the system memory, since the context of the system is saved on the disk. Cutting power to the memory may be done via the power supply, or by external FETs to the motherboard. The SLP\_S4# output signal is used to remove power to additional subsystems that are powered during SLP\_S3#.

SLP\_S5# output signal can be used to cut power to the system core supply, as well as power to the system memory, since the context of the system is saved on the disk. Cutting power to the memory may be done via the power supply, or by external FETs to the motherboard.

### 27.10.2 SLP\_S4# and Suspend-To-RAM Sequencing

The system memory suspend voltage regulator is controlled by Glue logic. The SLP\_S4# signal must be used to remove power to system memory rather than the SLP\_S5# signal. The SLP\_S4# logic in CMI provides a mechanism to fully cycle the power to the DRAM and/or detect if the power is not cycled for a minimum time.

*Note:* To utilize the hardware-enforced minimum DRAM power-down feature that is enabled by the SLP\_S4# Assertion Stretch Enable bit (Section 27.3.1.3, "Offset A4h: GEN\_PMCON\_3 - General PM Configuration 3 Register" bit 3), the DRAM power must be controlled by the SLP\_S4# signal.

### 27.10.3 PWROK Signal

The PWROK input must go active based on the core supply voltages becoming valid. PWROK must not go high until at least 99 ms after Vcc3\_3 and Vcc1\_5 have reached their nominal values. This is required to meet the 100 ms delay from valid power to PLTRST# deassertion in the *PCI Specification, Rev. 2.3*.

1. Traditional designs have an active-low reset button electrically ANDed with the PWROK signal from the power supply and the processor's voltage regulator module. If this is done with CMI, the PWROK\_FLR bit will be set. CMI treats this internally as if the RSMRST# signal had gone active. However, it is not treated as a full power failure. If PWROK goes inactive and then active (but RSMRST# stays high), then CMI will reboot (regardless of the state of the AFTERG3 bit). If the RSMRST# signal also goes low before PWROK goes high, then this is a full power failure, and the reboot policy is controlled by the AFTERG3 bit.
2. SYSRESET# is recommended for implementing the system reset button. This saves the external logic that is needed when the PWROK input is used. Additionally it allows for better handling of the SM-Bus and processor resets, and avoids improperly reporting or power failures.
3. PWROK and RSMRST# are sampled using the RTC clock. Therefore, low times that are less than one RTC clock period may not be detected by CMI.
4. In the case of true PWROK failure, PWROK will go low first before the VRMPWRGD.
5. If the PWROK input is used to implement the system reset button, CMI does not provide any mechanism to limit the amount of time that the processor is held in reset. The platform must externally guarantee that maximum reset assertion specs are met.

### 27.10.4 CPUPWRGD Signal

This signal is connected to the processor and is derived from two inputs: VRMPWRGD signal (from the processor's VRM) AND'd with the PWROK signal that comes from the system power supply.

### 27.10.5 Controlling Leakage and Power Consumption During Low-Power States

To control leakage in the system, various signals will tri-state or go low during some low-power states.

**General principles** (these are board-level guidelines and are NOT CMI behavioral rules):

- All signals going to powered down planes (either internal or external) must be either tri-states or driven low.
- Signals with pull-up resistors must not be low during low-power states. This is to avoid the power consumed in the pull-up resistor.
- Buses must be halted (and held) in a known state to avoid a floating input (perhaps to some other device). Floating inputs can cause extra power consumption.

**Based on the above principles, the following measures are taken:**

- During S3 (STR), all signals attached to powered down planes will be tri-stated or driven low.

## 27.10.6 VRMPWROK

The VRMPWROK signal is generated by the processor's VRM. It indicates that the voltage outputs from the VRM are on and within spec.

## 27.11 Legacy Power Management Theory of Operation

### 27.11.1 Overview

Instead of relying on ACPI software, legacy power management uses BIOS and various hardware mechanisms. The scheme relies on the concept of detecting when individual subsystems are idle, detecting when the whole system is idle, and detecting accesses are attempted to idle subsystems.

However, the OS is assumed to at least be APM enabled. Without APM calls, there is no quick way to know when the system is idle between keystrokes. CMI does not support burst modes.

### 27.11.2 APM Power Management

CMI has a timer, when enabled by the 1MIN\_EN bit in the SMI Control and Enable register, generates a periodic SMI# once per minute. There is also an option to have it generate the SMI# once per 32, 16, or 8 seconds. The SMI handler can check for system activity by reading the DEVTRAP\_STS register. If none of the system bits are set, the SMI handler can increment a software counter.

If there is activity, the various bits in the DEVTRAP\_STS register will be set. Software clears the bits by writing a 1 to the bit position.

The DEVTRAP\_STS register allows for monitoring of various internal devices or Super I/O devices (SP, PP, FDC) on LPC or PCI, keyboard controller accesses, or audio functions on PCI or LPC. Other PCI activity can be monitored by checking the PCI Interrupts.

## 28.0 IA-32 Core Interface

### 28.1 IA-32 Core Interface I/O-Mapped Register Details

Table 28-1. IA-32 Core Interface Signal State

| Signal Name | S3 Hot | S3 Cold | S5  |
|-------------|--------|---------|-----|
| A20#        | Low    | Off     | Off |
| CPUSLP#     | Low    | Off     | Off |
| IGNNE#      | Low    | Off     | Off |
| INIT#       | Low    | Off     | Off |
| INTR        | Low    | Off     | Off |
| NMI         | Low    | Off     | Off |
| SMI#        | Low    | Off     | Off |
| STPCLK#     | Low    | Off     | Off |
| FERR#       | X      | Low     | Low |

**Notes:**

X = Don't care

ND = Not Determined. May be high or low depending on programming.

Table 28-2. Summary of IA-32 Core Interface Registers Mapped in I/O Space

| Offset Start | Offset End | Register ID - Description   | Default Value |

### 28.1.1 Register Descriptions

For more information on the format of the register description tables that follow in this chapter, see Section 7.1.1, “Register Description Tables” on page 183.

#### 28.1.1.1 Offset 61h: NMI\_SC - NMI Status and Control Register

Table 28-3. Offset 61h: NMI\_STS\_CNT - NMI Status and Control Register

| Description: |                          |   |        |                                      |            |
|--------------|--------------------------|---|--------|--------------------------------------|------------|
| View: IA F   | Base Address: 0000h (IO) |   |        | Offset Start: 61h<br>Offset End: 61h |            |
| Size: 8 bit  | Default: 00h             |   |        | Power Well: Core                     |            |
| Bit Range    | Bit Acronym              | Bit Description   | Sticky | Bit Reset Value                      | Bit Access |
| 07           | SERR_N_NMI_STS           | <p><b>SERR# NMI Source Status:</b><br/>           0 = Bit is cleared when bit 2 is set to 1.<br/>           1 = Bit is set by any of the sources of the internal SERR on IICH; this includes SERR assertions forwarded from the secondary PCI bus, error from a port, Do_SERR or standard error message from internal Bus 0 functions that generate SERR#. Bit 2 must be cleared in this register in order for this bit to be set. This interrupt source is enabled by setting bit 2 to 0. To reset the interrupt, set bit 2 to 1 and then set it to 0.</p> <p>This bit is read-only. When writing to port 61h, this bit must be 0.</p> |        | 0b                                   | RO         |
| 06           | IOCHK_NMI_STS            | <p><b>IOCHK# NMI Source Status:</b><br/>           0 = Bit is cleared when bit 3 is set to 1.<br/>           1 = Bit is set if a legacy agent (via SERIRQ) asserts ISA IOCHK# and bit 3 is cleared (IOCHK_NMI_EN). This interrupt source is enabled by setting bit 3 to 0. To reset the interrupt, set bit 3 to 1 and then set bit 3 to 0.</p> <p>When writing to port 61h, this bit must be a 0.</p>   |        | 0b                                   | RO         |
| 05           | TMR2_OUT_STS             | <p><b>Timer Counter 2 OUT Status:</b> This bit reflects the current state of the 8254 counter 2 output. Counter 2 must be programmed following any PCI reset for this bit to have a determinate value. When writing to port 61h, this bit must be a 0.</p>  |        | 0b                                   | RO         |
| 04           | REF_TOGGLE               | <p><b>Refresh Cycle Toggle:</b> This signal toggles from either 0 to 1 or 1 to 0 at a rate that is equivalent to when refresh cycles would occur. When writing to port 61h, this bit must be a 0.</p> <p>Assumed for compatibility, although no legacy refreshes occur. Must toggle at legacy refresh rate (every 15 μs).</p>   |        | 0b                                   | RO         |
| 03           | IOCHK_NMI_EN             | <p><b>IOCHK# NMI Enable:</b><br/>           0 = ISA IOCHK# NMIs are enabled.<br/>           1 = ISA IOCHK# NMIs are disabled and cleared.</p>   |        | 0b                                   | RW         |
| 02           | PCI_SERR_EN              | <p><b>PCI SERR# Enable:</b><br/>           0 = SERR# NMIs are enabled.<br/>           1 = The SERR# NMIs are disabled and cleared.</p>  |        | 0b                                   | RW         |
| 01           | SPKR_DAT_EN              | <p><b>Speaker Data Enable:</b><br/>           0 = The SPKR output is a 0.<br/>           1 = The SPKR output is equivalent to the Counter 2 OUT signal value.</p>   |        | 0b                                   | RW         |
| 00           | TIM_CNT2_EN              | <p><b>Timer Counter 2 Enable:</b><br/>           0 = Counter 2 counting is disabled.<br/>           1 = Counting is enabled.</p>  |        | 0b                                   | RW         |

### 28.1.1.2 Offset 70h: NMI\_EN - NMI Enable (and Real Time Clock Index) Register

This register is write-only for normal operation. In Alt-Access mode, this register can be read to find the NMI Enable status and the RTC index value.

*Note:* The RTC Index field is write-only for normal operation. This field can only be read in Alt-Access Mode. Note, however, that this register is aliased to Port 74h and all bits are readable at that address. See Section 29.2, “RTC I/O Registers” for more information.

**Table 28-4. Offset 70h: NMI\_EN - NMI Enable (and Real Time Clock Index) Register**

| Description:       |                                 |   |        |  |            |
|--------------------|---------------------------------|---|--------|--|------------|
| <b>View:</b> IA F  | <b>Base Address:</b> 0000h (IO) |   |        | <b>Offset Start:</b> 70h<br><b>Offset End:</b> 70h |            |
| <b>Size:</b> 8 bit | <b>Default:</b> 80h             |   |        | <b>Power Well:</b> Core                            |            |
| Bit Range          | Bit Acronym                     | Bit Description   | Sticky | Bit Reset Value                                    | Bit Access |
| 07                 | NMI_EN                          | NMI Enable:<br>0 = NMI sources are enabled.<br>1 = All NMI sources are disabled.  |        | 1b   | RWS        |
| 06 : 00            | RTC_INDXX                       | <b>Real Time Clock Index (Address):</b> This data goes to the RTC to select which register or CMOS RAM address is being accessed. |        | 0000000b   | RWS        |

*Note:* Software must preserve the value of bit 7 at I/O addresses 70h. When writing to this address, software must first read the value, and then write the same value for bit 7 during the sequential address write. Note that port 70h is not directly readable. The only way to read this register is through Alt Access mode. Although RTC Index bits 06:00 are readable from port 74h, bit 7 will always return 0. If the NMI# enable is not changed during normal operation, software can alternatively read this bit once and then retain the value for all subsequent writes to port 70h.

### 28.1.1.3 Offset 92h: PORT92 - Fast A20 and Init Register

Table 28-5. Offset 92h: PORT92 - Fast A20 and Init Register

| Description: |                          |  |        |                                      |            |
|--------------|--------------------------|--|--------|--------------------------------------|------------|
| View: IA F   | Base Address: 0000h (IO) |  |        | Offset Start: 92h<br>Offset End: 92h |            |
| Size: 8 bit  | Default: 00h             |  |        | Power Well: Core                     |            |
| Bit Range    | Bit Acronym              | Bit Description  | Sticky | Bit Reset Value                      | Bit Access |

## 28.2 IA-32 Core Interface Signals

This section provides additional behavioral descriptions of the signals that interface between the IICH and the IA-32 core.

### 28.2.1 A20M# (Mask A20)

The A20M# signal is active (low) when both of the following conditions are true:

1. The ALT\_A20\_GATE bit (Bit 1 of PORT92 register) is a '0'.

and

2. The A20GATE input signal is a '0'.

The A20GATE input signal is expected to be generated by the external microcontroller (KBC).

### 28.2.2 INIT# (Initialization)

The INIT# signal is active (driven low) based on any one of several events described in Table 28-8. When any of these events occur, INIT# is driven low for 16 PCI clocks, then driven high.

The IICH supports the coprocessor error function with the FERR#/IGNNE# pins. The

**Table 28-8. INIT# Going Active**

| Cause of INIT# Going Active  | Comment   |
|--|---|
| Shutdown special cycle from IA-32 core observed on the IICH interconnect (from IMCH).              |   |
| PORT92 write, where INIT_NOW (bit 0) transitions from a 0 to a 1.                                  |   |
| PORTCF9 write, where SYS_RST (bit 1) was a 0 and RST_CPU (bit 2) transitions from 0 to 1.          |   |
| RCIN# input signal goes low. RCIN# is expected to be driven by the external microcontroller (KBC). | 0 to 1 transition on RCIN# must occur before the IICH arms INIT# to be generated again. RCIN# signal is expected to be high during S3-hot and low (due to core power being off) during S3-cold, S4, and S5 states. Transitions on the RCIN# signal in those states (or in the transition to those states) may not necessarily cause the INIT# signal to be generated to the .   |
| CPU BIST   | <p>The processor uses two processor pins, INIT# and RESET, to initiate BIST. The processor executes BIST when INIT# is active on RESET's falling edge. Another way to initiate BIST is to enter the RUNBIST command through the TAP serial port.</p> <p>By default, CPU BIST is disabled. In order to enter CPU BIST, software must set the RCBA.CBE bit 2 = '1' and then do a full processor reset using the CF9 register bit 2.</p> <p>NOTE: A3# functions in the same manner that INIT# does as a strap to run BIST.</p> |

function is enabled via the COPROC\_ERR\_EN bit (Device 31, Function 0, Offset D0, Bit 13); refer to Table 28-6 for details. FERR# is tied directly to the Coprocessor Error signal of the . If FERR# is driven active by the , IRQ13 goes active (internally). When it detects a write to the COPROC\_ERR register, the IICH negates the internal IRQ13 and drives IGNNE# active. IGNNE# remains active until FERR# is driven inactive. IGNNE# is never driven active unless FERR# is active.

Figure 28-1. Coprocessor Error Timing Diagram

If COPROC\_ERR\_EN is not set, then the assertion of FERR# does not generate an internal IRQ13, nor writes to F0h generate IGNNE#.

Non-Maskable Interrupts (NMIs) can be generated by several sources that are described in Table 28-9.

Table 28-9. NMI Sources

| Cause of NMI   | Comment   |
|--|---|
| SERR# goes active (either internally, externally via SERR# signal, or via message from IMCH) |   |
| ISA IOCHK# goes active via SERIRQ# stream (legacy system Error)                              | IOCHK# is a legacy signal. CMI does not have this pin, but it may be on the platform. |
| Watch Dog Timer (LPC bus: logical device 6) first stage 35-bit Down Counter reaches zero.    | Enabled by WDT_INT_TYPE field in the WDT Configuration Register.                      |

### 28.2.3 INTR# (Interrupt Signals)

The behavior of the INTR signal and I/O APIC interrupt signals are described in Chapter 30.0, "Interrupts".

### 28.2.4 STPCLK# and CPUSLP# (Stop Clock Request and Processor Sleep Signals)

These active-low signals are controlled by the power management logic. See Chapter 27.0, "Power Management" for more details.

### 28.2.5 Enhanced Intel SpeedStep Technology (EIST) Signals

Enhanced Intel SpeedStep Technology (EIST) is not supported.

### 28.2.6 DPSP# (Deeper Sleep)

DPSP# is not supported.

## 29.0 Real Time Clock

---

### 29.1 Overview

The Real Time Clock (RTC) module provides a battery backed-up date and time keeping device with two banks of static RAM with 128 bytes each. The first bank has 114 bytes for general purpose usage. Three interrupt features are available: time of day alarm with once a second to once a month range, periodic rates of 122  $\mu$ s to 500 ms, and end of update cycle notification. Seconds, minutes, hours, days, day of week, month, and year are counted. Daylight savings compensation is optional. The hour is represented in 12 or 24 hour format, and data can be represented in BCD or binary format. The design is meant to be functionally compatible with the Motorola\* MS146818B. The time keeping comes from a 32.768 KHz oscillating source, which is divided to achieve an update every second. The lower 14 bytes on the lower RAM block have very specific functions. The first ten are for time and date information. The next four (0Ah to 0Dh) are registers, which configure and report RTC functions.

The time and calendar data must match the data mode (BCD or binary) and hour mode (12 or 24 hour) as selected in register B. The programmer MUST make sure that data stored in these registers is within the reasonable values ranges and represents a possible date and time. The exception to these ranges is to store a value of C0 - FF in the alarm bytes to indicate a "don't care" situation. All alarm conditions must match to trigger an Alarm Flag, which could trigger an Alarm Interrupt if enabled. The SET bit in register B must be '1' while programming these locations to avoid clashes with update cycles. Access to time and date information is done through the RAM locations. If a RAM read from the ten time and date bytes is attempted during an update cycle, the value read will not necessarily represent the true contents of those locations. Any RAM writes under the same conditions are ignored.

*Note:* The leap year determination for adding a 29<sup>th</sup> day to February does not take into account the end-of-the-century exceptions. The logic simply assumes that all years divisible by four are leap years. According to the Royal Observatory Greenwich, years that are divisible by 100 are typically not leap years. In every fourth century (years divisible by 400, like 2000), the 100-year-exception is overridden and a leap-year occurs. Note that the year 2100 is the first time in which the current RTC implementation would incorrectly calculate the leap-year.

### 29.2 RTC I/O Registers

The RTC internal registers and RAM are organized as two banks of 128 bytes each, called the standard and extended banks. The first 14 bytes of the standard bank contain the RTC time and date information along with four registers, A-D, that are used for configuration of the RTC. The extended bank contains a full 128 bytes of battery backed SRAM, and is accessible even when the RTC module is disabled (via the RTC configuration register). Registers A - D do not physically exist in the RAM.

All data movement between the host CPU and the real-time clock is done through registers mapped to the standard I/O space. The register map appears below in [Table 29-1](#).

**Table 29-1. I/O Registers**

| I/O Locations | If U128E bit = 0          | Function:   |
|---------------|---------------------------|---|
| 70h and 74h   | Also alias to 72h and 76h | Real-Time Clock (Standard RAM) Index Register<br><b>Note:</b> Writes to 72h, 74h, and 76h do not affect NMI enable (bit 7 of 70h) |
| 71h and 75h   | Also alias to 73h and 77h | Real-Time Clock (Standard RAM) Target Register  |
| 72h and 76h   |                           | Extended RAM Index Register (if enabled)  |
| 73h and 77h   |                           | Extended RAM Target Register (if enabled)   |

I/O locations 70h and 71h are the standard legacy location for the real-time clock. The map for this bank is shown in [Table 29-2](#). Locations 72h and 73h are for accessing the extended RAM. The extended RAM bank is also accessed using an indexed scheme. I/O address 72h is used as the address pointer and I/O address 73h is used as the data register. Index addresses above 127h are not valid. If the extended RAM is not needed, it may be disabled.

*Note:* Software must preserve the value of bit 7 at I/O addresses 70h. When writing to this address, software must first read the value, and then write the same value for bit 7 during the sequential address write. Note that port 70h is not directly readable. The only way to read this register is through Alt Access mode. Although RTC Index bits 06:00 are readable from port 74h, bit 7 will always return 0. If the NMI# enable is not changed during normal operation, software can alternatively read this bit once and then retain the value for all subsequent writes to port 70h.

### 29.3 Real Time Clock Indexed Register Details

The RTC contains two sets of indexed registers that are accessed using the two separate Index and Target registers (70/71h or 72/73h), as shown in [Table 29-2](#).

**Table 29-2. RTC (Standard) RAM Bank**

| Index     | Name                  |
|-----------|-----------------------|
| 00h       | Seconds               |
| 01h       | Seconds Alarm         |
| 02h       | Minutes               |
| 03h       | Minutes Alarm         |
| 04h       | Hours                 |
| 05h       | Hours Alarm           |
| 06h       | Day of Week           |
| 07h       | Day of Month          |
| 08h       | Month                 |
| 09h       | Year                  |
| 0Ah       | Register A            |
| 0Bh       | Register B            |
| 0Ch       | Register C            |
| 0Dh       | Register D            |
| 0Eh – 7Fh | 114 Bytes of User RAM |

Table 29-3. Summary of Real Time Clock Indexed Registers

### 29.3.1 Real Time Clock Register Details

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values and are read-only. Writes to reserved locations may cause system failure and unpredictable results.

**Note:** Reserved bits are read only.

**Note:** For more information on the format of the register description tables that follow in this chapter, see Section 7.1.1, "Register Description Tables" on page 183.

#### 29.3.1.1 Offset 0Ah: RTC\_REGA - Register A (General Configuration)

| 07           | VRT                                 | <b>Valid RAM and Time Bit:</b> This bit is hard-wired to '1' in the RTC power well. This bit should always be written as a 0 for write cycle, however it will return a 1 for read cycles.  |        | 1b                                   | RW         |
| 06           | Reserved                            | <b>Reserved:</b> This bit always returns a 0 and should be set to 0 for write cycles.  |        | 0b                                   |            |
| 05 : 00      | DA                                  | <b>Date Alarm:</b> These bits store the date of month alarm value. If set to 000000, then a don't care state is assumed. The host must configure the dates alarm for these bits to do anything, yet they can be written at any time. If the date alarm is not enabled, these bits return zeros to mimic the functionality of the Motorola 146818B. These bits are not affected by any reset assertion. |        | XXXXXXb                              | RW         |

## 29.4 Update Cycles

An update cycle occurs once a second, if the SET bit of register B is not asserted and the divide chain is properly configured. During this procedure, the stored time and date are incremented, overflow is checked, a matching alarm condition is checked, and the time and date are rewritten to the RAM locations. The update cycle will start at least 488  $\mu$ s after the UIP bit of register A is asserted, and the entire cycle will not take more than 1984  $\mu$ s to complete. The time and date RAM locations (0–9) is disconnected from the external bus during this time.

To avoid update and data corruption conditions, external RAM access to these locations can safely occur upon the detection of either of two conditions.

1. When an updated-ended interrupt is detected, almost 999 ms is available to read and write the valid time and date data.
2. If the UIP bit of Register A is detected to be low, there is at least 488  $\mu$ s before the update cycle begins.

**Warning:** The overflow conditions for leap years and daylight savings adjustments are based on more than one date or time item. To ensure proper operation when adjusting the time, the new time and data values should be set at least two seconds before one of these conditions (leap year, daylight savings time adjustments) occurs.

## 29.5 Interrupts

The real-time clock interrupt is internally routed within the IICH both to the I/O APIC and the 8259. It is mapped to interrupt vector 8. This interrupt does not leave the IICH prior to connection to the interrupt controller, nor is it shared with any other interrupt. IRQ8# from the SERIRQ stream is ignored. However, the High Performance Event Timers can also be mapped to IRQ8#; in this case, the RTC interrupt is blocked.

## 29.6 Lockable RAM Ranges

The RTC's battery-backed RAM supports two 8-byte ranges that can be locked via the PCI configuration space. If the locking bit is set, the corresponding range in the RAM is not readable or writeable. A write cycle to those locations has no effect. A read cycle to those locations does not return the locations actual value (resultant value is undefined).

Once a range is locked, the range can be unlocked only by a hard reset, which will invoke the BIOS and allow it to relock the RAM range.

## 29.7 Century Rollover

The IICH detects a roll over when the Year byte (RTC I/O space, index offset 09h) transitions from 99 to 00 (e.g., a rollover from December 31, 2099, 11:59:59 p.m. to 12:00:00 a.m on January 1<sup>st</sup>, 2100). Upon detecting the rollover, the IICH sets the NEWCENTURY\_STS bit (TCOBASE + 04h, bit 7). If the system is in an S0 state, this causes an SMI#. The SMI# handler can update registers in the RTC RAM that are associated with the century value.

If the system is in a sleep state (S3 and S5) when the century rollover occurs, the IICH also sets the NEWCENTURY\_STS bit, but no SMI# is generated. When the system resumes from the sleep state, BIOS should check the NEWCENTURY\_STS bit and update the century value in the RTC RAM.

## 29.8 Month and Year Alarms

This function is not supported.

§ §

## 30.0 Interrupts

### 30.1 Overview

Only level-triggered interrupts can be shared. PCI interrupts (PIRQs) are inherently shared on the board. These must, therefore, be programmed as level-triggered.

Table 30-1 and Table 30-2 show the mapping of the various interrupts in Non-APIC and APIC modes. Table 30-3 lists the interrupt signals action in the associated power state

**Table 30-1. Interrupt Options - 8259 Mode**

| IRQ | SERIRQ | Pin | Internal Modules                    |
|-----|--------|-----|-------------------------------------|
| 0   | No     | No  | 8254 Counter 0, MMT 0               |
| 1   | Yes    | No  |                                     |
| 2   | No     | No  | 8259 2 cascade only                 |
| 3   | Yes    | No  | Option for PIRQx                    |
| 4   | Yes    | No  | Option for PIRQx                    |
| 5   | Yes    | No  | Option for PIRQx                    |
| 6   | Yes    | No  | Option for PIRQx                    |
| 7   | Yes    | No  | Option for PIRQx                    |
| 8   | No     | No  | RTC, MMT 1                          |
| 9   | Yes    | No  | Option for PIRQx, SCI, TCO          |
| 10  | Yes    | No  | Option for PIRQx, SCI, TCO          |
| 11  | Yes    | No  | Option for PIRQx, SCI, TCO, MMT 2   |
| 12  | Yes    | No  | Option for PIRQx                    |
| 13  | No     | No  | FERR# Logic                         |
| 14  | Yes    | Yes | PIRQx, SATA Primary (legacy mode)   |
| 15  | Yes    | Yes | PIRQx, SATA Secondary (legacy mode) |

**Notes:**

1. If an interrupt is used for PCI IRQ[A:H], SCI, or TCO, it must not be used for ISA (legacy)-style interrupts (via SERIRQ).
2. PIRQ[A-D] do not come out on the pins any longer.
3. In 8259 mode, PCI interrupts are mapped to IRQ3, 4, 5, 6, 7, 9, 10, 11, 12, 14, or 15.
4. If IRQ11 is used for MMT 2, software must ensure IRQ11 is not shared with any other devices to guarantee the proper operation of MMT 2. The hardware does not prevent sharing of IRQ11.

Table 30-2. Interrupt Options - APIC Mode

| IRQ # | SERIRQ | Pin      | PCI Message | Internal Modules  |
|-------|--------|----------|-------------|---|
| 0     | No     | No       | No          | Cascade from 8259 1   |
| 1     | Yes    | No       | Yes         |   |
| 2     | No     | No       | No          | 8254 Counter 0, MMT 0 (legacy mode)   |
| 3     | Yes    | No       | Yes         |   |
| 4     | Yes    | No       | Yes         |   |
| 5     | Yes    | No       | Yes         |   |
| 6     | Yes    | No       | Yes         |   |
| 7     | Yes    | No       | Yes         |   |
| 8     | No     | No       | No          | RTC, MMT 1 (legacy mode)  |
| 9     | Yes    | No       | Yes         | Option for SCI, TCO   |
| 10    | Yes    | No       | Yes         | Option for SCI, TCO   |
| 11    | Yes    | No       | Yes         | Option for SCI, TCO   |
| 12    | Yes    | No       | Yes         |   |
| 13    | No     | No       | No          | FERR# Logic   |
| 14    | Yes    | Yes      | Yes         | SATA Primary (legacy mode)  |
| 15    | Yes    | Yes      | Yes         | SATA Secondary (legacy mode)  |
| 16    | PIRQA  | No       | Yes         | See <a href="#">Section 30.5</a> for how internal devices are mapped.   |
| 17    | PIRQB  | No       |             |   |
| 18    | PIRQC  | No       |             |   |
| 19    | PIRQD  | No       |             |   |
| 20    | N/A    | PIRQE    |             | Option for SCI, TCO, and HPET (High Precision Event Timer) For other internal devices, see <a href="#">Section 30.5</a> |
| 21    | N/A    | PIRQF    |             |   |
| 22    | N/A    | PIRQG    |             |   |
| 23    | N/A    | PIRQH    |             |   |
| 24    | N/A    | GPIO[16] | N/A         | External GPIO driven interrupt  |
| 25    | N/A    | GPIO[17] | N/A         | External GPIO driven interrupt  |
| 26    | N/A    | GPIO[20] | N/A         | External GPIO driven interrupt  |
| 27    | N/A    | GPIO[21] | N/A         | External GPIO driven interrupt  |
| 28    | N/A    | GPIO[23] | N/A         | External GPIO driven interrupt  |
| 29    | N/A    | GPIO[24] | N/A         | External GPIO driven interrupt  |
| 30    | N/A    | GPIO[28] | N/A         | External GPIO driven interrupt  |
| 31    | N/A    | GPIO[30] | N/A         | External GPIO driven interrupt  |
| 32    | N/A    | GPIO[31] | N/A         | External GPIO driven interrupt  |

**Notes:**

1. If an interrupt is used for PCI IRQ[A:H], SCI, or TCO, it must not be used for ISA (legacy)-style interrupts (via SERIRQ).
2. PIRQ[A-D] do not come out on the pins any longer.
3. In APIC mode, the PCI interrupts A:H are mapped to IRQ[16:23].
4. When programming the polarity of internal interrupt sources on the APIC, interrupts 0 through 15 receive active-high internal interrupt sources; interrupts 16 through 23 receive active-low internal interrupt sources.
5. IRQ24-39 are externally driven interrupts through GPIO pins, enabled if GPIO\_IRQ\_STRAP\_STS field of Extended Test Mode Register3 (ETR3) is set to 1 (set by externally pulling strap siu2\_txd\_ad18 to LOW on the rising edge of PWROK) and if each of the 16 IRQ capable GPIO pins is configured to work in alternative mode (in GPIO\_USE\_SEL1/GPIO\_USE\_SEL2 registers).

**Table 30-2. Interrupt Options - APIC Mode**

|    |     |          |     |                                |
|----|-----|----------|-----|--------------------------------|
| 33 | N/A | GPIO[33] | N/A | External GPIO driven interrupt |
| 34 | N/A | GPIO[34] | N/A | External GPIO driven interrupt |
| 35 | N/A | GPIO[40] | N/A | External GPIO driven interrupt |
| 36 | N/A | GPIO[18] | N/A | External GPIO driven interrupt |
| 37 | N/A | GPIO[19] | N/A | External GPIO driven interrupt |
| 38 | N/A | GPIO[25] | N/A | External GPIO driven interrupt |
| 39 | N/A | GPIO[27] | N/A | External GPIO driven interrupt |

**Notes:**

1. If an interrupt is used for PCI IRQ[A:H], SCI, or TCO, it must not be used for ISA (legacy)-style interrupts (via SERIRQ).
2. PIRQ[A-D] do not come out on the pins any longer.
3. In APIC mode, the PCI interrupts A:H are mapped to IRQ[16:23].
4. When programming the polarity of internal interrupt sources on the APIC, interrupts 0 through 15 receive active-high internal interrupt sources; interrupts 16 through 23 receive active-low internal interrupt sources.
5. IRQ24-39 are externally driven interrupts through GPIO pins, enabled if GPIO\_IRQ\_STRAP\_STS field of Extended Test Mode Register3 (ETR3) is set to 1 (set by externally pulling strap siu2\_txd\_ad18 to LOW on the rising edge of PWROK) and if each of the 16 IRQ capable GPIO pins is configured to work in alternative mode (in GPIO\_USE\_SEL1/GPIO\_USE\_SEL2 registers).

**Table 30-3. Signals Associated with Interrupt Logic**

| Signal Name | S3  | S5  |
|-------------|-----|-----|
| SERIRQ      | Off | Off |
| PIRQ[A:H]#  | Off | Off |

## 30.2 8259 Interrupt Controllers (PIC)

### 30.2.1 Overview

The IICH incorporates the functionality of two 8259 interrupt controllers that provide system interrupts for the legacy (ISA) compatible interrupt controller (PIC). These interrupts are: system timer, keyboard controller, serial ports, parallel ports, floppy disk, mouse, and DMA channels. In addition, this interrupt controller can support the PCI based interrupts by mapping the PCI interrupt onto the compatible IRQ interrupt line. Each 8259 core supports eight interrupts, numbered 0–7. [Table 30-4](#) shows how the cores are connected.

**Table 30-4. 8259 Core Connection (Sheet 1 of 2)**

| 8259   | 8259 Input | Typical Interrupt Source | Connected Pin / Function                                |
|--------|------------|--------------------------|---|
| Master | 0          | Internal                 | Internal Timer / Counter 0 output or Multimedia Timer 0 |
|        | 1          | Keyboard                 | IRQ1 via SERIRQ   |
|        | 2          | Internal                 | Slave Controller INTR output                            |
|        | 3          | Serial Port A            | IRQ3 via SERIRQ, PIRQx                                  |
|        | 4          | Serial Port B            | IRQ4 via SERIRQ, PIRQx                                  |
|        | 5          | Parallel Port / Generic  | IRQ5 via SERIRQ, PIRQx                                  |
|        | 6          | Floppy Disk              | IRQ6 via SERIRQ, PIRQx                                  |
|        | 7          | Parallel Port / Generic  | IRQ7 via SERIRQ, PIRQx                                  |

**Table 30-4. 8259 Core Connection (Sheet 2 of 2)**

| 8259  | 8259 Input | Typical Interrupt Source | Connected Pin / Function  |
|-------|------------|--------------------------|---|
| Slave | 0          | Real Time Clock          | Inverted IRQ8# from internal RTC or Multimedia Timer 1  |
|       | 1          | Generic                  | IRQ9 via SERIRQ, SCI, or TCO, PIRQx   |
|       | 2          | Generic                  | IRQ10 via SERIRQ, SCI, or TCO, PIRQx  |
|       | 3          | Generic                  | IRQ11 via SERIRQ, SCI, or TCO, PIRQx  |
|       | 4          | PS/2 Mouse               | IRQ12 via SERIRQ, SCI, or TCO, PIRQx  |
|       | 5          | Internal                 | State Machine output based on processor FERR# assertion. Can optionally be used for SCI or TCO interrupts if FERR# is not needed. |
|       | 6          | SATA                     | SATA Primary (legacy mode), SERIRQ, PIRQx   |
|       | 7          | SATA                     | SATA Secondary (legacy mode), SATA Secondary (legacy mode), SERIRQ, PIRQx   |

The IICH cascades the slave controller onto the master controller through master controller interrupt input 2. This means there are only 15 possible interrupts for the IICH PIC.

Interrupts can individually be programmed to be edge or level, except for IRQ0, IRQ2, IRQ8#.

*Note:* Active-low interrupt sources, such as the PIRQ#s, are internally inverted in the IICH. In the following descriptions of the 8259s, the interrupt levels are in reference to the signals at the internal interface of the 8259s, after the required inversions have occurred. Therefore, the term “high” indicates “active”, which means “low” on an originating PIRQ#.

### 30.2.2 I/O Registers

The interrupt controller registers are located at 20h and 21h for the master controller (IRQ0–7), and at A0h and A1h for the slave controller (IRQ8–13). These registers have multiple functions depending upon the data written to them. Table 30-5 lists the different register possibilities for each address.

**Table 30-5. Summary of 8259 Interrupt Controller (PIC) Registers Mapped in I/O Space**

| Offset Start | Offset End | Register ID - Description  | Default Value |
|--------------|------------|--|---------------|
| 020h, 0A0h   | 020h, 0A0h | “ICW1[0-1] - Initialization Command Word 1 Register” on page 1119              | 0001X0XXb     |

### 30.2.2.1 ICW1[0-1] - Initialization Command Word 1 Register

A write to Initialization Command Word 1 starts the interrupt controller initialization sequence, during which the following occurs:

1. The Interrupt Mask register is cleared.
2. IRQ7 input is assigned priority 7.
3. The slave mode address is set to 7.
4. Special Mask Mode is cleared and Status Read is set to IRR.

Once this write occurs, the controller expects writes to ICW2, ICW3, and ICW4 to complete the initialization sequence.

**Table 30-6. ICW1[0-1] - Initialization Command Word 1 Register**

| Description: |                          |  |        |  |            |
|--------------|--------------------------|--|--------|--|------------|
| View: IA F   | Base Address: 0000h (IO) |  |        | Offset Start: 020h, 0A0h<br>Offset End: 020h, 0A0h |            |
| Size: 8 bit  | Default: 0001X0XXb       |  |        | Power Well: Core                                   |            |
| Bit Range    | Bit Acronym              | Bit Description  | Sticky | Bit Reset Value                                    | Bit Access |
| 07 : 05      | Reserved                 | Reserved. Must be programmed to zero.  |        | 000h   |            |
| 04           | Reserved                 | Reserved. Must be programmed to one.   |        | 1  |            |
| 03           | LTIM                     | <b>Edge/Level Bank Select:</b> Disabled. Replaced by the edge/level triggered control registers (ELCR, D31, F0, 4D0h and D31, F0, 4D1h). |        | X  | WO         |
| 02           | Reserved                 | Reserved. Must be programmed to zero.  |        | 0h   |            |
| 01           | SNGL                     | <b>Single or Cascade:</b> This bit must be programmed to a 0 to indicate that two controllers are operating in cascade mode.             |        | X  | WO         |
| 00           | IC4                      | <b>ICW4 Write Required:</b> This bit must be programmed to a 1 to indicate that ICW4 needs to be programmed.                             |        | X  | WO         |

### 30.2.2.2 ICW2[0-1] - Initialization Command Word 2 Register

ICW2 is used to initialize the interrupt controller with the five most significant bits of the interrupt vector address. The value programmed for bits[07:03] is used by the processor to define the base address in the interrupt vector table for the interrupt routines associated with each IRQ on the controller. Typical ISA (legacy) ICW2 values are 08h for the master controller and 70h for the slave controller.

| 07 : 00      | IRM                      | <b>Interrupt Request Mask:</b><br>0 = The corresponding IRQ mask bit is cleared and interrupt requests are again accepted by the controller.<br>1 = The corresponding IRQ line is masked.<br>Masking IRQ2 on the master controller also masks the interrupt requests from the slave controller. |        | 00h  | RW         |

### 30.2.2.7 OCW2[0-1] - Operational Control Word 2 Register

Following a device reset or ICW initialization, the controller enters the fully nested mode of operation. Non-specific EOI without rotation is the default. Both rotation mode and specific EOI mode are disabled following initialization.

**Table 30-12. OCW2[0-1] - Operational Control Word 2 Register**

### 30.2.3 Interrupt Handling

#### 30.2.3.1 Generating Interrupts

The PIC interrupt sequence involves three bits, from the IRR, ISR, and IMR, for each interrupt level. These bits are used to determine the interrupt vector returned and status of any other pending interrupts. These bits are defined in [Table 30-16](#).

**Table 30-16. Interrupt Handling**

| Bits | Name                       | Description  |
|------|----------------------------|--|
| IRR  | Interrupt Request Register | This bit is set on a low to high transition of the interrupt line in edge mode, and by an active high level in level mode. This bit is set whether or not the interrupt is masked. However, a masked interrupt will not generate INTR. |
| ISR  | Interrupt Service Register | This bit is set, and the corresponding IRR bit cleared, when an interrupt acknowledge cycle is seen, and the vector returned is for that interrupt.  |
| IMR  | Interrupt Mask Register    | Determines whether an interrupt is masked. Masked interrupts do not generate INTR.   |

#### 30.2.3.2 Acknowledging Interrupts

The processor generates an interrupt acknowledge cycle that is translated into an Interrupt Acknowledge Special Cycle to the IICH. The PIC translates this cycle into two internal INTA# pulses expected by the 8259 cores. The PIC uses the first internal INTA# pulse to freeze the state of the interrupts for priority resolution. On the second INTA# pulse, the master or slave sends the interrupt vector to the processor with the acknowledged interrupt code. This code is based upon bits [07:03] of the corresponding ICW2 register, combined with three bits representing the interrupt within that controller.

**Table 30-17. Content of Interrupt Vector Byte**

| Master, Slave Interrupt | Bits [07:03] | Bits [02:00] |
|-------------------------|--------------|--------------|
| IRQ7,15                 | ICW2[07:03]  | 111          |
| IRQ6,14                 |              | 110          |
| IRQ5,13                 |              | 101          |
| IRQ4,12                 |              | 100          |
| IRQ3,11                 |              | 011          |
| IRQ2,10                 |              | 010          |
| IRQ1,9                  |              | 001          |
| IRQ0,8                  |              | 000          |

#### 30.2.3.3 Hardware/Software Interrupt Sequence

1. One or more of the Interrupt Request lines (IRQ) are raised high in edge mode, or seen high in level mode, setting the corresponding IRR bit.
2. The PIC sends INTR active (high) to the processor if an asserted interrupt is not masked.
3. The processor acknowledges the INTR and responds with an interrupt acknowledge cycle.

4. Upon observing the acknowledge cycle, it is converted into two cycles that the internal 8259 pair can respond to. Each cycle appears as an interrupt acknowledge pulse on the internal INTA# pin of the cascaded interrupt controllers.
5. Upon receiving the first internally generated INTA# pulse, the highest priority ISR bit is set and the corresponding IRR bit is reset. On the trailing edge of the first pulse, a slave identification code is broadcast internally by the master PIC to the slave PIC. The slave controller determines if it must respond with an interrupt vector during the second INTA# pulse.
6. Upon receiving the second internally generated INTA# pulse, the PIC returns the interrupt vector. If no interrupt request is present, the PIC will return vector 7 from the master controller.
7. This completes the interrupt cycle. In AEOI mode the ISR bit is reset at the end of the second INTA# pulse. Otherwise, the ISR bit remains set until an appropriate EOI command is issued at the end of the interrupt subroutine.

### 30.2.4 Initialization Command Words (ICW)

Before operation can begin, each 8259 must be initialized. In the IICH, this is a four byte sequence. The four initialization command words are referred to by their acronyms: ICW1, ICW2, ICW3, and ICW4.

The base address for each 8259 initialization command word is a fixed location in the I/O memory space: 20h for the master controller, and A0h for the slave controller.

#### 30.2.4.1 ICW1

An I/O write to the master or slave controller base address with data bit 4 equal to 1 is interpreted as a write to ICW1. Upon sensing this write, the IICH PIC expects three more byte writes to 21h for the master controller or A1h for the slave controller to complete the ICW sequence.

A write to ICW1 starts the initialization sequence during which the following automatically occur:

1. Following initialization, an interrupt request (IRQ) input must make a low-to-high transition to generate an interrupt.
2. The Interrupt Mask Register is cleared.
3. IRQ7 input is assigned priority 7.
4. The slave mode address is set to 7.
5. Special Mask Mode is cleared and Status Read is set to IRR.

#### 30.2.4.2 ICW2

The second write in the sequence, ICW2, is programmed to provide bits [07:03] of the interrupt vector that are released during an interrupt acknowledge. A different base is selected for each interrupt controller.

#### 30.2.4.3 ICW3

The third write in the sequence, ICW3, has a different meaning for each controller.

- For the master controller, ICW3 is used to indicate which IRQ input line is used to cascade the slave controller. Within the IICH, IRQ2 is used. Therefore, bit 2 of ICW3 on the master controller is set to a 1, and the other bits are set to 0's.
- For the slave controller, ICW3 is the slave identification code used during an interrupt acknowledge cycle. On interrupt acknowledge cycles, the master

controller broadcasts a code to the slave controller if the cascaded interrupt won arbitration on the master controller. The slave controller compares this identification code to the value stored in its ICW3, and if it matches, the slave controller assumes responsibility for broadcasting the interrupt vector.

#### 30.2.4.4 ICW4

The final write in the sequence, ICW4, must be programmed by both controllers. At the very least, bit 0 must be set to a 1 to indicate that the controllers are operating in an Intel Architecture-based system.

### 30.2.5 Operation Command Words (OCW)

These command words reprogram the Interrupt Controller to operate in various interrupt modes.

- OCW1 masks and unmasks interrupt lines.
- OCW2 controls the rotation of interrupt priorities when in rotating priority mode, and controls the EOI function.
- OCW3 sets up ISR/IRR reads, enables/disables the Special Mask Mode SMM, and enables/disables polled interrupt mode.

### 30.2.6 Modes of Operation

#### 30.2.6.1 Fully Nested Mode

In this mode, interrupt requests are ordered in priority from 0 through 7, with 0 being the highest. When an interrupt is acknowledged, the highest priority request is determined and its vector placed on the bus. Additionally, the ISR for the interrupt is set. This ISR bit remains set until:

- The processor issues an EOI command immediately before returning from the service routine; or
- If in AEIOI mode, on the trailing edge of the second INTA#.

While the ISR bit is set, all further interrupts of the same or lower priority are inhibited, while higher levels generate another interrupt. Interrupt priorities can be changed in the rotating priority mode.

#### 30.2.6.2 Special Fully Nested Mode

This mode is used in the case of a system where cascading is used, and the priority has to be conserved within each slave. In this case, the special fully-nested mode is programmed to the master controller. This mode is similar to the fully-nested mode with the following exceptions:

- When an interrupt request from a certain slave is in service, this slave is not locked out from the master's priority logic and further interrupt requests from higher priority interrupts within the slave is recognized by the master and initiates interrupts to the processor. In normal nested mode, a slave is masked out when its request is in service.
- When exiting the Interrupt Service routine, software has to check whether the interrupt serviced was the only one from that slave. This is done by sending a Non-Specific EOI command to the slave and then reading its ISR. If it is 0, a non-specific EOI can also be sent to the master.

### 30.2.6.3 Automatic Rotation Mode (Equal Priority Devices)

In some applications, there are a number of interrupting devices of equal priority. Automatic rotation mode provides for a sequential eight-way rotation. In this mode, a device receives the lowest priority after being serviced. In the worst case, a device requesting an interrupt has to wait until each of seven other devices are serviced at most once.

There are two ways to accomplish automatic rotation using OCW2: the Rotation on Non-Specific EOI Command (R=1, SL=0, EOI=1) and the rotate in automatic EOI Mode which is set by (R=1, SL=0, EOI=0).

### 30.2.6.4 Specific Rotation Mode (Specific Priority)

Software can change interrupt priorities by programming the bottom priority. For example, if IRQ5 is programmed as the bottom priority device, then IRQ6 is the highest priority device. The Set Priority Command is issued in OCW2 to accomplish this, where: R=1, SL=1, and LO-L2 is the binary priority level code of the bottom priority device.

In this mode, internal status is updated by software control during OCW2. However, it is independent of the EOI command. Priority changes can be executed during an EOI command by using the Rotate on Specific EOI Command in OCW2 (R=1, SL=1, EOI=1 and LO-L2=IRQ level to receive bottom priority).

### 30.2.6.5 Poll Mode

Poll Mode can be used to conserve space in the interrupt vector table. Multiple interrupts that can be serviced by one interrupt service routine do not need separate vectors if the service routine uses the poll command. Polled Mode can also be used to expand the number of interrupts. The polling interrupt service routine can call the appropriate service routine, instead of providing the interrupt vectors in the vector table. In this mode, the INTR output is not used and the microprocessor internal Interrupt Enable flip-flop is reset, disabling its interrupt input. Service to devices is achieved by software using a Poll Command.

The Poll command is issued by setting P=1 in OCW3. The PIC treats its next I/O read as an interrupt acknowledge, sets the appropriate ISR bit if there is a request, and reads the priority level. Interrupts are frozen from the OCW3 write to the I/O read. The byte returned during the I/O read will contain a '1' in bit 7 if there is an interrupt, and the binary code of the highest priority level in bits 2:0.

### 30.2.6.6 Edge and Level Triggered Mode

In ISA (legacy) systems this mode is programmed using bit 3 in ICW1, which sets level or edge for the entire controller. In the IICH, this bit is disabled and a new register for edge and level triggered mode selection, per interrupt input, is included. This is the Edge/Level control Registers ELCR1 and ELCR2.

If an ELCR bit is '0', an interrupt request is recognized by a low to high transition on the corresponding IRQ input. The IRQ input can remain high without generating another interrupt. If an ELCR bit is '1', an interrupt request is recognized by a high level on the corresponding IRQ input and there is no need for an edge detection. The interrupt request must be removed before the EOI command is issued to prevent a second interrupt from occurring.

In both the edge and level triggered modes, the IRQ inputs must remain active until after the falling edge of the first internal INTA#. If the IRQ input goes inactive before this time, a default IRQ7 vector is returned.

## 30.2.7 End of Interrupt (EOI) operations

An EOI can occur in one of two fashions: by a command word write issued to the PIC before returning from a service routine, the EOI command; or automatically when AEIO bit in ICW4 is set to 1.

### 30.2.7.1 Normal EOI

In Normal EOI, software writes an EOI command before leaving the interrupt service routine to mark the interrupt as completed. There are two forms of EOI commands: Specific and Non-Specific. When a Non-Specific EOI command is issued, the PIC clears the highest ISR bit of those that are set to 1. Non-Specific EOI is the normal mode of operation of the PIC within the IICH, as the interrupt being serviced currently is the interrupt entered with the interrupt acknowledge. When the PIC is operated in modes which preserve the fully nested structure, software can determine which ISR bit to clear by issuing a Specific EOI.

An ISR bit that is masked will not be cleared by a Non-Specific EOI if the PIC is in the Special Mask Mode. An EOI command must be issued for both the master and slave controller.

### 30.2.7.2 Automatic EOI Mode

In this mode, the PIC automatically performs a Non-Specific EOI operation at the trailing edge of the last interrupt acknowledge pulse. From a system standpoint, this mode must be used only when a nested multi-level interrupt structure is not required within a single PIC. The AEIO mode can only be used in the master controller.

## 30.2.8 Masking Interrupts

### 30.2.8.1 Masking on an Individual Interrupt Request

Each interrupt request can be masked individually by the Interrupt Mask Register (IMR). This register is programmed through OCW1. Each bit in the IMR masks one interrupt channel. Masking IRQ2 on the master controller masks all requests for service from the slave controller.

### 30.2.8.2 Special Mask Mode

Some applications may require an interrupt service routine to dynamically alter the system priority structure during its execution under software control. For example, the routine may wish to inhibit lower priority requests for a portion of its execution but enable some of them for another portion.

The Special Mask Mode enables all interrupts not masked by a bit set in the Mask Register. Normally, when an interrupt service routine acknowledges an interrupt without issuing an EOI to clear the ISR bit, the interrupt controller inhibits all lower priority requests. In the Special Mask Mode, any interrupts may be selectively enabled by loading the Mask Register with the appropriate pattern. The special Mask Mode is set by OCW3.SSMM and OCW3.SMM set, and cleared when OCW3.SSMM and OCW3.SMM are cleared.

## 30.2.9 Steering of PCI Interrupts

The IICH can be programmed to allow PIRQA#-PIRQH# to be internally routed to interrupts 3-7, 9-12, 14 or 15, through the PARC, PBRC, PCRC, PDRC, PERC, PFRC, PGRC, and PHRC registers in [Section 19.2.3.1, "Offset 60h: PARC: PIRQA Routing Control Register"](#) on page 741. The assignment is programmable through the PIRQx

Route Control registers, located at 60–63h and 68–6Bh in Device 31, Function 0. One or more PIRQx# lines can be routed to the same IRQx input. If interrupt steering is not required, the Route registers can be programmed to disable steering.

The PIRQx# lines are defined as active low, level sensitive to allow multiple interrupts on a platform to share a single line across the connector. When PIRQx# is routed to specified IRQ line, software must change the corresponding ELCR1 or ELCR2 register to level sensitive mode. The IICH internally inverts the PIRQx# line to send an active high level to the PIC. When a PCI interrupt is routed onto the PIC, the selected IRQ can no longer be used by an ISA (legacy) device. Internal sources of the PIRQs, including SCI and TCO interrupts, cause the external PIRQ to be asserted. The IICH receives the PIRQ input, like all of the other external sources, and routes it accordingly.

## 30.3 Advanced Interrupt Controller: APIC

In addition to the standard ISA (legacy)-compatible PIC described in the previous chapter, the IICH also incorporates the APIC.

### 30.3.1 Interrupt Handling

The I/O APIC handles interrupts very differently than the 8259. Briefly, these differences are:

- **Method of Interrupt Transmission.** The I/O APIC transmits interrupts through memory writes on the normal data path to the processor, and interrupts are handled without the need for the processor to run an interrupt acknowledge cycle.
- **Interrupt Priority.** The priority of interrupts in the I/O APIC is independent of the interrupt number. For example, interrupt 10 can be given a higher priority than interrupt 3.
- **More Interrupts.** The I/O APIC in the IICH supports a total of 40 interrupts (24 interrupts only, when ETR3.GPIO\_IRQ\_STRAP\_STS is 0).
  - When GPIO\_IRQ\_STRAP\_STS field of Extended Test Mode Register3(ETR3) is 0, MRE field in the APIC\_VS register reports 17h (indicating 24 supported IRQs).
  - When ETR3.GPIO\_IRQ\_STRAP\_STS is 1 (Strap pulling “siu2\_txd\_ad18” to LOW on the rising edge of PWROK), IO-APIC can support additional 16, dedicated, GPIO driven IRQs (IRQ24-39). The function of IRQ capable GPIO pins are set to IRQ mode by default if ETR3.GPIO\_IRQ\_STRAP\_STS is 1, but can be changed to GPIO mode for any or all of those pins by programming the GPIO\_USE\_SEL registers. If the GPIO\_USE\_SEL register bits are configured to GPIO mode then those GPIO pins can not generate IRQ interrupt to IO-APIC.
  - Note: GPIO pins can not generate interrupt when ETR3.GPIO\_IRQ\_STRAP\_STS is 0.
- **Multiple Interrupt Controllers.** The I/O APIC architecture allows for multiple I/O APIC devices in the system with their own interrupt vectors.

### 30.3.2 PCI/PCI Express\* Message-Based Interrupts

When external devices through PCI/PCI Express\* wish to generate an interrupt, they send the message defined in the *PCI Express\* Specification* for generating INTA# - INTD#. These are translated internal assertions/deassertions of INTA# - INTD#.

### 30.3.2.1 Front Side Bus Interrupt Delivery

The IICH requires that the I/O APIC deliver interrupt messages to the processor in a parallel manner, rather than using the I/O APIC serial scheme.

Delivery of interrupts is completed by the IICH writing to a memory location that is snooped by the processor. The processors snoops the cycle to know which interrupt goes active.

The following sequence is used:

1. When the IICH detects an interrupt event (active edge for edge-triggered mode or a change for level-triggered mode), it sets or resets the internal IRR bit associated with that interrupt.
2. Internally, the IICH requests to use the bus in a way that automatically flushes upstream buffers. This can be internally implemented similar to a DMA device request.
3. The IICH delivers the message by performing a write cycle to the appropriate address with the appropriate data. The address and data formats are described in [Section 30.3.2.6, "Interrupt Message Format" on page 1133](#).

### 30.3.2.2 Edge-Triggered Operation

In this case, the "Assert Message" is sent when there is an inactive-to-active edge on the interrupt.

### 30.3.2.3 Level-Triggered Operation

In this case, the "Assert Message" is sent when there is an inactive-to-active edge on the interrupt. If after the EOI the interrupt is still active, then another "Assert Message" is sent to indicate that the interrupt is still active.

### 30.3.2.4 Registers Associated with Front-Side Bus Interrupt Delivery

Capabilities Indication is the capability to support front-side bus interrupt delivery indicated via ACPI configuration techniques. This involves the BIOS creating a data structure that gets reported to the ACPI configuration software.

### 30.3.2.5 EOI

The mechanism by which the processor may generate an EOI is PCI Express\* EOI message.

The PCI Express\* EOI message is used by IA-32 core. It is broadcast to the internal IOxAPIC. The data of the EOI message is the vector. This value is compared with all the vectors inside the IOxAPIC, and any match causes RTE[x].RIRR to be cleared. See [Section 17.1.6.1](#) for a description of the EOI vendor-specific message.

### 30.3.2.6 Interrupt Message Format

CMI writes the interrupt message internally as a 32-bit memory write cycle. It uses the following formats shown in [Table 30-18](#) and [Table 30-19](#) for the address and data.

**Table 30-18. Interrupt Delivery Address Format**

| Bits  | Description  |
|-------|--|
| 31:20 | Is always FEEh   |
| 19:12 | <b>Destination ID (DID):</b> This is the same as bits 63:56 of the I/O Redirection Table entry for the interrupt associated with this message.   |
| 11:04 | <b>Extended Destination ID (EDID):</b> This is the same as bits 55:48 of the I/O Redirection Table entry for the interrupt associated with this message.   |
| 03    | <b>Redirection Hint (DLM):</b> This bit is used by the processor host bridge to allow the interrupt message to be redirected.<br>0 = The message is delivered to the agent (processor) listed in bits 19:12.<br>1 = The message is delivered to an agent with a lower interrupt priority This can be derived from bits 10:8 in the Data Field (see below).<br>The Redirection Hint bit is a 1 if bits 10:8 in the delivery mode field associated with corresponding interrupt are encoded as 001 (Lowest Priority). Otherwise, the Redirection Hint bit is 0 |
| 02    | <b>Destination Mode (DSM):</b> This bit is used only when the Redirection Hint bit is set to 1. If the Redirection Hint bit and the Destination Mode bit are both set to 1, then the logical destination mode is used, and the redirection is limited only to those processors that are part of the logical group as based on the logical ID.  |
| 01:00 | Will always be 00b   |

**Table 30-19. Interrupt Delivery Data Format**

| Bits  | Description   |
|-------|---|
| 31:16 | Will always be 0000h  |
| 15    | <b>Trigger Mode:</b> 1 = Level, 0 = Edge. Same as the corresponding bit in the I/O Redirection Table for that interrupt.  |
| 14    | <b>Delivery Status:</b><br>0 = Deassert<br>1 = Assert<br>If using edge-triggered interrupts, then the bit will always be 1, since only the assertion is sent.<br>If using level-triggered interrupts, then this bit indicates the state of the interrupt input. |
| 13:12 | Will always be 0h   |
| 11    | <b>Destination Mode:</b> 1 = Logical. 0 = Physical. Same as the corresponding bit in the I/O redirection table  |
| 10:08 | <b>Delivery Mode:</b> This is the same as the corresponding bits in the I/O Redirection Table for that interrupt.<br>000 = Fixed 100 = NMI<br>001 = Lowest Priority 101 = INIT<br>010 = SMI/PMI 110 = Reserved<br>011 = Reserved 111 = ExtINT                   |
| 07:00 | <b>Vector:</b> This is the same as the corresponding bits in the I/O Redirection Table for that interrupt.  |

### 30.3.3 APIC Memory-Mapped Register Details

The APIC is accessed via an indirect addressing scheme. Two registers are visible by software for manipulation of most of the APIC registers. These registers are mapped into memory space. The registers are shown in [Table 30-20](#).

**Table 30-20. Summary of APIC Registers Mapped in Memory Space"**

| Offset Start | Offset End | Register ID - Description                | Default Value |
|--------------|------------|--|---------------|
| 0000h (4B)   | 0000h (4B) | "APIC_IDX - Index Register" on page 1135 | 00h           |
| 0010h (4B)   | 0010h (4B) | "APIC_DAT – Data Register" on page 1136  | 00h           |
| 0040h (4B)   | 0040h (4B) | "APIC_EOI - EOI Register" on page 1136   | 00h           |

#### 30.3.3.1 APIC\_IDX - Index Register

The Index register selects which APIC indirect register to be manipulated by software. The selector values for the indirect registers are listed in [Table 30-21](#). Software programs this register to select the desired APIC internal register.

**Table 30-21. APIC\_IDX - Index Register**

|                     |                                |  |               |  |                   |
|---------------------|--------------------------------|--|---------------|--|-------------------|
| <b>Description:</b> |                                |  |               |  |                   |
| <b>View:</b> IA F   | <b>Base Address:</b> FEC00000h |  |               | <b>Offset Start:</b> 0000h (4B)<br><b>Offset End:</b> 0000h (4B) |                   |
| <b>Size:</b> 8 bit  | <b>Default:</b> 00h            |  |               | <b>Power Well:</b> Core  |                   |
| <b>Bit Range</b>    | <b>Bit Acronym</b>             | <b>Bit Description</b>   | <b>Sticky</b> | <b>Bit Reset Value</b>   | <b>Bit Access</b> |
| 07 : 00             | APIC_Index                     | This is an 8-bit pointer into the I/O APIC indirect register table listed in <a href="#">Section 30-20</a> , "Summary of APIC Registers Mapped in Memory Space". |               | 00h  | RW                |

### 30.3.3.2 APIC\_DAT – Data Register

This register specifies the data to be read or written to the register pointed to by the Index register. This register can be accessed only in Dword quantities. The register is described in Section 30.3.4.

Table 30-22. APIC\_DAT – Data Register

|                     |                                |   |               |  |                   |
|---------------------|--------------------------------|---|---------------|--|-------------------|
| <b>Description:</b> |                                |   |               |  |                   |
| <b>View:</b> IA F   | <b>Base Address:</b> FEC00000h |   |               | <b>Offset Start:</b> 0010h (4B)<br><b>Offset End:</b> 0010h (4B) |                   |
| <b>Size:</b> 32 bit | <b>Default:</b> 00h            |   |               | <b>Power Well:</b> Core  |                   |
| <b>Bit Range</b>    | <b>Bit Acronym</b>             | <b>Bit Description</b>  | <b>Sticky</b> | <b>Bit Reset Value</b>   | <b>Bit Access</b> |
| 31 : 00             | WDW                            | This is a register for the data to be read or written to the APIC indirect register pointed to by the Index register (Table 30-21). |               | 00h  | RW                |

### 30.3.3.3 APIC\_EOI - EOI Register

When a write is issued to this register, the IOxAPIC checks the lower 8 bits written to this register, and compares it with the vector field for each entry in the I/O Redirection Table. When a match is found, RTE.RIRR for that entry is cleared. If multiple entries have the same vector, each of those entries has RTE.RIRR cleared. Only bits 07:00 are used and bits 31:08 are ignored.

Table 30-23. APIC\_EOI - EOI Register

|                     |                                |  |               |  |                   |
|---------------------|--------------------------------|--|---------------|--|-------------------|
| <b>Description:</b> |                                |  |               |  |                   |
| <b>View:</b> IA F   | <b>Base Address:</b> FEC00000h |  |               | <b>Offset Start:</b> 0040h (4B)<br><b>Offset End:</b> 0040h (4B) |                   |
| <b>Size:</b> 32 bit | <b>Default:</b> 00h            |  |               | <b>Power Well:</b> Core  |                   |
| <b>Bit Range</b>    | <b>Bit Acronym</b>             | <b>Bit Description</b>   | <b>Sticky</b> | <b>Bit Reset Value</b>   | <b>Bit Access</b> |
| 31 : 08             | Reserved                       | Reserved. software must always write a value of 0 to these bits.   |               | 00h  |                   |
| 07 : 00             | REC                            | <b>Redirection Entry Clear:</b> When a write is issued to this register, the I/O APIC checks this field, and compares it with the vector field for each entry in the I/O Redirection Table. When a match is found, the Remote_IRR bit for that I/O Redirection Entry is cleared. |               | 00h  | WO                |

### 30.3.4 Index Registers

Table 30-24 lists the registers which can be accessed within the APIC via the Index (IDX) register. When accessing these registers, accesses must be done a DWord at a time, otherwise unspecified behavior results. Software should not attempt to write to reserved registers. Some reserved registers may return non-zero values when read. For example, software must never access byte 2 from the Data Register before accessing bytes 0 and 1. The hardware does not attempt to recover from a bad programming model in this case.

**Table 30-24. APIC Index Register Space**

| Offset   | Symbol       | Register             |
|----------|--------------|----------------------|
| 00       | APIC_ID      | Identification       |
| 01       | APIC_VS      | Version              |
| 02 - 0F  | -            | Reserved             |
| 10 - 11h | APIC_RTE[0]  | Redirection Table 0  |
| 12 - 13h | APIC_RTE[1]  | Redirection Table 1  |
| ...      | ...          | ...                  |
| 5E - 5Fh | APIC_RTE[39] | Redirection Table 39 |
| 60 - FFh | -            | Reserved             |

*Note:* The supported message delivery type is parallel, i.e., interrupt message from the IOxAPIC is delivered on the (parallel) FSB bus only. Serial APIC bus is not supported.

**Table 30-25. Summary of APIC Indexed Registers**

| Offset Start    | Offset End      | Register ID - Description                               | Default Value         |
|-----------------|-----------------|---|-----------------------|
| 00h (4B)        | 00h (4B)        | "APIC_ID – Identification Register" on page 1138        | 0000h                 |
| 01h (4B)        | 01h (4B)        | "APIC_VS - Version Register" on page 1138               | 00170020h             |
| 10h at 02h (4B) | 11h at 02h (4B) | "APIC_RTE[0-39] - Redirection Table Entry" on page 1139 | XXXX0000000<br>1XXXXh |

### 30.3.4.1 APIC\_ID – Identification Register

The APIC ID serves as a physical name of the APIC. The APIC bus arbitration ID for the APIC is derived from its I/O APIC ID. This register is reset to 0 on power-up reset.

Table 30-26. APIC\_ID – Identification Register

| <b>Description:</b> |                                   |   |        |  |            |
|---------------------|-----------------------------------|---|--------|--|------------|
| <b>View:</b> IA I   | <b>Win:Idx:</b> APIC_WDW:APIC_IDX |   |        | <b>Offset Start:</b> 00h (4B)<br><b>Offset End:</b> 00h (4B) |            |
| <b>Size:</b> 32 bit | <b>Default:</b> 0000h             |   |        | <b>Power Well:</b> Core                                      |            |
| Bit Range           | Bit Acronym                       | Bit Description   | Sticky | Bit Reset Value  | Bit Access |

### 30.3.4.2 APIC\_VS - Version Register

Each I/O APIC contains a hardwired Version Register that identifies different implementation of APIC and their versions. The maximum redirection entry information also is in this register, to let software know how many interrupt are supported by this APIC.

Table 30-27. APIC\_VS - Version Register (Sheet 1 of 2)

| <b>Description:</b> |                                   |   |        |  |            |

### 30.3.4.3 APIC\_RTE[0-39] - Redirection Table Entry

The Redirection Table has a dedicated entry for each interrupt input pin. The information in the Redirection Table is used to translate the interrupt manifestation on the corresponding interrupt pin into an APIC message.

The APIC responds to an edge triggered interrupt as long as the interrupt is held until after the acknowledge cycle has begun. Once the interrupt is detected, a delivery status bit internally to the I/O APIC is set. The state machine steps ahead and wait for an acknowledgment from the APIC unit that the interrupt message was sent. Only then will the I/O APIC be able to recognize a new edge on that interrupt pin. That new edge only results in a new invocation of the handler if its acceptance by the destination APIC causes the Interrupt Request Register bit to go from 0 to 1. (In other words, if the interrupt was not already pending at the destination.) All bits are undefined except for bits 47:17 = 0 and bit 16 = 1.

a. 64 bit each, accessed as two 32 bit quantities

## 30.4 PCI Interrupts via /PCI Express\*

When external devices through PCI Express\* wish to generate an interrupt, they send the message defined in the *PCI Express\* Specification* for generating INTA# - INTD#. These are translated into internal assertions/deassertions of INTA# - INTD#.

see [Section 17.1.5, "Interrupt Configuration Registers" on page 701](#)

## 30.5 Serial Interrupt

### 30.5.1 Overview

The IICH interrupt controller supports a serial IRQ scheme. This allows a single signal to be used to report interrupt requests. The signal used to transmit this information is shared between the interrupt controller and all peripherals that support serial interrupts. The signal line, SERIRQ, is synchronous to the PCI clock, and follows the sustained tri-state protocol that is used by legacy PCI signals. This means that if a device has driven SERIRQ low, it first drives it high synchronous to the PCI clock and releases it after the following PCI clock. The serial IRQ protocol defines this sustained tri-state signaling in the following fashion:

- **S - Sample Phase:** Signal driven low.
- **R - Recovery Phase:** Signal driven high.
- **T - Turn-around Phase:** Signal released.

The IICH supports a message for 21 serial interrupts. These represent the 15 ISA (legacy) interrupts (IRQ0-1, 3-15), the four PCI interrupts, and the control signals SMI# and ISA (legacy) IOCHK#. The serial IRQ protocol does not support the additional APIC interrupts (20–39). The serial interrupt information is transferred using three types of frames:

- **Start Frame:** SERIRQ line driven low by the interrupt controller to indicate the start of IRQ transmission.
- **Data Frames:** IRQ information transmitted by peripherals. The interrupt controller supports 21 data frames.
- **Stop Frame:** SERIRQ line driven low by the interrupt controller to indicate end of transmission and next mode of operation.

### 30.5.2 Start Frame

The serial IRQ protocol has two modes of operation which affect the start frame:

- **Continuous Mode:** The interrupt controller is solely responsible for generating the start frame.
- **Quiet Mode:** Peripheral initiates the start frame, and the interrupt controller completes it.

The mode that must first be entered when enabling the serial IRQ protocol is continuous mode. In this mode, the IICH asserts the start frame. This start frame is four, six, or eight PCI clocks wide based upon the Serial IRQ Control Register(SCNT.SFPW) field, bits 01:00 at 64h in Device 31, Function 0 configuration space. This is a polling mode.

When the serial IRQ stream enters quiet mode (signaled in the Stop Frame), the SERIRQ line remains inactive and pulled up between the Stop and Start Frame until a peripheral drives the SERIRQ signal low. The IICH senses the line low and continues to drive it low for the remainder of the Start Frame. Since the first PCI clock of the start

frame was driven by the peripheral in this mode, the IICH drives the SERIRQ line low for one PCI clock less than in continuous mode. This mode of operation allows for a quiet, and therefore lower power, operation.

### 30.5.3 Data Frames

Once the Start frame has been initiated, the SERIRQ peripherals start counting frames based on the rising edge of SERIRQ. Each of the IRQ/DATA frames has exactly three phases of one clock each. The three phases are:

- **Sample Phase:** During this phase, the SERIRQ device drives SERIRQ low if the corresponding interrupt signal is low. If the corresponding interrupt is high, then the SERIRQ devices tri-state the SERIRQ signal. The SERIRQ line remains high due to pull-up resistors (there is no internal pull-up resistor on this signal, an external pull-up resistor is required). A low level during the IRQ0–1 and IRQ2–15 frames indicates that an active-high ISA (legacy) interrupt is not being requested, but a low level during the PCI INT[A:D], SMI#, and ISA (legacy) IOCHK# frame indicates that an active-low interrupt is being requested.
- **Recovery Phase:** During this phase, the device drives the SERIRQ line high if in the Sample Phase it was driven low. If it was not driven in the sample phase, it is tri-stated in this phase.
- **Turn-around Phase:** The device tri-states SERIRQ.

### 30.5.4 Stop Frame

After all the data frames, a Stop Frame is driven by the IICH. The SERIRQ signal is driven low for two or three PCI clocks. The number of clocks is determined by the SERIRQ configuration register (SCNT.MD field in D31, F0 configuration space). The number of clocks determines the next mode as shown in [Table 30-29](#).

**Table 30-29. Stop Frame Definition**

| Stop Frame Width | Next Mode  |
|------------------|--|
| 2 PCI clocks     | <b>Quite Mode:</b> Any SERIRQ device initiates a Start Frame     |
| 3 PCI clocks     | <b>Continuous Mode:</b> Only the IICH may initiate a Start Frame |

### 30.5.5 Serial Interrupts Not Supported via SERIRQ

There are three interrupts seen through the serial stream that are not supported by the IICH. These interrupts are generated internally, and are not sharable with other devices within the system. These interrupts are:

- IRQ0: Heartbeat interrupt generated off of the internal 8254 counter 0.
- IRQ8#: RTC interrupt can only be generated internally.
- IRQ13: ..... Floating point error interrupt generated off of the processor assertion of FERR#.

The IICH ignores the state of these interrupts in the serial stream, and does not adjust their level based on the level seen in the serial stream.

### 30.5.6 Special Notes on IRQ14 and IRQ15

IRQ14 and IRQ15 are special interrupts, used by the SATA controller when it is not running in Native IDE mode. If in a legacy mode, IRQ14 and IRQ15 are not accepted from the serial stream, and instead come from these controllers. If the controllers are in Native mode, these interrupts are used by the interrupt controller.

### 30.5.7 Data Frame Format

Table 30-30 shows the format of the data frames for the associated interrupts. For the legacy (PCI) interrupts (A–D), the output from the IICH is ANDed with the legacy (PCI) input signal. This way, the interrupt can be signaled via both the legacy (PCI) interrupt input signal and via the SERIRQ signal (they are shared).

Table 30-30. Data Frame Format

| Data Frame # | Interrupt | Clocks Past Start Frame | Comment  |
|--------------|-----------|-------------------------|--|
| 1            | IRQ0      | 2                       | Ignored. IRQ0 can only be generated via the internal 8524. |
| 2            | IRQ1      | 5                       | Before port 60h latch                                      |
| 3            | SMI#      | 8                       | Causes SMI# if low. Sets bit 15 in the SMI_STS register.   |
| 4            | IRQ3      | 11                      |  |

## 31.0 8254 Timers

### 31.1 Overview

The IICH contains three counters which have fixed uses. All registers and functions associated with the 8254 timers are in the core power well. The 8254 unit is clocked by a 14.31818 MHz clock.

There is one signal associated with the 8254. It is used to drive the PC speaker.

**Table 31-1. SPKR Signal**

| Signal Name | S3  | S5  |
|-------------|-----|-----|
| SPKR        | Off | Off |

### 31.2 8254 Timer I/O-Mapped Register Details

*Note:* For more information on the format of the register description tables that follow in this chapter, see [Section 7.1.1, "Register Description Tables"](#) on page 183.

### 31.2.1 Timer Registers

#### 31.2.1.1 Offset 43h: TCW - Timer Control Word Register

This register is programmed prior to any counter being accessed to specify counter modes. Following reset, the control words for each register are undefined and each counter output is 0. Each timer must be programmed to bring it into a known state.

**Table 31-3. Offset 43h: TCW - Timer Control Word Register**

The largest possible BCD count is 10 <sup>4</sup> .   |        | Xb                                   | WO         |

There are two special commands that can be issued to the counters through this register, the Read Back command (Section 31.5.3) and the Counter Latch command (Section 31.5.2). When these commands are chosen, several bits within this register are redefined. These register formats are described in Section 31.5.

#### 31.2.1.2 Offset 40h: TSB[0-2] - Interval Timer Status Byte Format Register

Each counter's status byte can be read following a Read Back command. If latch status is chosen (bit 4=0, Read Back command) as a read back option for a given counter, the next read from the counter's Counter Access Ports Register (40h for counter 0, 41h for counter 1, and 42h for counter 2) returns the status byte. The status byte returns the values shown in Table 31-4.

Table 31-4. Offset 40h: TSB[0-2] - Interval Timer Status Byte Format Register

The order of programming, either LSB only, MSB only, or LSB then MSB, is defined with the Interval Counter Control Register at port 43h. The counter port is also used to read the current count from the Count Register, and return the status of the counter programming following a Read Back command. |  |  | XXh                    |
|  |                                 |  |  |  | RW                     |

## 31.3 Counters

### 31.3.1 Counter 0, System Timer

This counter functions as the system timer by controlling the state of IRQ0 and is typically programmed for Mode 3 operation. The counter produces a square wave with a period equal to the product of the counter period (838 ns) and the initial count value. The counter loads the initial count value one counter period after software writes the count value to the counter I/O address. The counter initially asserts IRQ0 and decrements the count value by two each counter period. The counter negates IRQ0 when the count value reaches 0. It then reloads the initial count value and again decrements the initial count value by two each counter period. The counter then asserts IRQ0 when the count value reaches 0, reloads the initial count value and repeats the cycle, alternately asserting and negating IRQ0.

### 31.3.2 Counter 1, Refresh Request Signal

This counter provides the refresh request signal and is typically programmed for Mode 2 operation and only impacts the period of the REF\_TOGGLE bit in Port 61. The initial count value is loaded one counter period after being written to the counter I/O address. The REF\_TOGGLE bit has square wave behavior (alternate between 0 and 1) and toggles at a rate based on the value in the counter. Programming the counter to anything other than Mode 2 results in undefined behavior for the REF\_TOGGLE bit.

### 31.3.3 Counter 2, Speaker Tone

This counter provides the speaker tone and is typically programmed for Mode 3 operation. The counter provides a speaker frequency equal to the counter clock frequency (1.193 MHz) divided by the initial count value. The speaker must be enabled by a write to port 061h.

### 31.3.4 Counter Operating Modes

Table 31-6 lists the six operating modes for the interval counters.

**Table 31-6. Counter Operating Modes**

| Mode | Function                             | Description   |
|------|--------------------------------------|---|
| 0    | Out signal on end of count (=0)      | Output is '0'. When count goes to 0, output goes to '1' and stays at '1' until counter is reprogrammed.   |
| 1    | Hardware retriggerable one-shot      | Output is '0'. When count goes to 0, output goes to '1' for one clock time.   |
| 2    | Rate generator (divide by n counter) | Output is '1'. Output goes to '0' for one clock time, then back to '1' and counter is reloaded.   |
| 3    | Square wave output                   | Output is '1'. Output goes to '0' when counter rolls over, and counter is reloaded. Output goes to '1' when counter rolls over, and counter is reloaded, etc. |
| 4    | Software triggered strobe            | Output is '1'. Output goes to '0' when count expires for one clock time.  |
| 5    | Hardware triggered strobe            | Output is '1'. Output goes to '0' when count expires for one clock time.  |

## 31.4 Timer Programming

The counter/timers are programmed as follows:

1. Write a control word to select a counter.
2. Write an initial count for that counter.
3. Load the least and/or most significant bytes (as required by Control Word bits 5, 4) of the 16-bit counter.
4. Repeat with other counters.

Only two conventions need to be observed when programming the counters. First, for each counter, the control word must be written before the initial count is written. Second, the initial count must follow the count format specified in the control word (least significant byte only, most significant byte only, or least significant byte and then most significant byte).

A new initial count may be written to a counter at any time without affecting the counter's programmed mode. Counting is affected as described in the mode definitions. The new count must follow the programmed count format.

If a counter is programmed to read/write two-byte counts, the following precaution applies: A program must not transfer control between writing the first and second byte to another routine which also writes into that same counter. Otherwise, the counter is loaded with an incorrect count.

The Control Word Register at port 43h controls the operation of all three counters. Several commands are available:

- **Control Word Command:** Specifies which counter to read or write, the operating mode, and the count format (binary or BCD).
- **Counter Latch Command:** Latches the current count so that it can be read by the system. The countdown process continues.
- **Read Back Command:** Reads the count value, programmed mode, the current state of the OUT pins, and the state of the Null Count Flag of the selected counter.

## 31.5 Reading from the Interval Timer

It is often desirable to read the value of a counter without disturbing the count in progress. There are three methods for reading the counters: a Simple Read operation, Counter Latch command, and the Read-Back command. Each is explained in the following sections.

With the Simple Read and Counter Latch command methods, the count must be read according to the programmed format; specifically, if the counter is programmed for two byte counts, two bytes must be read. The two bytes do not have to be read sequentially. Read, write, or programming operations for other counters may be inserted between them.

### 31.5.1 Simple Read

The first method is to perform a simple read operation. The counter is selected through port 40h (counter 0), 41h (counter 1), or 42h (counter 2).

*Note:* Performing a direct read from the counter does not return a determinate value, because the counting process is asynchronous to read operations. However, in the case of counter 2, the count can be stopped by writing to the GATE bit in port 61h.

### 31.5.2 Counter Latch Command

The Counter Latch Command (Table 31-7), written to port 43h, latches the count of a specific counter at the time the command is received. This command is used to ensure that the count read from the counter is accurate, particularly when reading a two-byte count. The count value is then read from each counter's Count Register through the Counter Port's Access Ports Register (40h for counter 0, 41h for counter 1, and 42h for counter 2).

The count is held in the latch until it is read or the counter is reprogrammed. The count is then unlatched. This allows reading the contents of the counters on the fly without affecting counting in progress. Multiple Counter Latch commands may be used to latch more than one counter. Counter Latch commands do not affect the programmed mode of the counter in any way.

If a counter is latched and then, some time later, latched again before the count is read, the second Counter Latch command is ignored. The count read is the count at the time the first Counter Latch command was issued.

Table 31-7. Counter Latch Command

| Bits  | Description   |
|-------|---|
| 07:06 | <b>Counter Selection:</b> These bits select the counter for latching.         |
|       | 00 Counter 0  |
|       | 01 Counter 1  |
|       | 10 Counter 2  |
|       | 11 The write is interpreted as a read back command.                           |
| 05:04 | <b>Counter Latch Command:</b> Write '00' to select the Counter Latch Command. |
| 03:00 | Reserved. Must be 0.  |

### 31.5.3 Read Back Command

The Read Back command, written to port 43h, latches the count value, programmed mode, and current states of the OUT pin and Null Count flag of the selected counter or counters. The value of the counter and its status may then be read by I/O access to the counter address.

The Read Back command may be used to latch multiple counter outputs at one time. This single command is functionally equivalent to several counter latch commands, one for each counter latched. Each counter's latched count is held until it is read or reprogrammed. Once read, a counter is unlatched. The other counters remain latched until they are read. If multiple count Read Back commands are issued to the same counter without reading the count, all but the first are ignored. Both count and status of the selected counters may be latched simultaneously by setting both bit 5 and bit 4 to 0. If both are latched, the first read operation from that counter returns the latched status. The next one or two reads, depending on whether the counter is programmed for one or two byte counts, returns the latched count. Subsequent reads return an unlatched count.

The Read Back command may additionally be used to latch status information of selected counters. The status of a counter is accessed by a read from that counter's I/O port address. If multiple counter status latch operations are performed without reading the status, all but the first are ignored.

Both count and status of the selected counters may be latched simultaneously in any or all of the counters by selecting the counter during the register write. This is functionally the same as issuing two consecutive, separate Read Back commands. If multiple count and/or status Read Back commands are issued to the same counters without any intervening reads, all but the first are ignored.

If both count and status of a counter are latched, the first read operation from that counter will return the latched status, regardless of which was latched first. The next one or two reads, depending on whether the counter is programmed for one or two type counts, return the latched count. Subsequent reads return unlatched count.

**Table 31-8. Read Back Command**

| Bits  | Description  |
|-------|--|
| 07:06 | <b>Read Back Command:</b> Must be '11' to select the Read Back Command.  |
| 05    | <b>Latch Count of Selected Counters:</b><br>0 = Current count value of the selected counters are latched<br>1 = Current count value of the selected counters are not latched |
| 04    | <b>Latch Status of Selected Counters:</b><br>0 = Status of the selected counters are latched<br>1 = Status of the selected counters are not latched                          |

| 00    | Reserved. Must be 0.   |

## 32.0 High Precision Event Timers

---

*Note:* This section documents the CMI-specific behavior and the generic *HPET (High Precision Event Timers) Specification, Revision 1.0a*.

### 32.1 Overview

This function provides a set of timers that can be used by the operating system. The timers are defined such that in the future, the OS may be able to assign specific timers to be used directly by specific applications. Each timer can be configured to cause a separate interrupt. This specification allows for a block of 32 timers, with support for up to eight blocks, for a total of 256 timers. The timers are implemented as a single counter with a set of comparators. The counter increases monotonically. Each timer includes a value register and a comparator. Each individual timer can generate an interrupt when the value in its value register matches value in the main counter. Some of the timers can be enabled to generate a periodic interrupt.

The registers associated with these timers are mapped to a memory space (much like the I/O APIC). However, it is not implemented as a standard PCI function. The BIOS reports to the operating system the location of the register space. The hardware can support an assignable decode space; However, the BIOS sets this space prior to handing it over to the OS. It is not expected that the OS move the location of these timers once they are set by the BIOS.

*Note:* For additional information see [Section 1.3, "Referenced Documents and Related Websites"](#).

### 32.2 Register Details

The timer registers are memory mapped in a non-indexed scheme. This allows the CPU to directly access each register without having to use an index register. The timer register space is 1024 bytes. The registers are generally aligned on 64-bit boundaries.

#### General Behavioral Rules:

- Software must not attempt to read or write across register boundaries. For example, a 32-bit access must be to offset x0h, x4h, x8h, or xCh.
- 32-bit accesses must not be to 01h, 02h, 03h, 05h, 06h, 07h, 09h, 0Ah, 0Bh, 0Dh, 0Eh, or 0Fh. Any accesses to these offsets results in an unexpected behavior and may result in a master abort. However, these accesses may not result in system hangs.
- 64-bit accesses can only be to x0h and must not cross 64-bit boundaries.
- Software must not write to read-only registers.
- Software must not expect any particular or consistent value when reading reserved registers or bits.
- The timer register space is memory mapped to a 1 K block.

- There are four possible memory address ranges beginning at:
  1. FED0\_0000h
  2. FED0\_1000h
  3. FED0\_2000h
  4. FED0\_3000h
- The choice of address ranges will be selected by configuration bits in the High Performance Timer Configuration Register (in the memory-mapped chipset configuration area) [Table 17-26, “Offset 3404h: HPTC - High Performance Precision Timer Configuration Register” on page 705.](#)
- All registers are implemented in the Core well, and all bits are reset by PLTRST#.
- Reads to reserved registers or bits return a value of 0.

*Note:* Reads to reserved registers or bits returns a value of 0.

*Note:* Software must not attempt to lock the memory-mapped I/O ranges for High-Precision Timers. If attempted, the lock is not honored, which means potential deadlock conditions may occur.

## 32.2.1 Register Descriptions

### 32.2.1.1 Offset 000h: GCAP\_ID - General Capabilities and ID Register

#### General Behavioral Rules:

- Writes to this register must not be attempted by software.
- Software can read the various bytes in this register using 32-bit or 64-bit accesses.
- 32-bit accesses can be done to offset 00h or 04h, but not to offsets 01h, 02h, 03h, 05h, 06h, or 07h.
- 64-bit accesses can only be done to 00h.

**Table 32-2. Offset 000h: GCAP\_ID - General Capabilities and ID Register**

| Description: |                            |   |        |  |            |
|--------------|----------------------------|---|--------|--|------------|
| View: IA F   | Base Address: HPTC         |   |        | Offset Start: 000h<br>Offset End: 007h |            |
| Size: 64 bit | Default: 0429B17F8086A201h |   |        | Power Well: Core                       |            |
| Bit Range    | Bit Acronym                | Bit Description   | Sticky | Bit Reset Value                        | Bit Access |
| 63 : 32      | COUNTER_CLK_PER_CAP        | <b>Main Counter Tick Period:</b> This read-only field indicates the period at which the counter increments in femtoseconds ( $10^{-15}$ seconds). This returns 0429B17Fh when read indicating a period of 69841279 fs (69.841279 ns). |        | 0429B17Fh                              | RO         |
| 31 : 16      | VENDOR_ID_CAP              | <b>Vendor ID Capability:</b> These bits return 8086h when read. This is a 16-bit value assigned to Intel.   |        | 8086h                                  | RO         |
| 15           | LEG_RT_CAP                 | <b>Legacy Replacement Rout Capable:</b> This bit is always one when read, as the Legacy Replacement Interrupt Rout is supported.  |        | 1h                                     | RO         |
| 14           | Reserved                   | <b>Reserved:</b> This bit returns zero when read.   |        | 0h                                     |            |
| 13           | COUNT_SIZE_CAP             | <b>Counter Size Capability:</b> Indicates that the main counter is 64 bits wide. This bit returns one when read.  |        | 1h                                     | RO         |
| 12 : 08      | NUM_TIM_CAP                | <b>Number of Timer Capability:</b> This field indicates the number of timers in this block. This value in this field is 02h = Three timers.   |        | 02h                                    | RO         |
| 07 : 00      | REV_ID                     | <b>Revision Identification:</b> This field indicates which revision of the specification is implemented. The value in this field is 01h.  |        | 01h                                    | RO         |

### 32.2.1.2 Offset 010h: GEN\_CONF - General Configuration Register

**General Behavioral Rules:**

- Software can access the various bytes in this register using 32-bit or 64-bit accesses.
- 32-bit accesses can be done to offset 010h or 014h, but not to offsets 011h, 012h, 013h, 015h, 016h, or 017h.
- 64-bit accesses can only be done to 010h.

**Table 32-3. Offset 010h: GEN\_CONF - General Configuration Register**

| Description: |                            |  |        |  |            |
|--------------|----------------------------|--|--------|--|------------|
| View: IA F   | Base Address: HPTC         |  |        | Offset Start: 010h<br>Offset End: 017h |            |
| Size: 64 bit | Default: 0000000000000000h |  |        | Power Well: Core                       |            |
| Bit Range    | Bit Acronym                | Bit Description  | Sticky | Bit Reset Value                        | Bit Access |
| 63 :02       | Reserved                   | <b>Reserved:</b>   |        | 000000000000h                          | RO         |
| 01           | LEG_RT_CNF                 | <p><b>Legacy Replacement Route:</b> If the ENABLE_CNF and LEG_RT_CNF bits are set, then the interrupts are routed as follows:<br/>           Timer 0 is routed to IRQ0 in 8259 or IRQ2 in the I/O APIC<br/>           Timer 1 is routed to IRQ8 in 8259 or IRQ8 in the I/O APIC<br/>           Timer 2-n is routed as per the routing in the timer <i>n</i> config registers.</p> <p>0 = If the LEG_RT_CNF bit is not set, the individual routing bits for each of the timers are used.<br/>           1 = Legacy Rout: If the LEG_RT_CNF bit is set, the individual routing bits for timers 0 and 1 (APIC or FSB) have no impact.</p> |        | 0b                                     | RW         |
| 00           | ENABLE_CNF                 | <p><b>Overall Enable:</b><br/>           0 = The main counter halts (does not increment) and no interrupts are caused by any of these timers.<br/>           1 = Enable any of the timers to generate interrupts.</p> <p>For level-triggered interrupts, if an interrupt is pending when the ENABLE_CNF bit is changed from 1 to 0, the interrupt status indications (in the various Txx_INT_STS bits) are not cleared. Software must write to the Txx_INT_STS bits to clear the interrupts.</p>   |        | 0b                                     | RW         |

### 32.2.1.3 Offset 020h: GINTR\_STA - General Interrupt Status Register

#### General Behavioral Rules:

- Software can access the various bytes in this register using 32-bit or 64-bit accesses.
- 32-bit accesses can be done to offset 020h or 024h, but not to offsets 021h, 022h, 023h, 025h, 026h, or 027h.
- 64-bit accesses can only be done to 020h.

**Table 32-4. Offset 020h: GINTR\_STA - General Interrupt Status Register**

| Description:        |                                   |   |        |  |            |
|---------------------|-----------------------------------|---|--------|--|------------|
| <b>View:</b> IA F   | <b>Base Address:</b> HPTC         |   |        | <b>Offset Start:</b> 020h<br><b>Offset End:</b> 027h |            |
| <b>Size:</b> 64 bit | <b>Default:</b> 0000000000000000h |   |        | <b>Power Well:</b> Core                              |            |
| Bit Range           | Bit Acronym                       | Bit Description   | Sticky | Bit Reset Value                                      | Bit Access |
| 63 :03              | Reserved                          | <b>Reserved</b>   |        | 00h  | RO         |
| 02                  | T02_INT_STS                       | <b>Timer 2 Interrupt Active:</b> Same functionality as Timer 0.   |        | 0h   | RW         |
| 01                  | T01_INT_STS                       | <b>Timer 1 Interrupt Active:</b> Same functionality as Timer 0.   |        | 0h   | RW         |
| 00                  | T00_INT_STS                       | <b>Timer 0 Interrupt Active:</b> The functionality of this bit depends on whether the edge or level-triggered mode is used for this timer:<br>If set to level-triggered mode:<br>This bit is set by hardware if the corresponding timer interrupt is active. Once the bit is set, it can be cleared by software writing a 1 to the same bit position. Writes of 0 to this bit have no effect. If set to edge-triggered mode:<br>This bit must be ignored by software. Software must always write 0 to this bit. |        | 0h   | RWC        |

### 32.2.1.4 Offset 0F0h: MAIN\_CNT - Main Counter Value Register

**General Behavioral Rules:**

- Software can access the various bytes in this register using 32-bit or 64-bit accesses.
- 32-bit accesses can be done to offset 0F0h or 0F4h.
- 32-bit accesses must not be done starting at: 0F1h, 0F2h, 0F3h, 0F5h, 0F6h, or 0F7h.
- 64-bit accesses can be done to 0F0h.
- Writes to this register must only be done while the counter is halted.
- Reads to this register return the current value of the main counter.
- 32-bit counters will always return zero for the upper 32 bits of this register.
- If 32-bit software attempts to read a 64-bit counter, it must first halt the counter. Since this will delay the interrupts for all of the timers, this must be done only if the consequences are understood. It is strongly recommended that 32-bit software only operate the timer in 32-bit mode.

**Table 32-5. Offset 0F0h: MAIN\_CNT - Main Counter Value Register**

| Description: |                    |  |        |  |            |
|--------------|--------------------|--|--------|--|------------|

| Size: 64 bit | Default: Xh        |  |        | Power Well: Core                       |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky | Bit Reset Value                        | Bit Access |
| 63 :00       | COUNTER_VAL_63_0   | <p><b>Counter Value:</b> Bits 63:00 of the counter.</p> <p><b>Notes:</b></p> <ol style="list-style-type: none"> <li>Writes to this register must only be done while the counter is halted.</li> <li>Reads to this register return the current value of the main counter.</li> <li>32-bit counters always return zero for the upper 32 bits of this register.</li> <li>If 32-bit software attempts to read a 64-bit counter, it must first halt the counter. Since this delays the interrupts for all of the timers, this must be done only if the consequences are understood. It is strongly recommended that 32-bit software only operates the timer in 32-bit mode.</li> <li>Reads to this register are monotonic. No two consecutive reads return the same value. The second of two reads always returns a larger value, unless the timer has rolled over to 0.</li> </ol> |        | Xh                                     | RW         |

### 32.2.1.5 Offset 100h: HPTCC[0-2] - Timer *n* Configuration and Capabilities Register

**General Behavioral Rules:**

- Software can access the various bytes in this register using 32-bit or 64-bit accesses.
- 32-bit accesses can be done to offset 1x0h or 1x4h. 64-bit accesses can be done to 1x0h.
- 32-bit accesses must not be done to 1x1h, 1x2h, 1x3h, 1x5h, 1x6h, 1x7h.

*Note:* The letter *n* can be 0, 1 or 2, referring to Timer 0, 1 or 2.

### 32.2.1.6 Offset 108h: HPTCV[0-2] - Timer n Comparator Value Register

#### General Behavioral Rules:

- Software can access the various bytes in this register using 32-bit or 64-bit accesses.
- 32-bit accesses can be done to offset 1x8h or 1xCh. 64-bit accesses can be done to 1x8h.
- 32-bit accesses must not be done to 1x9h, 1xAh, 1xBh, 1xDh, 1xEh, or 1xFh.
- Reads to this register return the current value of the comparator.
- If the timer is configured to non-periodic mode:
  - Writes to this register load the value against which the main counter must be compared for this timer.
  - When the main counter equals the value last written to this register, the corresponding interrupt can be generated (if so enabled).

- The value in this register does not change based on the interrupt being generated.
- If the timer is configured to periodic mode:
  - When the main counter equals the value last written to this register, the corresponding interrupt can be generated (if so enabled).
  - After the main counter equals the value in this register, the value in this register is increased by the value last written to the register.
- For example, if the value written to the register is 00000123h, then:
  - An interrupt is generated when the main counter reaches 00000123h.
  - The value in this register is then adjusted by the hardware to 00000246h.
  - Another interrupt is generated when the main counter reaches 00000246h.
  - The value in this register is then adjusted by the hardware to 00000369h.
- As each periodic interrupt occurs, the value in this register increments. When the incremented value is greater than the maximum value possible for this register (FFFFFFFh for a 32-bit timer or FFFFFFFFFFFFFFFFh for a 64-bit timer), the value wraps around through 0. For example, if the current value in a 32-bit timer is FFFF0000h and the last value written to this register is 20000, then after the next interrupt the value changes to 00010000h.
- Default value for each timer is all 1's for the bits that are implemented. For example, a 32-bit timer has a default value of 00000000FFFFFFFFh. A 64-bit timer has a default value of FFFFFFFFFFFFFFFFh.

**Table 32-7. Offset 108h: HPTCV[0-2] - Timer n Comparator Value Register**

## 32.3 Theory Of Operation

### 32.3.1 Timer Accuracy Rules

- The timers are expected to be accurate over any 1 ms period to within 0.05% of the time specified in the timer resolution fields.
- Within any 100 microsecond period, the timer is permitted to report a time that is up to two ticks too early or too late. Each tick must be less than or equal to 100 ns; this represents an error of less than 0.2%.
- The timer must be monotonic. It must never return the same value on two consecutive reads (unless the counter has rolled over and actually reached the same value).
- The main counter is clocked by the 14.31818 MHz clock, synchronized into the 66.666 MHz domain. This results in a non-uniform duty cycle on the synchronized clock, but does have the correct average period. The accuracy of the main counter is as accurate as the 14.3818 MHz clock.

### 32.3.2 Interrupt Mapping

The interrupts associated with the various timers have several interrupt mapping options. When reprogramming the HPET (High Precision Event Timer) interrupt routing scheme (LEG\_RT\_CNF bit in the General Config Register), a spurious interrupt may occur. This is because the other source of the interrupt (8254 timer) may be asserted. Software must mask interrupts prior to clearing the LEG\_RT\_CNF bit.

#### Mapping Option 1: Legacy Replacement Option

In this case, the Legacy Rout bit (LEG\_RT\_CNF) is set. This forces the mapping found in Table .

Table 32-8. Legacy Replacement Routing

| Timer | 8259 Mapping             | APIC Mapping             | Comment  |
|-------|--------------------------|--------------------------|--|
| 0     | IRQ0                     | IRQ2                     | In this case, the 8254 timer does not cause any interrupts |
| 1     | IRQ8                     | IRQ8                     | In this case, the RTC does not cause any interrupts.       |
| 2     | As per IRQ Routing Field | As per IRQ Routing Field |  |

#### Mapping Option 2: Standard Option

In this case, the Legacy Rout bit (LEG\_RT\_CNF) is zero. Each timer has its own routing control. The interrupts can be routed to various interrupts in the I/O APIC. A capabilities field indicates which interrupts are valid options for the routing.

If a timer is set for edge-triggered mode, the timers must not be shared with any PCI interrupts.

Supported interrupt values are IRQ 20, 21, 22, and 23.

### 32.3.3 Periodic vs. Non-Periodic Modes

#### 32.3.3.1 Non-Periodic Mode

This mode can be thought of as creating a one-shot.

Timer 0 is configurable to 32-bit or 64-bit mode (default), whereas Timers 1 and 2 only support 32-bit mode.

All three timers support non-periodic mode.

When a timer is set up for non-periodic mode, it generates a value in the main counter that matches the value in the timer's comparator register. Also, another interrupt will be generated when the main counter matches the value in the timer's comparator register after a wrap around.

During run-time, the value in the timer's comparator value register is not changed by the hardware. Software can, of course, change the value.

The Timer 0 Comparator Value register cannot be programmed reliably by a single 64-bit write in a 32-bit environment **except** if only the periodic rate is being changed during run-time. If the actual Timer 0 Comparator Value needs to be reinitialized, then the following software solution always works regardless of the environment:

1. Set the lower 32 bits of the Timer0 Comparator Value register.
2. Set the upper 32 bits of the Timer0 Comparator Value register.

**Warning:** Software must be careful when programming the comparator registers. If the value written to the register is not sufficiently far in the future, then the counter may pass the value before it reaches the register and the interrupt will be missed. The BIOS will pass a data structure to the OS to indicate that the OS must not attempt to program the periodic timer to a rate faster than X. For the CMI, X is 5 microseconds.

Every timer is required to support the non-periodic mode of operation.

#### 32.3.3.2 Periodic Mode

When a timer is set up for periodic mode, the software writes a value in the timer's comparator value register. When the main counter value matches the value in the timer's comparator value register, an interrupt is generated. The hardware then automatically increases the value in the comparator value register by the last value written to that register.

To make the periodic mode work properly, the main counter is typically written with a value of 0 so that the first interrupt occurs at the right point for the comparator. If the main counter is not set to 0, interrupts may not occur as expected.

During run-time, the value in the timer's comparator value register can be read by software to find out when the next periodic interrupt will be generated (not the rate at which it generates interrupts). Software is expected to remember the last value written to the comparator's value register (the rate at which interrupts are generated).

If software wants to change the periodic rate, it must write a new value to the comparator value register. At the point when the timer's comparator indicates a match, this new value is added to derive the next matching point.

**Warning:** If the software resets the main counter, the value in the comparator's value register needs to reset as well. This can be done by setting the **TIMERN\_VAL\_SET\_CNF** bit. Again, to avoid race conditions, this must be done with the main counter halted. As the timer period approaches zero, the interrupts associated with the periodic timer may not

get completely serviced before the next timer match occurs. Interrupts may get lost and/or system performance may be degraded in this case.

Each timer is NOT required to support the periodic mode of operation. A capabilities bit indicates if the particular timer supports periodic mode. The reason for this is that supporting the periodic mode adds a significant number of gates.

For CMI, only Timer 0 supports periodic mode. The following usage model is expected:

1. Software clears the ENABLE\_CNF bit to prevent any interrupts.
2. Software clears the main counter by writing a value of 00h to it.
3. Software sets the TIMERO\_VAL\_SET\_CNF bit.
4. Software writes the new value in the TIMERO\_COMPARATOR\_VAL register.
5. Software sets the ENABLE\_CNF bit to enable interrupts.

The Timer 0 Comparator Value register cannot be programmed reliably by a single 64-bit write in a 32-bit environment except if only the periodic rate is being changed during run-time. If the actual Timer 0 Comparator Value needs to be reinitialized, then the following software solution will always work regardless of the environment:

1. Set TIMERO\_VAL\_SET\_CNF bit
2. Set the lower 32 bits of the Timer0 Comparator Value register
3. Set TIMERO\_VAL\_SET\_CNF bit
4. Set the upper 32 bits of the Timer0 Comparator Value register

### 32.3.4 Enabling the Timers

The BIOS or operating system PnP code must rout the interrupts. This includes the Legacy Rout bit, Interrupt Rout bit (for each timer), interrupt type (to select the edge or level type for each timer).

The Device Driver code must do the following for an available timer:

1. Set the Overall Enable bit (Offset 04h, bit 0).
2. Set the timer type field (selects one-shot or periodic).
3. Set the interrupt enable.
4. Set the comparator value.

### 32.3.5 Interrupt Levels

Interrupts directed to the 8259s are active high. See [Chapter 30.0, "Interrupts,"](#) for information regarding the polarity programming of the I/O APIC for detecting internal interrupts.

If the interrupts are mapped to the I/O APIC and set for level-triggered mode, they can be shared with PCI interrupts. If more than one timer is configured to share the same IRQ (using the TIMERn\_INT\_ROUT\_CNF fields), then the software must configure the timers to level-triggered mode. Edge-triggered interrupts cannot be shared.

### 32.3.6 Handling Interrupts

If each timer has a unique interrupt and the timer has been configured for edge-triggered mode, then there are no specific steps required. No read is required to process the interrupt.

If a timer has been configured to level-triggered mode, then its interrupt must be cleared by the software. This is done by reading the interrupt status register and writing a one back to the bit position for the interrupt to be cleared.

Independent of the mode, software can read the value in the main counter to see how time has passed between when the interrupt was generated and when it was first serviced.

If a timer 0 is set up to generate a periodic interrupt, the software can check to see how much time remains until the next interrupt by checking the timer value register.

### 32.3.7 Unloading Device Driver Issues

When unloading device drivers for the HPET High Precision Event Timer, some precautions may be needed. For example, if the legacy routing is used, when the HPET High Precision Event Timer is disabled, a spurious interrupt could occur. The OS must mask interrupts prior to clearing the LEG\_RT\_CNF bit.

§ §

## 33.0 Serial I/O Unit and Watchdog Timer

---

### 33.1 Overview

The Serial I/O unit and Watchdog Timer (SIW) is similar to currently available Super I/O controllers. It is specifically designed for integration into the IICH. It is connected via the LPC bus and currently consists of two UARTs, a Serial Interrupt Controller, a Watchdog Timer and the LPC interface.

### 33.2 Features

#### LPC Interface

- Multiplexed command, address and data bus.
- 8-bit I/O transfers.
- 16-bit address qualification for I/O transactions.
- Serial IRQ interface compatible with serialized IRQ support for PCI systems.

#### Serial Port

- Two Full Function 16550 Compatible Serial Ports.
- Configurable I/O addresses and interrupts.
- 16-Byte FIFOs.
- Supports up to 115 Kbps.
- Programmable Baud Rate Generator.
- Modem Control Circuitry.
- 14.7456 MHz and 48 MHz supported for UART baud clock input.

#### Watchdog Timer (WDT)

Selectable Prescaler – approximately 1 MHz (1  $\mu$ s to 1 s) and approximately 1 KHz (1 ms to 10 min).

- 33 MHz Clock (30 ns Clock Ticks).
- Multiple Modes (WDT and Free-Running).
- Free-Running Mode:
  - 1 Stage Timer - Toggles WDT\_TOUT# after programmable time.
- WDT Mode:
  - 2 Stage Timer (First stage generates interrupt, second stage drives WDT\_TOUT# low).  
First stage generates an SERIRQ, SMI or NMI interrupt (depending on which is enabled) after Programmable time.  
Second stage drives WDT\_OUT# low or inverts the previous value.  
Used only after first timeout occurs.

Status bit preserved in RTC well for possible error detection and correction.  
Drives WDT\_TOUT# if OUTPUT is enabled.

- Timer can be disabled (default state) or Locked (Hard Reset required to disable WDT).
- WDT Automatic Reload of Preload value when WDT Reload Sequence is performed.

### 33.3 Functional Description

#### 33.3.1 Host Processor Interface (LPC)

The host processor communicates with the SIW via the LPC bus. Access is through a series of read/ write registers and accomplished through I/O cycles. All registers are eight bits wide. The SIW registers include global configuration space and device specific regions accessed by setting the Logical Device Number in the SIW Configuration Register 07H (SCR7).

Table 33-1. Address Map

| Address                            | Block Name          | Logical Device |
|------------------------------------|---------------------|----------------|
| 04Eh or 20Eh (SIU1_DTR# dependent) | Configuration Index |                |
| 04Fh or 20Fh (SIU1_DTR# dependent) | Configuration Data  |                |
| Base+(0-7)                         | Serial Port 1       | 04H            |
| Base+(0-7)                         | Serial Port 2       | 05H            |
| Base+(0-18)                        | Watchdog Timer      | 06H            |

See Section 33.8 for configuration register descriptions and information on setting the base address.

### 33.4 LPC Interface

The LPC interface is used to control all the logical blocks on the SIW. LPC bus signals use PCI 33 MHz electrical signal characteristics. Refer to the *Low Pin Count (LPC) Interface Specification Rev 1.0*.

#### 33.4.1 LPC Cycles

The following cycle types are supported by the LPC protocol.

Table 33-2. Supported LPC Cycle Types

| Cycle Type | Transfer Size |
|------------|---------------|
| I/O Write  | 1 Byte        |
| I/O Read   | 1 Byte        |

The SIW ignores cycles that it does not support.

### 33.4.1.1 I/O Read and Write Cycles

The SIW is the target for I/O cycles. I/O cycles are initiated by the host for register or FIFO accesses and generally have minimal synchronization times.

Data transfers are assumed to be exactly 1-byte. If the CPU requested a 16-bit or 32-bit transfer, the host must break it up into 8-bit transfers.

See the *LPC Interface Specification* for the sequence of cycles for the I/O Read and Write cycles.

### 33.4.2 Policy

The following rules govern the reset policy:

SIW\_RESET# is tied to the internal PCI bus reset.

When SIW\_RESET# goes active (low):

- The host drives the LFRAME# signal high, tri-states the LAD[3:0] signals.
- The SIU ignores LFRAME#, tri-states the LAD[3:0] pins.

*Note:* LPC bus signals from SIW are internally tied to the primary LPC interface of the IICH device. Host LPC and SIW LPC names are used interchangeably throughout.

### 33.4.3 LPC Transfers

#### 33.4.3.1 I/O Transfers

These are generally used for register or FIFO accesses, and generally have minimal synchronization times. The minimum number of wait-states between bytes is one. Data transfers are assumed to be exactly one byte. The host is responsible for breaking up larger data transfers into 8-bit cycles.

**Table 33-3. I/O Sync Bits Description**

| Bits | Indication  |
|------|---|
| 0000 | Synchronization achieved with no error.   |
| 0101 | Indicates that synchronization not achieved yet, but the part is driving the bus.                                 |
| 0110 | Indicates that synchronization not achieved yet, but the part is driving the bus and expects long synchronization |
| 1010 | Special Case: peripheral indicating errors.   |

## 33.5 Logical Devices 4 and 5: Serial Ports (UART1 and UART2)

This section describes the Universal Asynchronous Receiver/Transmitter (UART) serial port used for the two UART integrated into the SIW. The UART can be controlled via programmed I/O. The basic programming model is the same for both UARTs with the only difference being the Logical Device Number assigned to each.

The serial port consists of a UART which supports all the functions of a standard 16550 UART including hardware flow control interface.

The UART performs serial-to-parallel conversion on data characters received from a peripheral device or a modem and parallel-to-serial conversion on data characters received from the processor. The processor can read the complete status of the UART at

any time during the functional operation. Available status information includes the type and condition of the transfer operations being performed by the UART and any error conditions (parity, overrun, framing, or break interrupt).

The serial port can operate in either FIFO or non-FIFO mode. In FIFO mode, a 16-byte transmit FIFO holds data from the processor to be transmitted on the serial link and a 16-byte Receive FIFO buffers data from the serial link until read by the processor.

Each UART includes a programmable baud rate generator which is capable of dividing the baud clock input by divisors of one to  $(2^{16} - 1)$  and producing a 16X clock to drive the internal transmitter and receiver logic. Each UART has complete modem control capability and a processor interrupt system. Interrupts can be programmed to the user's requirements, minimizing the computing required to handle the communications link. Each UART can operate in a polled or an interrupt driven environment as configured by software.

The baud rate generator input is a function of the UART\_CLK and a configurable predivide of 1, 8, or 26. See also SIW Configuration (address 29h) in [Section 33.8.3.1, "Global Control/Configuration Registers \[00h - 2Fh\]"](#) on page 1208. The output of the baud rate generator is 16 times the baud rate.

**Table 33-4. UART Clock Divider Support**

| Clock Frequency     | 14.7456 MHz | 48.0 MHz   |
|---------------------|-------------|------------|
| Predivide Value     | 8           | 26         |
| Generator Frequency | 1.8432 MHz  | 1.8462 MHz |

**Table 33-5. Baud Rate Example**

| Desired Baud Rate | Divisor | % error @ 1.8432 | % error @ 1.8462* |
|-------------------|---------|------------------|-------------------|
| 300               | 384     |                  | 0.16              |
| 1200              | 96      |                  | 0.16              |
| 2400              | 48      |                  | 0.16              |
| 4800              | 24      |                  | 0.16              |
| 9600              | 12      |                  | 0.16              |
| 19200             | 6       |                  | 0.16              |
| 38400             | 3       |                  | 0.16              |
| 56000             | 2       | 2.8              | 3                 |
| 115200            | 1       |                  | 0.16              |

### 33.5.1 UART Feature List

- Functionally compatible with National Semiconductor's\* PC16550D.
- Adds or deletes standard asynchronous communications bits (start, stop, and parity) to or from the serial data.
- Independently controlled transmit, receive, line status and data set interrupts.
- Programmable baud rate generator allows division of clock by 1 to  $(2^{16} - 1)$  and generates an internal 16X clock.
- Modem control functions (CTS#, RTS#, DSR#, DTR#, RI#, and DCD#).

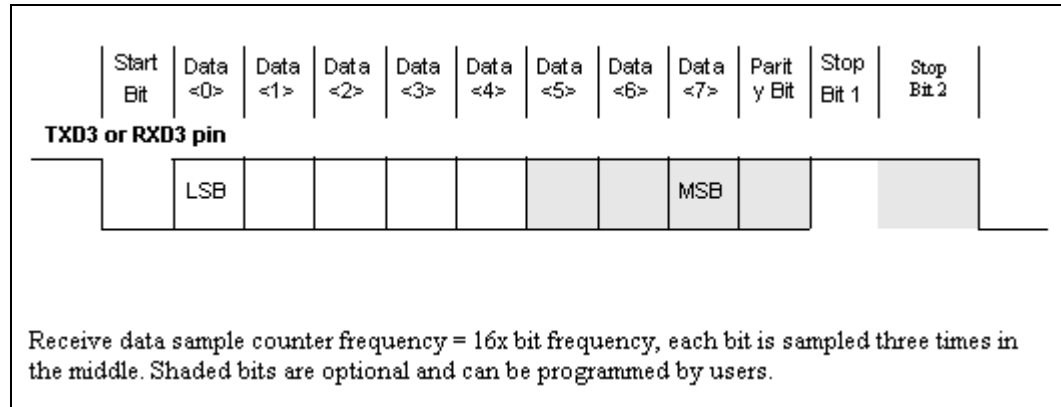

- Fully programmable serial-interface characteristics:
- 5, 6, 7 or 8-bit characters.
- Even, odd, or no parity detection.
- 1, 1-1/2, or 2 stop bit generation.
- Baud rate generation (up to 115 kbps).
- False start bit detection.
- 16-byte Receive FIFO.
- Complete status reporting capability.
- Line break generation and detection.
- Internal diagnostic capabilities include:
  - Loopback controls for communications link fault isolation.
  - Break, parity, overrun, and framing error simulation.
  - Fully prioritized interrupt system controls.

### 33.5.2 UART Operational Description

The format of a UART data frame is shown in [Figure 33-1](#).

**Figure 33-1. Example UART Data Frame**

Each data frame is between seven bits and 12 bits long depending on the size of data programmed, if parity is enabled and if two stop bits is selected. The frame begins with a start bit that is represented by a high to low transition. Next, 5 to 8 bits of data are transmitted, beginning with the least significant bit. An optional parity bit follows, which is set if even parity is enabled and an odd number of ones exist within the data byte, or if odd parity is enabled and the data byte contains an even number of ones. The data frame ends with one, one and a half or two stop bits as programmed by the user, which is represented by one or two successive bit periods of a logic one.

The unit is disabled upon reset, the user needs to enable the unit by setting bit six of Interrupt Enable Register. When the unit is enabled, the receiver starts looking for the start bit of a frame; the transmitter starts transmitting data to the transmit data pin if there is data available in the transmit FIFO. Transmit data can be written to the FIFO

before the unit is enabled. When the unit is disabled, the transmitter/receiver finishes the current byte being transmitted/received if it is in the middle of transmitting/receiving a byte and stops transmitting/receiving more data.

An SIU\_RESET# to the SIU forces the internal register and output signals on the serial port to the values listed below.

**Table 33-6. UART Register/Signal Reset States**

| Register/Signal             | Reset Control                              | Reset State  |
|-----------------------------|--|--|
| Interrupt Enable Register   | RESET                                      | All bits are low.  |
| Interrupt ID Register       | RESET                                      | Bit 0 is forced high. Bits 1-3 and 6-7 are forced low. Bits 4-5 are permanently low. |
| Line Control Register       | RESET                                      | All bits are forced low.   |
| Line Status Register        | RESET                                      | Bits 0-4,7 are forced low. Bits 5 and 6 are forced high.                             |
| Modem Control Register      | RESET                                      | Bits 0,1,2,3,4 are forced low. Bits 5,6,7 are permanently low.                       |
| Modem Status Register       | RESET/Modem signal, read MSR for bits 3-0. | Low  |
| Infrared Selection Register | RESET                                      | All bits are permanently low.  |
| Txd                         | RESET                                      | High   |
| Int                         | RESET/ clear LINE STATUS REG               | Low  |
| rts_n                       | RESET                                      | High   |
| dtr_n                       | RESET                                      | High   |

### 33.5.2.1 Programmable Baud Rate Generator

The UART contains a programmable Baud Rate Generator that is capable of taking the UART\_CLK input and dividing it by any divisor from 1 to  $(2^{16} - 1)$ . The output frequency of the Baud Rate Generator is 16 times the baud rate. Two 8-bit latches store the divisor in a 16-bit binary format. These Divisor Latches must be loaded during initialization to ensure proper operation of the Baud Rate Generator. If both Divisor Latches are loaded with 0, the 16X output clock is stopped. Upon loading either of the Divisor latches, a 16-bit baud counter is immediately loaded. This prevents long counts on initial load. Access to the Divisor latch can be done with a word write.

*Note:* The UART\_CLK is the SIW\_CLK input divided by the prescaler set by the SIW Configuration Register (Offset 29h).

The baud rate of the data shifted in/out of the UART is given by:

$$\text{Baud Rate} = \text{UART\_CLK(MHz)} / [16X \text{ Divisor}]$$

For example, if UART\_CLK is 14.7456MHz and the divisor is 96, the baud rate is 9600.

A Divisor value of 0 in the Divisor Latch Register is not allowed. The reset value of the divisor is 02.

### 33.5.3 UART Register Details

There are 12 registers in the UART. These registers share eight address locations in the I/O address space. Table 33-10 shows the registers and their addresses as offsets of a base address. The state of the Divisor Latch Bit (DLAB), which is the MOST significant bit of the Serial Line Control Register, affects the selection of certain of the UART registers. The DLAB bit must be set high by the system software to access the Baud Rate Generator Divisor Latches.

**Table 33-7. Summary of UART Registers in I/O Space (DLAB=0)**

| Offset Start | Offset End | Register ID - Description                                  | Default Value |

**Table 33-10. Internal Register Descriptions**

| UART Register Addresses (Base + offset) | DLAB Bit Value | Register Accessed                      |
|---|----------------|--|
| Base                                    | 0              | Receive BUFFER (Read-Only)             |
| Base                                    | 0              | Transmit BUFFER (Write-Only)           |
| Base + 01H                              | 0              | Interrupt Enable (Read/Write)          |
| Base + 02H                              | X              | Interrupt I.D. (Read-Only)             |
| Base + 02H                              | X              | FIFO Control (Write-Only)              |
| Base + 03H                              | X              | Line Control (Read/Write)              |
| Base + 04H                              | X              | Modem Control (Read/Write)             |
| Base + 05H                              | X              | Line Status (Read-Only)                |
| Base + 06H                              | X              | Modem Status (Read-Only)               |
| Base + 07H                              | X              | Scratch Pad (Read/Write)               |
| Base                                    | 1              | Divisor Latch (Lower Byte, Read/Write) |
| Base + 01H                              | 1              | Divisor Latch (Upper Byte, Read/Write) |

*Note:* Base Address for the UART registers listed in Table 33-10 is configurable. See Section 33.8.3, “SIW Configuration Register Summary” on page 1207 for details.

### 33.5.3.1 Offset 00h: RBR - Receive Buffer Register

In non-FIFO mode, this register holds the character received by the UART's Receive Shift Register. If fewer than eight bits are received, the bits are right-justified and the leading bits are zeroed. Reading the register empties the register and resets the Data Ready (DR) bit in the Line Status Register to zero. Other (error) bits in the Line Status Register are not cleared. In FIFO mode, this register latches the value of the data byte at the top of the FIFO.

**Table 33-11. Offset 00h: RBR - Receive Buffer Register**

| Description:       |   |  |        |  |            |
|--------------------|---|--|--------|--|------------|
| <b>View:</b> IA F  | <b>Base Address:</b> Base (IO) (DLAB = 0) |  |        | <b>Offset Start:</b> 00h<br><b>Offset End:</b> 00h |            |
| <b>Size:</b> 8 bit | <b>Default:</b> 00h                       |  |        | <b>Power Well:</b> Core                            |            |
| Bit Range          | Bit Acronym                               | Bit Description  | Sticky | Bit Reset Value                                    | Bit Access |
| 07 : 00            | RB_7_0                                    | Data byte received (bits [7:0]), least significant bit first |        | 00h  | RO         |

### 33.5.3.2 Offset 00h: THR - Transmit Holding Register

This register holds the next data byte to be transmitted. When the Transmit Shift Register becomes empty, the contents of the Transmit Holding Register are loaded into the shift register and the transmit data request (TDRQ) bit in the Line Status Register is set to one.

Table 33-12. Offset 00h: THR - Transmit Holding Register

| Description: |                                    |  |        |                                      |            |
|--------------|------------------------------------|--|--------|--------------------------------------|------------|
| View: IA F   | Base Address: Base (IO) (DLAB = 0) |  |        | Offset Start: 00h<br>Offset End: 00h |            |
| Size: 8 bit  | Default: 00h                       |  |        | Power Well: Core                     |            |
| Bit Range    | Bit Acronym                        | Bit Description  | Sticky | Bit Reset Value                      | Bit Access |
| 07 : 00      | TB_7_0                             | Data byte received (bits [7:0]), least significant bit first |        | 00h                                  | WO         |

In FIFO mode, writing to THR puts data to the top of the FIFO. The data at the bottom of the FIFO is loaded to the shift register when it is empty.

### 33.5.3.3 Offset 01h: IER - Interrupt Enable Register

This register enables five types of interrupts which independently activate the int signal and set a value in the Interrupt Identification Register. Each of the five interrupt types can be disabled by resetting the appropriate bit of the IER register. Similarly, by setting the appropriate bits, selected interrupts can be enabled. Receiver time out interrupt can be configured to be separated from the receive data available interrupt (using the bit 5: COMP)

The use of bit 5 to bit 4 is different from the register definition of standard 16550.

Table 33-13. Offset 01h: IER - Interrupt Enable Register (Sheet 1 of 2)

| Description: |                                    |   |        |                                      |            |

**33.5.3.4 Offset 02h: IIR - Interrupt Identification Register**

In order to minimize software overhead during data character transfers, the UART prioritizes interrupts into four levels (listed in Table 33-14) and records these in the Interrupt Identification Register. The Interrupt Identification Register (IIR) stores information indicating that a prioritized interrupt is pending and the source of that interrupt.

**Table 33-14. Interrupt Conditions**

| Priority Level | Interrupt Origin  |
|----------------|---|
| 1 (highest)    | Receiver Line Status. One or more error bits were set.  |
| 2              | Received Data is available. In FIFO mode, trigger level was reached; in non-FIFO mode, RBR has data.                                |
| 2              | Receiver Time out occurred. It happens in FIFO mode only, when there is data in the receive FIFO but no activity for a time period. |
| 3              | Transmitter requests data. In FIFO mode, the transmit FIFO is half or more than half empty; in non-FIFO mode, THR is read already.  |
| 4              | Modem Status: one or more of the modem input signals has changed state  |

Table 33-15. Offset 02h: IIR - Interrupt Identification Register

| Description: |                         |   |        |                                      |            |

**33.5.3.5 Offset 02h: FCR - FIFO Control Register**

FCR is a write-only register that is located at the same address as the IIR (IIR is a read-only register). FCR enables/disables the transmitter/receiver FIFOs, clears the transmitter/receiver FIFOs, and sets the receiver FIFO trigger level.

**Table 33-17. Offset 02h: FCR - FIFO Control Register (Sheet 1 of 2)**

| Description:       |                                |  |        |  |            |

| 01           | RESETRF                 | <p><b>Reset Receiver FIFO:</b> When RESETRF is set to 1, the receiver FIFO counter is reset to 0, effectively clearing all the bytes in the FIFO. The DR bit in LSR is reset to 0. All the error bits in the FIFO and the FIFOE bit in LSR are cleared. Any error bits, OE, PE, FE or BI, that had been set in LSR are still set. The receiver shift register is not cleared. If IIR had been set to Received Data Available, it is cleared. After the FIFO is cleared, RESETRF is automatically reset to 0.</p> <p>0 = Writing 0 has no effect<br/>1 = The receiver FIFO is cleared (FIFO counter set to 0). After clearing, bit is automatically reset to 0</p> |        | 0b                                   | WO         |
| 00           | TRFIFOE                 | <p><b>Transmit and Receive FIFO Enable:</b> TRFIFOE enables/disables the transmitter and receiver FIFOs. When TRFIFOE = 1, both FIFOs are enabled (FIFO Mode). When TRFIFOE = 0, the FIFOs are both disabled (non-FIFO Mode). Writing a 0 to this bit clears all bytes in both FIFOs. When changing from FIFO mode to non-FIFO mode and vice versa, data is automatically cleared from the FIFOs. This bit must be 1 when other bits in this register are written or the other bits are not programmed.</p> <p>0 = FIFOs are disabled<br/>1 = FIFOs are enabled</p>   |        | 0b                                   | WO         |

### 33.5.3.6 Offset 03h: LCR - Line Control Register

In the Line Control Register (LCR), the system programmer specifies the format of the asynchronous data communications exchange. The serial data format consists of a start bit (logic 0), five to eight data bits, an optional parity bit, and one or two stop bits (logic 1). The LCR has bits for accessing the Divisor Latch and causing a break condition. The programmer can also read the contents of the Line Control Register. The read capability simplifies system programming and eliminates the need for separate storage in system memory.

Table 33-18. Offset 03h: LCR - Line Control Register (Sheet 1 of 2)

| Description: |                         |   |        |                                      |            |
|--------------|-------------------------|---|--------|--------------------------------------|------------|
| View: IA F   | Base Address: Base (IO) |   |        | Offset Start: 03h<br>Offset End: 03h |            |
| Size: 8 bit  | Default: 00h            |   |        | Power Well: Core                     |            |
| Bit Range    | Bit Acronym             | Bit Description   | Sticky | Bit Reset Value                      | Bit Access |
| 07           | DLAB                    | <p><b>Divisor register access bit:</b> This bit is the Divisor Latch Access Bit. It must be set high (logic 1) to access the Divisor Latches of the Baud Rate Generator during a READ or WRITE operation. It must be set low (logic 0) to access the Receiver Buffer, the Transmit Holding Register, or the Interrupt Enable Register.</p> <p>0 = Access Transmit Holding register (THR), Receive Buffer Register (RBR) and Interrupt Enable Register.</p> <p>1 = Access Divisor Latch Registers (DLL and DLH).</p>   |        | 0b                                   | RW         |
| 06           | SB                      | <p><b>Set break:</b> This bit is the set break control bit. It causes a break condition to be transmitted to the receiving UART. When SB is set to a logic 1, the serial output (TXD) is forced to the spacing (logic 0) state and remains there until SB is set to a logic 0. This bit acts only on the TXD pin and has no effect on the transmitter logic.</p> <p>This feature enables the processor to alert a terminal in a computer communications system. If the following sequence is executed, no erroneous characters are transmitted because of the break:<br/>Load 00H in the Transmit Holding register in response to a TDRQ interrupt<br/>After TDRQ goes high (indicating that 00H is being shifted out), set the break bit before the parity or stop bits reach the TXD pin<br/>Wait for the transmitter to be idle (TEMT = 1) and clear the break bit when normal transmission has to be restored<br/>During the break, the transmitter can be used as a character timer to accurately establish the break duration. In FIFO mode, wait for the transmitter to be idle (TEMT=1) to set and clear the break bit.</p> <p>0 = No effect on TXD output<br/>1 = Forces TXD output to 0 (space)</p> |        | 0b                                   | RW         |

Table 33-18. Offset 03h: LCR - Line Control Register (Sheet 2 of 2)

| Description: |                         |   |        |                                      |            |
|--------------|-------------------------|---|--------|--------------------------------------|------------|
| View: IA F   | Base Address: Base (IO) |   |        | Offset Start: 03h<br>Offset End: 03h |            |
| Size: 8 bit  | Default: 00h            |   |        | Power Well: Core                     |            |
| Bit Range    | Bit Acronym             | Bit Description   | Sticky | Bit Reset Value                      | Bit Access |
| 05           | STKYP                   | <b>Sticky Parity:</b> This bit is the “sticky parity” bit, which can be used in multiprocessor communications. When PEN and STKYP are logic 1, the bit that is transmitted in the parity bit location (the bit just before the stop bit) is the complement of the EPS bit. If EPS is 0, then the bit at the parity bit location are transmitted as a 1. In the receiver, if STKYP and PEN are 1, then the receiver compares the bit that is received in the parity bit location with the complement of the EPS bit. If the values being compared are not equal, the receiver sets the Parity Error bit in LSR and causes an error interrupt if line status interrupts were enabled. For example, if EPS is 0, the receiver expects the bit received at the parity bit location to be 1. If it is not, then the parity error bit is set. By forcing the bit value at the parity bit location, rather than calculating a parity value, a system with a master transmitter and multiple receivers can identify some transmitted characters as receiver addresses and the rest of the characters as data. If PEN = 0, STKYP is ignored.<br>0 = No effect on parity bit<br>1 = Forces parity bit to be opposite of EPS bit value |        | 0b                                   | RW         |
| 04           | EPS                     | <b>Even parity Select:</b> This bit is the even parity select bit. When PEN is a logic 1 and EPS is a logic 0, an odd number of logic ones is transmitted or checked in the data word bits and the parity bit. When PEN is a logic 1 and EPS is a logic 1, an even number of logic ones is transmitted or checked in the data word bits and parity bit. If PEN = 0, EPS is ignored.<br>0 = Sends or checks for odd parity<br>1 = Sends or checks for even parity  |        | 0b                                   | RW         |
| 03           | PEN                     | <b>Parity enable:</b> This is the parity enable bit. When PEN is a logic 1, a parity bit is generated (transmit data) or checked (receive data) between the last data word bit and Stop bit of the serial data. (The parity bit is used to produce an even or odd number of ones when the data word bits and the parity bit are summed.)<br>0 = No parity function<br>1 = Allows parity generation and checking   |        | 0b                                   | RW         |
| 02           | STB                     | <b>Stop bits:</b> This bit specifies the number of stop bits transmitted and received in each serial character. If STB is a logic 0, one stop bit is generated in the transmitted data. If STB is a logic 1 when a 5-bit word length is selected via bits 0 and 1, then 1 and one half stop bits are generated. If STB is a logic 1 when either a 6, 7, or 8-bit word is selected, then two stop bits are generated. The receiver checks the first stop bit only, regardless of the number of stop bits selected.<br>0 = 1 stop bit<br>1 = 2 stop bits, except for 5-bit character then 1-1/2 bits  |        | 0b                                   | RW         |
| 01 : 00      | WLS_1_0                 | <b>Word Length select:</b> The Word Length Select bits specify the number of data bits in each transmitted or received serial character.<br>00 5-bit character (default)<br>01 6-bit character<br>10 7-bit character<br>11 8-bit character  |        | 00b                                  | RW         |

### 33.5.3.7 Offset 04h: MCR - Modem Control Register

This 8-bit register controls the interface with the modem or data set (or a peripheral device emulating a modem).

Table 33-19. Offset 04h: MCR - Modem Control Register (Sheet 1 of 2)

| Description:       |                                |   |        |  |            |

When bit 0 is reset to a logic 0, the DTR# output pin is forced to a logic 1.<br>• The DTR# output of the UART may be applied to an EIA inverting line driver (such as the DS1488) to obtain the proper polarity input at the succeeding modem or data set.<br>0 = DTR# pin is 1<br>1 = DTR# pin is 0 |        | 0b                                   | RW         |

### 33.5.3.8 Offset 05h: LSR - Line Status Register

This register provides status information to the processor concerning the data transfers. Bits 5 and 6 show information about the transmitter section. The rest of the bits contain information about the receiver.

In non-FIFO mode, three of the LSR register bits, parity error, framing error, and break interrupt, show the error status of the character that has just been received. In FIFO mode, these three bits of status are stored with each received character in the FIFO. LSR shows the status bits of the character at the top of the FIFO. When the character at the top of the FIFO has errors, the LSR error bits are set and are not cleared until software reads LSR, even if the character in the FIFO is read and a new character is now at the top of the FIFO.

Bits one through four are the error conditions that produce a receiver line status interrupt when any of the corresponding conditions are detected and the interrupt is enabled. These bits are not cleared by reading the erroneous byte from the FIFO or receive buffer. They are cleared only by reading LSR. In FIFO mode, the line status interrupt occurs only when the erroneous byte is at the top of the FIFO. If the erroneous byte being received is not at the top of the FIFO, an interrupt is generated only after the previous bytes are read and the erroneous byte is moved to the top of the FIFO.

### 33.5.3.9 Offset 06h: MSR - Modem Status Register

This 8-bit register provides the current state of the control lines from the modem or data set (or a peripheral device emulating a modem) to the processor. In addition to this current state information, four bits of the Modem Status register provide change information. Bits 03:00 are set to a logic 1 when a control input from the Modem changes state. They are reset to a logic 0 when the processor reads the Modem Status register.

When bits 0, 1, 2, or 3 are set to logic 1, a Modem Status interrupt is generated if bit 3 of the Interrupt Enable Register is set.

Table 33-21. Offset 06h: MSR - Modem Status Register

| Description: |                         |  |        |                                      |            |

## 33.5.4 FIFO Operation

### 33.5.4.1 FIFO Interrupt Mode Operation

#### 33.5.4.1.1 Receiver Interrupt

When the Receive FIFO and receiver interrupts are enabled (FCR[0]=1 and IER[0]=1), receiver interrupts occur as follows:

- The receive data available interrupt is invoked when the FIFO has reached its programmed trigger level. The interrupt is cleared when the FIFO drops below the programmed trigger level.
- The IIR receive data available indication also occurs when the FIFO trigger level is reached, and like the interrupt, the bits are cleared when the FIFO drops below the trigger level.
- The receiver line status interrupt (IIR = C6H), as before, has the highest priority. The receiver data available interrupt (IIR=C4H) is lower. The line status interrupt occurs only when the character at the top of the FIFO has errors.
- The data ready bit (DR in LSR register) is set to 1 as soon as a character is transferred from the shift register to the Receive FIFO. This bit is reset to 0 when the FIFO is empty.

#### 33.5.4.1.2 Character Timeout Interrupt

When the receiver FIFO and receiver time out interrupt are enabled, a character timeout interrupt occurs when all of the following conditions exist:

- At least one character is in the FIFO.
- The last received character was longer than four continuous character times ago (if two stop bits are programmed the second one is included in this time delay).
- The most recent processor read of the FIFO was longer than four continuous character times ago.
- The receive FIFO trigger level is greater than one.

The maximum time between a received character and a timeout interrupt is 160 ms at 300 baud with a 12-bit receive character (i.e., one start, eight data, one parity, and two stop bits).

When a time out interrupt occurs, it is cleared and the timer is reset when the processor reads one character from the receiver FIFO. If a timeout interrupt has not occurred, the timeout timer is reset after a new character is received or after the processor reads the receiver FIFO.

#### 33.5.4.1.3 Transmit Interrupt

When the transmitter FIFO and transmitter interrupt are enabled (FCR[0]=1, IER[1]=1), transmit interrupts occur as follows:

The transmitter holding register interrupt occurs when the transmit FIFO is empty; it is cleared as soon as the transmitter holder register is written to (1 to 16 characters may be written to the transmit FIFO while servicing this interrupt) or the IIR is read.

The transmitter FIFO empty indications are delayed one character time minus the last stop bit time whenever the following occurs: THRE = 1 and there have not been at least two bytes at the same time in the transmit FIFO since the last THRE = 1. The first transmitter interrupt after changing FCRO is immediate if it is enabled.

### 33.5.4.2 FIFO Polled Mode Operation

With the FIFOs enabled (TRFIFOE bit of FCR set to 1), setting IER[3:0] to all zeros puts the serial port in the FIFO polled mode of operation. Since the receiver and the transmitter are controlled separately, either one or both can be in the polled mode of operation. In this mode, software checks receiver and transmitter status via the LSR. As stated in the register description:

- LSR[0] is set as long as there is one byte in the receiver FIFO.
- LSR[1] through LSR[4] specify which error(s) has occurred for the character at the top of the FIFO. Character error status is handled the same way as interrupt mode. The IIR is not affected since IER[2] = 0.
- LSR[5] indicates when the transmitter FIFO needs data.
- LSR[6] indicates that both the transmitter FIFO and shift register are empty.
- LSR[7] indicates whether there are any errors in the receiver FIFO.

## 33.6 Logical Device 6: Watchdog Timer

### 33.6.1 Overview

This device is a Watchdog timer that provides a resolution that ranges from 1  $\mu$ s to 10 minutes. The timer uses a 35-bit down-counter.

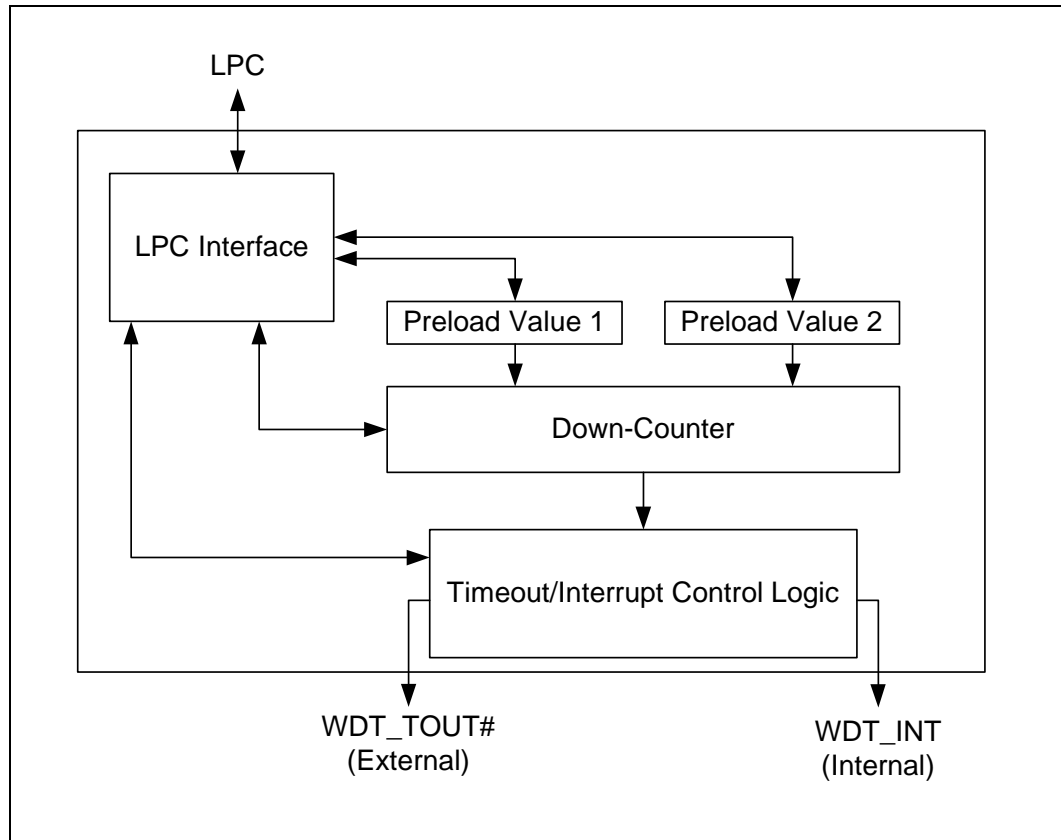

The counter is loaded with the value from the 1<sup>st</sup> Preload register. The timer is then enabled and it starts counting down. The time at which the WDT first starts counting down is called the first stage. If the host fails to reload the WDT before the 35-bit down counter reaches zero the WDT generates an internal interrupt.

After the interrupt is generated the WDT loads the value from the 2<sup>nd</sup> Preload register into the WDT's 35-bit Down-Counter and starts counting down. The WDT is now in the second stage. If the host still fails to reload the WDT before the second timeout, the WDT drives the WDT\_TOUT# pin low and sets the timeout bit (WDT\_TIMEOUT). This bit indicates that the System has become unstable. The WDT\_TOUT# pin is held low until the system is Reset or the WDT times out again (Depends on TOUT\_CNF). The process of reloading the WDT involves the following sequence of writes:

1. Write "80" to offset BAR1 + 0Ch
2. Write "86" to offset BAR1 + 0Ch
3. Write '1' to WDT\_RELOAD in Reload Register.

The same process is used for setting the values in the preload registers. The only difference exists in step 3. Instead of writing a '1' to the WDT\_RELOAD, you write the desired preload value into the corresponding Preload register. This value is not loaded into the 35-bit down counter until the next time the WDT reenters the stage. For example, if Preload Value 2 is changed, it is not loaded into the 35-bit down counter until the next time the WDT enters the second stage.

Figure 33-2. WDT Block Diagram

### 33.6.2 Watchdog Timer Register Details

All registers not mentioned are reserved.

**Table 33-25. Summary of Watchdog Timer Registers in I/O Space**

Write is only allowed from "0" to "1" once. It cannot be changed until either power is cycled or a hard-reset occurs.</p>  |        | 0h                                   | RWL        |

### 33.6.3 Theory Of Operation

#### 33.6.3.1 RTC Well and WDT\_TOUT# Functionality

The WDT\_TIMEOUT bit is set to a '1' when the WDT 35-bit down counter reaches zero for the second time in a row. Then the WDT\_TOUT# pin is toggled LOW by the WDT from the IICH. The board designer must attach the WDT\_TOUT# to the appropriate external signal. If WDT\_TOUT\_CNF is a '1' the WDT toggles WDT\_TOUT# again the next time a time out occurs. Otherwise WDT\_TOUT# is driven low until the system is reset or power is cycled.

#### 33.6.3.2 Register Unlocking Sequence

The register unlocking sequence is necessary whenever writing to the RELOAD register or either PRELOAD\_VALUE registers. The host must write a sequence of two writes to offset BAR1 + 0Ch before attempting to write to either the WDT\_RELOAD and WDT\_TIMEOUT bits of the RELOAD register or the PRELOAD\_VALUE registers. The first writes are "80" and "86" (in that order) to offset BAR1 + 0Ch. The next write is to the proper memory mapped register (e.g., RELOAD, PRELOAD\_VALUE\_1, PRELOAD\_VALUE\_2). Any deviation from the sequence (writes to memory-mapped registers) causes the host to have to restart the sequence.

When performing register unlocking, software must issue the cycles using byte access only. Otherwise the unlocking sequence will not work properly.

The following is an example of how to prevent a timeout:

1. Write "80" to offset BAR1 + 0Ch.
2. Write "86" to offset BAR1 + 0Ch.
3. Write a '1' to RELOAD [8] (WDT\_RELOAD) of the Reload Register.

*Note:* Any subsequent writes require that this sequence be performed again.

#### 33.6.3.3 Reload Sequence

To keep the timer from causing an interrupt or driving WDT\_TOUT#, the timer must be updated periodically. Other timers refer to "updating the timer" as "kicking the timer". The frequency of updates required is dependent on the value of the Preload values. To update the timer the Register Unlocking Sequence must be performed followed by writing a '1' to bit 8 at offset BAR1 + 0Ch within the watchdog timer memory mapped space. This sequence of events is referred to as the "Reload Sequence".

#### 33.6.3.4 Low Power State

The Watchdog Timer does not operate when PCICLK is stopped.

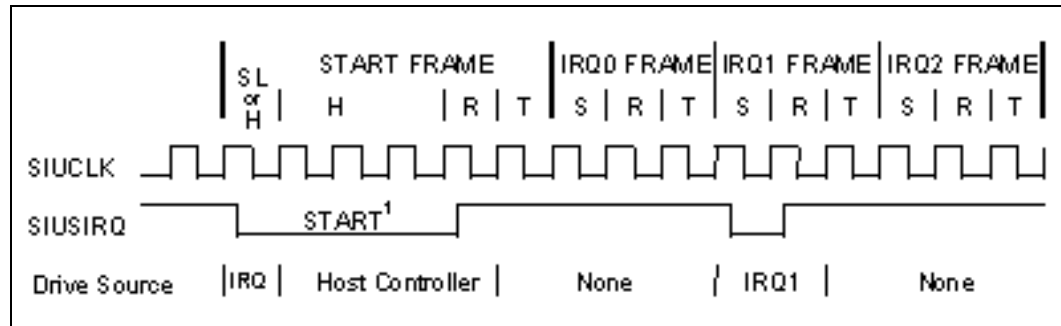

### 33.7 Serial IRQ

The SIW supports the serial interrupt to transmit interrupt information to the host system. The serial interrupt scheme adheres to the *Serial IRQ Specification*.

#### 33.7.1 Timing Diagrams For SIW\_SERIRQ Cycle

Figure 33-3. Start Frame Timing with Source Sampled a Low Pulse on IRQ1

**Notes:**

1. H=Host Control; R=Recovery; T=Turn-Around; SL=Slave Control; S=Sample
2. Start Frame pulse can be 4-8 clocks wide depending on the location of the device in the PCI bridge hierarchy in a synchronous bridge design.

Figure 33-4. Stop Frame Timing with Host Using Quiet Mode Sampling Period

**Notes:**

1. H=Host Control; R=Recovery; T=Turn-Around; S=Sample; I=Idle
2. Stop pulse is two clocks wide for Quiet mode, three clocks wide for Continuous mode.
3. There may be none, one or more Idle states during the Stop Frame.
4. The next SIW\_SERIRQ cycle's Start Frame pulse may or may not start immediately after the turn-around clock of the Stop Frame.

#### 33.7.1.1 SIW\_SERIRQ Cycle Control

There are two modes of operation for the SIW\_SERIRQ Start Frame.

1. **Quiet (Active) Mode:** Any device may initiate a Start Frame by driving the SIW\_SERIRQ low for one clock, while the SIW\_SERIRQ is Idle. After driving low for one clock the SIW\_SERIRQ is immediately tri-stated without at any time driving high. A Start Frame may not be initiated while the SIW\_SERIRQ is Active. The SIW\_SERIRQ is Idle between Stop and Start Frames. The SIW\_SERIRQ is Active

between Start and Stop Frames. This mode of operation allows the SIW\_SERIRQ to be Idle when there are no IRQ/Data transitions which should be most of the time.

Once a Start Frame has been initiated the Host Controller takes over driving the SIW\_SERIRQ low in the next clock and continues driving the SIW\_SERIRQ low for a programmable period of three to seven clocks. This makes a total low pulse width of four to eight clocks. Finally, the Host Controller drives the SIW\_SERIRQ back high for one clock, then tri-state.

Any SIW\_SERIRQ Device (i.e., The SIU and WDT) which detects any transition on an IRQ/Data line for which it is responsible must initiate a Start Frame in order to update the Host Controller unless the SIW\_SERIRQ is already in an SIW\_SERIRQ Cycle and the IRQ/Data transition can be delivered in that SIW\_SERIRQ Cycle.

2. **Continuous (Idle) Mode:** Only the Host controller can initiate a Start Frame to update IRQ/ Data line information. All other SIW\_SERIRQ agents become passive and may not initiate a Start Frame. SIW\_SERIRQ is driven low for four to eight clocks by Host Controller. This mode has two functions. It can be used to stop or idle the SIW\_SERIRQ or the Host Controller can operate SIW\_SERIRQ in a continuous mode by initiating a Start Frame at the end of every Stop Frame.

An SIW\_SERIRQ mode transition can only occur during the Stop Frame. Upon reset, SIW\_SERIRQ bus is defaulted to Continuous mode, therefore only the Host controller can initiate the first Start Frame. Slaves must continuously sample the Stop Frames pulse width to determine the next SIW\_SERIRQ Cycle's mode.

### 33.7.1.2 SIW\_SERIRQ Data Frame

Once a Start Frame has been initiated, the SIW watches for the rising edge of the Start Pulse and start counting IRQ/Data Frames from there. Each IRQ/Data Frame is three clocks: Sample phase, Recovery phase, and Turn-around phase. During the Sample phase the SIW drives the SIW\_SERIRQ low, if and only if, its last detected IRQ/Data value was low. If its detected IRQ/Data value is high, SIW\_SERIRQ is left tri-stated. During the Recovery phase the SIW drives the SIW\_SERIRQ high, if and only if, it had driven the SIW\_SERIRQ low during the previous Sample Phase. During the Turn-around Phase the SIW tri-states the SIU\_SERIRQ. The SIW drives the SIW\_SERIRQ line low at the appropriate sample point if its associated IRQ/Data line is low, regardless of which device initiated the Start Frame.

The Sample Phase for each IRQ/Data follows the low to high transition of the Start Frame pulse by a number of clocks equal to the IRQ/Data Frame times three, minus one. (e.g., The IRQ5 Sample clock is the sixth IRQ/Data Frame,  $(6 \times 3) - 1 = 17$ th clock after the rising edge of the Start Pulse).

Table 33-37. SIW\_SERIRQ Sampling Periods (Sheet 1 of 2)

| SIW_SERIRQ PERIOD | SIGNAL SAMPLED | # OF CLOCKS PAST START |
|-------------------|----------------|------------------------|
| 1                 | Not Used       | 2                      |
| 2                 | IRQ1           | 5                      |
| 3                 | IRQ2           | 8                      |
| 4                 | IRQ3           | 11                     |
| 5                 | IRQ4           | 14                     |
| 6                 | IRQ5           | 17                     |
| 7                 | IRQ6           | 20                     |
| 8                 | IRQ7           | 23                     |
| 9                 | IRQ8           | 26                     |
| 10                | IRQ9           | 29                     |
| 11                | IRQ10          | 32                     |

Table 33-37. SIW\_SERIRQ Sampling Periods (Sheet 2 of 2)

| SIW_SERIRQ PERIOD | SIGNAL SAMPLED | # OF CLOCKS PAST START |
|-------------------|----------------|------------------------|
| 12                | IRQ11          | 35                     |
| 13                | IRQ12          | 38                     |
| 14                | IRQ13          | 41                     |
| 15                | IRQ14          | 44                     |
| 16                | IRQ15          | 47                     |

SIW\_SERIRQ Period 14 is used to transfer IRQ13. Logical devices 4 (Serial Port 1), 5 (Serial Port 2) and 6 (WDT) shall have IRQ13 as a choice for their primary interrupt.

### 33.7.1.3 Stop Cycle Control

Once all IRQ/Data Frames have completed the Host Controller terminates SIW\_SERIRQ activity by initiating a Stop Frame. Only the Host Controller can initiate the Stop Frame. A Stop Frame is indicated when the SIW\_SERIRQ is low for two or three clocks. If the Stop Frame's low time is two clocks then the next SIW\_SERIRQ Cycle's sampled mode is the Quiet mode; and any SIW\_SERIRQ device may initiate a Start Frame in the second clock or more after the rising edge of the Stop Frame's pulse. If the Stop Frame's low time is three clocks then the next SIW\_SERIRQ Cycle's sampled mode is the Continuous mode; and only the Host Controller may initiate a Start Frame in the second clock or more after the rising edge of the Stop Frame's pulse.

### 33.7.1.4 Latency

Latency for IRQ/Data updates over the SIW\_SERIRQ bus in bridge-less systems with the minimum Host supported IRQ/Data Frames of seventeen, ranges up to 96 clocks (2.88  $\mu$ s with a 33 MHz PCI Bus). If one or more PCI to PCI Bridge is added to a system, the latency for IRQ/ Data updates from the secondary or tertiary buses are a few clocks longer for synchronous buses, and approximately double for asynchronous buses.

### 33.7.1.5 EOI/ISR Read Latency

Any serialized IRQ scheme has a potential implementation issue related to IRQ latency. IRQ latency could cause an EOI or ISR Read to precede an IRQ transition that it should have followed. This could cause a system fault. The host interrupt controller is responsible for ensuring that these latency issues are mitigated. The recommended solution is to delay EOIs and ISR Reads to the interrupt controller by the same amount as the SIW\_SERIRQ Cycle latency in order to ensure that these events do not occur out of order.

### 33.7.1.6 Reset and Initialization

The SIW\_SERIRQ bus uses SIW\_LRESET# as its reset signal. The SIW\_SERIRQ pin is tri-stated by all agents while SIW\_LRESET# is active. With reset, SIW\_SERIRQ Slaves are put into the (continuous) IDLE mode. The Host Controller is responsible for starting the initial SIW\_SERIRQ Cycle to collect system's IRQ/Data default values. The system then follows with the Continuous/ Quiet mode protocol (Stop Frame pulse width) for subsequent SIW\_SERIRQ Cycles. It is Host Controller's responsibility to provide the default values to the Interrupt controller and other system logic before the first SIW\_SERIRQ Cycle is performed. For SIW\_SERIRQ system suspend, insertion, or removal application, the Host controller must be programmed into Continuous (IDLE) mode first. This is to guarantee SIW\_SERIRQ bus is in IDLE state before the system configuration changes.

## 33.8 Configuration

The configuration of the SIW is very flexible and is based on the configuration architecture implemented in typical Plug-and-Play components. The SIW is designed for motherboard applications in which the resources required by their components are known. With its flexible resource allocation architecture, the SIW allows the BIOS to assign resources at POST.

### 33.8.1 Configuration Port Address

The SIW configuration port addresses for INDEX and DATA are controlled by the strap pin SIU1\_DTR# during reset. When SIU1\_DTR# is driven to '1' or left floating during reset SIW configuration port addresses are fixed at 4Eh/4Fh. When SIU1\_DTR# is driven to '0' during reset SIW configuration port addresses are fixed at 20Eh/20Fh.

### 33.8.2 Primary Configuration Address Decoder

After a PCI Reset (SIW\_LRESET# pin asserted) or Power On Reset the SIW is in the Run Mode with the UARTs and Watchdog timer disabled. They may be configured through two standard Configuration I/O Ports (INDEX and DATA) by placing the SIW into Configuration Mode.

The BIOS uses these configuration ports to initialize the logical devices at POST. The INDEX and DATA ports are only valid when the SIW is in Configuration Mode.

The INDEX and DATA ports are effective only when the chip is in the Configuration State. When the SIW is not in the Configuration State, reads return FFh and write data is ignored.

#### 33.8.2.1 Entering the Configuration State

The device enters the Configuration State by the following contiguous sequence:

1. Write 80H to Configuration Index Port.
2. Write 86H to Configuration Index Port.

#### 33.8.2.2 Exiting the Configuration State

The device exits the Configuration State by the following contiguous sequence:

1. Write 68H to Configuration Index Port.
2. Write 08H to Configuration Index Port.

#### 33.8.2.3 Configuration Sequence

To program the configuration registers, the following sequence must be followed.

1. Enter Configuration Mode.
2. Configure the Configuration Registers.
3. Exit Configuration Mode.

#### 33.8.2.4 Configuration Mode

The system sets the logical device information and activates desired logical devices through the INDEX and DATA ports. In configuration mode, the INDEX PORT is located at the CONFIG PORT address and the DATA PORT is at INDEX PORT address + 1.

The desired configuration registers are accessed in two steps:

1. Write the index of the Logical Device Number Configuration Register (i.e., 07) to the INDEX PORT and then write the number of the desired logical device to the DATA PORT.
2. Write the address of the desired configuration register within the logical device to the INDEX PORT and then write or read the configuration register through the DATA PORT.

**Note:** If accessing the Global Configuration Registers, step (1) is not required. The chip returns to the RUN State.

**Note:** Only two states are defined (Run and Configuration). In the Run State the chip is always ready to enter the Configuration State.

### 33.8.3 SIW Configuration Register Summary

The default values are defined with an h for hex, a bi for binary, or 00 for zero. If there is not a letter following the default value, assume it is a binary number.

**Warning:** Address locations that are not listed are considered reserved register locations. Reads to reserved registers may return non-zero values. Writes to reserved locations may cause system failure.

**Note:** Reserved bits are Read Only.

**Table 33-38. Configuration Register Summary (Sheet 1 of 2)**

| Global Configuration Registers             |      |         |                                  |
|--|------|---------|----------------------------------|
| Index                                      | Type | Default | Configuration Register           |
| 07h  | RW   | 00h     | Logical Device Number            |
| 20h  | R    | 00h     | Device ID                        |

### 33.8.3.1 Global Control/Configuration Registers [00h - 2Fh]

The chip-level (global) registers lie in the address range [00h-2Fh]. The design MUST use all eight bits of the ADDRESS Port for register selection. All unimplemented registers and bits ignore writes and return zero when read.

The INDEX PORT is used to select a configuration register in the chip. The DATA PORT is then used to access the selected register. These registers are accessible only in the Configuration Mode.

| Register                           | Address (Type)                           | Description  |
|------------------------------------|--|--|
| Logical Device #<br>Default = 00h  | 07h<br>(RW)                              | <b>Logical Device Select:</b> A write to this register selects the current logical device. This allows access to the control and configuration registers for each logical device.  |
| Device ID<br>Default = 00h         | 20h<br>(R)                               | <b>Device ID:</b> A read only register which provides the Device ID.   |
| Device Rev<br>Default = 01h        | 21h<br>(R)                               | <b>Device Rev:</b> A read only register which provides device revision information.  |
| SIW Interface<br>Default = 01h     | 28h<br>c                                 | Bit 7:1 RSVD = 0<br>Bit 0 LPC bus wait states<br>0 = Not Supported<br>1 = Long wait states (sync 6)  |
| SIW Configuration<br>Default = 02h | 29h<br>(RW - bit 0, 2, 3)<br>(R - bit 1) | Bit 0 SIWQ enable<br>1 = enabled; enabled logical devices participate in interrupt generation<br>0 = disabled; serial interrupts disabled<br>Bit 1 IRQ mode (READ ONLY, WRITES IGNORED)<br>1 = Continuous mode<br>0 = Quiet mode<br>Bit 3:2 UART_CLK predivide<br>00 = divide by 1<br>01 = divide by 8<br>10 = divide by 26<br>11 = reserved<br>Bit 7:4 RSVD = 0 |

| Register   | Address (Type)                        | Description  |
|--|---------------------------------------|--|
| SIW Monitor Port Control Register<br>Default = 00h | 2D<br>(RO - bit 7)<br>(RW - bits 6:0) | <p>Bit 0 UART1 Monitor Port Enable (UART1_MONPORTEN):<br/>Setting this bit enables the monitor port for UART1. This signal turns on all 8 UART2 monitor ports.<br/>Note: wdt_monporten, uart2_monporten and uart1_monporten must be set in a mutually exclusive manner i.e., only one monitor port enable must be set at one time.</p> <p>Bit 1 UART2 Monitor Port Enable (UART2_MONPORTEN):<br/>Setting this bit enables the monitor port for UART2. This signal turns on all 8 UART1 monitor ports.<br/>Note: wdt_monporten, uart2_monporten and uart1_monporten must be set in a mutually exclusive manner i.e., only one monitor port enable must be set at one time.</p> <p>Bit 2 WDT Monitor Port Enable (WDT_MONPORTEN):<br/>Setting this bit enables the monitor port for WDT. This signal turns on all 16 SIW monitor ports.<br/>Note: wdt_monporten, uart2_monporten and uart1_monporten must be set in a mutually exclusive manner i.e., only one monitor port enable must be set at one time.</p> <p>Bit 6:3 Monitor Port Slot Select[3:0] (MONPORTSEL):<br/>These bits select which Monitor Port Slot is enabled. These bits are used to select up to 16 slots within each UART1 and UART2 source group.<br/>Note: WDT has only 1 slot. So, port slot selection is not required.<br/>Bit 7 RSVD = 0</p> |
| Default = 00h                                      | 2Eh                                   | Reserved   |

### 33.8.3.2 Logical Device Configuration Registers [30h — FFh]

Used to access the registers that are assigned to each logical unit. This chip supports three logical units and has three sets of logical device registers. The three logical devices are UART1, UART2 and Watchdog Timer. A separate set (bank) of control and configuration registers exists for each logical device and is selected with the Logical Device # Register.

The INDEX PORT is used to select a specific logical device register. These registers are then accessed through the DATA PORT.

The Logical Device registers are accessible only when the device is in the Configuration State. The logical register addresses are shown in the tables below.

Table 33-39. Logical Device 4 (Serial Port 1)

| Logical Device Register                   | Address  | Description   |
|---|--|---|
| Enable<br>Default = 00h                   | 30h<br>(RW)  | Bits[7:1] Reserved, set to zero.<br>Bit[0]<br>1 = enable the logical device currently selected through the Logical Device # register.<br>0 = Logical device currently selected is inactive  |
| I/O Base Address<br>Default = 00h         | 60h<br>(RW)<br>61h<br>(Bits 7:3 RW<br>Bits 2:0 RO) | Registers 60h (MSB) and 61h (LSB) set the base address for the device. Note: Decode is on 8 Byte boundaries<br>Comm Decode Ranges<br>3F8 - 3FF (COM 1)<br>2F8 - 2FF (COM 2)<br>220 - 227<br>228 - 22F<br>238 - 23F<br>2E8 - 2EF (COM 4)<br>338 - 33F<br>3E8 - 3EF (COM 3)   |
| Primary Interrupt Select<br>Default = 00h | 70h<br>(RW)  | Bits[3:0] selects which interrupt level is used for the primary Interrupt.<br>00= no interrupt selected<br>01= IRQ1<br>02= IRQ2<br>03= IRQ3<br>04= IRQ4<br>05= IRQ5<br>06= IRQ6<br>07= IRQ7<br>08= IRQ8<br>09= IRQ9<br>0A= IRQ10<br>0B= IRQ11<br>0C= IRQ12<br>0D= IRQ13<br>0E= IRQ14<br>0F= IRQ15<br>Bits[7:4] Reserved<br>Note: An Interrupt is activated by enabling this device (offset 30h), setting this register to a non-zero value and setting any combination of bits 0-4 in the corresponding UART IER and the occurrence of the corresponding UART event (i.e. Modem Status Change, Receiver Line Error Condition, Transmit Data Request, Receiver Data Available or Receiver Time Out) and setting the OUT2 bit in the MCR. |
| Reserved<br>Default = 04h                 | 74h  | Bit 7:0 - Reserved  |

## 34.0 PCI-to-PCI Bridge

### 34.1 Summary

The PCI-to-PCI bridge provides an interface between the AIOC and the MCH/IA. PCI-to-PCI Bridge forwards data and commands from AIOC memory target to the PCI-to-PCI bridge (Upstream interface). It also provide the IA a path into the AIOC via the PCI-to-PCI bridge (Downstream Interface).

### 34.2 PCI-to-PCI Bridge Detailed Register Descriptions

**Table 34-1. Bus 0, Device 4, Function 0: Summary of PCI-to-PCI Bridge PCI Configuration Registers (Sheet 1 of 2)**

### 34.2.2.16 Offset 1Ch: IOB – I/O Base Register

This register (together with IOBU) specifies the starting I/O address of devices in the AIOC infrastructure. The range is aligned to a 4k boundary, so address bits [11:0] are assumed to be zero.

Table 34-18. Offset 1Ch: IOB: I/O Base Register

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |   | Bus:Device:Function: 0:4:0 | Offset Start: 1Ch<br>Offset End: 1Ch |            |
| Size: 8 bit  | Default: F0        |   |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description   | Sticky                     | Bit Reset Value                      | Bit Access |
| 07 : 04      | IOB                | These bits correspond to address bits [15:12] of the I/O transaction. Address bits [13:16] are matched with IOBU. |                            | Fh                                   | RW         |
| 03 : 00      | IOAW               | The value "1" means that we implement 32-bit I/O space.   |                            | 0                                    | RO         |

### 34.2.2.17 Offset 1Dh: IOL – I/O Limit Register

This register (together with IOLU) specifies the ending I/O address of devices in the AIOC infrastructure. The range is aligned to a 4k boundary, so address bits [11:0] are assumed to be FFF.

**Table 34-19. Offset 1Dh: IOL: I/O Limit Register**

| Description: |                    |   |                            |                                      |            |

### 34.2.2.19 Offset 20h: MEMB – Memory Base Register

This register specifies the starting memory address of devices in the AIOC infrastructure. The range is aligned to a 1M boundary, so address bits [19:0] are assumed to be zero.

Table 34-21. Offset 20h: MEMB: Memory Base Register

| Description: |                    |   |                            |                                      |            |
|--------------|--------------------|---|----------------------------|--------------------------------------|------------|

### 34.2.2.20 Offset 22h: MEML – Memory Limit Register

This register specifies the ending memory address of devices in the AIOC infrastructure. The range is aligned to a 1M boundary, so address bits [19:0] are assumed to be FFFF.

Table 34-22. Offset 22h: MEML: Memory Limit Register

| Description: |                    |   |                            |                                      |            |

## 35.0 PCI-to-PCI Bridge: AIOC Configuration

### 35.1 Overview

The PCI-to-PCI bridge provides the IA-32 core/MCH fabric an interface to the AIOC. It implements PCI configuration registers that enable the IA-32 core to enumerate and configure the AIOC devices.

### 35.2 Feature List

The PCI-to-PCI bridge implements the following:

- Provides the IA-32 core/MCH complex access into the AIOC.

### 35.3 PCI Configuration Registers

The AIOC Type 1 PCI configuration registers can only be accessed using Type 1 Config Read/Write request types.

#### 35.3.1 Description of PCI Configuration Header Space

The PCI configuration headers expose the various PCI devices on the AIOC to the IA infrastructure.

The PCI Specification requires implementation of 64 bytes of PCI Configuration registers as shown in [Table 35-1](#). After a system reset, these registers are initially configured by the BIOS, and/or “Plug and Play” aware operating system. Device drivers will then read these registers to determine what resources (interrupt number, memory mapping location, etc.), the BIOS and/or OS assigned to the device.

**Table 35-1. Type 0 PCI Configuration Header**

| Byte Offset    |      |           |       |                     |    |           |    |
|----------------|------|-----------|-------|---------------------|----|-----------|----|
| +7             | +6   | +5        | +4    | +3                  | +2 | +1        | +0 |
| Status         |      | Command   |       | Device ID           |    | Vendor ID |    |
| BIST           | Type | LT        | CLS   | Class Code          |    | Rev       |    |
| Base Address 1 |      |           |       | Base Address 0      |    |           |    |
| Base Address 3 |      |           |       | Base Address 2      |    |           |    |
| Base Address 5 |      |           |       | Base Address 4      |    |           |    |
| Subsys ID      |      | Subsys ID |       | CardBus CIS Pointer |    |           |    |
| Reserved       |      |           | CP    | Expansion ROM Base  |    |           |    |
| Mx L           | Mn G | IRQ P     | IRQ L | Reserved            |    |           |    |

The fields shaded in grey are required in all PCI devices, and the other fields are optional. In each device section (below) the implemented fields are listed. An explanation of various PCI registers is provided below:

1. **Vendor ID** This uniquely identifies all Intel PCI products. A value of 0x8086 is the default for this field upon power up.
2. **Device ID** This uniquely identifies the Device.
3. **Command Reg.** Layout is shown below. Un-used bits are hard-wired to 0.

Figure 35-1. PCI Configuration Command Register Layout

| Bit(s) | Initial Value | Description  |
|--------|---------------|--|
| 0      | 0             | I/O Access Enable  |
| 1      | 0             | Memory Access Enable   |
| 2      | 0             | Enable Mastering; Device in PCI-X mode is permitted to initiate a Split Completion transaction regardless of the state of this bit |
| 3      | 0             | Special Cycle Monitoring   |
| 4      | 0             | Memory Write and Invalidate Enable, ignored by the device in PCI-X mode  |
| 5      | 0             | Palette Snoop Enable   |
| 6      | 0             | Parity Error Response  |
| 7      | 0             | Wait Cycle Enable  |
| 8      | 0             | SERR# Enable   |
| 9      | 0             | Fast Back-to-Back Enable, ignored by the device in PCI-X mode  |
| 10     | 0             | Interrupt Disable.   |
| 15:10  | 0             | Reserved   |

4. **Status Register** Layout is shown below. Shaded bits are not used by this implementation and are hard-wired to 0.

Figure 35-2. PCI Configuration Status Register Layout

| Bit(s) | Initial Value | Description  |
|--------|---------------|--|
| 2:0    | 0             | Reserved   |
| 3      | 0             | Interrupt Status.  |
| 4      | 1             | New Capabilities: Indicates that a device implements Extended Capabilities. A device sets this bit, and implements a capabilities list, to indicate that it supports PCI Power Management, PCI-X, and message signaled interrupts. |
| 5      | 1             | 66MHz Capable  |
| 6      | 0             | UDF Supported  |
| 7      | 0             | Fast Back-to-Back Capable, This bit must be set to 0 in PCI-X mode.  |
| 8      | 0             | Data Parity Reported   |
| 10:9   | 01            | DEVSEL Timing (indicates medium device): Indicates conventional DEVSEL timing regardless of the operating mode.  |
| 11     | 0             | Signaled Target Abort  |
| 12     | 0             | Received Target Abort  |
| 13     | 0             | Received Master Abort  |
| 14     | 0             | Signaled System Error  |
| 15     | 0             | Detected Parity Error  |

5. **Revision:** This is the 1st version of this device, so the revision number is 0x00.
6. **Class Code:** The class code, 0x020000 identifies this device as an Ethernet adapter.
7. **Cache Line Size:** Used to store the cache line size. The value is in units of 4 bytes. A system with a cache line size of 64B sets the value of this register to 0x10. The only sizes that are supported are 16, 32, 64, and 128 bytes. All other sizes are treated as 0. See exceptions in section 2.11.8 The default value at power up in 0x00.
8. Unsupported values affect PCI cache line support. All writes default to using the memory write (MW) command, and memory read command determination uses a cache-line size of 32 bytes.
9. **Latency Timer:** The lower 2 bits are not implemented and return 0. The upper 6 bits are RW. The default value of the Latency Timer register is 64 in PCI-X mode.
10. **Header Type:** This indicates if a device is single function or multifunction. The EP80579 returns a value of 0x00, indicating that it is a normal single function device.
11. **BIST:** BIT (Built in Self-test) will be not be implemented as supportable from PCI config space in this version of the device.
12. **Base Address Register:** The Base Address Registers (or BARs) are used to map the EP80579 register space to system memory space.

## 35.4 Interrupt Handling for AIOC Devices

Interrupts from the AIOC devices are routed towards the IA-32 core as either an MSI or by asserting the level-sensitive signal INTX.

The configuration provides a mechanism via the PCI configuration header space for functional units in the AIOC to interrupt the IA-32 core.

Most PCI configuration headers for AIOC devices implement two capability records to support interrupt and signal handling.

- A Message Signalled Interrupt capability record that follows the standard PCI format and describes the format of an IA MSI.
- An EP80579-specific Signal Target capability record that is unique to the EP80579 and describes how to target signals from the device.

The hardware will provide these capabilities to most of the devices implemented in the Configuration Bridge except for MDIO and the Local Expansion Bus. The software is responsible to enabling/disabling this functionality for each of the devices.

**Table 35-2. Messaging and Signalling Capability Record per PCI Device (Sheet 1 of 2)**

| PCI Device   | Function | Message Capable? | Signal Capable? | Interrupts (Max 8 per device)                                | Comment |
|--------------|----------|------------------|-----------------|--|---------|
| 0<br>(GbE0)  | GbE      | Yes              | Yes             | GBE0 Interrupt 0<br>GBE0 Interrupt 1<br>GBE0 Error Interrupt |         |
| 1<br>(GbE 1) | GbE      | Yes              | Yes             | GBE1 Interrupt 0<br>GBE1 Interrupt 1<br>GBE1 Error Interrupt |         |
| 2<br>(GbE 2) | GbE      | Yes              | Yes             | GBE2 Interrupt 0<br>GBE2 Interrupt 1<br>GBE2 Error Interrupt |         |

**Table 35-2. Messaging and Signalling Capability Record per PCI Device (Sheet 2 of 2)**

| PCI Device              | Function            | Message Capable? | Signal Capable? | Interrupts (Max 8 per device)                        | Comment |

| 8 (Local Expansion Bus) | Local Expansion Bus | Yes              | Yes             | EXP Expansion-Bus Parity Error<br>Internal Interrupt |         |

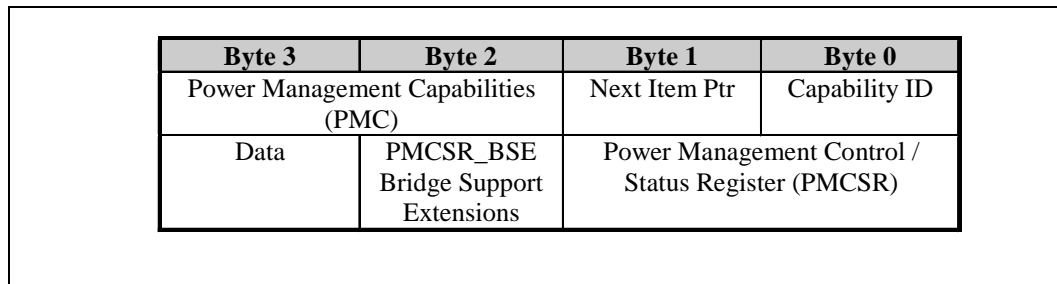

### 35.5 Power Management of AIOC Devices

The AIOC devices support PCI Bus power management (PM). The supported states are:

- D0: Device is on and running which maximum power dissipation
- D3: Device is off and power can be removed. The device has lost its context information and will have to be re-booted before it can enter the D0 state again.

The PM capabilities for the AIOC devices are defined as part of the capabilities list in the PCI Configuration space for each device. [Figure 35-3](#) describes the contents of a power management entry in the capability list.

**Figure 35-3. PCI Power Management Register Block**

PMCSR control bits are provided in part of PCI PM registers. These bits control the state of the device. The default value of this bit is 0 and corresponds to the D0 state.

*Note:* It is the responsibility of software to ensure that the devices and all of its function are in quiescent state

It is also the responsibility of software to disable Memory, I/O space (as appropriate) disabled, and interrupts (as appropriate) in the PCICMD register prior to powering down the device.

## 35.6 Gigabit Ethernet MAC Configuration Spaces: Bus M, Device 0-2, Function 0

Gigabit MAC 0, 1, and 2 are Devices 0, 1, and 2 of Bus M, respectively, and are accessed using type 1 configuration cycles. All MACs implement configuration spaces as defined in this section.

During an EEPROM read the configuration space will stall any configuration read or write cycles until after the EEPROM read has completed. For MEM/IO transfers it is up to the MAC to stall the transfer.

### 35.6.1 Register Details

**Table 35-3. Bus M, Device 0, Function 0: Summary of Gigabit Ethernet MAC Interface PCI Configuration Registers (Sheet 1 of 2)**

| Offset Start | Offset End | Register ID - Description   | Default Value |

### 35.6.1.1 Offset 00h: VID – Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identifies any PCI device. Writes to this register have no effect.

Table 35-6. Offset 00h: VID: Vendor Identification Register

| Description: |                    |   |                            |                                      |            |

### 35.6.1.10 Offset 10h: CSRBAR – Control and Status Registers Base Address Register

The CSRBAR is a PCI BAR in memory space that allows access to the CSRs of a Gigabit Ethernet MAC. See Section 37.6, “GbE Controller Register Summary” for a description of the individual registers that this region exposes.

Table 35-15. Offset 10h: CSRBAR: Control and Status Registers Base Address Register

| Description: |                    |  |                            |                                      |            |

### 35.6.1.17 Offset DCh: PCID – Power Management Capability ID Register

The Power Management Capability record controls power management in the device. It is a 6B PCI SIG-defined capability record and includes the PCID, PCP, PMCAP, and PMCS fields of the configuration header.

For an overview of the power management capability of AIOC devices, see [Section 35.5, “Power Management of AIOC Devices”](#).

**Table 35-22. Offset DCh: PCID: Power Management Capability ID Register**

| Description: |                    |   |                            |                                      |            |

The upper 16 bits of the transaction are written as 0. |                            | 0h                                   | RW         |

## 35.7 Gigabit Ethernet MAC I/O Spaces: Bus M, Device 0-2, Function 0

The PCI-to-PCI Bridge implements IOADDR and IODATA registers in IA I/O space to allow access to Gigabit MAC structures through the IOBAR of a Gigabit MAC (see [Section 35.6.1.11, "Offset 14h: IOBAR – CSR I/O Mapped BAR Register" on page 1247](#)). These registers are used to indirectly access Gigabit MAC structures before the entire system memory map is available to use the MEMBAR. There are two registers for each MAC

During an EEPROM read the configuration space will stall any configuration read or write cycles until after the EEPROM read has completed. MEM/IO transfers generate an AIOC internal bus command and it is up to the Gig to stall the transfer.

## 35.7.1 Register Details

**Table 35-37. Bus M, Device 0, Function 0: Gigabit Ethernet MAC I/O Spaces Registers**

| Offset Start | Offset End | Register ID - Description                             | Default Value |

**Table 35-40. Gigabit Ethernet MAC I/O IOBAR Register Summary**

| Offset    | Mnemonic | Name   | RW  | Size   |
|-----------|----------|--|-----|--------|
| 00h - 03h | IOADDR   | Internal register or internal memory address.<br>0000_0000h - 0001_FFFFh: Internal Registers/Memories<br>0002_0000h - FFFF_FFFFh: Undefined                                | RW  | 4 Byte |
| 04h - 07h | IODATA   | Data field for reads or writes to the Internal Register or Internal Memory as identified by the current value in IOADDR. All 32 bits of this register are read/write-able. | RW  | 4 Byte |
| 08h - 3Fh | Reserved | Reserved   | N/A | N/A    |

### 35.7.1.1 Offset 0000h: IOADDR - IOADDR Register

The IOADDR register specifies the structure within a GbE device that should be accessed on reads or writes to the IODATA register (see [Section 35.7.1.2, "Offset 0004h: IODATA - IODATA Register" on page 1264](#)).

Table 35-41. Offset 0000h: IOADDR - IOADDR Register

| Description: |                   |  |        |  |            |
|--------------|-------------------|--|--------|--|------------|
| View: PCI 1  | BAR: IOBAR        | Bus:Device:Function: M:0:0   |        | Offset Start: 0000h<br>Offset End: 0003h |            |
| View: PCI 2  | BAR: IOBAR        | Bus:Device:Function: M:1:0   |        | Offset Start: 0000h<br>Offset End: 0003h |            |
| View: PCI 3  | BAR: IOBAR        | Bus:Device:Function: M:2:0   |        | Offset Start: 0000h<br>Offset End: 0003h |            |
| Size: 32 bit | Default: 0000000h |  |        | Power Well: Vcc                          |            |
| Bit Range    | Bit Acronym       | Bit Description  | Sticky | Bit Reset Value                          | Bit Access |
| 31 : 17      | Reserved          | Reserved   |        | 0000h                                    | RO         |
| 16 : 00      | IOADDR            | <b>Address for I/O Operation:</b> Provides the address for accesses to the GbE internal registers and memories allows access to full 128KB of space. |        | 00000h                                   | RW         |

The IOADDR register must always be written as a DWORD access. Writes that are less than 32 bits will be ignored. Reads of any size will return a DWORD of data. However, the chipset or CPU may only return a subset of that DWORD. IOADDR must be DWORD aligned.

Because only a particular range is addressable, the upper bits of this register are hard coded to zero. Bits 31 through 17 are not write-able and always read back as 0b.

At hardware reset, this register value resets to 00000000h. Once written, the value is retained until the next write or reset.

### 35.7.1.2 Offset 0004h: IODATA - IODATA Register

The IODATA register exposes the internal structures within the GbE identified by the last value written to the IOADDR register (see Section 35.7.1.1, “Offset 0000h: IOADDR - IOADDR Register” on page 1262) to read and write accesses.

Table 35-42. Offset 0004h: IODATA - IODATA Register

| Description: |                   |  |                            |  |                 |            |
|--------------|-------------------|--|----------------------------|--|-----------------|------------|
| View: PCI 1  | BAR: IOBAR        |  | Bus:Device:Function: M:0:0 | Offset Start: 0004h<br>Offset End: 0007h |                 |            |
| View: PCI 2  | BAR: IOBAR        |  | Bus:Device:Function: M:1:0 | Offset Start: 0004h<br>Offset End: 0007h |                 |            |
| View: PCI 3  | BAR: IOBAR        |  | Bus:Device:Function: M:2:0 | Offset Start: 0004h<br>Offset End: 0007h |                 |            |
| Size: 32 bit | Default: 0000000h |  |                            | Power Well: Vcc                          |                 |            |
| Bit Range    | Bit Acronym       | Bit Description  |                            | Sticky                                   | Bit Reset Value | Bit Access |
| 31 : 00      | IODATA            | <b>Data for I/O Operation:</b> Exposes the GbE device structure that IOADDR identifies to read and write accesses. |                            |  | 0000000h        | RW         |

The IODATA register must always be written as a DWORD access when the IOADDR register contains a value for the Internal Registers and Memories. In this case, writes that are less than 32 bits will be ignored.

Reads to IODATA of any size will return a DWORD of data. However, the chipset or CPU may only return a subset of that DWORD.

Writes and reads to IODATA when the IOADDR register value is in an undefined range (0002\_0000h -FFFF\_FFFFh) should not be performed. Results are indeterministic.

*Note:* There are no special software timing requirements on accesses to IOADDR or IODATA. All accesses will be immediate except when data is not readily available or acceptable. In this case, the GbE will delay the results through normal bus methods (e.g., split transaction or NP Complete).

*Note:* Because a register/read or write takes two IO cycles to complete, software must provide a guarantee that the two IO cycles occur as an atomic operation. Otherwise, results can be non-deterministic from the software viewpoint.

## 35.8 GCU Configuration Space: Bus M, Device 3, Function 0

The GCU and MDIO port is Device 3 of Bus M, and is accessed using type 1 configuration cycles.

### 35.8.1 Register Details

**Table 35-43. Bus M, Device 3, Function 0: Summary of GCU PCI Configuration Registers**

#### 35.8.1.1 Offset 00h: VID – Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identifies any PCI device. Writes to this register have no effect.

**Table 35-44. Offset 00h: VID: Vendor Identification Register**

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|

## 35.9 CAN Controller Configuration Spaces: Bus M, Device 4-5, Function 0

CAN controllers 0 and 1 are devices 4 and 5 of bus M, respectively and are accessed using type 1 configuration cycles. Both controllers implement configuration spaces as defined in this section.

### 35.9.1 Register Details

**Table 35-59. Bus M, Device 4, Function 0: Summary of CAN Interface PCI Configuration Registers (Sheet 1 of 2)**

| Offset Start | Offset End | Register ID - Description  | Default Value |

### 35.9.1.1 Offset 00h: VID – Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identifies any PCI device. Writes to this register have no effect.

**Table 35-61. Offset 00h: VID: Vendor Identification Register**

| Description: |                |  |                  |                 |            |
|--------------|----------------|--|------------------|-----------------|------------|
| View         | BAR            | Bus:Device:Function  | Offset Start     | Offset End      |            |
| PCI 1        | Configuration  | M: 4: 0  | 00h              | 01h             |            |
| PCI 2        | Configuration  | M: 5: 0  | 00h              | 01h             |            |
| Size: 16 bit | Default: 8086h |  | Power Well: Core |                 |            |
| Bit Range    | Bit Acronym    | Bit Description  | Sticky           | Bit Reset Value | Bit Access |
| 15 : 00      | VID            | <b>Vendor Identification:</b> This register field contains the PCI standard identification for Intel, 8086h. |                  | 8086h           | RO         |

### 35.9.1.2 Offset 02h: DID – Device Identification Register

This 16-bit register combined with the Vendor Identification register uniquely identifies any PCI device. Each CAN controller has its own device ID. Writes to this register have no effect.

**Table 35-62. Offset 02h: DID: Device Identification Register**

| Description: |                |   |                  |                 |            |
|--------------|----------------|---|------------------|-----------------|------------|
| View         | BAR            | Bus:Device:Function   | Offset Start     | Offset End      |            |
| PCI          | Configuration  | M: 4: 0   | 02h              | 03h             |            |
| Size: 16 bit | Default: 5039h |   | Power Well: Core |                 |            |
| Bit Range    | Bit Acronym    | Bit Description   | Sticky           | Bit Reset Value | Bit Access |
| 15 : 00      | DID            | <b>Device Identification Number:</b> This is a 16-bit value assigned to the CAN controller #1 device. |                  | 5039h           | RO         |

### 35.9.1.3 Offset 02h: DID – Device Identification Register

This 16-bit register combined with the Vendor Identification register uniquely identifies any PCI device. Each CAN controller has its own device ID. Writes to this register have no effect.

Table 35-63. Offset 02h: DID: Device Identification Register

| Description: |                    |   |                            |                                      |            |
