### 35.9.1.16 Offset DCh: PCID – Power Management Capability ID Register

The Power Management Capability record controls power management in the device. It is a 6B PCI SIG-defined capability record and includes the PCID, PCP, PMCAP, and PMCS fields of the configuration header.

For an overview of the power management capability of AIOC devices, see [Section 35.5, “Power Management of AIOC Devices”](#) on page 1236.

**Table 35-76. Offset DCh: PCID: Power Management Capability ID Register**

### 35.9.1.20 Offset E4h: SCID – Signal Target Capability ID Register

The Signal Target Capability record defines how the device targets its signals to IA agents. It is an 9B vendor-specific capability record and includes the SCID, SCP, SBC, STYP, SMIA, and SINT fields of the configuration header.

For more information on signaling by AIOC devices, see Section 35.4, “Interrupt Handling for AIOC Devices” on page 1235.

**Table 35-80. Offset E4h: SCID: Signal Target Capability ID Register**

### 35.9.1.28 Offset F0h: MCID – Message Signalled Interrupt Capability ID Register

The Message Signalled Interrupt Capability record defines how the device generates PCI MSI messages. It is an 10B PCI SIG-defined capability record and includes the MCID, MCP, MCTL, MADR, and MDATA fields of the configuration header.

**Table 35-86. Offset F0h: MCID: Message Signalled Interrupt Capability ID Register**

### 35.10.1.1 Offset 00h: VID – Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identifies any PCI device. Writes to this register have no effect.

**Table 35-92. Offset 00h: VID: Vendor Identification Register**

| Description: |                    |  |                              |                                      |            |
|--------------|--------------------|--|------------------------------|--------------------------------------|------------|

### 35.10.1.14 Offset DCh: PCID – Power Management Capability ID Register

The Power Management Capability record controls power management in the device. It is a 6B PCI SIG-defined capability record and includes the PCID, PCP, PMCAP, and PMCS fields of the configuration header.

For an overview of the power management capability of AIOC devices, see [Section 35.5, “Power Management of AIOC Devices”](#) on page 1236.

**Table 35-105.Offset DCh: PCID: Power Management Capability ID Register**

| Description: |                    |  |                            |                                      |            |

### 35.10.1.18 Offset E4h: SCID – Signal Target Capability ID Register

The Signal Target Capability record defines how the device targets its signals to IA agents. It is an 9B vendor-specific capability record and includes the SCID, SCP, SBC, STYP, SMIA, and SINT fields of the configuration header.

For more information on signaling by AIOC devices, see [Section 35.4, “Interrupt Handling for AIOC Devices”](#) on page 1235.

**Table 35-109.Offset E4h: SCID: Signal Target Capability ID Register**

### 35.10.1.26 Offset F0h: MCID – Message Signalled Interrupt Capability ID Register

The Message Signalled Interrupt Capability record defines how the device generates PCI MSI messages. It is an 10B PCI SIG-defined capability record and includes the MCID, MCP, MCTL, MADR, and MDATA fields of the configuration header.

Table 35-115.Offset F0h: MCID: Message Signalled Interrupt Capability ID Register

| Description: |                    |   |                             |                                      |            |

### 35.11.1.1 Offset 00h: VID – Vendor Identification Register

The VID Register contains the vendor identification number. This 16-bit register combined with the Device Identification Register uniquely identifies any PCI device. Writes to this register have no effect.

**Table 35-121.Offset 00h: VID: Vendor Identification Register**

| Description: |                    |  |                             |                                      |            |

### 35.11.1.8 Offset 10h: CSRBAR – Control and Status Registers Base Address Register

The CSRBAR is a PCI BAR in memory space that allows access to the control and status registers for the 1588 Hardware Assist Unit. See [Section 41.6, “Register Summary”](#) on page 1637 for a description of the registers this region exposes.

**Table 35-128.Offset 10h: CSRBAR: Control and Status Registers Base Address Register**

| Description: |                    |  |                             |                                      |            |

### 35.11.1.9 Offset 2Ch: SVID – Subsystem Vendor ID Register

This register is a write-once register. Once any byte in the register has been written, the register locks against further writes until reset.

Table 35-129.Offset 2Ch: SVID: Subsystem Vendor ID Register

| Description: |                    |   |                             |                                      |            |

### 35.11.1.14 Offset DCh: PCID – Power Management Capability ID Register

The Power Management Capability record controls power management in the device. It is a 6B PCI SIG-defined capability record and includes the PCID, PCP, PMCAP, and PMCS fields of the configuration header.

For an overview of the power management capability of AIOC devices, see [Section 35.5, “Power Management of AIOC Devices”](#) on page 1236.

**Table 35-134.Offset DCh: PCID: Power Management Capability ID Register**

| Description: |                    |  |                              |                                      |            |

### 35.11.1.18 Offset E4h: SCID – Signal Target Capability ID Register

The Signal Target Capability record defines how the device targets its signals to IA agents. It is an 9B vendor-specific capability record and includes the SCID, SCP, SBC, STYP, SMIA, and SINT fields of the configuration header.

For more information on signaling by AIOC devices, see [Section 35.4, “Interrupt Handling for AIOC Devices”](#) on page 1235.

**Table 35-138. Offset E4h: SCID: Signal Target Capability ID Register**

### 35.11.1.26 Offset F0h: MCID – Message Signalled Interrupt Capability ID Register

The Message Signalled Interrupt Capability record defines how the device generates PCI MSI messages. It is an 10B PCI SIG-defined capability record and includes the MCID, MCP, MCTL, MADR, and MDATA fields of the configuration header.

Table 35-144. Offset F0h: MCID: Message Signalled Interrupt Capability ID Register

| Description: |                    |  |                             |                                      |            |

### 35.12.1.8 Offset 10h: CSRBAR – Control and Status Registers Base Address Register

The CSRBAR is a PCI BAR in memory space that allows access to the control and status registers for the Local Expansion bus. See [Chapter 42.0, “Register Summary”](#) for a description of the registers this region exposes.

**Table 35-157.Offset 10h: CSRBAR: Control and Status Registers Base Address Register**

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: M:8:0 | Offset Start: 10h<br>Offset End: 13h |            |

### 35.12.1.9 Offset 14h: MMBAR – Expansion Bus Base Address Register

The MMBAR is a PCI BAR in memory space that allows access to the devices on the external Local Expansion bus. Expansion device 0 occupies the first 16MB/32MB of the region, device 1 occupies the next 16MB/32MB, etc. Refer to [Section 42.0, “Local Expansion Bus Controller”](#) for a description of the local expansion bus.

**Table 35-158.Offset 14h: MMBAR: Expansion Bus Base Address Register**

| Description: |                    |  |                            |                                      |            |
|--------------|--------------------|--|----------------------------|--------------------------------------|------------|
| View: PCI    | BAR: Configuration |  | Bus:Device:Function: M:8:0 | Offset Start: 14h<br>Offset End: 17h |            |
| Size: 32 bit | Default: 00000000h |  |                            | Power Well: Core                     |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                     | Bit Reset Value                      | Bit Access |
| 31 : 25      | ADDR               | <b>Upper Programmable Base Address:</b> These bits are set by BIOS to locate the base address of the region. Their behavior is described in <a href="#">Table 35-159</a> . |                            | 0h                                   | RW         |
| 24 : 04      | ZERO               | <b>Lower Bits:</b> Hardwired to 0 to set the region size to 32MB.  |                            | 0h                                   | RO         |
| 03           | PREF               | <b>Prefetchable:</b> Hardwired to 0 to indicate that the region is not prefetchable.   |                            | 0h                                   | RO         |
| 02 : 01      | TYP                | <b>Addressing Type:</b> Hardwired to 0 to indicate a 32-bit region.  |                            | 00b                                  | RO         |
| 00           | MEM                | <b>Memory Space Indicator:</b> Hardwired to 0 to identify the region as in memory space.   |                            | 0h                                   | RO         |

Table 35-159 defines the behavior of the ADDR field in MMBAR along with the resulting number of devices (chip selects) that the LEB supports for the configuration. The device count depends on the 16/32MB mode that the EXP\_TIMING\_CS[0-7] registers in the LEB controller select (refer to Section 42.5.1.1, “EXP\_TIMING\_CS0 - Expansion Bus Timing Register” and Section 42.5.1.2, “EXP\_TIMING\_CS[1-7] - Expansion Bus Timing Registers”). Specifically, the LEB is in 32MB mode if bit 9 (this bit is in the CNFG\_4\_0 field) in any of these registers is set, otherwise it is in 16MB mode.

Table 35-159 defines the behavior of the ADDR field in MMBAR.

**Table 35-159.MMBAR ADDR Field Behavior**

| LEBSIZE | ADDR Field |              | BAR Size | Number of LEB Devices Supported <sup>a</sup> |           |
|---------|------------|--------------|----------|--|-----------|
|         | RW Bits    | RO Zero Bits |          | 16MB Mode                                    | 32MB Mode |
| 0       | None       | 31:25        | Zero     | None   | None      |
| 1       | 31:25      | None         | 32 MB    | 2  | 1         |
| 2       | 31:26      | 25           | 64 MB    | 4  | 2         |
| 3       | 31:27      | 26:25        | 128 MB   | 8  | 4         |
| 4       | 31:28      | 27:25        | 256 MB   | 8  | 8         |

a. The number of LEB devices supported depends on the device mode (16MB or 32MB) mode selected of the EXP\_TIMING\_CS[0-7] registers in the LEB controller.

**35.12.1.10 Offset 2Ch: SVID – Subsystem Vendor ID Register**

This register is a write-once register. Once any byte in the register has been written, the register locks against further writes until reset.

**Table 35-160.Offset 2Ch: SVID: Subsystem Vendor ID Register**

|                     |                           |   |                                   |  |                   |

### 35.12.1.20 Offset E4h: SCID – Signal Target Capability ID Register

The Signal Target Capability record defines how the device targets its signals to IA agents. It is an 9B vendor-specific capability record and includes the SCID, SCP, SBC, STYP, SMIA, and SINT fields of the configuration header.

For more information on signaling by AIOC devices, see [Section 35.4, “Interrupt Handling for AIOC Devices”](#) on page 1235.

**Table 35-170.Offset E4h: SCID: Signal Target Capability ID Register**

§ §

## 36.0 AIOC Interfaces

---

### 36.1 Overview

The AIOC interfaces include:

- Gigabit Ethernet MACs
- TDM interface  
Note: This interface is only available on the Intel® EP80579 Integrated Processor with Intel® QuickAssist Technology. See [Table 47-1, "Base Features of EP80579 SKUs" on page 1730](#).
- Local Expansion Bus interface
- Controller Area Network interfaces
- IEEE-1588 time synchronization hardware assist unit
- Synchronous Serial Port (SSP)

The details for the TDM interface are available in the software for the Intel® EP80579 Integrated Processor product line enabling documentation.

### 36.2 Gigabit Ethernet (GbE)

The three Gigabit Ethernet controllers off-load various tasks from the IA-32 core to improve performance. This off-load is often times referred to as "Network Interface Card" or NIC functionality.

Provided features fall into these five general categories:

- MAC features
- Host off-loading
- Link interface
- Power Management (Wake On LAN)
- Serial EEPROM Interface
- Integrated DMA

The GbE controller is based on an Intel fourth-generation Gigabit MAC to provide a standard IEEE 802.3 Ethernet interface for 1000BASE-T, 100BASE-T, and 10BASE-T applications (802.3, 802.3u, and 802.3ab). The controller is capable of transmitting and receiving data rates of 1,000 Mbps, 100 Mbps or 10 Mbps.

By using hardware acceleration, the controller is able to off-load tasks, such as checksum calculations and TCP segmentation from the host processor.

The native interfaces supported by the GbE controller are MII and GMII. Protocol translation gaskets are used to provide the RMII and RGMII interfaces.

Power management features include support for APM and ACPI. Each controller supports the D0 and D3 states including internal clock gating for reduced power consumption in the D3 state. Further, one controller is located in an independent auxiliary power well for particularly power sensitive applications.

The DMA function provides the capability for packet data transfer and descriptor management. The GbE controller is able to cache up to 64-packet descriptors. A 64-KByte, on-chip packet buffer maintains performance as available bandwidth changes.

Finally, each controller is capable of self-configuration via an optional, external serial EEPROM.

### 36.2.1 Integrated DMA Features

- Performs descriptor-driven receive packet transfers from Rx MAC to system memory.
- Performs descriptor-driven transmit packet transfers from system memory to Tx MAC.
- Separate transmit and receive DMA engines.
- 64-entry descriptor caches for transmit and receive.
- Descriptor ring management hardware.
- Configurable 64KB packet buffer.

### 36.2.2 MAC Features

The MAC controller's CSMA/CD unit handles all the IEEE 802.3 receive and transmit MAC functions while interfacing between the DMA and link interface (RMII/RGMII) The MAC unit supports:

- Complete CSMA/CD function supporting IEEE 802.3 (10Mb/s), 802.3u (100Mb/s), 802.3z and 802.3ab (1000Mb/s).
- Half- and full-duplex operation at 10/100.
- Full-duplex operation at 1000 Mbps.
- Up to 16 addresses for exact match unicast/multicast address filtering.
- Multicast address filtering based on 4,096-bit vectors in addition to promiscuous unicast and promiscuous multicast filtering.
- MAC strips IEEE 802.1q VLAN tags and filters packets based on their VLAN ID. Up to 4,096 VLAN tags are supported.
- Transmit path supports insertion of VLAN tag information on a packet-by-packet basis.
- Flow control as defined in IEEE 802.3x as well as specific operation of asymmetrical flow control defined by IEEE 802.3z and software controllable pause times and threshold values.
- Programmable host memory receive buffers (256 Byte to 16 KByte) and cache line size (16 to 256 Byte).
- 16 KByte configurable transmit and receive FIFO buffers with ECC protection.
- Wakeup.
- ACPI down functionality supporting D0 & D3 states.

### 36.2.3 Host Off-Loading Features

The GbE controller provides the ability to off-load IP, TCP, and UDP checksum for transmit, packet filtering, and hardware VLAN support. The functionality provided by these features significantly reduce the IA processor utilization by shifting the burden of the functions from the driver to the hardware.

- IPv4 checksum calculation
- TCP/UDP checksum calculation
- 16 KByte jumbo-frame support
- Interrupt coalescing (multiple packets per interrupt)
- TCP segmentation for transmits that off-loads packet segmentation and encapsulation
- RMON statistics
- IPv6 support for IP/TCP and IP/UDP receive checksum off-load
- IP v6 wake-up filters
- IP v6 TCP segmentation

### 36.2.4 Interfaces

The GbE controller provides the following serial interfaces:

- RMII — 8-pin interface
- RGMII — 12-pin interface
- MDIO/MDC Interface

*Note:*

For information on PHY selection:

1. Go to <http://www.intel.com/go/soc>.
2. Select the "Technical Documentation" tab.
3. Search for "Ethernet PHY Selection Criteria for the Intel® EP80579 Integrated Processor product line".

### 36.2.5 Power Management

Each controller supports the following Power Management related features:

- Power states of D0 & D3hot with optional D3cold support.
  - D3cold support on GbE0 only.
- Wake On LAN.

Each GbE may be configured to generate a PME signal on the reception of a Magic packet or a network wake-up packet. A combination of pre-defined and user configurable filters are provided to support this functionality. The PME\_N wake-up signals from all GbE units are wired-OR together and brought out to a single external pin. This pin should be externally wired to the PME\_N pin of the ICH.

When transitioned to the D3hot state, the GbE controller internally performs clock-gating on many of its blocks to reduce power.

Additionally, one of the GbE controllers (GbE0) is located in the auxiliary power well. This allows monitoring of LAN traffic on this interface while the rest of the EP80579 is in ultra-low-power mode. The details of power well manipulation is outside the scope of this chapter and the reader is referred to [Chapter 37.0, "Gigabit Ethernet Controller"](#) for details.

### 36.2.6 Serial EEPROM Interface

A single four-wire Microwire\* interface is provided for connection of an optional, externally connected serial EEPROM. The serial EEPROM may be used to provide configuration information to the GbE controllers upon power-up or reset. All three controllers share the same EEPROM. A fixed priority arbiter controls access to the EEPROM where highest priority is given to GbE 0 then GbE 1 and finally GbE 2.

Software may also access this EEPROM. It can either use the controller built in to the MAC to read the EEPROM, or access the EEPROM directly using the EEPROM's 4-wire interface via registers also provided in the MAC.

## 36.3 Local Expansion Bus Interface (LEB)

The Local Expansion Bus Controller (LEB) provides a low-speed interface to external expansion target devices.

The Expansion Bus Controller includes a 25-bit address bus and a 16-bit-wide data path. The Expansion Bus controller maps transfers between the EP80579 and external devices. The Expansion Bus supports these target devices:

- Intel multiplexed
- Intel non-multiplexed
- Intel StrataFlash® technology
- Intel StrataFlash® Synchronous Memory
- Micron\* Flow-Through ZBT
- Motorola\* multiplexed
- Motorola\* non-multiplexed
- Texas Instruments\* Host Port Interface\* (HPI)

Applications having less than 16-bit, external target devices may connect to an 8-bit interface. For TI DSPs that support an internal bus width of 32 bits, the multiplexed HPI-8 or HPI-16 interface can be used to complete these transfers.

The Expansion Bus Controller features include:

- Outbound transfers — the EP80579 is the master to an external target device.
- Eight programmable target chip selects.
- Twenty-five bits of address; 16 bits of data.
- Supports Intel-mode and Motorola-mode bus cycles.
- Supports Intel StrataFlash.
- Supports 66-MHz Synchronous Intel StrataFlash Memory (16-bit only).
- Supports 16-bit Micron\* Flow-Through ZBT (Zero bus turnaround) SRAMS.
- Supports 8-bit and 16-bit Texas Instruments\* *HPI specifications*.
- Multiplexed or non-multiplexed address/data buses for Intel/Motorola/HPI bus cycles.

- Supports even- and odd-parity generation and calculation.
- Maximum clock input frequency of 80 MHz.

## 36.4 Serial Synchronous Port (SSP)

The SSP is a full-duplex, synchronous, serial interface. It can connect to a variety of external analog-to-digital (A/D) converters, audio and telecom CODECs, and many other devices that use serial protocols for transferring data.

The interface supports National Microwire\*, Texas Instruments\* Synchronous Serial Protocol (SSP), and Motorola\* Serial Peripheral Interface (SPI) protocol.

Key features of the SSP Port are:

- Operates in master mode (the attached peripheral functions as a slave).
- Supports serial bit rates from 7.2 Kb/s to 1.84 Mb/s.
- Serial data formats may range from 4 to 16 bits in length.
- Two on-chip register blocks function as independent FIFOs for data, one for each direction.
- The buffers are 16 entries deep x 16 bits wide.

Buffers may be burst-loaded or emptied by the system processor using SRAM-like burst transfers, from 1 to 8 words per transfer. Each 32-bit word from the system fills one entry in a FIFO using the lower half 16-bits of a 32-bit word.

## 36.5 Controller Area Network (CAN)

The Controller Area Network (CAN) is a serial bus system used in a broad range of embedded as well as automation control systems. It usually links two or more microcontroller-based physical devices.

CAN protocol is based on a broadcast communication mechanism. This broadcast communication is achieved by using a message-oriented transmission protocol. In this protocol, station and station addresses are not defined. Only messages are defined.

These messages are identified by using a message identifier. The message identifier has to be unique within the whole network and it defines not only the content but also the priority of the message.

A high degree of system and configuration flexibility is achieved as a result of the content-oriented addressing scheme. This content-oriented addressing scheme allows for a high degree of system and configuration flexibility.

It is very easy to add stations to a existing CAN network without making any hardware or software modifications to the existing stations as long as the new stations are purely receivers. This allows the concept of modular electronics and also permits multiple reception and the synchronization of distributed processes. Data needed as information by several stations can be transmitted via the network in such a way that it is unnecessary for each station to have to know who the producer of the data is. This allows easy servicing and upgrading of networks as data transmission is not based on the availability of specific types of stations.

Key features include:

- Support for CAN 2.0B protocol
- Support for 11-bit and 29-bit identifiers
- Bit rates up to 1 Mbps

- Clock frequency of 40 MHz

## 36.6 IEEE 1588 Time Synchronization Hardware Assist

In a distributed control system containing multiple clocks, individual clocks tend to drift apart. Some kind of correction mechanism is necessary to synchronize the individual clocks to maintain global time, which is accurate to some requisite clock resolution. The IEEE 1588 standard for a precision-clock-synchronization protocol for networked measurement and control systems can be used for this purpose.

The IEEE standard defines several messages that can be used to exchange timing information. The hardware-assist logic required to achieve precision clock synchronization using the IEEE 1588 standard is left to implementation.

The time-synchronization logic monitors the internal MII/GMII signals on two of the three Gigabit Ethernet interfaces. Additionally, this block monitors both CAN interfaces.

An interrupt signal to the IA-32 core is generated when any of the following conditions occur and are enabled:

- Target time expiration
- Auxiliary Master Mode snapshot is taken
- Auxiliary Slave Mode snapshot is taken

The System Time and Target Time registers are both 64 bits wide. When the system time is greater than or equal to the target time, the target time expiration condition will set. An interrupt enable mask must be set to allow the target time interrupt to pass to the core.

## 37.0 Gigabit Ethernet Controller

---

### 37.1 Overview

The three Gigabit Ethernet controllers off load various tasks from the IA-32 core to improve performance. This off load is often times referred to “Network Interface Card” or NIC functions. The Gigabit Ethernet controller is based on an Intel fourth generation Gigabit MAC to provide a standard IEEE 802.3 Ethernet interface for 1000BASE-T, 100BASE-TX, and 10BASE-T applications. The controller is capable of transmitting and receiving data rates of 10/100/1000 Mbps. The Convergence and PMD Sublayer communication of the Physical Layer are implemented in MII/GMII (internally) and RMII/RGMII (externally).

*Note:* The RGMII, and RMII, while not natively supported in the Gigabit Ethernet controller are supported by protocol translators between the Gigabit Ethernet controller and the pins.

*Note:* For information on PHY selection:

1. Go to <http://www.intel.com/go/soc>.
2. Select the "Technical Documentation" tab.
3. Search for "Ethernet PHY Selection Criteria for the Intel® EP80579 Integrated Processor product line".

#### 37.1.1 Terminology and Conventions

##### 37.1.1.1 Register and Bit References

This document refers to device register names with all capital letters. To refer to a specific bit in a register the convention REGISTER.BIT is used. For example, CTRL.BEM refers to the Big Endian Mode bit in the [Device Control Register \(CTRL\)](#).

##### 37.1.1.2 Byte and Bit Designations

This document uses “B” to abbreviate quantities of bytes, i.e. a 4KB represents 4096 bytes. Similarly, “b” is used to represent quantities of bits, i.e. 100Mbps represents 100 Megabits per second.

##### 37.1.1.3 Numbering

All numbers are in decimal unless otherwise indicated. Hexadecimal numbers will be preceded by a 0x or followed by an h. If not clear from the context, binary numbers will be followed by a b or (b). Single bits are generally given as simply 0 or 1, since the value is identical in binary or decimal.

#### 37.1.1.4 Memory Alignment Terminology

Some GbE data structures have special memory alignment requirements. This implies that the starting physical address of a data structure must be aligned as specified in this GbE chapter. The following terms are used for this purpose:

- BYTE alignment implies that the physical addresses can be odd or even. Examples: 0FECBD9A1h, 02345ADC6h.
- WORD alignment implies that physical addresses must be aligned on even boundaries; i.e., the last nibble of the address may only end in 0, 2, 4, 6, 8, Ah, Ch, or Eh. For example, 0FECBD9A2h.
- DWORD (Double-Word) alignment implies that the physical addresses may only be aligned on 4-byte boundaries; i.e., the last nibble of the address may only end in 0, 4, 8, or Ch. For example, 0FECBD9A8h.
- QWORD (Quad-Word) alignment: Implies that the physical addresses may only be aligned on 8byte boundaries; i.e., the last nibble of the address may only end in 0, or 8. For example, 0FECBD9A8h.
- PARAGRAPH alignment implies that the physical addresses may only be aligned on 16-byte boundaries; i.e., the last nibble must be a 0. For example, 02345ADC0h.

#### 37.1.1.5 Alignment and Byte Ordering

It should be noted that the data stream in Ethernet has no notion of byte alignment. All data on the wire is referenced as bit ordered. Data is presented “on the wire” least significant bit (lsb) first.

For example: A big-endian destination address in the Ethernet header may be represented in as 0x00\_11\_22\_33\_44\_55. In this case, the data is seen on the wire in the byte order as written from left to right, however the bits are seen lsb first, i.e. bit 0 of the first “00” byte occurs first.

Representations of these fields internal to the EP80579 may reverse the byte ordering as shown above. Care must be taken to avoid byte ordering errors when programming the device.

Refer to [Section 37.5.14, “Endianness” on page 1422](#) and [Section 3.6, “Endianness” on page 119](#).

#### 37.1.1.6 Packet Buffer

The GbE Packet Buffer (PB) is an ECC protected 64KB dedicated memory used for buffering transmit and receive packets as they are communicated. The proportions of the PB dedicated to TX and RX operations is software configurable.

Throughout this chapter, the TX portion of PB is referred to as the TX FIFO and the RX portion of the PB is referred to as the RX FIFO. These terms are interchangeable.

It is also worthwhile to note that any information in the PB, either for incoming or outgoing data, is volatile. The GbE will receive packets into the RX PB and transfer the RX descriptor(s) and payload into host memory for the host CPU before sending interrupt notification. Conversely, the host CPU will transfer TX descriptor(s) and payload into host memory for the GbE before notifying the GbE that the packet information is available. After this notification, the GbE transfers the TX information to the TX PB and sends the data out on the wire. The host CPU will never have to directly access the GbE’s PB, however diagnostic access is supported.

### 37.1.2 Wake On LAN

The GbE does not support preservation of Magic Packets for Wake On LAN. Additionally, the storage of other packets received after a qualifying wake event is not supported until the GbE has been returned to a D0a state. If the GbE was in D3 then it must be specifically moved to D0 by the IA software writing to the Power Capability register or Reset must be cycled and the GbE re-initialized. Software intervention is required to move the GbE to D0a and restart packet receive processing.

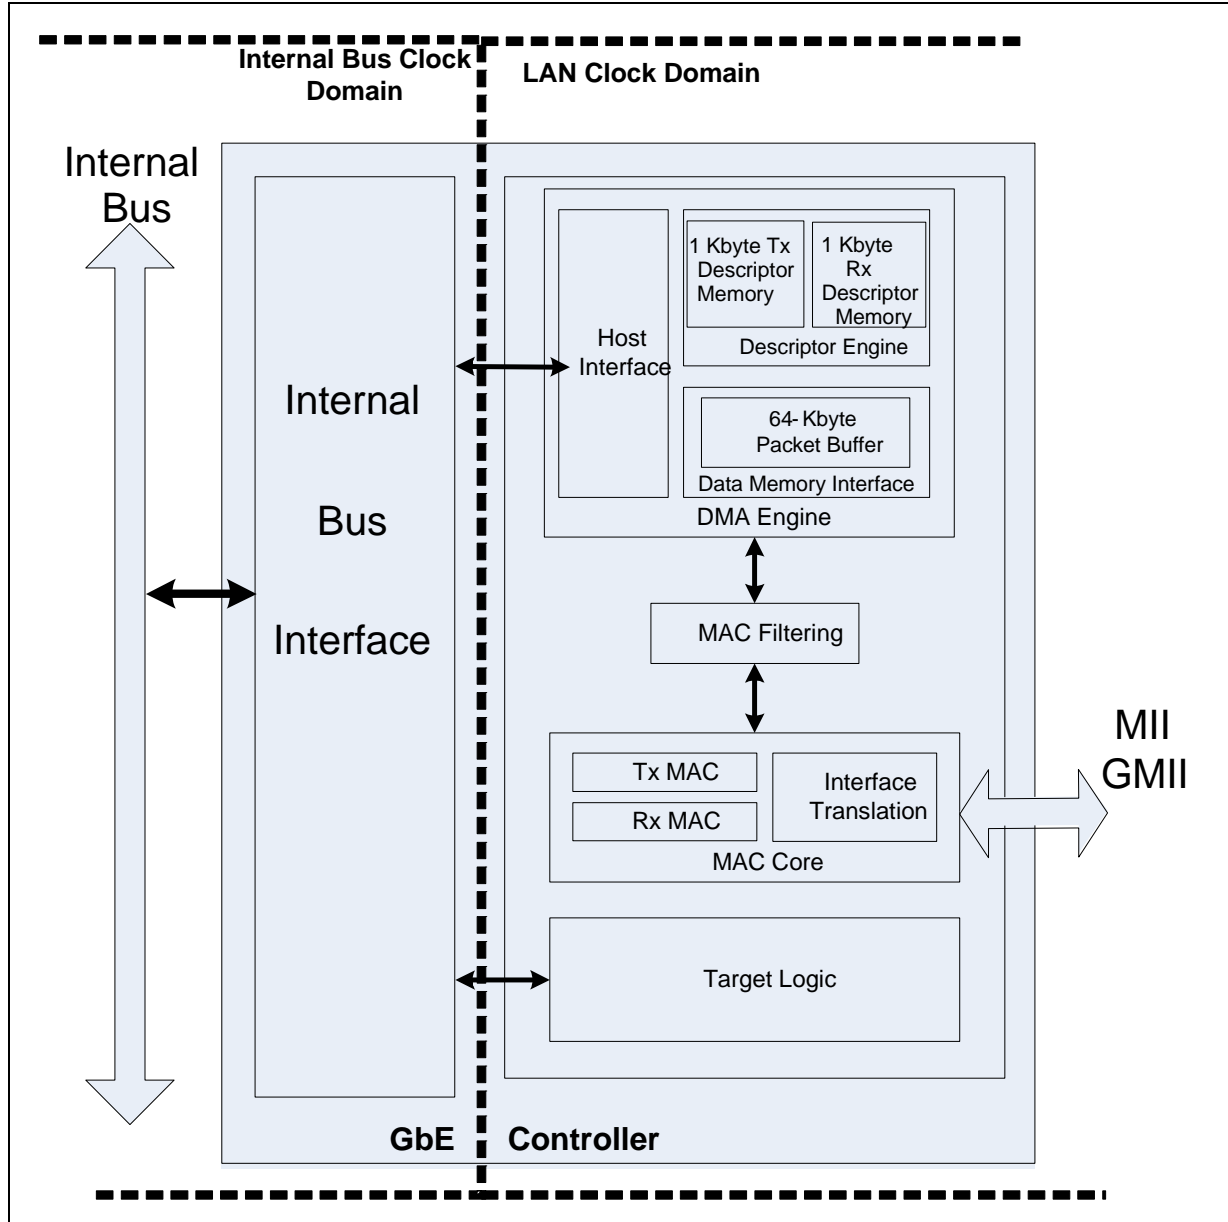

## 37.2 Feature List

The following is a list of GbE MAC features:

- Compliant with the 1000 Mbps Ethernet/802.3z specification.
- Half-duplex MII operation.
- Full-duplex operation at all MII and GMII speeds.
- Programmable system memory receive buffers (256B to 16KB).
- 64B cache-line size.
- 64KB RX/TX packet buffer (defaulted to 48 KB RX and 16 KB TX, but configurable).
- Descriptor ring management hardware for TX packet buffer.
- Support for little-endian or big-endian byte ordering.
- Flow Control Support: send/receive PAUSE frames & receive FIFO thresholds.
- Statistics for Local Management and Software Optimization.
- A mechanism for delaying/reducing transmit interrupts.
- Functional and Error interrupt signals.
- Software-controlled reset bit.
- Frame formats supported by the EP80579's GbE include:
  - Ethernet 802.3
  - IEEE 802.1q VLAN (Ethernet 802.3ac)
  - Ethernet Type 2
  - Ethernet SNAP
  - IPv4 headers with options
  - IPv6 headers with IP option next headers.
  - IPv6 packet tunneled in IPv4.
  - TCP with options.
  - UDP with options.
- Multi-speed operation: 10/100/1000 Mbps.
- All local memories and buffers are protected.

### 37.3 Functional Block Diagram

Figure 37-1. GbE Controller Block Diagram

The internal bus interfaces provide the access to the GbE CSRs as well as the medium over which ethernet packets are transferred between the Ethernet client and the EP80579.

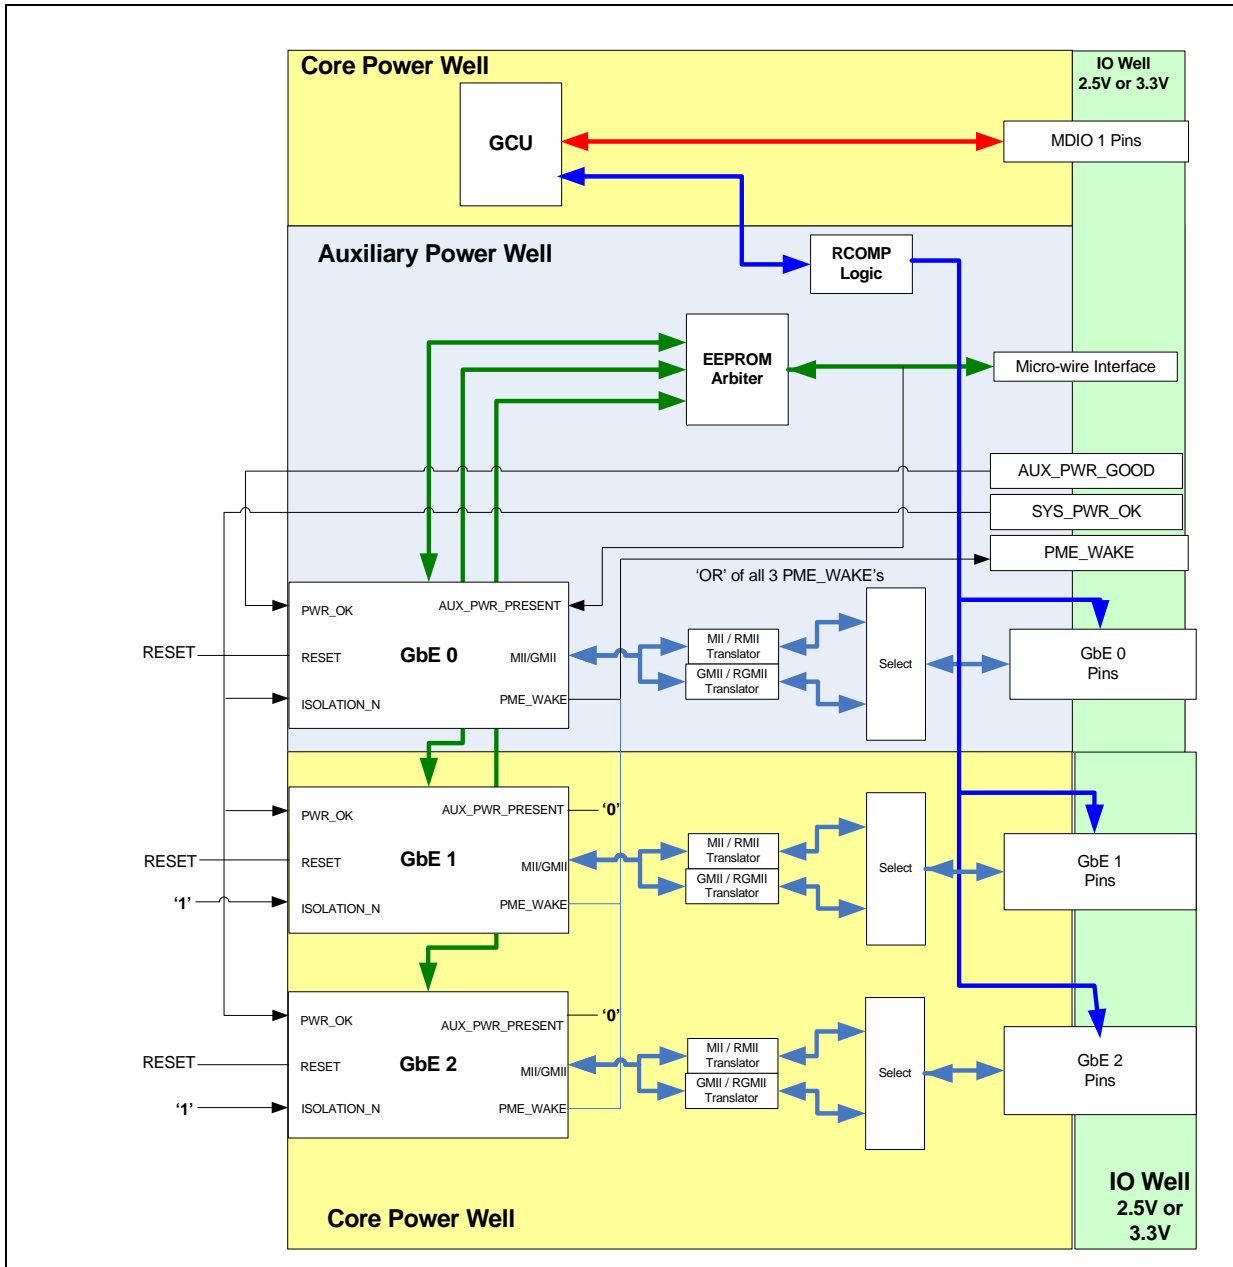

The DMA Engine buffers the packets between system memory and the MAC Core. The MAC Core transfers packets between the DMA Engine and the Ethernet Client. The internal bus interface accepts the PCI Configuration transactions and routes those transactions to the proper internal LAN module. These blocks all operate in the LAN clock domain.

### 37.4 Usage Model

The EP80579 implements three GbE controllers. In addition to the three controllers, protocol translation gaskets and an MDIO interface are provided. Also, a multiplexor to allow the three GbE controllers to share access to a common serial EEPROM is implemented. A block diagram of these units is shown in Figure 37-2:

Figure 37-2. GbE Ethernet Complex

### 37.4.1 Protocol Translation

While the GbE's does not natively support RGMII or RMII a protocol translator is implemented between the GbE and the pins that converts RGMII to GMII and RMII to MII for the GbE. Even though the pins may be using an RGMII or RMII protocol the GbE is still only communicating in its native GMII and/or MII protocols.

The selection of the appropriate translator is controlled by the Auxiliary Device Control Register. Refer to [Section 37.6.2.4, "CTRL\\_AUX – Auxiliary Device Control/Status Register"](#)

Note that when the translator selection register has enabled RGMII, the GbE must be configured to GMII/MI operation. Likewise, when the settings have enabled RMII, the GbE must be configured to MII operation.

### 37.4.2 Power Management

As shown in [Figure 37-2, "GbE Ethernet Complex" on page 1345](#), GbE0 is located in a separate auxiliary power well. This gives the user the ability to bring the rest of the chip into an ultra-low power mode (power removed) while GbE0 continues to operate in D3cold to support Wake On LAN. If a separate auxiliary power source is used for GbE0, then platform must also supply an Aux\_Pwr\_Good signal which is asserted to indicate that the auxiliary power supply is stable and that the reference clock for the GbE is stable. Additionally, the EEDI pin should be pulled-up to provide the internal aux\_pwr\_present signal indicating that an auxiliary supply is being used. If an auxiliary power supply is not being used and the power supplied to the auxiliary well is the same as that for the core logic, then EEDI must be tied low. In this situation the same signal as provided to Sys\_Pwr\_OK is also routed to Aux\_Pwr\_Good.

Note that if an auxiliary supply is used for GbE0 then the corresponding PHY and also the serial EEPROM, if present, must be powered.

Refer to the [Section 6.3.2, "Power Management Support"](#) and [Section 37.5.10, "Wake on LAN"](#) for more details.

### 37.4.3 Software Initialization and Diagnostics

This section discusses general software notes for the GbE, especially initialization steps. This includes general hardware power-up state, basic device configuration, initialization of transmit and receive operation, link configuration, software reset capability, statistics, and diagnostic hints.

#### 37.4.3.1 Power Up State

When the MAC powers up it will read the optional EEPROM. The EEPROM contains sufficient information to bring the link up and configure the MAC for manageability and/or APM wakeup. However, software initialization is required for normal operation and if the EEPROM is not present.

The power-up sequence, as well as transitions between power states, is described in [Section 37.7.3, "Power States" on page 1550](#). The detailed timing is given in [Section 37.7.4, "Timing of Power-State Transitions" on page 1551](#). [Section 37.6, "GbE Controller Register Summary" on page 1425](#) gives detailed registers descriptions with details on power on defaults.

### 37.4.3.2 Memory Initialization

The GbE's internal memory must be initialized after the GbE unit has been powered-up, to insure that no ECC or parity errors are generated from the random state of memory after a power-up. If an ECC or parity error is encountered, a soft reset must be issued, then the entire affected memory (that reported the error) must be re-initialized to remove the error, so that it doesn't re-occur.

After each power-up and soft reset, and after the memories have been initialized as described below, software must clear the appropriate ECC disable bits described in [Section 37.6.8.3, "MEM\\_STS – Memory Error Status Register" on page 1546](#). Neither ECC nor parity errors will be reported nor will the GbE error handling be enabled (as described in [Section 37.5.12, "Error Handling" on page 1418](#)) until these bits have been cleared out. These may be cleared immediately after a soft reset if the error condition that resulted in the soft reset did not involve an ECC or parity error from one of these memories.

#### 37.4.3.2.1 Packet Buffer Memory

The Packet Buffer memory is initialized through write accesses to the PBM locations. A single PBM access will initialize four locations within the Packet Buffer memory, using address bits 15:4 of the PBM access to select the 128bit Packet Buffer Memory location. Therefore, 4096 writes are required to initialize the 64KB of packet memory, writing every four PBM locations (PBM(0), PBM(4), PBM(8), etc.).

#### 37.4.3.2.2 Descriptor Tx and Rx Memory

The Descriptor Tx and Rx memories are each initialized through write accesses to the TXDESCM and RXDESCM locations. A single DESCCTX or DESCRX access will initialize four locations within the Descriptor memory, using address bits 15:4 of the access to select the 128bit Descriptor Memory location. Therefore, 64 writes are required to initialize the 1KB of descriptor memory, writing every four DESC locations (DESCRX(0), DESCRX(4), DESCRX(8), etc.).

#### 37.4.3.2.3 Multicast Filter and Special Packets Memory

The Multicast and VLAN filter memories are each initialized through write accesses to the MTA and VFTA locations as described in [Section 37.6.4.14, "MTA\[0-127\] – 128 Multicast Table Array Registers" on page 1488](#) and [Section 37.6.4.17, "VFTA\[0-127\] – 128 VLAN Filter Table Array Registers" on page 1490](#). Initialization will require 128 writes to initialize the 512B of descriptor memory, writing every MTA or VLAN filter location.

#### 37.4.3.2.4 Flexible Filter Memory

The Flexible Filter memories are each initialized through write accesses to the FFVT and FFMT locations as described in [Section 37.6.7.12, "FFVT\[0-127\] – Flexible Filter Value Table Registers" on page 1543](#) and [Section 37.6.7.11, "FFMT\[0-127\] – Flexible Filter Mask Table Registers \(0x9000 - 0x93F8; RW\)" on page 1542](#).

Initialization will require 128 writes to initialize the 512B of descriptor memory, writing every MTA or VLAN filter location. Initialization will require 256 writes to initialize the memories, writing every one of the 128 FFMT and FFVT locations.

#### 37.4.3.2.5 Statistics Memory

The Statistics memory provides no write access, but is initialized by the GbE automatically after a power-up reset or software reset.

### 37.4.3.3 General Configuration

Several values in the [CTRL – Device Control Register](#), [CTRL\\_EXT – Extended Device Control Register](#) and [CTRL\\_AUX – Auxiliary Device Control/Status Register](#) need to be set upon power up or after a device reset for normal operation.

- Convergence Layer Mode of the MAC is programmed by the [CTRL\\_EXT.LINK\\_MODE](#) setting. This value may also be read by software from the [STATUS – Device Status Register](#) at [STATUS.TBIMODE](#).
- Duplex mode is determined via Auto-Negotiation between the external PHY and its link partner. Software either continuously polls the PHY registers via MDIO until a link is detected or the host CPU is interrupted when the link is established via the PHY's MDINT capability. Software then programs [CTRL.FD](#) per the interface negotiation. Status information can be found at [STATUS.FD](#).
- Speed is determined via Auto-Negotiation between the external PHY and its link partner. Software either continuously polls the PHY registers via MDIO until a link is detected or the host CPU is interrupted when the link is established. Software then programs [CTRL.SPEED](#) per the interface negotiation. Status information can be found at [STATUS.SPEED](#).
- Desired endianness configuration must be set in [CTRL\\_AUX](#).

### 37.4.3.4 Link Setup Mechanisms and Control/Status Bit Summary

- MAC duplex and speed settings forced by software based on resolution of PHY
  - [CTRL.FD](#) and [CTRL.SPEED](#) is set by software based on reading PHY status register after PHY has successfully auto-negotiated a link with the link partner.
  - [CTRL.RFCE](#) and [CTRL.TFCE](#) must be set by software after reading flow control resolution from PHY registers

### 37.4.3.5 Receive Initialization

Software must program the Receive Address Low Register (RAL) and Receive Address High Register (RAH) registers to represent the receive address(es) per the station address. The station address (a.k.a the MAC address) is [RAL/RAH\(0\)](#), fifteen additional receive addresses can be programmed in addition to this.

Software must also set up the 128 Multicast Table Array Registers ([MTA\[127:0\]](#)). This probably means zeroing all entries initially and adding in entries to the Multicast Table Array as requested.

[Figure 37-3](#) diagrams the multicast lookup algorithm. The destination address shown represents the internally stored ordering of the received Destination Address. Note that bit 0 indicated in this diagram is the first on the wire. Refer to [“Ethernet Addressing” on page 1351](#) for more details. Note that the bank bits is the [RCTL.MO](#) setting.

Program the Interrupt Mask Set/Read Register (IMS) to pass any interrupt the driver cares about to the Interrupt Controller for routing further to the EP80579's IA-32 core. Suggested bits include [IMS.RXT0](#), [IMS.RXO](#), and [IMS.RXDMT0](#).

Program Receive Control Register (RCTL) with appropriate values. If initializing, it is necessary to leave the receive logic disabled, [RCTL.EN](#) = 0, until after the receive descriptor ring has been initialized. If VLANs are not used, software should clear [RCTL.VFE](#). Then there is no need to initialize the 128 VLAN Filter Table Array Registers ([VFTA\[127:0\]](#)). Initialize the remainder of RCTL as desired, refer to [“Section 37.6.4.1, “RCTL – Receive Control Register”](#) or details.

Figure 37-3. Multicast Table Array Algorithm

To properly receive packets requires only that the receiver is enabled. This should be done only after all other setup is accomplished. If software uses the Receive Descriptor Minimum Threshold Interrupt ( $IMS.RXD\text{MT}0 = 1$ ), that Receive Threshold value should be set in the Flow Control Receive Threshold Low Register (FCRTL) and Flow Control Receive Threshold High Register (FCRTH) MMRs.

Allocate a contiguous region of memory for the receive descriptors. Program the receive descriptor region into the following MMRs describing the memory region:

- Receive Descriptor Base Address Low Register (RDBAL)
- Receive Descriptor Base Address High Register (RDBAH)
- Receive Descriptor Length Register (RDLEN)

The Receive Descriptor Head Register (RDH) and Receive Descriptor Tail Register (RDT) pointers are initialized (by hardware) to 0 after a power-on or a software-initiated device reset. Receive buffers of appropriate size should be allocated using RCTL.BSEX and RCTL.BSIZE. Pointers to these buffers should be stored in the descriptor ring. The tail pointer should be set to point one descriptor beyond the end.

### 37.4.3.6 Transmit Initialization

Packet transmission is configured via the Transmit Control Register (TCTL). For example, values for this MMR could be:

- TCTL.CT = 0x0F
- TCTL.COLD = 0x200 (512d); for half-duplex mode
- TCTL.COLD = 0x040 (64d); for full-duplex mode
- TCTL.PSP = 1

*Note:* Not all of these values are needed in all duplex modes, but it is more concise to simply always program them to the values shown regardless of mode.

Program the Transmit IPG Register (TIPG) with the following values to get the minimum legal inter packet gap (IPG):

- TIPG.IPGT = 0x8 (8d)
- TIPG.IPGR1 = 0x8 (8d)
- TIPG.IPGR2 = 0x6 (6d)

*Note:* Not all of these values are needed in all duplex modes, but it is more concise to simply always program them to the values shown regardless of mode.

Allocate a contiguous region of memory for the transmit descriptor list. Program the transmit descriptor region into the following MMRs describing the memory region:

- Transmit Descriptor Base Address Low Register (TDBAL),
- Transmit Descriptor Base Address High Register (TDBAH),
- Transmit Descriptor Length Register (TDLEN),
- Transmit Descriptor Head Register (TDH), and
- Transmit Descriptor Tail Register (TDT).

### 37.4.3.7 Initialization of Statistics

Statistics registers are hardware-initialized to values as detailed in each particular register's description. No initialization of these registers through software is necessary.

### 37.4.3.8 GbE Line Rate Configuration Change

The GbE unit must be reconfigured when switching rates with the RGMII gasket. The following guidelines apply:

- Disable receiver and transmitter by setting the RCTL.EN and TCTL.EN bits to 0.
- Wait an appropriate time for any packet being received to finish.
- Write CTRL.SPEED, CTRL.FRCSPD, CTRL.FD, CTRL.FRCDPLX with the targeted interface parameters.
- Re-enable receiver and transmitter by setting the RCTL.EN and TCTL.EN bits to 1.

### 37.4.3.9 Network Boot

Initialization of the GbE controller at power-up and/or reset from an optional serial EEPROM is supported. Refer to [Section 37.5.11, "Serial EEPROM" on page 1412](#) for details on the use and configuration of the serial EEPROM.

*Note:* Section 22.2.4 of the IEEE 802.3 specification requires that PHY devices enter a normal operating state after power-up and/or reset without management intervention. As a result, it is believed that the MAC is not required to perform any sort of PHY initialization in the support of network boot.

### 37.4.3.10 Diagnostics

To assist in test and debug of device-driver software, a set of software-usable features have been provided. These features include controls for specific test-mode usage, as well as some registers for verifying device internal state against what the device-driver might be expecting.

The GbE provides software visibility (and controllability) into certain major internal data structures, including all of the transmit & receive FIFO space. However, interlocks are not provided for any operations, so diagnostic accesses should only be performed under very controlled circumstances.

The device also provides software-controllable support for certain loopback modes, to allow a device-driver to test transmit and receive flows to itself. Loopback modes may also be used to diagnose communication problems and attempt to isolate the location of a break in the communications path.

#### 37.4.3.10.1 FIFO Pointer Accessibility

The internal pointers into the transmit and receive data FIFOs are visible through the head and tail diagnostic data FIFO registers. Diagnostic software may read these FIFO pointers to confirm an expected hardware state following a sequence of operations. Diagnostic software may further write to these pointers as a partial-step to verify expected FIFO contents following specific operation, or to subsequently write data directly to the data FIFOs.

#### 37.4.3.10.2 FIFO Data Accessibility

The internal transmit and receive data FIFO contents are accessible through the Packet Buffer Memory (64KB) (PBM[n]) registers. The specific locations read/written are determined by the values of the FIFO pointers, which may also be read/written. When accessing the actual FIFO data structures, locations must be accessed as 32-bit words.

#### 37.4.3.10.3 Loopback Operations

Loopback transmit/receive operation is a recommended debug tool. There are two points where the transmit data can be looped back to the receive path: in the PHY and in the MAC.

It is highly recommended that the PHY selected to interface with the GbE has implemented loopback operations in order to assist with system and device debug. Loopback operation may be used to test transmit & receive aspects of software drivers, as well as verify electrical integrity of the connections between the GbE and the system.

All loopback modes are only allowed when the MAC and PHY are configured for full duplex operation.

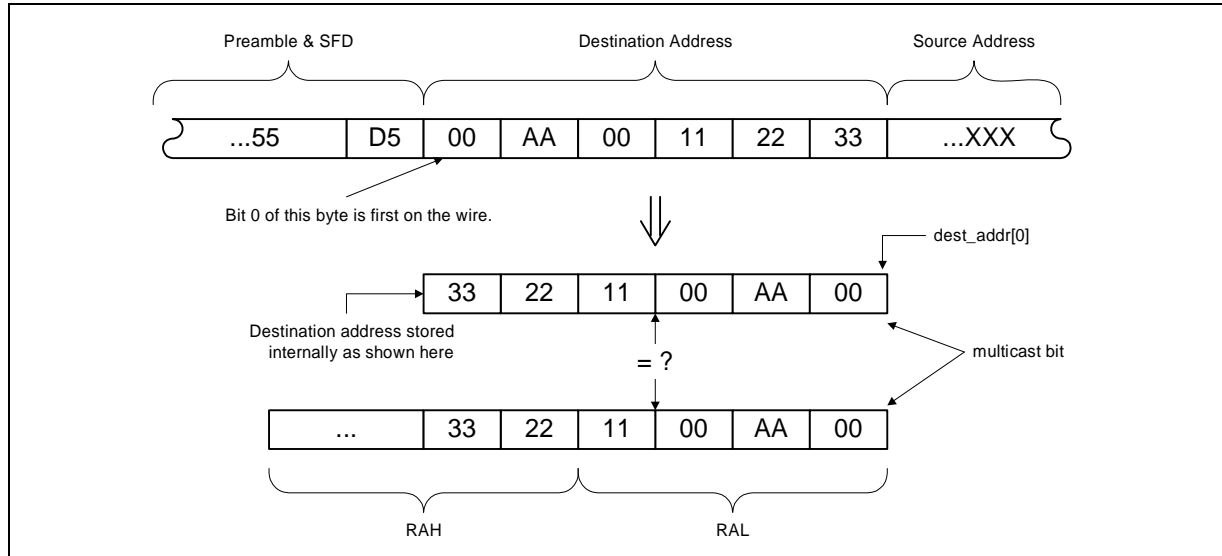

## 37.5 Functional Description

### 37.5.1 Ethernet Addressing

Several registers store Ethernet addresses in the GbE. Two 32-bit registers make up the address, the "high" and the "low". For example, the Receive Address Register is comprised of Receive Address High (RAH) and Receive Address Low (RAL). The least significant bit of the least significant byte of the address stored in the register (i.e., bit 0 of RAL) is the multicast bit. The LS byte is the first byte to appear on the wire. This notation applies to all Ethernet address registers including flow control.

Figure 37-4 illustrates the bit/byte addressing order comparison between what is on the wire and the values in the unique receive address registers.

**Figure 37-4. Example Address Byte Ordering**

The address byte order numbering from the above example maps as shown below in Figure 37-5. Byte #1 is the first on the wire.

**Figure 37-5. DA Byte Ordering**

| IA Byte Number   | 1 (lsB) | 2  | 3  | 4  | 5  | 6 (msB) |
|------------------|---------|----|----|----|----|---------|
| Byte Value (HEX) | 00      | AA | 00 | 11 | 22 | 33      |

*Note:* The notation in this document follows the above convention. For example, the above address would be indicated as 0x00\_AA\_00\_11\_22\_33, where the first byte (00\_) is the first byte on the wire with bit 0 of that byte transmitted first.

### 37.5.2 Interrupt Control & Tuning

The GbE provides a complete set of interrupts for efficient management by software. The interrupt structure is carefully designed to:

- Make accesses thread safe by using set and clear-on-read rather read-modify-write operations.
- Minimize the interrupts per work accomplished.
- Minimize the processing overhead associated with each interrupt.

The interrupt logic consists of four interrupt registers that accomplish the first goal. These registers are described in more detail in [Section 37.6.3, "Interrupt Registers: Detailed Descriptions" on page 1454](#).

Three actions minimize the number of interrupts: reducing the frequency of all interrupts, accepting multiple receive packets before signaling an interrupt, and by eliminating (or reducing) the need for interrupts on transmit. Refer to ["Interrupt Throttling Register" on page 1353](#), ["Receive Interrupts" on page 1360](#), and ["Transmit Interrupts" on page 1378](#) for details.

### 37.5.2.1 Interrupt Cause Set/Read Registers

The read register records the cause of the interrupt. All bits set at the time of the read are auto-cleared. The cause bit is set for each bit written as one in the set register. If there is a race between hardware setting a cause and software clearing an interrupt, the bit remains set. No race condition exists on writing the set register. Set provides for software posting of an interrupt. Reads are auto-cleared to avoid expensive write operations. Most systems have write buffering that minimizes overhead, but this typically requires a read operation to guarantee that the write has been flushed from posted buffers. Without auto-clear, the cost of clearing an interrupt can be as high as two reads and one write.

### 37.5.2.2 Interrupt Mask Set (Read)/Clear Registers

Interrupts appear only if the interrupt cause bit is a one and the corresponding interrupt mask bit is a one. Software blocks assertion of the interrupt wire by clearing the bit in the mask register. The cause bit stores the interrupt event regardless of the state of the mask bit. Clear and set make this register more “thread safe” by avoiding a read-modify-write operation on the mask register. The mask bit is set for each bit written to a one in the set register and cleared for each bit written in the clear register. Reading the set register returns the current value.

### 37.5.2.3 Interrupt Throttling Register

The frequency of functional interrupts from the network controller can be reduced when inter-interrupt interval value is non-zero. Controller asserts pending interrupts only at regularly scheduled intervals. When inter-interrupt interval value is zero, controller asserts pending interrupts immediately.

The Interrupt throttling register only applies to the GbE functional interrupt 0.

## 37.5.3 Hardware Acceleration Capability

The GbE provides CPU off loading capabilities. The functionality provided by these features may significantly reduce CPU utilization by shifting the burden of the functions from the driver to the hardware.

These features include:

- Receive & Transmit Checksum Off loading
- TCP Segmentation

These functions are covered in more detail in [“Receive Packet Checksum Off loading” on page 1363](#), [“Transmit Checksum Off loading” on page 1379](#), and [“TCP Segmentation” on page 1380](#). The following sections provide a brief overview of these capabilities.

### 37.5.3.1 Checksum Off-Loading

The GbE provides the ability to off load the IPv4, TCP & UDP checksum requirements from the software device driver. For common frame types, the hardware automatically calculates, inserts and checks the appropriate checksum values typically handled by software.

*Note:* IPv6 headers do not have a checksum.

For transmits where the device is doing non-TCP segmentation, every transmitted Ethernet packet may have two checksums calculated and inserted by the device. Typically these would be the IPv4 and either TCP or UDP checksums. The driver

specifies which portions of the packet are included in the checksum calculations, and where the calculated values are inserted, via descriptor(s). See [“TCP/IP Context Transmit Descriptor Format” on page 1369](#) for details.

For receives, the hardware recognizes the packet type and performs the checksum calculations as well as error checking automatically. Checksum and error information is provided to software via the receive descriptor(s). Refer to [“Receive Packet Checksum Off loading” on page 1363](#) for details.

### 37.5.3.2 TCP Segmentation

The GbE implements a TCP segmentation capability for transmits which allows the software device driver to off load packet segmentation and encapsulation to the hardware. The device driver may send the GbE the entire IP (IPv4 or IPv6), TCP, or UDP message sent down by the NOS for transmission. The device will segment the packet into legal Ethernet frames and transmit them on the wire. By handling the segmentation tasks, the hardware alleviates the software from handling some of the framing responsibilities. This reduces the overhead on the CPU for the transmission process thus reducing overall CPU utilization. See [“TCP Segmentation” on page 1380](#) for details.

### 37.5.4 Buffer and Descriptor Structure

Software allocates transmit and receive buffers and forms descriptors that contain pointers to and status of those buffers. A conceptual ownership boundary exists between the driver software and the hardware for buffers and descriptors.

Software gives hardware ownership of a queue of buffers for receive. These buffers store data that software acquires ownership of once a valid packet arrives.

For transmit, software maintains a queue of buffers. The software “owns” a buffer until it is ready to transmit. Software commits the buffer to the hardware at which time the hardware “owns” the buffer until data is transmitted or loaded in the transmit FIFO.

Descriptors store information about the buffers. They contain the physical address, length, and status information about the referenced buffer. An end-of-packet field indicates the last buffer for a packet.

The descriptors also contain packet specific information indicating type of packet and specific operations to perform in the context of transmitting a packet such as those for VLAN or checksum off load support. The following sections describe descriptor structure and operation in more detail in the context of packet transmission and reception.

### 37.5.5 Packet Reception

In the general case, packet reception consists of recognizing the presence of a packet on the wire, performing address filtering, storing the packet in the receive data FIFO, transferring the data to the receive buffer in host memory, updating the state of a receive descriptor, and setting the interrupt cause register to pass ownership of the received packet information to software.

#### 37.5.5.1 Packet Address Filtering

Hardware stores incoming packets in host memory subject to the following filter modes. If there is insufficient space in the receive FIFO for an incoming packet, hardware drops the packet and indicates the missed packet in the appropriate statistics registers.

The following filter modes are supported:

**Exact Unicast/Multicast** - The destination address must exactly match one of 16 stored addresses. These addresses can be unicast or multicast.

**Promiscuous Unicast** - Receive all unicasts.

**Multicast** - The upper bits of the incoming packet's destination address index a bit vector that indicates whether to accept the packet; if the bit in the vector is one, accept the packet, otherwise, reject it. The EP80579's GbE provides a 4096 bit vector. Software provides four choices of which bits are used for indexing. These are [47:36], [46:35], [45:34], or [43:32] of the internally stored representation of the destination address.

**Promiscuous multicast** - Receive all multicast packets.

**VLAN** - Receive all VLAN packets that are for this station and have the appropriate bit set in the VLAN filter table. A detailed discussion and explanation of VLAN packet filtering is contained in "802.1q VLAN Packet Filtering" on page 1401.

Normally, only good packets are received. These are defined as those packets with no CRC error, symbol error, sequence error, length error, alignment error, or where carrier extension or RX\_ERR errors are detected. However, if the store-bad-packet bit is set in the Device Control register (RCTL.SBP), then bad packets that pass the filter function are stored in host memory. Packet errors are indicated by error bits in the receive descriptor (RDESC.ERRORS). It is possible to receive all packets, regardless of whether they are bad, by setting the promiscuous enables and the store-bad-packet bit.

### 37.5.5.2 Receive Data Storage

Memory buffers pointed to by descriptors store packet data. Hardware supports various receive buffer sizes; explicitly 256B, 512B, 1024B, 2048B, 4096B, 8192B, and 16384B.

Buffer size is selected by bit settings in the Receive Control register (RCTL.BSIZE & RCTL.BSEX). See Section 37.6.4.1, "RCTL – Receive Control Register" for details.

The EP80579's GbE places no alignment restrictions on receive memory buffer addresses. This is desirable in situations where the receive buffer was allocated by higher layers in the networking software stack, as these higher layers may have no knowledge of a specific device's buffer alignment requirements.

Although alignment is completely unrestricted, it is highly recommended that software allocate receive buffers on cache-line boundaries.

### 37.5.5.3 Receive Descriptor Format

A receive descriptor is a data structure that contains the receive data buffer address and fields for hardware to store packet information. Refer to Figure 37-6, where the shaded areas indicate fields that are modified by hardware upon packet reception.

Figure 37-6. Receive Descriptor (RDESC) Layout

|   |                      |        |    |        |    |                              |    |        |    |   |
|---|----------------------|--------|----|--------|----|------------------------------|----|--------|----|---|
|   | 63                   | 48     | 47 | 40     | 39 | 32                           | 31 | 16     | 15 | 0 |
| 0 | Buffer Address[63:0] |        |    |        |    |                              |    |        |    |   |
| 8 | Special              | Errors |    | Status |    | Packet Checksum <sup>†</sup> |    | Length |    |   |

† The checksum indicated here is the unadjusted "16 bit ones complement" of the packet. A software assist may be required to back out appropriate information prior to sending it up to upper software layers. The packet checksum is always reported in the first descriptor (even in the case of multi-descriptor packets).

† The Packet Checksum is reported in Little Endian format

Upon receipt of a packet for this device, hardware stores the packet data into the indicated buffer and writes the length, packet checksum, status, errors, and status fields. Length covers the data written to a receive buffer including CRC bytes (if any). Software must read multiple descriptors to determine the complete length for packets that span multiple receive buffers.

For standard 802.3 packets (non-VLAN) the Packet Checksum is by default computed over the entire packet from the first byte of the DA through the last byte of the CRC, including the Ethernet and IP headers. Software may modify the starting offset for the packet checksum calculation, refer to [Section 37.6.4.13, "RXCSUM – Receive Checksum Control Register"](#) for details. To verify the TCP checksum using the Packet Checksum, software must adjust the Packet Checksum value to back out the bytes that are not part of the true TCP Checksum.

Status information indicates whether the descriptor has been used and whether the referenced buffer is the last one for the packet. Refer to [Figure 37-7](#) for the layout of the status field. Error status information is shown in [Figure 37-8](#).

**Figure 37-7. Receive Status (RDESC.Status) Layout**

| 7   | 6    | 5     | 4    | 3  | 2    | 1   | 0  |
|---|------|-------|------|----|------|-----|----|
| PIF   | IPCS | TCPCS | Rsvd | VP | IXSM | EOP | DD |
| <b>PIF:</b> Passed in-exact filter              |      |       |      |    |      |     |    |
| <b>IPCS:</b> IPv4 Checksum Calculated on Packet |      |       |      |    |      |     |    |
| <b>TCPCS:</b> TCP Checksum Calculated on Packet |      |       |      |    |      |     |    |
| <b>Rsvd:</b> Reserved                           |      |       |      |    |      |     |    |
| <b>VP:</b> Packet is 802.1q (matched VET MMR)   |      |       |      |    |      |     |    |
| <b>IXSM:</b> Ignore Checksum Indication         |      |       |      |    |      |     |    |
| <b>EOP:</b> End of Packet                       |      |       |      |    |      |     |    |
| <b>DD:</b> Descriptor Done                      |      |       |      |    |      |     |    |

Packets that exceed the receive buffer size span multiple receive buffers. EOP indicates whether this is the last buffer for an incoming packet. DD indicates whether hardware is done with the descriptor. When set along with EOP, the received packet is complete in main memory. Software can determine buffer usage by setting the status byte to 0 before making the descriptor available to hardware, and checking it for non-zero content at a later time. For multi-descriptor packets, packet status is provided in the final descriptor of the packet (EOP set). If EOP is not set for a descriptor, only the Address, Length, and DD bits are valid.

The VP field indicates whether the incoming packet's type matches VET (i.e., if the packet is a VLAN (802.1q) type). It will be set if the packet type matches VET and CTRL.VME is set. For a further description of 802.1q VLANs please see ["802.1q VLAN Support" on page 1400](#).

When the Ignore Checksum Indication bit is deasserted (IXSM = 0), the IPCS and TCPCS bits indicate whether the hardware performed the IPv4 or TCP/UDP checksum(s) on the received packet, respectively. Pass/Fail information regarding the checksum is indicated in the status bits as described below for IPE & TCPE. When IXSM = 1, software should ignore the IPCS and TCPCS bits.

Refer to [Table 37-1, “Supported Receive Checksum Capabilities”](#) on page 1363 for a description of supported packet types for receive checksum off loading. Unsupported packet types will either have the IXSM bit set, or they will not have the IPCS or TCPCS bits set. IPv6 packets will not have the IPCS bit set, but may have the TCPCS bit set if the TCP or UDP packet was recognized by the EP80579's GbE.

Hardware supplies the PIF field to expedite software processing of packets. Software must examine any packet with PIF set to determine whether to accept the packet. If PIF is clear, then the packet is known to be for this station, so software need not look at the packet contents. Packets passing only the Multicast Vector will have PIF set.

Most error information appears only when the store-bad-packet bit (RCTL.SBP) is set and a bad packet is received. Refer to [Figure 37-8](#) below for a definition of the possible errors and their bit positions.

**Figure 37-8. Receive Errors (RDESC.ERRORS) Layout**

| 7  | 6   | 5    | 4   | 3    | 2    | 1    | 0  |
|--|-----|------|-----|------|------|------|----|
| RXE  | IPE | TCPE | CXE | Rsvd | Rsvd | Rsvd | CE |
| <b>RXE:</b> RX Data Error                      |     |      |     |      |      |      |    |
| <b>IPE:</b> IPv4 Checksum Error                |     |      |     |      |      |      |    |
| <b>TCPE:</b> TCP/UDP Checksum Error            |     |      |     |      |      |      |    |
| <b>CXE:</b> Carrier Extension Error (Reserved) |     |      |     |      |      |      |    |
| <b>Rsvd:</b> Reserved                          |     |      |     |      |      |      |    |
| <b>Rsvd:</b> Reserved                          |     |      |     |      |      |      |    |
| <b>Rsvd:</b> Reserved                          |     |      |     |      |      |      |    |
| <b>CE:</b> CRC Error or Alignment Error        |     |      |     |      |      |      |    |

The IP and TCP checksum error bits from [Figure 37-8](#) are valid only when the IPv4 or TCP/UDP checksum(s) is performed on the received packet as indicated via IPCS and TCPCS. These, along with the other error bits, are valid only when the EOP and DD bit are set in the descriptor.

*Note:* Receive checksum errors have no affect on packet filtering.

If receive checksum off loading is disabled (`RXCSUM.IPOFL` & `RXCSUM.TUOFL`), the IPE and TCPE bits will be 0.

In GMII/MII mode, the RXE bit indicates that a data error occurred during the packet reception that has been detected by the PHY. This generally corresponds to signal errors occurring during the packet reception. This bit is valid only when the EOP and DD bits are set and will not be set in descriptors unless RCTL.SBP (store-bad-packets) is set.

CRC and alignment errors are indicated via the CE bit. Software may distinguish between these errors by monitoring the respective statistics registers.

Hardware stores additional information in the receive descriptor for 802.1q packets. If the packet type is 802.1q (determined when a packet matches VET and RCTL.VME = 1), then the special field records the VLAN information and the four byte VLAN information is stripped from the packet data storage. Otherwise, the special field contains 0x0000.

Figure 37-9. Special Descriptor Field Layout

| 802.1q Packets    |  |          |   |     |            |  |   |
|-------------------|--|----------|---|-----|------------|--|---|
| 15 thru 8         |  | 7 thru 5 |   | 4   | 3 thru 0   |  |   |
| VLAN[7..0]        |  | PRI      |   | CFI | VLAN[11:8] |  |   |
|                   |  |          |   |     |            |  |   |
| All Other Packets |  |          |   |     |            |  |   |
| 15                |  |          | 8 | 7   |            |  | 0 |
| 00                |  |          |   | 00  |            |  |   |

### 37.5.5.4 Receive Descriptor Fetching

The descriptor fetching strategy has been designed for the EP80579’s GbE to support larger bursts across the internal bus. This is made possible by increasing the number of GbE hardware receive descriptors (from 8 to 64), and by modifying the fetch algorithm. The algorithm attempts to make the best use of the internal bus by fetching a cache-line (or more) of descriptors with each burst. The following paragraphs briefly describe the descriptor fetch algorithm and the software control provided.

When the descriptor buffer is empty, a fetch will happen as soon as any descriptors are made available (host writes to the tail pointer). When the descriptor buffer is nearly empty (as defined by RXDCTL.PTHRESH) a prefetch will be performed whenever enough valid descriptors (as defined by RXDCTL.HTHRESH) are available in host memory and no other internal bus activity of greater priority is pending (descriptor fetches, descriptor write-backs, or packet data transfers).

When the number of descriptors in host memory is greater than the available descriptor buffer storage, the GbE may elect to perform a fetch which is not a multiple of cache line size. The hardware performs this non-aligned fetch if doing so will result in the next descriptor fetch being aligned on a cache line boundary. This allows the descriptor fetch mechanism to be most efficient in the cases where it has fallen behind software.

*Note:* The GbE NEVER fetches descriptors beyond the descriptor TAIL pointer.

### 37.5.5.5 Receive Descriptor Write-Back

Processors have cache line sizes that are larger than the receive descriptor size (16 bytes). Consequently, writing back descriptor information for each received packet would cause expensive partial cache line updates. Two mechanisms minimize the occurrence of partial line write backs: receive descriptor packing and null descriptor padding.

#### 37.5.5.5.1 Receive Descriptor Packing

To maximize memory efficiency, receive descriptors are “packed” together and written as a cache line whenever possible. Descriptors accumulate and are opportunistically written out in cacheline-oriented chunks. Used descriptors will also be explicitly written out under the following scenarios:

- RXDCTL.WTHRESH descriptors have been used (the specified max threshold of unwritten used descriptors has been reached)
- The last descriptors of the allocated descriptor ring have been used (to allow the hardware to re-align to the descriptor ring start)
- A receive timer expires (RADV or RDTR)

- Explicit software flush (RDTR.FPD)

When the numbers of descriptors specified by RXDCTL.WTHRESH have been used, they are written back, regardless of cacheline alignment. It is therefore recommended that WTHRESH be a multiple of cacheline size. When a receive timer (RADV or RDTR) expires, all used descriptors are forced to be written back prior to initiating the interrupt, for consistency. Software may explicitly flush accumulated descriptors by writing the RDTR register with the high order bit (FPD) set.

### 37.5.5.5.2 Null Descriptor Padding

Hardware stores no data in descriptors with a null data address. Software can make use of this property to cause the first condition under receive descriptor packing to occur early. Hardware writes back null descriptors with the DD bit set in the status byte and all other bits unchanged.

### 37.5.5.6 Receive Descriptor Queue Structure

Figure 37-10. Receive Descriptor Ring Structure

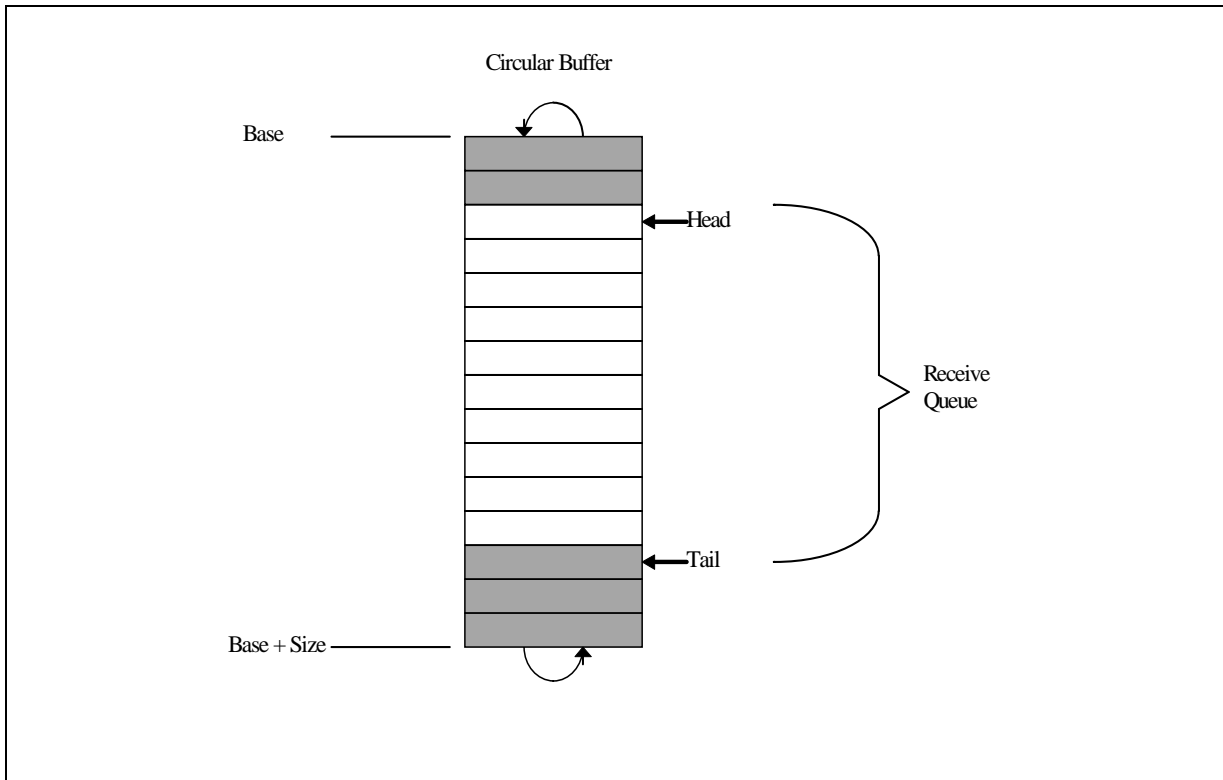

Figure 37-10 shows the structure of the receive descriptor ring. Hardware maintains a circular queue of descriptors and writes back used descriptors just prior to advancing the head pointer. Head and tail pointers wrap back to base when “size” descriptors have been processed.

Software adds receive descriptors by advancing the tail pointer to refer to the address of the entry just beyond the last valid descriptor. This is accomplished by writing the descriptor tail register with the offset of the entry beyond the last valid descriptor. The hardware adjusts its internal tail pointer accordingly. As packets arrive, they are stored

in memory and the head pointer is incremented by hardware. When the head pointer is equal to the tail pointer, the queue is empty. Hardware stops storing packets in system memory until software advances the tail pointer, making more receive buffers available.

The receive descriptor head and tail pointers reference 16-byte blocks of memory. Shaded boxes in the figure represent descriptors that have stored incoming packets but have not yet been recognized by software. Software can determine if a receive buffer is valid by reading descriptors in memory. Any descriptor with a non-zero status byte has been processed by the hardware, and is ready to be handled by the software.

*Note:*

The head pointer points to the next descriptor that will be written back. At the completion of the descriptor write-back operation, this pointer is incremented by the number of descriptors written back. Hardware “owns” all descriptors between the head and tail. Any descriptor not in this range is owned by software.

The receive descriptor ring is described by the following registers:

**The Receive Descriptor Base Address High Register and the Receive Descriptor Base Address Low Register (RDBAH and RDBAL)** - These registers indicate the start of the descriptor ring buffer; this 64-bit address is aligned on a 16B boundary. Hardware ignores the lower 4 bits.

**Receive Descriptor Length Register (RDLEN)** - This register determines the number of bytes allocated to the circular buffer. This value must be a multiple of 128. Since each descriptor is 16 bytes in length, the total number of receive descriptors is always a multiple of 8.

**Receive Descriptor Head Register (RDH)** - This register holds a value that is an offset from the base, and indicates the in-progress descriptor. There can be up to 64K descriptors in the circular buffer. Hardware maintains a shadow copy that includes those descriptors completed but not yet stored in memory.

**Receive Descriptor Tail Register (RDT)** - This register holds a value that is an offset from the base, and identifies the location beyond the last descriptor hardware can process. This is the location where software writes the first new descriptor.

If software statically allocates buffers, and uses memory read to check for completed descriptors, it simply has to zero the status byte in the descriptor to make it ready for reuse by hardware. This is not a hardware requirement (moving the hardware tail pointer is), but is necessary for performing an in-memory scan.

### 37.5.5.7 Receive Interrupts

The following sections indicate the presence of new packets.

#### 37.5.5.7.1 Receive Timer (ICR.RXT0) Due to Absolute Timer (RADV)

- When a packet is received the Absolute Timer starts counting down. When it reaches 0 it generates an interrupt and resets itself. It is also reset if an interrupt is generated due to the Packet Delay Timer expiration. The absolute timer is disabled if RADV is 0. To use the Absolute Timer only the RDTR register must be set to an equal or greater value than RADV.

#### 37.5.5.7.2 Receive Timer (ICR.RXT0) Due to Packet Delay Timer (RDTR)

- When a packet is received the Packet Delay Timer starts counting down. Every time an additional packet is received the Packet Delay Timer is reset to its starting value. When it reaches 0 it generates an interrupt and resets itself. It is also reset if an interrupt is generated due to the Absolute Timer expiration.
- When RDTR is 0 interrupts are immediate. If RADV is non-0, and RDTR is equal to or higher than RADV then the Packet Delay Timer will never generate any interrupts as the Absolute Timer will always generate them first.

- Writing RDTR with its high order bit 1 forces an explicit flush of any partial cache lines worth of consumed descriptors. Hardware writes all used descriptors to memory and updates the globally visible value of the RDH head pointer.

Figure 37-11 further describes the Packet Delay Timer operation, in general.

**Figure 37-11. Packet Delay Timer operation illustrated with a state diagram**

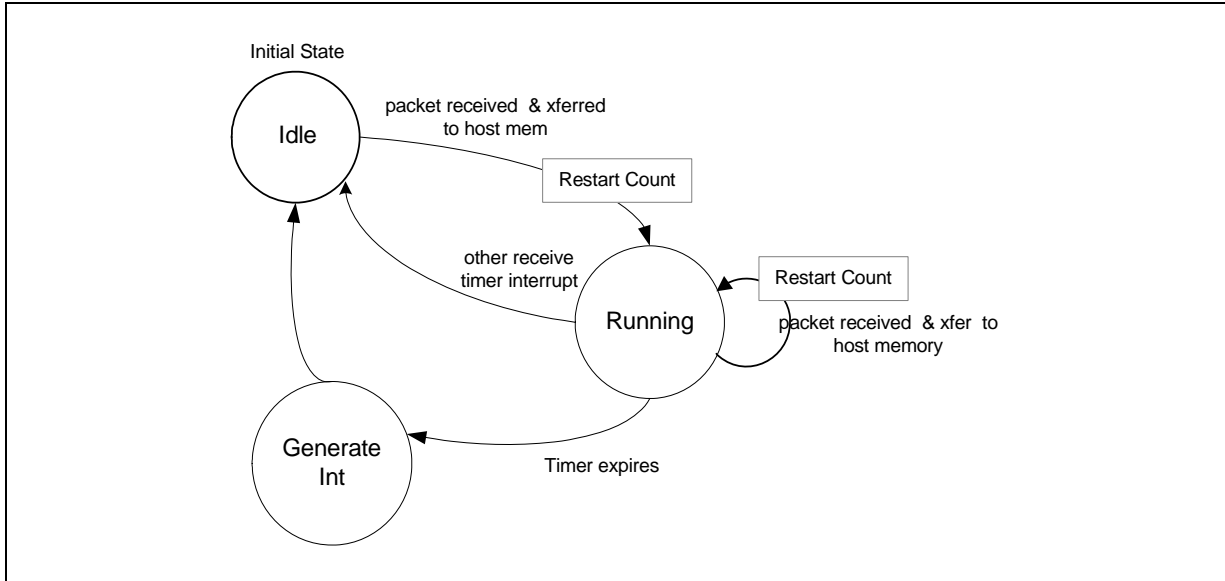

Figure 37-12, Figure 37-13, and Figure 37-14 illustrate the uses of the two timers.

**Figure 37-12. Case A: Using only an Absolute Timer**

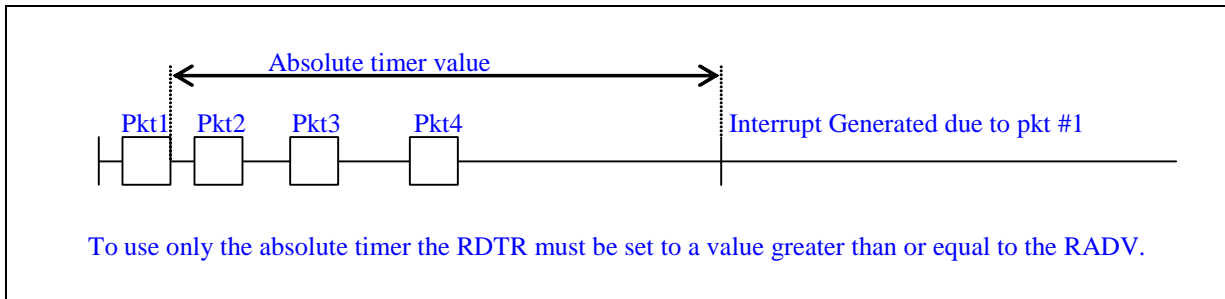

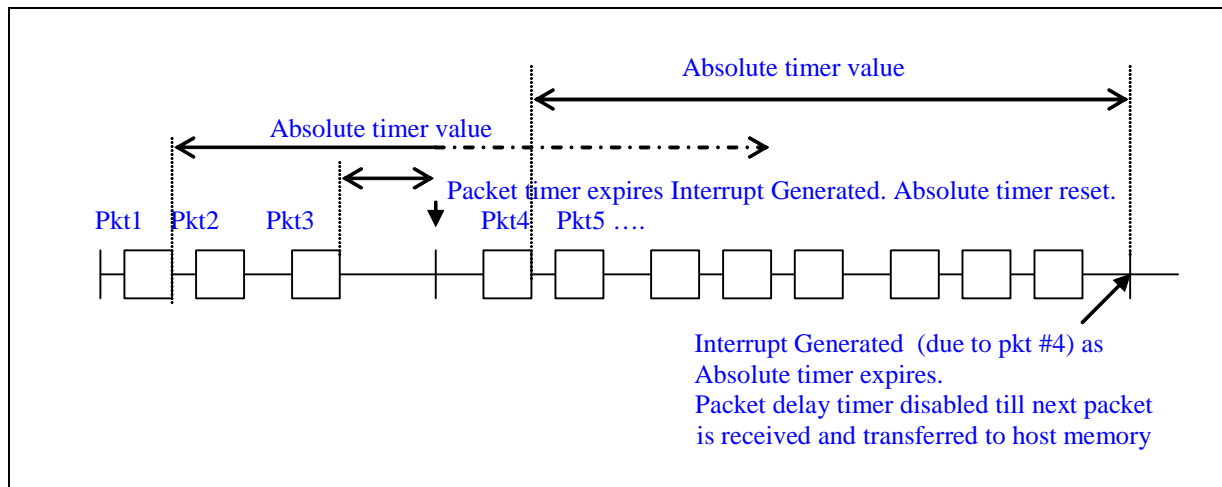

Figure 37-13. Case B: Using an Absolute Timer in conjunction with the Packet Timer

Case C in Figure 37-14 shows a scenario in which the packet timer expires even though a packet was being transferred to the host memory. Illustrating the fact that the packet timer is re-started only after a packet is transferred to host memory.

Figure 37-14. Case C: Packet Timer Expires Even Though A Packet Was Being Transferred to the Host Memory.

### 37.5.5.7.3 Small Receive Packet Detect (ICR.SRPD)

The Small Packet Receive Detect timer is independent of the other timers. It will generate a receive interrupt when small-packet detection is enabled (*RSRPD* is set with a non-zero value) and a packet of size less than or equal to *RSRPD.SIZE* has been transferred into the host memory. When comparing the size the headers and CRC are included (if CRC stripping is not enabled). CRC and VLAN headers are not included if they have been stripped.

Receiving a small packet does not clear the absolute or packet delay timers, so one packet may generate two receive interrupts, one due to the small packet reception and one due to a timer expiration.

#### 37.5.5.7.4 Receive Descriptor Minimum Threshold (ICR.RXDMT)

The minimum descriptor threshold helps avoid descriptor under-run by generating an interrupt when the number of free descriptors becomes equal to the minimum. It is measured as a fraction of the receive descriptor ring size. This interrupt would stop and re-initialize all of the active delayed receives interrupt timers until a new packet is observed.

#### 37.5.5.7.5 Receiver FIFO Overrun (ICR.RXO)

FIFO overrun occurs when hardware attempts to write a byte to a full FIFO. An overrun could indicate that software has not updated the tail pointer to provide enough descriptors/buffers, or that the internal bus is too slow draining the receive FIFO. Incoming packets that overrun the FIFO are dropped and do not affect future packet reception. This interrupt would stop and re-initialize all of the active delayed receive interrupts.

#### 37.5.5.8 Receive Packet Checksum Off loading

The GbE supports the off loading of three receive checksum calculations: the Packet Checksum, the IPv4 Header Checksum, and the TCP/UDP Checksum. Ethernet II and Ethernet SNAP frame types are supported.

The Packet checksum is the one's complement of the receive packet, starting from the byte indicated by RXCSUM.PCSS (0 corresponds to the first byte of the packet), after stripping. For example, for an Ethernet II frame encapsulated as an 802.3ac VLAN packet and with RXCSUM.PCSS set to 14, the Packet Checksum would include the entire encapsulated frame, excluding the 14-byte Ethernet header (DA, SA, Type and Length) and the 4-byte q-tag. The Packet checksum will not include the Ethernet CRC if the RCTL.SECRC bit is set.

Software must make the required offsetting computation (to back out the bytes that should not have been included and to include the pseudo-header) prior to comparing the Packet Checksum against the TCP checksum stored in the packet.

For supported packet/frame types, the entire checksum calculation may be off-loaded to the GbE. If RXCSUM.IPOFLD is set to one, the GbE will calculate the IPv4 checksum and indicate a pass/fail indication to software via the IPv4 Checksum Error bit (RDESC.IPE) in the ERROR field of the receive descriptor. Similarly, if RXCSUM.TUOFLD is set to one, the GbE will calculate the TCP or UDP checksum and indicate a pass/fail condition to software via the TCP/UDP Checksum Error bit (RDESC.TCPE). These error bits are valid when the respective status bits indicate the checksum was calculated for the packet (RDESC.IPCS and RDESC.TCPCS respectively).

If neither RXCSUM.IPOFLD nor RXCSUM.TUOFLD are set, the Checksum Error bits (IPE & TCPE) will be 0 for all packets.

**Table 37-1. Supported Receive Checksum Capabilities (Sheet 1 of 2)**

| Packet Type                           | HW IP Checksum Calculation | HW TCP/UDP Checksum Calculation |
|---------------------------------------|----------------------------|---------------------------------|
| IPv4 packets                          | Yes                        | Yes                             |
| IPv6 packets                          | N/A                        | Yes                             |
| IPv6 packet with next header options: |                            |                                 |
| • Hop-by-Hop options                  | N/A                        | Yes                             |
| • Destinations options                | N/A                        | Yes                             |
| • Routing                             | N/A                        | Yes                             |
| • Fragment                            | N/A                        | No                              |

**Table 37-1. Supported Receive Checksum Capabilities (Sheet 2 of 2)**

|   |            |      |
|---|------------|------|
| IPv4 tunnels:   |            |      |
| • IPv4 packet in an IPv4 tunnel   | No         | No   |
| • IPv6 packet in an IPv4 tunnel   | Yes (IPv4) | Yes* |
| IPv6 tunnels:   |            |      |
| • IPv4 packet in an IPv6 tunnel   | No         | No   |
| • IPv6 packet in an IPv6 tunnel   | No         | No   |
| Packet is an IPv4 fragment  | Yes        | No   |
| Packet is greater than 1552 bytes                                       |            |      |
| • LPE=1   | Yes        | Yes  |
| Packet has 802.3ac tag  | Yes        | Yes  |
| IPv4 Packet has IP options  |            |      |
| • IP header is longer than 20 bytes                                     | Yes        | Yes  |
| Packet has TCP or UDP options   | Yes        | Yes  |
| IP header's protocol field contains a protocol # other than TCP or UDP. | Yes        | No   |

\* The IPv6 header portion can include supported extension headers as described in the IPv6 Filter section.

Table 37-1 gives general details about what packets are processed. In more detail, the packets are passed through a series of filters to determine if a receive checksum is calculated.

#### 37.5.5.8.1 MAC Address Filter

This filter checks the MAC destination address to be sure it is valid (e.g. DA match, broadcast, multicast, etc.). The receive configuration settings determine which MAC addresses are accepted. See the various receive control configuration registers such as RCTL (RCTL.UPE, RCTL.MPE, RCTL.BAM), MTA[127:0], RAL, and RAH.

#### 37.5.5.8.2 SNAP/VLAN Filter

This filter checks the next headers looking for an IP header. It is capable of decoding Ethernet II, Ethernet SNAP, and IEEE 802.3ac headers. It will skip past any of these intermediate headers and will look for the IP header. The receive configuration settings determine which next headers are accepted. See the various receive control configuration registers such as RCTL (RCTL.VFE), VET, and VFTA[127:0].

#### 37.5.5.8.3 IPv4 Filter

This filter checks for valid IPv4 headers. The version field is checked for a correct value (i.e. 4). IPv4 headers are accepted if they are any size greater than or equal to 5 (dwords). If the IPv4 header is properly decoded, the IP checksum will be checked for validity. The RXCSUM.IPOFL bit must be set for this filter to pass.

#### 37.5.5.8.4 IPv6 Filter

This filter checks for valid IPv6 headers, which are a fixed size and have no checksum. The IPv6 extension headers accepted are: Hop-by-Hop, Destination Options, and Routing. The maximum size next header accepted is 16 dwords (64 bytes).

All of the IPv6 extension headers supported by the GbE have the same header structure, as shown in Figure 37-15.

**Figure 37-15. IPv6 Extension Header Structure**

Byte 0                      Byte 1                      Byte 2                      Byte 3

**Figure 37-15. IPv6 Extension Header Structure**

NEXT HEADER is a value that identifies the header type. The supported IPv6 next headers values are:

- Hop-by-Hop = 00h
- Destination Options = 3Ch
- Routing = 2Bh

HDR EXT LEN is the 8 byte count of the header length, not including the first 8 bytes. For example, a value of 3 means that the total header size including the NEXT HEADER and HDR EXT LEN fields is 32 bytes (8 + 3\*8).

#### 37.5.5.8.5 UDP/TCP Filter

This filter checks for a valid UDP or TCP header. The prototype next header values are 11h and 06h, respectively. The RXCSUM.TUOFL bit must be set for this filter to pass.

### 37.5.6 Packet Transmission

Output packets are made up of pointer-length pairs constituting a descriptor chain (so called descriptor based transmission). Software forms transmit packets by assembling the list of pointer-length pairs, storing this information in the transmit descriptor, and then updating the GbE hardware transmit tail pointer to the descriptor. The transmit descriptor and buffers are stored in host memory. Hardware typically transmits the packet only after it has completely fetched all packet data from host memory and deposited it into the TX portion of the packet buffer. This permits TCP or UDP checksum computation, and avoids problems with internal bus under-runs.

Another transmit feature of the GbE is TCP Segmentation. The hardware has the capability to perform packet segmentation on large data buffers off-loaded from the NOS. This feature is discussed in detail in [“TCP Segmentation” on page 1380](#).

#### 37.5.6.1 Transmit Data Storage

Data are stored in buffers pointed to by the descriptors. Alignment of data is on an arbitrary byte boundary with the maximum size per descriptor limited only to the maximum allowed packet size (16288 bytes<sup>1</sup>). A packet typically consists of two (or more) descriptors, one (or more) for the header and one for the actual data. Some software implementations copy the header(s) and packet data into one buffer and use only one descriptor per transmitted packet.

#### 37.5.6.2 Transmit Descriptor Formats

The EP80579's GbE has an expanded transmit descriptor format in that additional descriptor types have been introduced. The intent of the descriptor type field is to provide an extensible interface to the GbE descriptor mechanisms while maintaining a great deal of compatibility with the existing descriptor format that the 82542 used.

1. This value is based on the default packet buffer allocation of 16KB Transmit; 48KB Receive. The maximum allowable transmit packet size is the transmit allocation minus 96 bytes with an upper limit of 24KB due to receive synchronization limitations.

The original (82542 compatible) descriptor will be referred to as the "legacy" descriptor format and is described in "Legacy Transmit Descriptor Format" on page 1366. The two new descriptor types are collectively referred to as extended descriptors. One of the new descriptor types is quite similar to the legacy descriptor in that it points to a block of packet data. This descriptor type is called the TCP/IP Data Descriptor and is offered as a replacement for the legacy descriptor since it offers access to new off loading capabilities. The other new descriptor type is fundamentally different as it does not point to packet data. It merely contains control information which are loaded into registers of the GbE and affect the processing of future packets. The following paragraphs describe the three descriptor formats.

Note: The extended descriptor types are accessed by setting the TDESC.DEXT bit to 1. If this bit is set, the TDESC.DTYP field is examined to control the interpretation of the remaining bits of the descriptor. Figure 37-16 shows the generic layout for all extended descriptors. Fields marked as NR are not reserved for any particular function and are defined on a per-descriptor type basis. Notice that the DEXT and DTYP fields are non-contiguous in order to accommodate legacy mode operation. For legacy mode operation, bit 29 is set to 0 and the descriptor is defined as described in "Legacy Transmit Descriptor Format" on page 1366.

Figure 37-16. Transmit Descriptor (TDESC) Layout

### 37.5.6.3 Legacy Transmit Descriptor Format

To select legacy (82542 compatible) mode operation, bit 29 (TDESC.DEXT) should be set to 0. In this case, the descriptor format is defined as shown in Figure 37-17. Address and length must be supplied by software. Bits in the command byte are optional, as are the CSO, and CSS fields.

Figure 37-17. Legacy Transmit Descriptor (TDESC) Layout

Length (TDESC.LENGTH) specifies the length in bytes to be fetched from the buffer address provided. The maximum length associated with any single legacy descriptor is 16288 bytes. Although a buffer as short as one byte is allowed, the total length of the packet, before padding and CRC insertion, must be at least 17 bytes.

Note: The maximum allowable packet size for transmits changes based on the value written to the Packet Buffer Allocation Register, whose settings can modify the size of the transmit FIFO.

Descriptor length(s) may be further limited by the size of the transmit FIFO. Due to the need to support optional checksum calculation & insertion, all buffers comprising a single packet must be able to be stored simultaneously in the transmit FIFO. For any individual packet, the sum of the individual descriptor lengths must be at least 80 bytes less than the allocated size of the transmit FIFO.

A Checksum offset (TDESC.CSO) field indicates where to insert a TCP checksum if this mode is enabled, relative to the start of the packet. A Checksum start (TDESC.CSS) field indicates where to begin computing the checksum. Both CSO and CSS are in units of bytes. These must both be in the range of data provided to the device in the descriptor. This means for short packets which are padded by software, CSS and CSO must be in the range of the unpadded data length, not the eventual padded length (64 bytes). Hardware will not add the 802.1Q EtherType or the VLAN field following the 802.1Q EtherType to the checksum. So for VLAN packets, software can compute the values to back out only on the encapsulated packet rather than on the added fields.

*Note:* Although the EP80579's GbE can be programmed to calculate and insert TCP checksum using the legacy descriptor format as described above, it is recommended that software use the newer TCP/IP Context Transmit Descriptor Format. This newer descriptor format allows the hardware to calculate both the IP and TCP checksums for outgoing packets. Refer to [“Transmit Checksum Off loading” on page 1379](#) for more information about how the new descriptor format can be used to accomplish this task.

The CMD byte stores the applicable command and has the fields shown in [Figure 37-18](#).

**Figure 37-18. Transmit Command (TDESC.CMD) Layout**

| 7   | 6   | 5    | 4   | 3  | 2  | 1    | 0   |
|-----|-----|------|-----|----|----|------|-----|
| IDE | VLE | DEXT | RPS | RS | IC | IFCS | EOP |

**IDE:** Interrupt Delay Enable

**VLE:** VLAN Packet Enable

**DEXT:** Descriptor Extension (0 for legacy mode)

**RPS:** Report Packet Sent

**RS:** Report Status

**IC:** Insert Checksum

**IFCS:** Insert FCS

**EOP:** End of Packet

EOP indicates the last descriptor making up the packet when asserted. One or many descriptors can be used to form a packet. Hardware inserts a checksum at the offset indicated by the CSO field if the Insert Checksum bit (IC) is set. Checksum calculations are for the entire packet starting at the byte indicated by the CSS field. A value of 0 corresponds to the first byte in the packet. Hardware ignores IC, and CSO unless EOP is set. CSS must be set in the first descriptor for a packet. In addition, IC is ignored if CSO or CSS are out of range. This occurs if  $(CSS \geq \text{length})$  OR  $(CSO \geq \text{length} - 1)$ .

Software must compute an offsetting entry-to back out the bytes of the header that should not be included in the TCP checksum-and store it in the position where the hardware computed checksum is to be inserted.

TDESC.CMD.RS tells the hardware to report the status information. This is used by software that does in-memory checks of the transmit descriptors to determine which ones are done. For example, if software queues up 10 packets to transmit, it can set the RS bit in the last descriptor of the last packet. If software maintains a list of descriptors with the RS bit set, it can look at them to determine if all packets up to (and including) the one with the RS bit set have been buffered in the output FIFO. This is done by looking at the status byte and checking the Descriptor Done (DD) bit. If DD is set, the descriptor has been processed. Refer to [Figure 37-19 on page 1368](#) for the layout of the status field.

**Note:** Descriptors with the null address (0), or zero length, transfer no data. If they have the RS bit in the command byte set, then the DD field in the status word is written after hardware processes them. Hardware only sets the DD bit for descriptors with RS set.

**Note:** Null Descriptors are intended for padding descriptor queues, in case a specific alignment of descriptors comprising a packet are desired. Null transmit descriptors should not be used to convey any meaningful command information (such as EOP); they are consumed with no processing other than status reporting (if requested).

**Note:** Hardware is considered “done processing” a descriptor when any data specified in the descriptor has been completely fetched and loaded in the transmit FIFO.

**Note:** VLE, IFCS, and IC are qualified by EOP. In other words, hardware interprets these bits ONLY when EOP is set.

IDE activates a transmit interrupt delay timer. Hardware loads a countdown register when it writes back a transmit descriptor that has RS and IDE set. The value loaded comes from Transmit Interrupt Delay Value Register (TIDV.IDV). When the count reaches 0, a transmit interrupt occurs if transmit descriptor write-back interrupts (ICR.TXDW) are enabled. Hardware always loads the transmit interrupt counter whenever it processes a descriptor with IDE set even if it is already counting down due to a previous descriptor. If hardware encounters a descriptor that has RS set, but not IDE, it generates an interrupt immediately after writing back the descriptor and the interrupt delay timer is cleared.

**Note:** Although the transmit interrupt may be delayed, the descriptor write-back requested by setting the RS bit is performed without delay unless descriptor write-back bursting is enabled. See [Section 37.6.5.10, “TXDCTL – Transmit Descriptor Control Register”](#).

VLE indicates that the packet is a VLAN or ISL packet (i.e. that the hardware should add the VLAN Ethertype and an 802.1q VLAN tag to the packet).

**Note:** If the VLE bit is set, the CTRL.VME bit should also be set to enable VLAN tag insertion. If the CTRL.VME bit is not set, the device will not insert VLAN tags on outgoing packets, but may instead insert ISL headers.

**Table 37-2. VLAN Tag Insertion Decision Table when VLAN Mode Enabled (CTRL.VME=1)**

| VLE | Action  |
|-----|---|
| 0   | Send generic Ethernet packet. IFCS controls insertion of FCS in normal Ethernet packets.  |
| 1   | Send 802.1Q packet; the Ethernet Type field comes from the VET register and the VLAN data comes from the special field of the TX descriptor; hardware always appends the FCS/CRC. |

Three bits provide transmit status. These are only present in cases where RS is set in the command. DD indicates that the descriptor is done and is written back after the descriptor has been processed. The bits EC and LC indicate collision behavior when in half-duplex mode. They have no meaning when in full-duplex mode.

**Figure 37-19. Transmit Status Layout (TDESC.STATUS)**

**TU:** Transmit Underrun

**LC:** Late Collision

**EC:** Excess Collisions

**Figure 37-19. Transmit Status Layout (TDESC.STATUS)**

DD: Descriptor Done

The SPECIAL field is used to provide the 802.1q/802.1ac tagging information. The special field is ignored if the VLE bit is 0 or if the EOP bit is 0.

**Figure 37-20. Transmit Special Field Layout (TDESC.SPECIAL)**

#### 37.5.6.4 TCP/IP Context Transmit Descriptor Format

The TCP/IP context transmit descriptor provides access to the enhanced checksum off load and TCP Segmentation facilities available in the GbE. These features allow TCP and UDP packet types to be handled more efficiently by performing additional work in hardware, thus reducing the software overhead associated with preparing these packets for transmission.

The TCP/IP context transmit descriptor is called a “context” descriptor for a reason. A context descriptor differs from a data descriptor as it does not point to packet data. Instead, this descriptor provides access to two, GbE hardware contexts that support the transmit checksum off loading and the segmentation features of the EP80579’s GbE. A “context” refers to a set of registers loaded or unloaded as a group to provide a particular function. Only one context is active at any given time.

##### 37.5.6.4.1 Overview of GbE hardware “Contexts”

The previous section mentions access to two, separate GbE hardware contexts. There are actually three such contexts corresponding to legacy mode, “normal” mode, and segmentation mode. The first context (legacy) is an implied context as it is not explicitly specified with a context descriptor. This context is constructed by the device from the first and last descriptors of a legacy transmit and from some internal constants. This context then mimics the behavior of the legacy (82542) device. This is completely transparent to the user and is included here for clarification only.

The other two contexts are explicit and directly accessible via the TCP/IP context transmit descriptor. One context is used to control the checksum off loading feature for normal packet transmission. The second context is used to control the packet segmentation capabilities of the device. The TSE bit selects which context will be updated. A TCP/IP context transmit descriptor with TSE=0 will update the normal (checksum off loading only) context. Conversely, the segmentation context is updated when TSE=1. Refer to [Figure 37-22 on page 1371](#) for details on all of the TDESC.TUCMD fields, including TSE.

The device automatically selects the appropriate context to use based on the current packet transmission: legacy, normal, or segmentation.

*Note:* While the architecture supports arbitrary ordering rules for the various descriptors, there are restrictions. The context descriptors should not occur in the middle of a packet (or of a segmentation) and data descriptors of different packet types (legacy, normal, or segmentation) should not be intermingled except at the packet (or segmentation) level.

All three contexts control calculation and insertion of up to two checksums. This portion of the context is referred to as the checksum context. In addition to a checksum context, the segmentation context includes information specific to the segmentation capability. This additional information includes the total payload for the message (TDESC.PAYLEN), the total size of the header (TDESC.HDRLEN), the amount of payload

data that should be included in each packet (TDESC.MSS), and information about what type of protocol (TCP, IPv4, IPv6, etc.) is used. This information is specific to the segmentation capability and is therefore ignored for context descriptors that do not have the TSE bit set.

Due to the fact that there are dedicated resources in the GbE hardware for both the normal and segmentation contexts, these contexts will remain constant until they are modified by another context descriptor. This means that a context can be used for multiple packets unless a new context is loaded prior to each new packet. Depending on the environment, it may be completely unnecessary to load a new context for each packet. For example, if most traffic generated from a given node is standard TCP frames, this context could be setup once and used for many frames. Only when some other frame type is required would a new context need to be loaded by software. After the “non-standard” frame is transmitted, the “standard” context would be setup once more by software. This method avoids the “extra descriptor per packet” penalty for most frames. The penalty can be eliminated altogether if software elects to use TCP/IP checksum off loading only for a single frame type, and thus performing those operations in software for other frame types.

A segmentation context similarly describes parameters which are setup once and used for many frames. Since a segmentation operation results in the generation of multiple frames, the context parameters such as checksum generation are applied to all frames generated. Unlike the “normal” TCP/IP context, a segmentation context cannot be re-used for multiple TCP messages, however, a new segmentation context is required for each segmentation operation.

**37.5.6.4.2 TCP/IP Context descriptor layout**

*Note:* The TCP/IP context transmit descriptor does not transfer any packet data. It merely prepares the checksum and segmentation hardware for the TCP/IP Data descriptors that follow.

To select the TCP/IP context transmit descriptor format, shown below in [Figure 37-21](#), bit 29 (TDESC.DEXT) must be set to 1 and TDESC.DTYP must be set to “0000”.

**Figure 37-21. TCP/IP Context Transmit Descriptor (TDESC) - (Type = 0000)**

|   |       |       |        |       |       |          |       |      |        |       |
|---|-------|-------|--------|-------|-------|----------|-------|------|--------|-------|
|   | 63    | 48 47 | 40 39  |       | 32 31 |          | 16 15 | 8 7  | 0      |       |
| 0 | TUCSE |       | TUCSO  |       | TUCSS |          | IPCSE |      | IPCSO  | IPCSS |
| 8 | MSS   |       | HDRLEN |       | Rsvd  | TUSTATUS | TUCMD | DTYP | PAYLEN |       |
|   | 63    | 48 47 | 40 39  | 36 35 | 32 31 | 24 23    | 20 19 |      |        | 0     |

The first QWORD of this descriptor type contains parameters used to calculate the two checksums which may be off-loaded.

TDESC.IPCSS, TDESC.IPCSO, and TDESC.IPCSE specify the start, offset, and ending byte for the IP checksum off-load feature. Similarly, TDESC.TUCSS, TDESC.TUCSO, TDESC.TUCSE specify the same parameters for the TCP or UDP checksum. Setting either CSE field to 0 indicates the given checksum will cover from CSS to the end of packet. While the names imply particular packet types, the mechanisms are generic.

*Note:* When setting the TCP Segmentation context, IPCSS and TUCSS are used to indicate the start of the IP and TCP headers respectively, and must be set even if checksum insertion is not desired.

In certain situations, software may need to calculate a partial checksum (the TCP pseudo-header for instance) to include bytes which are not contained within the range of start and end. If this is the case, this partial checksum should be placed in the

packet data buffer, at the appropriate offset for the checksum. If no partial checksum is required, software must write a value of zero at this offset. Refer to the [“Transmit Checksum Off loading” on page 1379](#) for additional details.

The second QWORD of this descriptor primarily contains information to support the TCP Segmentation feature. A number of the fields are ignored if the TCP Segmentation enable bit indicates that the descriptor does not refer to the TCP Segmentation context (TSE=0).

MSS controls the Maximum Segment Size. This specifies the maximum TCP or UDP payload “segment” sent per frame, not including any header. The total length of each frame (or “section”) sent by the TCP Segmentation mechanism (excluding 802.3ac tagging and Ethernet CRC) will be MSS bytes + HDRLEN. The one exception is the last packet of a TCP segmentation context which will (typically) be shorter than “MSS + HDRLEN”. This field is ignored if TSE is not set.

HDRLEN is used to specify the length (in bytes) of the header to be used for each frame (or “section”) of a TCP Segmentation operation. The first HDRLEN bytes fetched from data descriptor(s) will be stored internally and used as a prototype header for each section, and will be prepended to each payload segment to form individual frames. For UDP packets this will normally be equal to “UDP checksum offset + 2”. For TCP packets it will normally be equal to “TCP checksum offset + 4 + TCP header option bytes”. This field is ignored if TDESC.TSE is not set.

Maximum limits for the HDRLEN and MSS fields are dictated by the length variables. However, there is a further restriction that the for any TCP Segmentation operation, the hardware must be capable of storing a complete framed fragment (completely-built frames) in the transmit FIFO prior to transmission. Therefore, the size of the TX packet buffer must be greater than or equal to ((MSS + HDRLEN) x Number of Frames Formed for this fragment). The quantity (HDRLEN x Number of Frames) should be set by software in the TCP Segmentation Pad And Minimum Threshold Register (TSPMT.TSPBP) to prevent packet buffer overflow.

The packet payload length field (TDESC.PAYLEN) is the total number of payload bytes for this TCP Segmentation off load context (i.e. the total number of payload bytes that could be distributed across multiple frames after TCP segmentation is performed). Following the fetch of the prototype header, PAYLEN specifies the length of data that will be fetched next from data descriptor(s). This field is also used to determine when “last-frame” processing needs to be performed. Typically, a new data descriptor is used to denote the start of the payload data buffer(s), but this is not required. PAYLEN specification should not include any header bytes. There is no restriction on the overall PAYLEN specification with respect to the transmit FIFO size, once the MSS and HDRLEN specifications are legal. This field is ignored if TDESC.TSE is not set. Refer to [“TCP Segmentation” on page 1380](#) for details on the TCP Segmentation off-loading feature.

Setting the descriptor type (TDESC.DTYP) field to 0000 identifies this descriptor as a TCP/IP context transmit descriptor.

The command field (TDESC.TUCMD) provides options that control the checksum off-loading and TCP Segmentation features, along with some of the generic descriptor processing functions. [Figure 37-22](#) shows the bit definitions for the TDESC.TUCMD field. The IDE, DEXT, and RS bits are valid regardless of the state of TSE. All other bits are ignored if TSE=0.

**Figure 37-22. TCP/IP Context Transmit Descriptor Command Field (TDESC.TUCMD)**

| 7   | 6    | 5    | 4    | 3  | 2   | 1  | 0   |
|-----|------|------|------|----|-----|----|-----|
| IDE | Rsvd | DEXT | Rsvd | RS | TSE | IP | TCP |

**IDE:** Interrupt Delay Enable

Figure 37-22. TCP/IP Context Transmit Descriptor Command Field (TDESC.TUCMD)

- Rsvd:** Reserved
- DEXT:** Descriptor Extension (Must be 1 for this descriptor type)
- Rsvd:** Reserved
- RS:** Report Status
- TSE:** TCP Segmentation Enable
- IP:** IP Packet Type (IPv4=1, IPv6=0)
- TCP:** Packet Type (TCP=1, UDP=0)

The TCP bit identifies the packet as either TCP or UDP (non-TCP). This effects the processing of the header information. The IP bit is used to indicate what type of IP packet is used in the segmentation process. This is necessary for the EP80579's GbE to know where the IP Payload Length field is located. This does not override the checksum insertion bit, TDESC.POPTS IXSM bit. The IP bit must only be set for IPv4 packets and cleared for IPv6 packets.

The TCP Segmentation feature also provides access to a generic block send function and may be useful for performing "segmentation offload" in which the header information is constant. By clearing both the TCP and IP bits, a block of data may be broken down into frames of a given size, a constant, arbitrary length header may be prepended to each frame, and two checksums optionally added.

TSE indicates that this descriptor is setting the TCP segmentation context. If this bit is not set, the checksum off loading context for normal (non-"TCP Segmentation") packets is written. When a descriptor of this type is processed, the device will immediately update the context in question (TCP Segmentation or checksum off loading) with values from the descriptor. This means that if any normal packets or TCP Segmentation packet are in progress (a descriptor with EOP set has not been received for the given context) the results will likely be undesirable.

RS tells the hardware to report the status information for this descriptor. Because this descriptor does not transmit data, only the DD bit in the status word will be valid. Refer to Figure 37-23 for the layout of the status field.

Figure 37-23. TCP/IP Context Transmit Descriptor Status (TDESC.TUSTATUS)

- Rsvd:** Reserved
- DD:** Descriptor Done

The reserved bits are reserved values and are ignored, but if written should be set to 0 for future compatibility.

The DEXT bit identifies this descriptor as one of the extended descriptor types and must be set to 1.

IDE activates the transmit interrupt delay timer. Hardware loads a countdown register when it writes back a transmit descriptor that has the RS bit and the IDE bit set. The value loaded comes from the Transmit Interrupt Delay Value Register (TIDV.IDV). When the count reaches 0, a transmit interrupt occurs. Hardware always loads the transmit interrupt counter whenever it processes a descriptor with IDE set even if it is already

counting down due to a previous descriptor. If hardware encounters a descriptor that has RS set, but not IDE, it generates an interrupt immediately after writing back the descriptor and the interrupt delay timer is cleared.

Four bits are reserved to provide transmit status, although only one is currently assigned for this specific descriptor type. The status word will only be written back to host memory in cases where the RS is set in the command. DD indicates that the descriptor is done and is written back after the descriptor has been processed.

### 37.5.6.5 TCP/IP Data Descriptor Format

The TCP/IP data descriptor is the companion to the TCP/IP context descriptor described in the previous section. This descriptor type provides similar functionality to the legacy mode descriptor but also integrates the checksum off loading and TCP Segmentation features.

To select the TCP/IP data transmit descriptor format, shown below in [Figure 37-24](#).

**Figure 37-24. TCP/IP Data Transmit Descriptor Layout (TDESC) - (Type = 0001)**

The first QWORD of this descriptor type contains the address of a data buffer in host memory which contains a portion of a transmit packet. The second QWORD of this descriptor contains information about the data pointed to by this descriptor as well as descriptor processing options.

Setting TDESC.DEXT to 1 and the descriptor type (TDESC.DTYP) field to “0001” identifies this descriptor as a TCP/IP data descriptor.

The data length field (TDESC.DTALEN) is the total length of the data pointed to by this descriptor, in bytes. For data descriptors not associated with a TCP Segmentation operation (TDESC.TSE not set), the descriptor lengths are subject to the same restrictions specified for legacy descriptors (the sum of the lengths of the data descriptors comprising a single packet must be at least 80 bytes less than the allocated size of the transmit FIFO). In addition, although a buffer as short as one byte is allowed, the total length of the packet, before padding and CRC insertion, must be at least 17 bytes.

The command field (TDESC.DCMD) provides options that control the checksum off-loading TCP Segmentation features, along with some of the generic descriptor processing features. [Figure 37-25](#) shows the bit definitions for the DCMD field.

**Figure 37-25. TCP/IP Data Transmit Descriptor Command Field (TDESC.DCMD)**

**IDE:** Interrupt Delay Enable

**VLE:** VLAN Enable

**DEXT:** Descriptor Extension (Must be 1 for this descriptor type)

Figure 37-25. TCP/IP Data Transmit Descriptor Command Field (TDESC.DCMD)

- Rsvd:** Reserved (must be set to 0)
- RS:** Report Status
- TSE:** TCP Segmentation Enable
- IFCS:** Insert FCS
- EOP:** End of Packet

TSE indicates that this descriptor is part of the current TCP Segmentation context. If this bit is not set, the descriptor is part of the “normal” context.

A packet is sent from one or more data buffers in host memory. The EOP bit indicates that the buffer associated with this descriptor contains the last data for the packet or given TCP segmentation context. In the case of a TCP Segmentation context, the DTALLEN length of this descriptor should match the amount remaining of the original PAYLEN. If it does not, the TCP Segmentation context will be terminated but the end of packet processing may be incorrectly performed. These abnormal termination events will be counted in the TSCTFC statistics register detailed in Section 37.6.6.53, “TSCTFC – TCP Segmentation Context Transmit Fail Count Register”.

IFCS controls insertion of the Ethernet CRC.

RS tells the hardware to report the status information for this descriptor as soon as the corresponding data buffer has been fetched and stored in the EP80579’s GbE internal packet buffer. Refer to Figure 37-26 for the layout of the status field.

The DEXT bit identifies this descriptor as one of the extended descriptor types and must be set to 1.

VLE indicates that the packet is a VLAN packet (i.e. that the hardware should add the VLAN Ethertype and an 802.1q VLAN tag to the packet).

*Note:* If the VLE bit to enable VLAN tag insertion, the CTRL.VME bit should also be set. If the CTRL.VME bit is not set, the device will not insert VLAN tags on outgoing packets.

Table 37-3. VLAN Tag Insertion Decision Table

| VLE | Action  |
|-----|---|
| 0   | Send generic Ethernet packet. IFCS controls insertion of FCS in normal Ethernet packets.  |
| 1   | Send 802.1Q packet; the Ethernet Type field comes from the VET register and the VLAN data comes from the special field of the TX descriptor; hardware always appends the FCS/CRC. |

*Note:* The VLE, IFCS, and VLAN fields are only valid in certain descriptors. If TSE is enabled, the VLE, IFCS, and VLAN fields are only valid in the first data descriptor of the TCP segmentation context. If TSE is not enabled, then these fields are only valid in the last descriptor of the given packet (qualified by the EOP bit).

IDE activates the transmit interrupt delay timer. Hardware loads a countdown register when it writes back a transmit descriptor that has RS and IDE set. The value loaded comes from Transmit Interrupt Delay Value Register (TIDV.IDV). When the count reaches 0, a transmit interrupt occurs. Hardware always loads the transmit interrupt counter whenever it processes a descriptor with IDE set even if it is already counting down due to a previous descriptor. If hardware encounters a descriptor that has RS set, but not IDE, it generates an interrupt immediately after writing back the descriptor and the interrupt delay timer is cleared.

Four bits are reserved to provide transmit status, although only the DD bit (bit 0) is valid. The status word will only be written back to host memory in cases where the RS bit is set in the command field. The DD bit indicates that the descriptor is done and is written back after the descriptor has been processed.

**Figure 37-26. TCP/IP Data Transmit Descriptor Status (TDESC.DSTATUS)**

The POPTS field provides a number of options which control the handling of this packet. This field is ignored except on the first data descriptor of a packet or segmentation context.

**Figure 37-27. TCP/IP Data Transmit Descriptor Packet Options Field (TDESC.POPTS)**

IXSM and TXSM are used to control insertion of the IP and TCP/UDP checksums, respectively. If the corresponding bit is not set, whatever value software has placed into the checksum field of the packet data will be placed on the wire. These bits are only valid in the first data descriptor for a given packet or TCP segmentation context.

The VLAN field is used to provide the 802.1q tagging information. The special field is ignored if the VLE bit is 0.

**Figure 37-28. TCP/IP Data Transmit Descriptor Special Field (TDESC.VLAN)**

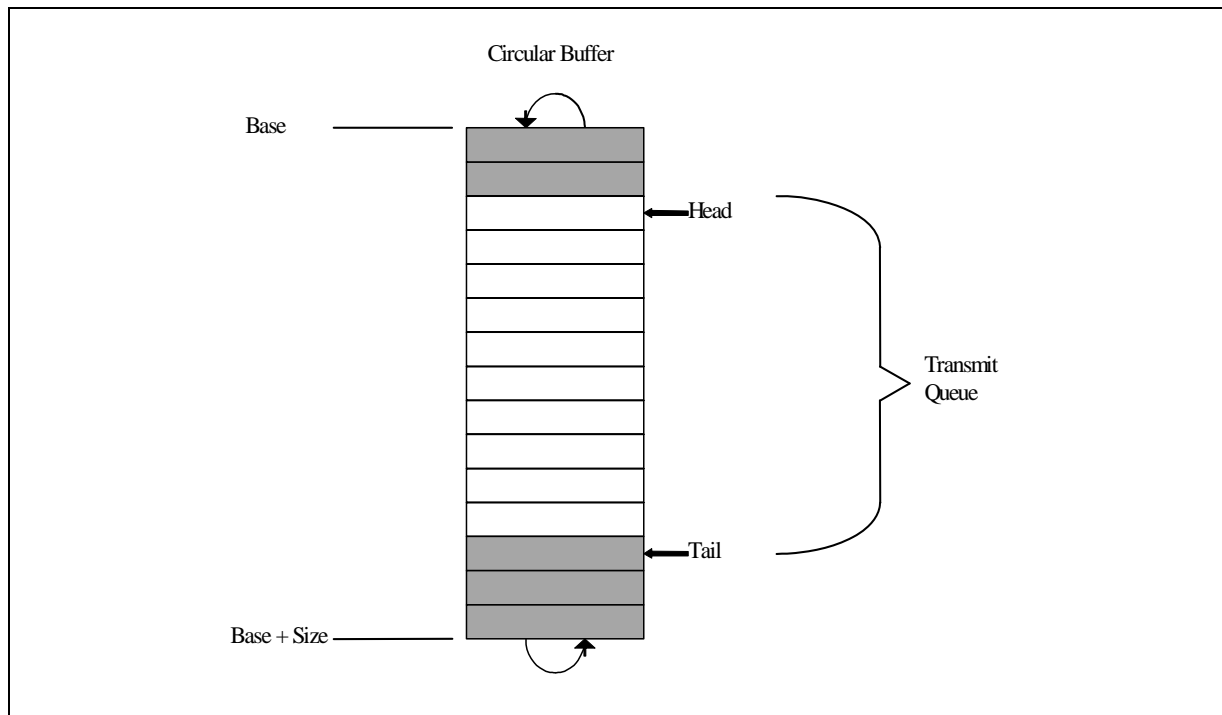

**37.5.6.6 Transmit Descriptor Structure**

A pair of hardware registers maintains the transmit descriptor ring in the host memory. New descriptors are added to the queue by software by writing descriptors into the circular buffer memory region and moving the tail pointer associated with that queue. The tail pointer points one entry beyond the last hardware owned descriptor. Transmission continues up to the descriptor where head equals tail at which point the queue is empty.

Descriptors passed to hardware should not be manipulated by software until the head pointer has advanced past them.

The transmit descriptor ring structure is shown in [Figure 37-29](#). Shaded boxes represent descriptors that have been transmitted but not yet reclaimed by software. Reclaiming involves freeing up buffers associated with the descriptors.

Figure 37-29. Transmit Descriptor Ring Structure

The transmit descriptor ring is described by the following registers:

**The Transmit Descriptor Base Address High Register and the Transmit Descriptor Base Address Low Register (TDBAH and TDBAL)** - These registers indicate the start of the descriptor ring buffer in the host memory; this 64-bit address is aligned on a 16B boundary. Hardware ignores the lower 4 bits.

**Transmit Descriptor Length Register (TDLEN)** - This register determines the number of bytes allocated to the circular buffer. This value must be 0 modulo 128.

**Transmit Descriptor Head Register (TDH)** - This register holds a value which is an offset from the base, and indicates the in-progress descriptor. There can be up to 64K descriptors in the circular buffer. Reading this register returns the value of "head" corresponding to descriptors already loaded in the output FIFO.

**Transmit Descriptor Tail Register (TDT)** - This register holds a value which is an offset from the base, and indicates the location beyond the last descriptor hardware can process. This is the location where software writes the first new descriptor.

The base register indicates the start of the circular descriptor queue and the length register indicates the maximum size of the descriptor ring. The lower seven bits of length are hard-wired to 0. Byte addresses within the descriptor buffer are computed as follows:  $address = base + (pointer * 16)$ , where pointer is the value in the hardware head or tail register.

The size chosen for the head and tail registers permit a maximum of 64K descriptors, or approximately 16K packets for the transmit queue given an average of four descriptors per packet.

Once activated, hardware fetches the descriptor indicated by the hardware head register. The hardware tail register points one beyond the last valid descriptor. Software reads the head register to determine which packets (those logically before the head) have been transmitted.

*Note:* Software can determine if a packet has been sent by either of two methods: setting the RS bit in the transmit descriptor command field or by performing a host CPU read of the transmit head register. Checking the transmit descriptor DD bit in memory eliminates a potential race condition. All descriptor data is written to the host bus prior to incrementing the head register, but a read of the head register could “pass” the data write in systems performing write buffering. Updates to transmit descriptors use the same write path and follow all data writes. Consequently, they are not subject to the race.

Hardware pre-fetches the entire packet data prior to transmission, and updates the value of the head pointer after storing each descriptor's data in the transmit FIFO.

The process of checking for completed packets consists of one of the following:

- Scan memory.
- Read the hardware head register. All packets up to but **excluding** the one pointed to by head have been sent or buffered and can be reclaimed.
- Take an interrupt. An interrupt condition is generated whenever a transmit queue goes empty (ICR.TXQE). This interrupt can either be enabled or masked.

### 37.5.6.7 Transmit Descriptor Fetching

The descriptor processing strategy for transmit descriptors is essentially the same as for receive descriptors except that a different set of thresholds are used. Just as with receives, the number of transmit descriptors held in hardware has been increased (from 8 to 64), and the fetch and write-back algorithms modified.

When the hardware descriptor buffer is empty, a fetch will happen as soon as any descriptors are made available (host writes to the tail pointer). When the hardware descriptor buffer is nearly empty (TXDCTL.PTHRESH), a prefetch will be performed whenever enough valid descriptors (TXDCTL.HTHRESH) are available in host memory and no other DMA activity of greater priority is pending (descriptor fetches, descriptor write-backs, or packet data transfers).

When the number of descriptors in host memory is greater than the available hardware descriptor storage, the GbE may elect to perform a fetch which is not a multiple of cache line size. The hardware performs this non-aligned fetch if doing so will result in the next descriptor fetch being aligned on a cache line boundary. This allows the descriptor fetch mechanism to be most efficient in the cases where it has fallen behind software.

*Note:* The GbE NEVER fetches descriptors beyond the descriptor TAIL pointer. This is different from the 82542 design.

### 37.5.6.8 Transmit Descriptor Write-back

The descriptor write-back policy for transmit descriptors is similar to that for receive descriptors with a few additional factors. First, since transmit descriptor write-backs are optional (controlled by RS in the transmit descriptor), only descriptors which have one (or both) of these bits set will start the accumulation of write-back descriptors. Secondly, to preserve backward compatibility with the 82542, if the TXDCTL.WTHRESH value is 0, the device will write back a single byte of the descriptor (TDESCR.STA) and all other bytes of the descriptor will be left unchanged.

The benefit of delaying and then bursting transmit descriptor write-backs is small at best. In this case, it is recommended the threshold be left at the default value (0) to force immediate write-back of transmit descriptors and to preserve backward compatibility.

Descriptors are written back in one of three cases:

- TXDCTL.WTHRESH = 0 and a descriptor which has RS set is ready to be written back,
- Transmit Interrupt Delay timer expires, or
- TXDCTL.WTHRESH > 0 and TXDCTL.WTHRESH descriptors have accumulated.

For the first condition, write-backs are immediate. This is the default operation and is backward compatible with the 82542 implementation. For this case, the Transmit Interrupt delay function works as described in [“Delayed Transmit Interrupts” on page 1378](#).

The other two conditions are only valid if descriptor bursting is enabled [“TXDCTL – Transmit Descriptor Control Register” on page 1500](#). In the second condition, the [“TIDV – Transmit Interrupt Delay Value Register” on page 1499](#) is used to force timely write-back of descriptors. The first packet after timer initialization starts the timer. Timer expiration flushes any accumulated descriptors and sets an interrupt event (ICR.TXDW).

For the final condition, if TXDCTL.WTHRESH descriptors are ready for write-back, the write-back is performed.

### 37.5.6.9 Transmit Interrupts

Hardware supplies three transmit interrupts. These interrupts are initiated via the following conditions:

**Transmit Descriptor Ring empty (ICR.TXQE)** - All descriptors have been processed. The head pointer is equal to the tail pointer.

**Descriptor done (Transmit Descriptor Write-back (ICR.TXDW))** - Set when hardware writes back a descriptor with RS set. This is only expected to be used in cases where, for example, the streams interface has run out of descriptors and wants to be interrupted whenever progress is made.

**Transmit Delayed Interrupt (ICR.TXDW)** - In conjunction with IDE (Interrupt Delay Enable), the ICR.TXDW indication is delayed per the TIDV and/or TADV registers. The interrupt is set when one of the transmit interrupt countdown timers expires. A Transmit Delayed Interrupt is scheduled for a transmit descriptor with its RS and IDE bits both set. When a Transmit Delayed Interrupt occurs, the ICR.TXDW interrupt cause bit is set (just as when a Transmit Descriptor Write-back interrupt occurs). This interrupt may be masked in the same manner as the ICR.TXDW interrupt. This interrupt will be used frequently by software that performs dynamic transmit chaining, by adding packets one at a time to the transmit chain.

*Note:*

The transmit delay interrupt is indicated with the same interrupt bit as the transmit write-back interrupt, ICR.TXDW. The transmit delay interrupt is only delayed in time as discussed above.

**Transmit Descriptor Ring Low Threshold Hit (ICR.TXD\_LOW)** - Set when the total number of transmit descriptors available (as measured by the difference between the TX descriptor ring Head and Tail pointer) hits the low threshold specified in the TXDCTL.LWTHRESH field in the transmit descriptor control register.

#### 37.5.6.9.1 Delayed Transmit Interrupts

This mechanism allows software the flexibility of delaying transmit interrupts until no more descriptors are added to a transmit chain for a certain amount of time, rather than when the device's head pointer catches the tail pointer. This will occur if the device is processing packets slightly faster than the software, a likely scenario for gigabit operations.

This feature is desirable, because a software driver usually has no knowledge of when it is going to be asked to send another frame, and for performance reasons, it is best to generate only one transmit interrupt after a burst of packets have been sent.

Refer to [“Transmit Descriptor Formats” on page 1365](#) for specific details.

#### 37.5.6.10 Transmit Checksum Off loading

The previous section on TCP Segmentation off load describes the IP/TCP/UDP checksum off loading mechanism used in conjunction with TCP Segmentation. The same underlying mechanism can also be applied as a standalone feature. The main difference in normal packet mode (non-TCP Segmentation) is that only the checksum fields in the IP/TCP/UDP headers need to be updated.

Before taking advantage of the GbE enhanced checksum off load capability, a checksum context must be initialized. For the normal transmit checksum off load feature this is performed by providing the device with a TCP/IP Context Descriptor with TSE=0. Setting TSE=0 indicates that the normal checksum context is being set, as opposed to the segmentation context. For additional details on contexts, refer to [“Overview of GbE hardware “Contexts”” on page 1369](#).

*Note:* Enabling the checksum off loading capability without first initializing the appropriate checksum context will lead to unpredictable results.

Once the checksum context has been set, that context will be used for all normal packet transmissions until a new context is loaded. Also, since checksum insertion is controlled a per packet basis, there is no need to clear/reset the context.

The GbE is capable of performing two transmit checksum calculations. Typically these would be used for TCP/IP and UDP/IP packet types; however, the mechanism is general enough to support other checksums as well. Each checksum operates independently and provides identical functionality. Only the IP checksum case is discussed below.

Three fields in the TCP/IP Context Descriptor set the context of the IPv4 checksum off loading feature: IPCSS, IPCSO, and IPCSE.

IPCSS specifies the byte offset from the start of the data fetched from host memory to the first byte to be included in the checksum. Setting this value to “0” means the first byte of the data would be included in the checksum. Note that the maximum value for this field is 255. This is adequate for typical applications.

*Note:* The CSS value needs to be less than the total DMA length for a packet. If this is not the case, the results will be unpredictable.

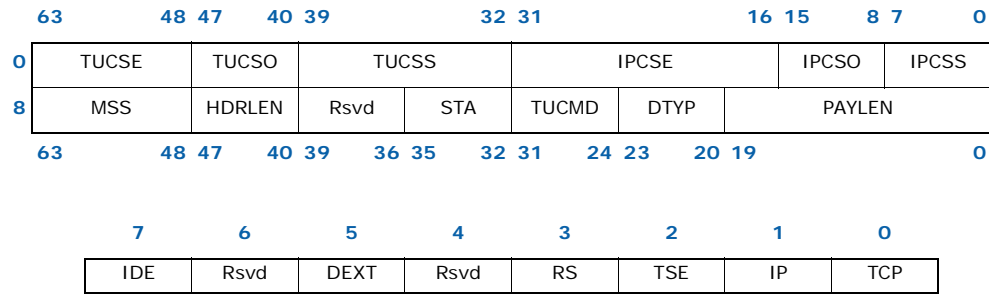

The IPCSO field specifies where the resulting checksum should be placed. Again, this is limited to the first 256 bytes of the packet and must be less than or equal to the total length of a given packet. If this is not the case, the checksum will not be inserted.

IPCSE specifies where the checksum should stop. A 16-bit value supports checksum off loading of packets as large as 64KB. Setting the IPCSE field to all zeros means End-of-Packet. In this way, the length of the packet does not need to be calculated.

As mentioned in [“Overview of GbE hardware “Contexts”” on page 1369](#), it is not necessary to set a new context for each new packet. In many cases, the same checksum context can be used for a majority of the packet stream. In this case, some performance can be gained by only changing the context on an as needed basis or electing to use the off load feature only for a particular traffic type, thereby avoiding all context descriptors except for the initial one.

### 37.5.7 TCP Segmentation

Hardware TCP Segmentation is one of the off-loading options of the Windows 2000\* TCP/IP stack. This is often referred to as “Large send” off loading. This feature allows the TCP/IP stack to pass to the network device driver a message to be transmitted that is bigger than the Maximum Transmission Unit (MTU) of the medium. It is then the responsibility of the device driver and hardware to carve the TCP message into MTU size frames that have appropriate layer 2 (Ethernet), 3 (IP), and 4 (TCP) headers. These headers must include sequence number, checksum fields, options and flag values as required. Note that some of these values (such as the checksum values) will be unique for each packet of the TCP message, and other fields such as the source IP address will be constant for all packets associated with the TCP message.

The off loading of these mechanisms to the device driver and the EP80579’s GbE will save significant CPU cycles. The device driver and the EP80579’s GbE will share the additional tasks in order to support this feature.

Prior to Windows 2000\*, the Microsoft\* TCP/IP stack (TCPIP.SYS) had always transferred (to the miniport device driver and eventually to the MAC) a frame with bytes up to the size of MTU for the media (up to 1514 bytes for 802.3 Ethernet packets).

*Note:* Although the GbE TCP segmentation off load implementation was specifically designed to take advantage of the new “TCP Segmentation offload” feature from Microsoft, the hardware implementation was made generic enough so that it could also be used to “segment” traffic from other protocols. For instance this feature could be used any time it is desirable for HW to segment a large block of data for transmission into multiple packets that contain the same generic header.

### 37.5.7.1 Assumptions

The GbE TCP Segmentation implementation assumes the RS bit operation is not changed. Interrupts are set after data in buffers pointed to by individual descriptors is transferred from host memory to GbE hardware.

### 37.5.7.2 Transmission Process

The transmission process for regular (non-TCP Segmentation packets) involves the following:

- The protocol stack receives a block of data that is to be transmitted from an application.
- The protocol stack calculates the number of packets required to transmit this block based on the MTU size of the media and required packet headers.
- For each packet of the data block:
  - The stack prepares Ethernet, IP and TCP/UDP headers.
  - The stack interfaces with the device driver and commands the driver to send the individual packet.
  - The driver gets the frame and interfaces with the hardware.
  - The hardware reads the packet from host memory (via DMA transfers).
  - The driver returns ownership of the packet to the NOS when the hardware has completed the DMA transfer of the frame (indicated by an interrupt).

The transmission process for the GbE TCP segmentation off load implementation involves the following:

- The protocol stack receives a block of data that is to be transmitted from an application.
- The stack interfaces to the device driver and passes the block down with the appropriate header information.
- The device driver sets up the interface to the hardware (via descriptors) for the TCP Segmentation context.
- The hardware transfers the packet data from host memory and performs the Ethernet packet segmentation and transmission based on offset and payload length parameters in the TCP/IP context descriptor including:
  - Packet encapsulation
  - Header generation and field updates including IP and TCP/UDP checksum generation
- The driver returns ownership of the block of data to the NOS when the hardware has completed the DMA transfer of the entire data block (indicated by an interrupt).

#### 37.5.7.2.1 TCP Segmentation Data Fetch Control

To perform TCP Segmentation in the GbE, the DMA must ensure that the entire payload of the **segmented** packet will fit into the available space in the GbE Packet Buffer. The segmentation process should be performed without interruption. The DMA will do various comparisons between the payload and the Packet Buffer to ensure no interruptions occur as well as general efficiencies in the operation of the TCP Segmentation feature. The [“TSPMT – TCP Segmentation Pad and Minimum Threshold Register” on page 1503](#) is used to allow software to program the minimum threshold required for a TCP Segmentation payload. Consideration should be made for the MTU

value when writing this field. The TSPMT register is also used to program the threshold padding overhead. This padding is necessary due to the indeterminate nature of the MTU and the associated headers.

### 37.5.7.3 TCP Segmentation Performance

Performance improvements for a hardware implementation of TCP Segmentation off load include:

- The stack does not need to partition the block to fit the MTU size, saving CPU cycles.
- The stack only computes one Ethernet, IP, and TCP header per segment, saving CPU cycles.
- The Stack interfaces with the device driver only once per block transfer, instead of once per frame.
- Larger internal bus bursts are used which improves bus efficiency (i.e. lowering transaction overhead).
- Interrupts are easily reduced to one per TCP message instead of one per packet.
- Fewer I/O accesses are required to command the hardware.

### 37.5.7.4 Packet Format

Typical TCP/IP transmit window size is 8760 bytes (about 6 full size frames). Today the average size on corporate Intranets is 12-14KB, and normally the maximum window size allowed is 64KB. A TCP message can be as large as 64KB and is generally fragmented across multiple pages in host memory. The GbE partitions the data packet into standard Ethernet frames prior to transmission. The GbE also supports calculating the Ethernet, IP, TCP, and even UDP headers, including checksum, on a frame by frame basis.

Figure 37-31.TCP/IP Packet Format

|          |    |         |      |     |
|----------|----|---------|------|-----|
| Ethernet | IP | TCP/UDP | Data | FCS |
|----------|----|---------|------|-----|

Frame formats supported by the GbE include:

- Ethernet 802.3,
- IEEE 802.1q VLAN (Ethernet 802.3ac),
- Ethernet Type 2,
- Ethernet SNAP,
- IPv4 headers with options,
- IPv6 headers with IP option next headers,
- IPv6 packet tunneled in IPv4,
- TCP with options, and
- UDP with options.

VLAN tag insertion is also handled by hardware.

Note:

UDP (unlike TCP) is not a “reliable protocol”, and fragmentation is not supported at the UDP level. UDP messages that are larger than the MTU size of the given network medium are normally fragmented at the IP layer. This is different from TCP, where large TCP messages can be fragmented at either the IP or TCP layers depending on the software implementation. The GbE has the ability to segment UDP traffic (in addition to TCP traffic), but because UDP packets are generally fragmented at the IP layer the GbE “TCP Segmentation” feature will normally not be conducive to handling UDP traffic.

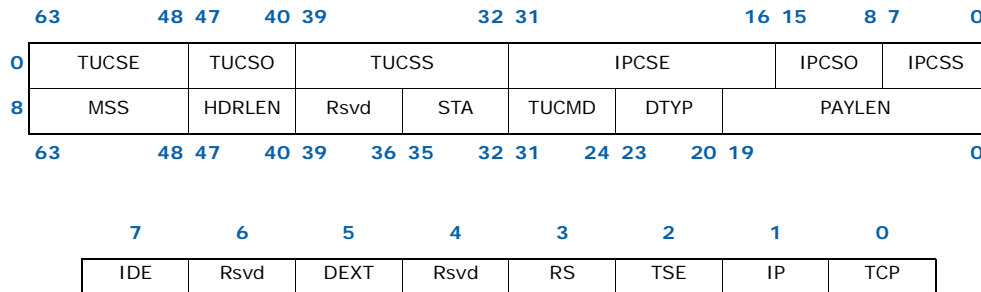

Note: IP tunneled packets are not supported for Large Send operation.

### 37.5.7.5 TCP Segmentation Indication

Software indicates a TCP Segmentation transmission context to the hardware by setting up a TCP/IP Context Transmit Descriptor (refer to “TCP/IP Context Transmit Descriptor Format” on page 1369). The purpose of this descriptor is to provide information to the hardware to be used during the TCP segmentation off load process. The layout of this descriptor is reproduced in Figure 37-32.

Figure 37-32. TCP/IP Context Transmit Descriptor & Command Layout

Setting the TSE bit in the Command field to ‘1’ indicates that this descriptor refers to the TCP Segmentation context (as opposed to the normal checksum off loading context). This will cause the checksum off loading, packet length, header length, and maximum segment size parameters to be loaded from the descriptor into the device.

The TCP Segmentation prototype header is taken from the packet data itself. Software must identify the type of packet that is being sent (IP/TCP, IP/UDP, other), calculate appropriate checksum off loading values for the desired checksums, and calculate the length of the header which is prepended. The header may be up to 240 bytes in length.

### 37.5.7.6 TCP Segmentation Data Descriptors

#### 37.5.7.6.1 TCP Segmentation Source Data

Once the TCP Segmentation context has been set, the next descriptor provides the initial data to transfer. This first descriptor(s) must point to a packet of the type indicated. Furthermore, the data it points to may need to be modified by software as it will serve as the prototype header for all packets within the TCP Segmentation context. The following sections describe the supported packet types and the various updates which are performed by hardware. This should be used as a guide to determine what must be modified in the original packet header to make it a suitable prototype header.

The following summarizes the fields considered by the driver for modification in constructing the prototype header.

- IPv4 Header
  - Length should be set to zero
  - Identification Field should be set as appropriate for first packet of send (if not already)
  - Header Checksum should be zeroed out unless some adjustment is needed by the driver
- IPv6 Header
  - Length should be set to zero
- TCP Header

- Sequence Number should be set as appropriate for first packet of send (if not already)
- PSH, and FIN flags should be set as appropriate for LAST packet of send
- TCP Checksum should be set to the partial pseudo-header checksum as follows (there is a more detailed discussion of this in “IP and TCP/UDP Headers” just before Figure 37-40:

Figure 37-33.TCP Partial Pseudo-Header Checksum for IPv4

|                        |             |      |
|------------------------|-------------|------|
| 0                      | 31          |      |
| IP Source Address      |             |      |
| IP Destination Address |             |      |
| Zero                   | Protocol ID | Zero |

Figure 37-34.TCP Partial Pseudo-Header Checksum for IPv6

|                        |             |
|------------------------|-------------|
| 0                      | 31          |
| IP Source Address      |             |
| IP Destination Address |             |
| Zero                   |             |
| Zero                   | Next Header |

- UDP Header
  - Checksum should be set as in TCP header, shown in Figure 37-33 and Figure 37-34.

The GbE DMA function will fetch the Ethernet, IP, and TCP/UDP prototype header information from the initial descriptor(s) and save them in hardware for individual packet header generation. The following sections describe the updating process performed by the hardware for each frame sent using the TCP Segmentation capability.

### 37.5.7.6.2 TCP Segmentation Use of Multiple Data Descriptors

TCP Segmentation allows the packet to be segmented to be describe more than one data descriptor. A large packet contained in a single virtual-address buffer may be more simply described by a series of data descriptors, each referencing a single physical address page.

There is only one requirement for multiple data descriptors for TCP segmentation:

- If multiple data descriptors are used to describe the IP/TCP/UDP header section, each descriptor must describe one or more complete headers; descriptors referencing only parts of headers are not supported.

*Note:* It is recommended that the entire header section, as described by the TCP Context Descriptor HDRLEN field, be coalesced into a single buffer and described using a single data descriptor.

### 37.5.7.7 IP and TCP/UDP Headers

This section outlines the format and content for the IP, TCP and UDP headers. The GbE requires baseline information from the device driver in order to construct the appropriate header information during the segmentation process.

Header fields that are modified by the GbE are highlighted in the figures below.

*Note:* The IPv4 header is first shown in the traditional (i.e., RFC 791) representation, and because byte and bit ordering is confusing in that representation. The IP header is also shown in Little-Endian format, since the actual data will be fetched from memory in Little-Endian format.

**Figure 37-35. IPv4 Header (Traditional Representation)**

0 0 0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1 1 1 2 2 2 2 2 2 2 2 2 2 3 3  
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1

|                     |               |                     |              |                 |  |
|---------------------|---------------|---------------------|--------------|-----------------|--|

| Destination Address |   |   |   |        |   |   |   |                     |   |   |   |         |   |                      |   |               |   |     |   |   |   |   |   |   |   |                |   |   |   |   |   |  |  |     |  |  |  |  |  |  |  |
| Options             |   |   |   |        |   |   |   |                     |   |   |   |         |   |                      |   |               |   |     |   |   |   |   |   |   |   |                |   |   |   |   |   |  |  |     |  |  |  |  |  |  |  |

Figure 37-35 and Figure 37-36: Flag Bit Definition:

- MF: More Fragments (hardware does not evaluate or change this bit)
- NF: No Fragments (hardware does not evaluate or change this bit)
- RSV: Reserved

*Note:* The IPv6 header is shown in the traditional (i.e. RFC 2460), Big-Endian representation. The actual data will be fetched from memory in Little-Endian format, similar to the IPv4 header shown above.

**Figure 37-37. IPv6 Header (Traditional Representation)**

0 0 0 0 0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1 1 1 2 2 2 2 2 2 2 2 2 2 3 3  
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1

|                     |               |             |  |           |
|---------------------|---------------|-------------|--|-----------|
| Version             | Traffic Class | Flow Label  |  |           |
| Payload Length      |               | Next Header |  | Hop Limit |
| Source Address      |               |             |  |           |
| Destination Address |               |             |  |           |

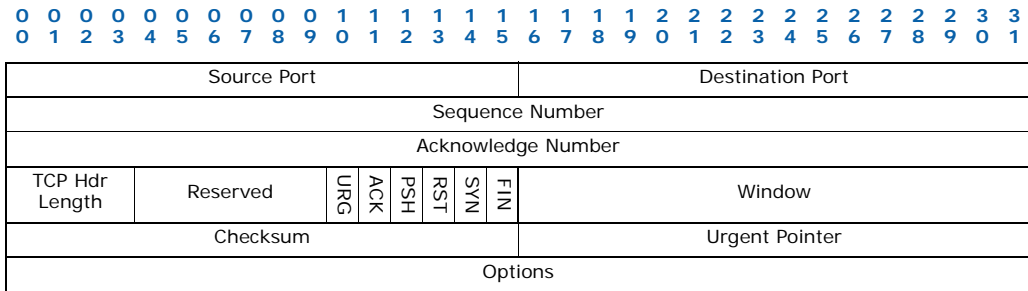

A TCP or UDP frame uses a 16 bit wide one's complement checksum. The checksum word is computed on the outgoing TCP or UDP header and payload, and on the Pseudo Header. Refer to [“Transmit Checksum Off loading with TCP Segmentation”](#) on page 1388 for details on checksum computations.

*Note:* TCP requires the use of checksum, where it is optional for UDP.

*Note:* The TCP header is first shown in the traditional (i.e. RFC 793) representation, and because byte and bit ordering is confusing in that representation, the TCP header is also shown in Little-Endian format. The actual data will be fetched from memory in Little-Endian format.

**Figure 37-38. TCP Header (Traditional Representation)**

**Figure 37-39. TCP Header (Little-Endian Order)**

The TCP header is always a multiple of 32 bit words. TCP options may occupy space at the end of the TCP header and are a multiple of 8 bits in length. All options are included in the checksum.

The checksum also covers a pseudo header conceptually prefixed to the TCP Header (see [Figure 37-40](#) and [Figure 37-41](#) below). The IPv4 pseudo header contains the IPv4 Source Address, the IPv4 Destination Address, the IPv4 Protocol field, and TCP Length. The IPv6 pseudo header contains the IPv6 Source Address, the IPv6 Destination Address, the IPv6 Payload Length, and the IPv6 Next Header field. Software pre-calculates the partial pseudo header sum, which includes IP SA, DA and protocol type/next header, but NOT the TCP/Payload length, and stores this value into the TCP checksum field of the packet.

*Note:* When calculating the TCP pseudo header, the byte ordering can be tricky. One common question is whether the Protocol ID field is added to the “lower” or “upper” byte of the 16 bit sum. The Protocol ID field should be added the least significant byte (LSB) of the 16 bit pseudo header sum, where the most significant byte (MSB) of the 16 bit sum is the byte that corresponds to the first checksum byte out on the wire.

The TCP Length field is the TCP Header Length including option fields plus the data length in bytes, which is calculated by hardware on a frame by frame basis. The TCP Length does not count the 12 bytes of the pseudo header. The TCP length of the packet is determined by hardware as:

$$\text{TCP Length} = \text{Payload} + \text{HDRLEN} - \text{TUCSS}$$

“Payload” is normally MSS except for the last packet where it represents the remainder of the payload.

**Figure 37-40. TCP Pseudo Header Content (Traditional Representation)**

| IP Destination Address    |             |
| Upper Layer Packet Length |             |
| Zero                      | Next Header |

*Note:* The IP Destination Address is the final destination of the packet. Therefore, if a routing header is used, the last address in the route list is used in this calculation. The upper-layer packet length is the length of the TCP header and TCP payload.

The UDP header is always 8 bytes in size with no options.

**Figure 37-42. UDP Header (Traditional Representation)**

|   |   |
|---|---|
| 0 0 0 0 0 0 0 0 0 0 1 1 1 1 1 1 1 1 1 1 2 2 2 2 2 2 2 2 2 2 3 3 | 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 |
| Source Port   | Destination Port  |
| Length  | Checksum  |

**Figure 37-43. UDP Header (Little-Endian Order)**

|                  |                 |                 |                 |
|------------------|-----------------|-----------------|-----------------|
| Byte 3           | Byte 2          | Byte 1          | Byte 0          |
| 7 6 5 4 3 2 1 0  | 7 6 5 4 3 2 1 0 | 7 6 5 4 3 2 1 0 | 7 6 5 4 3 2 1 0 |
| Destination Port |                 | Source Port     |                 |
| Checksum         |                 | Length          |                 |

UDP pseudo header has the same format as the TCP pseudo header. The IPv4 pseudo header conceptually prefixed to the UDP header contains the IPv4 source address, the IPv4 destination address, the IPv4 protocol field, and the UDP length (same as the TCP Length discussed above). The IPv6 pseudo header for UDP is the same as the IPv6 pseudo header for TCP. The checksum procedure is the same as is used in TCP.

Figure 37-44.UDP Pseudo Header Diagram for IPv4

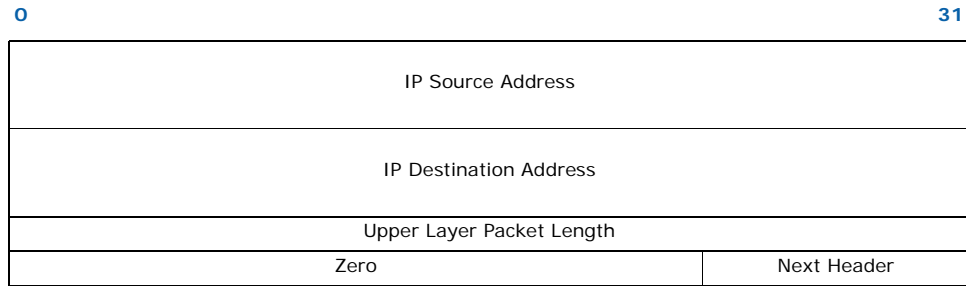

Figure 37-45.UDP Pseudo-Header Diagram for IPv6

Note: The IP Destination Address is the final destination of the packet. Therefore, if a routing header is used, the last address in the route list is used in this calculation. The upper-layer packet length is the length of the UDP header and UDP payload.

Unlike the TCP checksum, the UDP checksum is optional. Software must set the TXSM bit in the TCP/IP Context Transmit Descriptor to indicate that a UDP checksum should be inserted. Hardware will not update the UDP checksum unless the TXSM bit is set.

### 37.5.7.8 Transmit Checksum Off loading with TCP Segmentation

The GbE supports checksum off-loading as a component of the TCP Segmentation off load feature and as a standalone capability. Refer to "TCP/IP Context Transmit Descriptor Format" on page 1369 for details on the interface for controlling the checksum off-loading feature. This section describes the feature as it relates to TCP Segmentation.

The GbE supports IP and TCP/UDP header options in the checksum computation for packets that are derived from the TCP Segmentation feature.

Note: The GbE is capable of computing one level of IP header checksum and one TCP/UDP header and payload checksum. In the case of multiple IP headers, the driver will have to compute all but one IP header checksum. The GbE calculates checksums on the fly on a frame by frame basis and inserts the result in the IP/TCP/UDP headers of each frame. TCP and UDP checksum are a result of performing the checksum on all bytes of the payload and the pseudo header.

Three specific types of checksum are supported by the hardware in the context of the TCP Segmentation off load feature IPv4 checksum (IPv6 does not have a checksum), TCP checksum, and UDP checksum.

Each packet that is sent via the TCP segmentation off load feature optionally includes the IPv4 checksum and either the TCP or UDP checksum.

All checksum calculations use a 16-bit wide one's complement checksum calculated of all 16-bit words in the range of CSS to CSE, including the checksum field itself. The checksum field is written with this hardware computed value.

### 37.5.7.9 IP/TCP/UDP Header Updating

IP/TCP/UDP header is updated for each outgoing frame based on the IP/TCP header prototype which hardware DMA's from the first descriptor(s) and stores in hardware. The IP/TCP/UDP headers are fetched from host memory into a 240 byte header buffer once for each TCP segmentation context (for performance reasons, this header is not fetched again for each additional packet that will be derived from the TCP segmentation process). The checksum fields and other header information are later updated on a frame by frame basis. The updating process is performed concurrently with the packet data fetch.

The following sections define what fields are modified by hardware during the TCP Segmentation process by the GbE.

#### 37.5.7.9.1 TCP/IP/UDP Header for the First Frame

The hardware makes the following changes to the headers of the first packet that is derived from each TCP segmentation context.

- IPv4 Header
  - IP Total Length = MSS + HDRLEN - IPCSS
  - IP Checksum
- IPv6 Header
  - Payload Length = MSS + HDRLEN - IPCSS
- TCP Header
  - Sequence Number: The value is the Sequence Number of the first TCP byte in this frame.
  - If FIN flag = 1, it is cleared in the first frame.
  - If PSH flag = 1, it is cleared in the first frame.
  - TCP Checksum
- UDP Header
  - UDP length: MSS + HDRLEN - TUCSS
  - UDP Checksum

#### 37.5.7.9.2 TCP/IP/UDP Header for the Subsequent Frames

The hardware makes the following changes to the headers for subsequent packets that are derived as part of a TCP segmentation context:

*Note:* Number of bytes left for transmission = PAYLEN - (N \* MSS). Where N is the number of frames that have been transmitted.

- IPv4 Header
  - IP Identification: incremented from last value (wraps around)
  - IP Total Length = MSS + HDRLEN - IPCSS
  - IP Checksum
- IPv6 Header
  - Payload Length = MSS + HDRLEN - IPCSS
- TCP Header
  - Sequence Number update: Add previous TCP payload size to the previous sequence number value. This is equivalent to adding the MSS to the previous sequence number.

- If FIN flag = 1, it is cleared in these frames.
- If PSH flag = 1, it is cleared in these frames.
- TCP Checksum
- UDP Header
  - UDP Length:  $MSS + HDRLEN - TUCSS$
  - UDP Checksum

### 37.5.7.9.3 TCP/IP/UDP Header for the Last Frame

The hardware makes the following changes to the headers for the last frame of a TCP segmentation context:

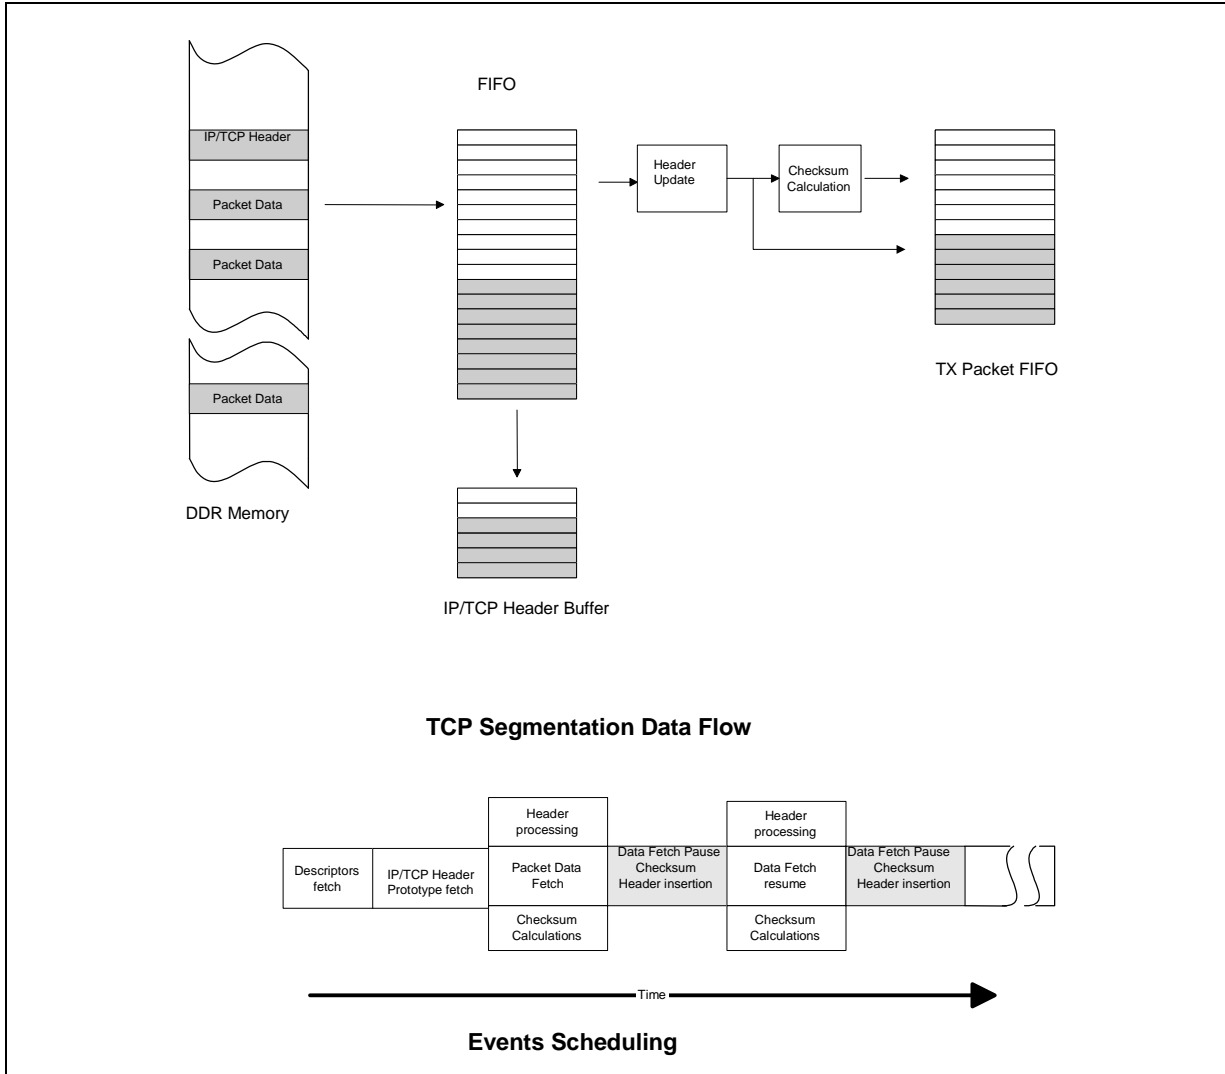

*Note:* Last frame payload bytes =  $PAYLEN - (N * MSS)$

- IPv4 Header
  - IP Total Length = (last frame payload bytes + HDRLEN) - IPCSS
  - IP Identification: incremented from last value (wraps around)
  - IP Checksum
- IPv6 Header
  - Payload Length =  $MSS + HDRLEN - IPCSS$
- TCP Header
  - Sequence Number update: Add previous TCP payload size to the previous sequence number value. This is equivalent to adding the MSS to the previous sequence number.
  - If FIN flag = 1, set it in this last frame
  - If PSH flag = 1, set it in this last frame
  - TCP Checksum
- UDP Header
  - UDP length: (last frame payload bytes + HDRLEN) - TUCSS
  - UDP Checksum

### 37.5.7.10 Data Flow

Figure 37-46. Data Flow

### 37.5.8 Ethernet Interfaces

The GbE MAC provides a complete CSMA/CD function supporting IEEE 802.3 (10Mbps), 802.3u (100Mbps), 802.3z and 802.3ab (1000Mbps) implementations. The device performs all of the functions required for transmission, reception and collision handling called out in the standards.

The GbE may be configured to be used with different media interfaces. The following native configurations are supported:

- External RGMII/RMII device (these interfaces are provided via gasket between the GbE's native GMII/MII interfaces)

Selection between the various configurations is programmable via the MAC Extended Device Control Register (CTRL\_EXT.LINK\_MODE bits).

TGMII/MII interface used to communicate between the MAC and the RGMII/RMII gasket supports 10/100/1000 Mbps operation, with both half- and full-duplex operation at 10/100 Mbps, and full-duplex operation at 1000 Mbps.

*Note:* The GbE MAC is optimized for full-duplex operation in 1000 Mbps mode. Half-duplex 1000 Mbps operation is not supported.

### 37.5.8.1 MAC/PHY GMII/MII Interface

The GbE MAC communicates through a GMII/MII interface which may be configured for either 1000 Mbps operation (GMII) or 10/100 Mbps (MII) mode of operation. For proper network operation, both the internal MAC and the external PHY must be properly configured to identical speed & duplex settings. Additionally, the translators may need to be configured in the “CTRL\_AUX – Auxiliary Device Control/Status Register”. All MAC configuration is performed using device control registers mapped into system memory. The PHY will either auto-negotiate the link with the link partner’s PHY at the other end of the copper line, or will be forced into its configuration by software.

#### 37.5.8.1.1 GMII - 1000 Mbps Operation

During 1000Mbps operation, the MAC/PHY communication occurs via an interface utilizing a pair of 8-bit buses operating at 125 MHz and accompanied by a handful of additional clocks and/or qualifiers. This signaling (GMII mode) includes the following communication:

**CRS (carrier sense):** Carrier sense is detected by the PHY and indicates activity on the cable, either incoming or outgoing. This signal is driven by the PHY to the MAC to enable the MAC to generate link status-change alerts, and suspend transmit / ignore receive symbols when no link is present.

**COL (collision detection):** Collision detection is performed by the PHY, signaled to the MAC upon detection of a collision on the medium, and remains asserted while the collision condition persists. For half-duplex operation, COL indicates detection of simultaneous transmission and reception. Since collisions do not occur between full-duplex transceivers, the GbE MAC ignores any errant collision-signaling when in full-duplex mode.

**TX\_ER (transmit code error):** This signaling is used by the MAC to indicate carrier extension and IPG during packet bursts to the PHY, as well as to force propagation of transmit errors. Note that the GbE will not transmit error codes.

**TX\_EN (transmit enable):** This signal is asserted from the MAC to the PHY while transmitting, and used to indicate when the MAC is presenting frame data on the GMII interface to the PHY for transmission. The MAC asserts TX\_EN synchronously with the first byte of the preamble, and it remains asserted until the final data byte in a frame, deasserted after the final byte.

**GTX\_CLK (transmit data clock):** In GMII mode, the MAC provides a 125 MHz transmit clock to the PHY accompanying any transmit data.

**TX\_DATA (transmit data):** Data is transmitted from the MAC to PHY in 8-bit quantities at 125 MHz when in GMII mode.

**RX\_CLK (receive clock):** In GMII mode, receive data provided from the PHY to the MAC is accompanied by a 125 MHz receive clock.

**RX\_DATA (receive data):** Data received by the PHY is transferred to the MAC in 8-bit quantities at 125 MHz in GMII mode.

**RX\_ER (receive error):** Receive errors are detected by the PHY and signaled to the MAC. Receive errors may include link coding errors, or any other error detected by the PHY. If receive errors are signaled during packet reception, the MAC can be configured to either receive or drop these packets.

**RX\_DV (receive data valid):** This signal is asserted from the PHY to the MAC to transfer valid frame data to the MAC. It is asserted from the first through the final bytes of a frame, de-asserted after the final byte. The PHY asserts carrier sense with this data-valid signal de-asserted to indicate to the MAC reception of broken packet headers (fragments).

#### 37.5.8.1.2 MII - 10/100 Mbps Operation

During 10/100 Mbps operation (MII mode), the communication between the GbE MAC and the external PHY occurs via the same interface as in GMII mode, used in a similar way. In MII mode, transmit and receive data is transferred in nibble-wide (4-bit) quantities instead of 8-bit quantities, and at either 25MHz (100 Mbps operation) or 2.5 MHz (10 Mbps operation).

Differences in signaling between GMII and MII modes are as follows:

**MTX\_CLK (transmit clock):** In MII mode, this clock is supplied from the PHY to the MAC, and is used by the MAC for transmit-data synchronization. This clock operates at either 25MHz (for 100Base-T) or 2.5MHz (for 10BASE-T).

**TX\_DATA (transmit data):** Transmit data is transferred from the MAC to the PHY in 4-bit (nibble) quantities at either 25 MHz or 2.5 MHz. in MII mode.

**RX\_CLK (receive clock):** In MII mode, the receive clock provided from the PHY to the MAC operates at either 25 MHz (for 100BASE-T) or 2.5MHz (for 10BASE-T).

**RX\_DATA (receive data):** Receive data is transferred from the PHY to the MAC in 4-bit (nibble) quantities at either 25 MHz or 2.5 MHz in MII mode.

If a pin is listed in GMII mode, but not MII mode, then it functions identically to GMII mode.

#### 37.5.8.2 Duplex Operation

The GbE supports half-duplex MII mode and full-duplex GMII/MII mode. Configuration of the duplex operation of the device must be programmed by software.

##### 37.5.8.2.1 Full Duplex

All aspects of the IEEE 802.3, 802.3u, 802.3z, and 802.3ab specifications are supported in full duplex operation. During full duplex operation, the GbE may transmit and receive packets simultaneously across the link interface.

In full-duplex GMII/MII mode, transmission and reception are delineated independently by the control signals. Transmission starts upon the assertion of TX\_EN which indicates there is valid data on the TX\_DATA bus driven from the MAC to the PHY. Reception is signaled by the PHY by the assertion of the RX\_DV signal which indicates valid receive data on the RX\_DATA lines to the MAC.

The GbE can receive carrier-extended packets, although it cannot transmit carrier-extended packets. Note that errors received the extended portion of the packet (carrier-extend errors) will not be detected by the GbE.

##### 37.5.8.2.2 Half Duplex

The GbE MAC may operate in half duplex when configured for MII mode, but GMII mode does not support half duplex operation.

In half duplex operation, the MAC attempts to avoid contention with other traffic on the link by monitoring the CRS signal provided by the PHY and deferring to passing traffic. When the CRS signal is de-asserted or after a sufficient inter-packet gap (IPG) has elapsed after a transmission, frame transmission may begin. The MAC signals the PHY with TX\_EN at the start of transmission.

In the case of a collision, the PHY detects the collision and asserts the COL signal to the MAC. Transmission of the frame stops within four link clock times, and the GbE sends a JAM sequence onto the link. After the end of a collided transmission, the GbE will back off and attempt to retransmit per the standard CSMA/CD method. Note that the re-transmissions are done from the data stored internally in the GbE transmit packet buffer (no re-access to the data in host memory is necessary).

In the case of a successful transmission, the GbE is ready to transmit any other frame(s) queued in the transmit FIFO, after the minimum inter-frame spacing (IFS) of the link has elapsed.

During transmit, the PHY is expected to signal a carrier-sense (assert the CRS signal) back to the MAC before one slot time has elapsed. The transmission will complete successfully even if the PHY fails to indicate CRS within the slot time window. If this situation occurs, the PHY may either be configured incorrectly or be in a link down situation. Such an event will be counted in the statistic register space, refer to “[TNCRS – Transmit with No CRS Count Register](#)” on page 1510.

MII mode half duplex reception occurs exactly as indicated in “[Full Duplex](#)” on page 1393. Reception is signaled by the PHY by the assertion of the RX\_DV signal which indicates valid receive data on the RX\_DATA lines to the MAC.

### 37.5.8.3 Physical Layer Auto-Negotiation & Link Setup Features

The method for configuring the link between two link partners is highly dependent on the mode of operation as well as the functionality provided by the specific physical layer device. For GMII/MII mode, the PCS and Auto-Negotiation functions are expected to be maintained within the external PHY.

Configuration of the link may be accomplished by several methods ranging from software's forcing link settings, to software-controlled negotiation, to auto-negotiation initiated by the PHY. The following sections describe processes of bringing the link up including configuration of the GbE and the transceiver, as well as the various methods of determining duplex and speed configuration in order to configure the MAC.

When operating in a GMII/MII mode, the external PHY performs auto-negotiation per 802.3ab clause 40 and extensions to clause 28. Link resolution is obtained by software from the PHY after the link has been established and programs the MAC with these settings.

#### 37.5.8.3.1 GMII/MII/Copper Link Configuration

When operating in GMII/MII mode, link configuration is generally determined by Auto-Negotiation between the PHY and its link partner. The driver must poll the configuration in cases after a successful link is established or the user desires to manually configure the link. The following sections discuss the methods of link configuration for copper PHY operation.

#### 37.5.8.3.2 GMII/MII/Copper Auto-Negotiation (Speed, Duplex, Flow-Control)

When using a copper PHY, the PHY performs the Auto-Negotiation function. The actual operational details of this operation are described in the IEEE P802.3ab draft standard, and are not included here.

Auto-Negotiation provides a method for two link partners to exchange information in a systematic manner in order to establish a link configuration providing the highest level of functionality supported by both partners. Once configured, the link partners exchange configuration information to resolve link settings such as:

- Speed (10/100/1000 Mbps)

- Duplex (Full or Half)
- Flow Control Operation

PHY specific information required for establishing the link is also exchanged.

*Note:* If flow control is enabled in the GbE, the settings for the desired flow control behavior must be set by software in the PHY registers and Auto-Negotiation restarted. After Auto-Negotiation is complete, the driver must read the PHY registers to determine the resolved flow control behavior of the link and reflect these in the MAC register settings (CTRL.TFCE and CTRL.RFCE).

*Note:* There are two recommended methods for coordination between the PHY/PHY Auto-Negotiation and the GbE. First, the PHY can be programmed to issue an MDINT to the host CPU when the link changes. When the EP80579 receives the MDINT indicator via an interrupt, the ISR routine will poll the PHY's MDIO interface and programs the GbE accordingly. Second, software may continuously poll the PHY's configuration registers through the MDIO interface and reprogram the GbE when the configuration changes from the previous state.

### MAC Speed Resolution

For proper link operation, both the MAC and PHY must be configured for the same speed of link operation. The speed of the link may be determined and set by one of the following methods:

- Hardware uses the default MAC speed of 1 Gbps and no software action is necessary, or
- Software reads the PHY registers to determine the PHY's Auto-Negotiated speed and configures the MAC by setting CTRL.FRCSPEED to 1 and CTRL.SPEED to the proper speed value (refer to "[CTRL – Device Control Register](#)" on page 1438 for details), or
- Software writes the non Auto-Negotiated PHY registers with the desired speed and configures the MAC by to the same setting by programming CTRL.FRCSPEED to 1 and CTRL.SPEED to the proper speed value (refer to "[CTRL – Device Control Register](#)" on page 1438 for details).

*Note:* Forcing the MAC speed using CTRL.FRCSPEED can yield non-functional links if the MAC and PHY are not operating at the same speed/configuration.

*Note:* The forcing of the speed settings by CTRL.SPEED may also be accomplished by setting the CTRL\_EXT.SPD\_BYPS bit. This bit bypasses the MAC's internal clock switching logic and allows the driver complete control of when the speed setting takes place. The CTRL.FRCSPEED bit uses the MAC's internal clock switching logic, which does slightly delay the affect of the speed change.

### MAC Full/Half Duplex Resolution

The duplex configuration of the link is also resolved by the PHY during the Auto-Negotiation process. For proper link operation, both the MAC and PHY must be also configured for the same duplex configuration. The duplex configuration of the link may be determined and set by one of the following methods:

- Hardware uses the default MAC speed of Full Duplex and no software action is necessary (the PHY configuration must be KNOWN to be Full-Duplex for this option), or
- Software reads the PHY registers to determine the PHY's Auto-Negotiated duplex setting and configures the MAC by setting CTRL.FRCDPLX to 1 and CTRL.FD to the proper value (refer to "[CTRL – Device Control Register](#)" on page 1438 for details), or

- Software writes the non Auto-Negotiated PHY registers with the desired duplex configuration and configures the MAC by to the same setting by programming [CTRL.FRCDPLX](#) to 1 and [CTRL.FD](#) to the proper speed value (refer to “[CTRL – Device Control Register](#)” on page 1438 for details).

### Using PHY Registers

The driver may be required under some circumstances to read from, or write to, the MII management registers in the PHY. These accesses are performed via the MDIO registers in the GCU (refer to the GCU EAS Chapter for details). The MII registers allow the driver to have direct control over the PHY's operation which may include:

- Resetting the PHY,
- Setting preferred link configuration for advertisement during the Auto-Negotiation process,
- Restarting the Auto-Negotiation process,
- Reading Auto-Negotiation status from the PHY, and
- Forcing the PHY to a specific link configuration.

The set of PHY management registers required for all PHY devices may be found in the IEEE P802.3ab draft standard.

### Comments Regarding Forcing Link

Forcing link in GMII/MII mode requires the driver to configure both the MAC and PHY in a consistent manner with respect to each other as well as the link partner. After initialization, the driver configures the desired modes in the MAC, then accesses the PHY registers to set the PHY to the same configuration.

Before enabling the link, the speed and duplex settings of the MAC may be forced by software using the [CTRL.FRCDSPD](#), [CTRL.FRCDPX](#), [CTRL.SPEED](#), and [CTRL.FD](#) bits. After the PHY and MAC have both been configured, the driver should write a 1 to the [CTRL.SLU](#) bit.

## 37.5.8.4 10/100Mbps Specific Performance Enhancements

### 37.5.8.4.1 Adaptive IFS

The GbE supports back-to-back transmit Inter-Frame-Spacing (IFS) of 960 ns in 100 Mbit operation and 9.6 us in 10M bit operation. Although back-to-back transmission is normally desirable, sometimes it can actually hurt performance in half-duplex environments due to excessive collisions. Excessive collisions are likely to occur in environments where one station is attempting to send large frames back-to-back, while another station is attempting to send acknowledge (ACK) packets.

The GbE contains the AIT register that enables the implementation of a driver based adaptive IFS algorithm for collision reduction, which is similar to Intel's other Ethernet products (e.g. PRO/100 adapters). Refer to “[AIT – Adaptive IFS Throttle Register](#)” on page 1495 for explicit details. Essentially, the Adaptive IFS throttles back-to-back transmissions in the transmit MAC and delays their transfer to the CSMA/CD transmit function, and thus can be used to delay the transmission of back-to-back packets on the wire. Normally, this register should be set to 0. However, if additional delay is desired between back-to-back transmits, then this register may be set with a value greater than zero.

The [AIT.AIFS](#) provides a similar function to [TIPG.IGPT](#) (see “[TIPG – Transmit IPG Register](#)” on page 1493). However this Adaptive IFS throttle register counts in units of GTX/MTX\_CLK clocks (which are 8ns, 80ns, 800ns for 10, 100, 1000 Mb/s mode respectively), and is 16 bits wide, thus providing a greater maximum delay value.

Using values lower than a certain minimum (determined by the ratio of GTX/MTX\_CLK clock to link speed), will have no effect on back-to-back transmission. This is because the device will not start transmission until the minimum IEEE IFS (9.6 us at 10Mb, 960 ns at 100 b, and 96 ns at 1 Gb) has been met regardless of the value of Adaptive IFS. For example, if the GbE is configured for 100 Mbps operation, the minimum IEEE IFS at 100 Mbps is 960 nanoseconds. Setting AIFS to a value of 10 (decimal) would not effect back-to-back transmission time on the wire, because the 800 ns delay introduced ( $10 * 80 \text{ ns} = 800 \text{ ns}$ ) is less than the minimum IEEE IFS delay of 960 ns. However, setting this register with a value of 20, which corresponds to 1600 ns for the above example, would delay back-to-back transmits because the ensuing 1600 ns delay is greater than the minimum IFS time of 960 ns.

It is important to note that this register has no effect on transmissions that occur immediately after receives, or on transmissions that are not back-to-back (unlike the TIPG.IPGR1 and TIPG.IPGR2 settings -- see "[TIPG – Transmit IPG Register](#)" on [page 1493](#)). In addition, Adaptive IFS also has no effect on re-transmission timing (re-transmissions occur after collisions). Therefore, AIT.AIFS is only enabled in back-to-back transmission.

*Note:* The AIT.AIFS value is not additive to the TIPG.IPGT value; instead, the actual IPG equals the larger of AIT.AIFS and TIPG.IPGT.

### 37.5.8.5 Flow Control

Flow control as defined in 802.3x, as well as the specific operation of asymmetrical flow control defined by 802.3z, is supported in the MAC. The following six registers are defined for the implementation of flow control:

**The Flow Control Address High Register and the Flow Control Address Low Register (FCAH and FCAL)** - 6 byte flow control multicast address

**Flow Control Type Register (FCT)** - 16 bit field to indicate flow control type

**Flow Control Receive Threshold High Register (FCRTH)** - 13 bit high water mark indicating receive buffer fullness

**Flow Control Receive Threshold Low Register (FCRTL)** - 13 bit low water mark indicating receive buffer emptiness

**Flow Control Transmit Timer Value Register (FCTTV)** - 16 bit timer value to include in transmitted PAUSE frame

Flow control is implemented as a means of reducing the possibility of receive buffer overflows which result in the dropping of received packets, and allows for local controlling of network congestion levels. This may be accomplished by sending an indication to a transmitting station of a nearly-full receive buffer condition at a receiving station.

The implementation of asymmetric flow control allows for one link partner to send flow control packets while being allowed to ignore their reception; i.e. not required to respond to PAUSE frames.

#### 37.5.8.5.1 MAC Control Frames & Reception of Flow Control Packets

Three comparisons are used to determine the validity of a flow control frame:

- A match on the six byte multicast address for MAC Control Frames or to the station address of the device (Receive Address Register 0).
- A match on the type field.
- A comparison of the MAC Control Opcode field.

The 802.3x standard defines the MAC Control Frame multicast address as 01-80-C2-00-00-01. This address must be loaded into the Flow Control Address High Register and the Flow Control Address Low Register (FCAH and FCAL).

The Flow Control Type Register (FCT) contains a 16 bit field which is compared against the flow control packet's type field to determine if it is a valid flow control packet: XON or XOFF. 802.3x reserves this as 0x8808. This value must be loaded into the FCT.

The final check for a valid PAUSE frame is the MAC Control Opcode. At this time only the PAUSE control frame opcode is defined. It has a value of 0x0001.

Frame based flow control differentiates XOFF from XON based on the value of the PAUSE timer field. Non-zero values constitute XOFF frames while a value of zero constitutes an XON frame. Values in the timer field are in units of slot time. A "slot time" is hard wired to 64 byte times, or 512ns.

*Note:* An XON frame signals the cancellation of the "pause" initiated by an XOFF frame. "Pause for zero slot times."

**Figure 37-47.802.3x MAC Control Frame Format**

Where "S" is the Start-of-Packet delimiter and "T" is the first part of the End-of-Packet delimiters for 802.3z encapsulation.

The receiver is enabled to receive flow control frames via the Device Control Register (CTRL.RFCE).

*Note:* Flow control capability must be negotiated between link partners via the Auto-Negotiation process. The Auto-Negotiation process may modify the value of these bits based on the resolved capability between the local device and the link partner.

Once the receiver has validated the reception of an XOFF, or PAUSE frame, the device will:

- Increment the appropriate statistics register(s)
- Set the STATUS.TXOFF bit
- Initialize the pause timer based on the packet's PAUSE timer field

- Disable packet transmission or schedule the disabling of transmission after the current packet completes.

Resumption of transmission may occur after:

- Expiration of the PAUSE timer
- Reception of on XON frame (a frame with its PAUSE timer set to 0)

Either condition clears the Device Status Register (STATUS.TXOFF) and transmission may resume. Hardware records the number of received XON frames.

#### 37.5.8.5.2 “Discard PAUSE Frames” & “Pass MAC Control Frames”

Two bits in the Receive Control Register are implemented specifically for control over receipt of PAUSE and MAC control frames. These bits are Discard PAUSE Frames (RCTL.DPF) and Pass MAC Control Frames (RCTL.PMCF). See “RCTL – Receive Control Register” on page 1474 for explicit definitions.

RCTL.DPF bit will force the discarding of any valid PAUSE frame addressed to the device's station address. If the packet is a valid PAUSE frame and is addressed to the station address (receive address [0]), the device will not pass the packet to host memory if RCTL.DPF bit is set to logic high. However, if a flow control packet is sent to the station address, and is a valid flow control frame, it will be DMA'd when RCTL.DPF is set to zero. This bit has no affect on PAUSE operation, only the DMA function.

RCTL.PMCF bit allows for the passing of any valid MAC control frames to the system which do not have a valid PAUSE opcode. In other words, the frame must have the correct MAC control frame multicast address (or the MAC station address) as well as the correct type field match with the FCT register, but will not have the defined PAUSE opcode of 0x0001. Frames of this type are DMA'd to host memory when RCTL.PMCF is logic high.

#### 37.5.8.5.3 Transmission of PAUSE Frames

Transmission of PAUSE frames is enabled by software with the [Device Control Register \(CTRL.TFCE\)](#).

*Note:* Similar to the reception flow control packets mentioned above, XOFF packets may be transmitted only if this configuration has been negotiated between the link partners via the Auto-Negotiation process. In other words, the setting of this bit indicates the desired configuration. The resolution of the Auto-Negotiation process is indicated in “[Physical Layer Auto-Negotiation & Link Setup Features](#)” on page 1394.

The content of the [Flow Control Receive Threshold High Register](#) determines at what point hardware transmits a PAUSE frame. Hardware monitors the fullness of the receive FIFO and compares it with the contents of FCRTH. When the threshold is reached, hardware sends a PAUSE frame with its pause time field equal to FCTTV register. Once the receive buffer fullness reaches the low water mark, hardware sends an XON message (a PAUSE frame with a timer value of 0). Software enables this capability with the Flow Control Receive Threshold Low Register (FCRTL.XONE).

Hardware will send one more PAUSE frame if it has previously sent one and the FIFO overflows (so the threshold must not be set greater than the FIFO size). This is intended to minimize the amount of packets dropped if the first PAUSE frame does not reach its target. Since the secure receive packets use the same data path, the behavior is identical when secure packets are received.

*Note:* The transmission of Flow Control frames should only be enabled in full duplex mode per the IEEE 802.3 standard. Software should ensure that the transmission of flow control packets is disabled when the device is operating in half-duplex mode.

### 37.5.8.5.4 Software Initiated PAUSE Frame Transmission

The GbE has the added capability to transmit an XOFF frame via software. This is accomplished by software using the Transmit Control Register (TCTL.SWXOFF). Once this bit is set, hardware will initiate the transmission of a PAUSE frame in a manner similar to that automatically generated by hardware.

TCTL.SWXOFF is self clearing after the PAUSE frame has been transmitted.

The state of the CTRL.TFCE bit or the negotiated flow control configuration does not affect software generated PAUSE frame transmission.

*Note:* Software sends an XON frame by programming a zero in the PAUSE timer field of the FCTTV register. XOFF transmission is not supported in 802.3x for half duplex links. Software should not initiate an XOFF or XON transmission if the device is configured for half duplex operation.

### 37.5.9 802.1q VLAN Support

The GbE provides specific mechanisms to support 802.1q VLANs, namely:

- Optional adding (for transmits) and ping (for receives) of IEEE 802.1q VLAN tags.
- Optional ability to filter packets belonging to certain 802.1q VLANs.

The difference between an untagged 802.3 Ethernet packet and an 802.1q VLAN tagged packet is minimal, as shown in Table 37-4.

Table 37-4. Untagged 802.3 Packet vs 802.1q VLAN tagged Packet

| 802.3 Packet | Number of Octets | 802.1q VLAN Packet | Number of Octets |
|--------------|------------------|--------------------|------------------|
| DA           | 6                | DA                 | 6                |
| SA           | 6                | SA                 | 6                |
| Type/Length  | 2                | 802.1q Tag         | 4                |
| Data         | 46-1500          | Type/Length        | 2                |
| CRC          | 4                | Data               | 46-1500          |
|              |                  | CRC*               | 4                |

\* The CRC for the 802.1q tagged frame is re-computed, so that it covers the entire tagged frame including the 802.1q tag header. Also, max frame size for an 802.1q VLAN packet is 1522 octets as opposed to 1518 octets for a normal 802.3z Ethernet packet.

#### 37.5.9.0.1 802.1q Tagged Frames

For 802.1q, the Tag Header field consists of four octets comprised of the Tag Protocol Identifier (TPID) and Tag Control Information (TCI); each taking 2 octets. The first 16 bits of the tag header makes up the TPID. It contains the "protocol type" which identifies the packet as a valid 802.1q tagged packet.

The two octets making up the TCI contain three fields:

- User Priority (UP)
- Canonical Form Indicator (CFI), which should be "0" for transmits. For receives, the device has the capability to filter out packets that have this bit set. Refer to RCTL.CFIEN and RCTL.CFI described in Section 37.6.4.1, "RCTL – Receive Control Register".
- VLAN Identifier (VID)

Figure 37-48. TCI Bit Ordering

### 37.5.9.1 Transmitting and Receiving 802.1q Packets

Since the 802.1q tag is only four bytes, adding and stripping of tags could be done completely in software. (i.e., For transmits, software inserts the tag into packet data before it builds the transmit descriptor list, and for receives, software strips the 4 byte tag from the packet data before delivering the packet to upper layer software.)

However, because adding and stripping of tags in software results in more over-head for the host, the GbE has additional capabilities to add and strip tags in hardware.

#### 37.5.9.1.1 Adding 802.1q Tags on Transmits

Software may command the GbE to insert an 802.1q VLAN tag on a per packet basis. If CTRL.VME is set to 1, and the VLE bit in the transmit descriptor is set to 1, then the EP80579's GbE will insert a VLAN tag into the packet that it transmits over the wire. The Tag Protocol Identifier (TPID) field of the 802.1q tag comes from the VET register, and the Tag Control Information (TCI) of the 802.1q tag comes from the special field [Figure 37-9, "Special Descriptor Field Layout" on page 1358](#) of the transmit descriptor. Refer to [Table 37-2, "VLAN Tag Insertion Decision Table when VLAN Mode Enabled \(CTRL.VME=1\)" on page 1368](#), for more information regarding hardware insertion of tags for transmits.

Similarly, software can instruct the GbE to insert an 802.1q VLAN tag for secure packets. Software gives the command "transmit with VLAN" to the security subsystem to instruct hardware that a VLAN tag should be inserted before the packet is sent on the wire. The Tag Protocol Identifier (TPID) field of the 802.1q tag comes from the VET register, and the Tag Control Information (TCI) of the 802.1q tag is specified in the "transmit with VLAN" command itself.

#### 37.5.9.1.2 Stripping 802.1q Tags on Receives

Software may instruct the GbE to strip 802.1q VLAN tags from received packets. If the CTRL.VME bit is set to 1, and the incoming packet is an 802.1q VLAN packet (i.e. it's Ethernet Type field matched the VET register), then the EP80579's GbE strips the 4 byte VLAN tag from the packet, and stores the TCI in the Special field (see [Figure 37-9, "Special Descriptor Field Layout" on page 1358](#)) of the receive descriptor.

The EP80579's GbE also sets the VP bit in the receive descriptor to indicate that the packet had a VLAN tag that was stripped. If the CTRL.VME bit is not set, the 802.1Q packets can still be received if they pass the receive filter, but the VLAN tag will not be stripped and the VP bit will not be set. Refer to [Table 37-5 on page 1402](#) for more information regarding receive packet filtering.

### 37.5.9.2 802.1q VLAN Packet Filtering

VLAN filtering is enabled by setting the RCTL.VFE bit to 1. If enabled, hardware compares the type field of the incoming packet to a 16 bit field in the VLAN EtherType Register (VET). If the VLAN type field in the incoming packet matches the VET register, the packet is then compared against the VLAN Filter Table Array for acceptance.

The Virtual LAN ID field indexes a 4096 bit vector. If the indexed bit in the vector is one; there is a Virtual LAN match. Software may set the entire bit vector to ones if the node does not implement 802.1q filtering. The register description of the VLAN Filter Table Array is described in detail in “VFTA[0-127] – 128 VLAN Filter Table Array Registers” on page 1490.

In summary, the 4096 bit vector is comprised of 128, 32-bit registers. Matching to this bit vector follows the same algorithm as indicated in section 0 for Multicast Address filtering. The VLAN Identifier (VID) field consists of 12 bits. The upper 7 bits of this field are decoded to determine the 32-bit register in the VLAN Filter Table Array to address and the lower 5 bits determine which of the 32 bits in the register to evaluate for matching.

Two other bits RCTL.CFIEN and RCTL.CFI (refer to “RCTL – Receive Control Register” on page 1474), are also used in conjunction with 802.1q VLAN filtering operations. RCTL.CFIEN enables the comparison of the value of the RCTL.CFI bit to the 802.1q packet data as an acceptance criteria for the packet.

*Note:* The VFE bit does not effect whether the VLAN tag is stripped. It only effects whether the VLAN packet passes the receive filter.

The following table lists reception actions per control bit settings.

**Table 37-5. Packet Reception Decision Table**

| Is packet 802.1q? | CTRL. VME | RCTL. VFE | Action   |
|-------------------|-----------|-----------|--|
| No                | X         | X         | Normal packet reception  |
| Yes               | 0         | 0         | Receive a VLAN packet if it passes the standard filters (only). Leave the packet as received in the data buffer. VP bit in receive descriptor is clear.  |
| Yes               | 0         | 1         | Receive a VLAN packet if it passes the standard filters and the VLAN filter table. Leave the packet as received in the data buffer (e.g. the VLAN tag would not be stripped). VP bit in receive descriptor is clear.   |
| Yes               | 1         | 0         | Receive a VLAN packet if it passes the standard filters (only). Strip off the VLAN information (four bytes) from the incoming packet and store in the descriptor. Set VP bit in receive descriptor.                    |
| Yes               | 1         | 1         | Receive a VLAN packet if it passes the standard filters and the VLAN filter table. Strip off the VLAN information (four bytes) from the incoming packet and store in the descriptor. Set VP bit in receive descriptor. |

*Note:* A packet is defined as a VLAN/802.1q packet if its type field matches the VET.

### 37.5.10 Wake on LAN

Two types of wakeup mechanisms are supported:

- Advanced Power Management (APM) Wakeup
- ACPI Power Management Wakeup

When so configured, if a wake-up packet is received, the GBE\_PME\_WAKE signal will be asserted. The GBE\_PME\_WAKE signal of all three GbE MACs are wired-or together and brought to the external pin GBE\_PME\_WAKE. The user must externally connect this pin to the PME\_N input pin.

#### 37.5.10.1 Advanced Power Management Wakeup

“Advanced Power Management Wakeup”, or “APM Wakeup”, was previously known as “Wake on LAN”. It is an feature that has existed in ethernet NICs for several generations. The basic premise is to receive a broadcast or unicast packet with an

explicit data pattern, and then to assert a signal to wake-up the system. In the earlier generations, this was accomplished by using a special signal that ran across a cable to a defined connector on the motherboard. The NIC would assert the signal for approximately 50ms to signal a wakeup. In more recent implementations, the PCI PME# signal has been used to wake-up the system.

On power-up, the APM Enable bits from the EEPROM Initialization Control Word 2 are read into the APM Enable (APME) bits of the Wakeup Control Register (WCR). These bits control enabling of APM Wakeup.

When APM Wakeup is enabled, the controller checks all incoming packets for “Magic Packets”.

Once a matching magic packet is received, the following occurs:

- If the Assert PME On APM Wakeup (APMPME) bit is set in the Wake Up Control Register (WUCR):
  - set the PME\_Status bit in the Power Management Control / Status Register (PMCSR) and assert GBE\_PME\_WAKE.
- Set the Magic Packet Received bit in the Wake Up Status Register (WUS).

The controller will assert GBE\_PME\_WAKE until the driver does one of the following:

- clears the Magic Packet Received AMAG bit in the Wake Up Status Register (WUS)
- clears the Assert PME On APM Wakeup (APMPME) bit in the Wake Up Control Register (WUC)
- disables APM Wakeup.

“APM Wakeup” is supported in all power states and only disabled if a subsequent EEPROM read results in the APM Wake Up bit being cleared or the software explicitly writes a 0 to the APM Wake Up (APM) bit of the WUC register.

### 37.5.10.2 ACPI Power Management Wakeup

Three sources of ACPI Power Management based Wakeups are supported:

- Reception of a “Magic Packet”.

Reception of a Network Wakeup Packet.

Activating ACPI Power Management Wakeup requires the following steps:

- The driver programs the Wake Up Filter Control Register (WUFC) to indicate the packets it wishes to wake up and supplies the necessary data to the IPv4/v6 Address Table (IP4AT, IP6AT) and the Flexible Filter Mask Table (f), Flexible Filter Length Table (FFLT), and the Flexible Filter Value Table (FFVT). The OS writes a 1 to the Pme\_En bit of the Power Management Control / Status Register (PMCSR.8).

Normally, after enabling wakeup, the OS will write (11)b to the lower two bits of the PMCSR to put the GbE controller into low-power mode.

Once Wakeup is enabled, the controller monitors incoming packets, first filtering them according to its standard address filtering method, then filtering them with all of the enabled wakeup filters. If a packet passes both the standard address filtering and at least one of the enabled wakeup filters, the controller will:

- Set the PME\_Status bit in the Power Management Control / Status Register (PMCSR)
- If the PME\_En bit in the Power Management Control / Status Register (PMCSR) is set, assert GBE\_PME\_WAKE.

- Set one or more of the “Received” bits in the Wake Up Status Register (WUS). (The controller will set more than one bit if a packet matches more than one filter.)

GBE\_PME\_WAKE will remain asserted until the OS either writes a 1 to the PME\_Status bit of the PMCSR register or writes a 0 to the Pme\_En bit.

After receiving a wakeup packet, the controller will ignore any subsequent wakeup packets until the driver clears all of the “Received” bits in the Wake Up Status Register (WUS).

### 37.5.10.3 Wake-up Packets: Pre-defined Filters

Various wakeup packets are supported using two types of filters:

- Pre-defined Filters
- Flexible Filters

Each of these filters will be enabled if the corresponding bit in the Wake Up Filter Control Register (WUFC) is set to 1.

This section describes the functioning of the Pre-defined Filters.

The following packets are supported by the Pre-defined Filters:

- Directed Packet (including exact, multicast indexed, and broadcast)
- Magic Packet
- ARP/IPv4 Request Packet
- Directed IPv4 Packet
- Directed IPv6 Packet

Each of these filters will be enabled if the corresponding bit in the Wakeup Filter Control Register (WUFC) is set to 1.

The explanation of each filter includes a table showing which bytes at which offsets are compared to determine if the packet passes the filter.

#### VLAN and LLC/SNAP Packets

Various tables may also include a reference to a possible VLAN Tag and LLC/SNAP Header. The controller detects VLAN and LLC/Snap frames by checking the initial size/type field. It first checks for a VLAN header by comparing the size/type field to the value programmed in the VLAN EtherType register. If the field matches then the frame is considered a VLAN frame. It will then check the VLAN ID against the values programmed in the VLAN Filter Table Array. If the ID matches the packet processing continues. If the ID doesn't match, or the CTRL.VME bit is 0, and the VLAN Tag is listed as “Compare” in the table, the packet will not be considered a wakeup packet.

After processing a possible VLAN Tag the controller will check for a LLC/SNAP Header. If the size/type field is less than or equal to 1500 bytes, the controller will check the following 6 bytes for the pattern AA\_AA\_03\_00\_00\_00. If the pattern matches then the packet processing continues. If the pattern doesn't match, and the LLC/SAP Header is listed as “Compare” or “Check” in the table the packet will not be considered a wakeup packet.

### 37.5.10.3.1 Directed Exact Packet

The GbE controller will generate a wakeup event upon reception of any packet whose destination address matches one of the 16 valid programmed Receive Addresses if the Directed Exact Wake Up Enable bit is set in the Wake Up Filter Control Register (WUFC.EX).

| Offset | # of bytes | Field               | Value        | Action  | Comment                          |
|--------|------------|---------------------|--------------|---------|----------------------------------|
| 0      | 6          | Destination Address | Programmable | Compare | Match any pre-programmed address |

### 37.5.10.3.2 Directed Multicast Packet

For multicast packets, the upper bits of the incoming packet's destination address index a bit vector in the Multicast Table Array, that indicates whether to accept the packet. If the Directed Multicast Wake Up Enable bit set in the Wake Up Filter Control Register (WUFC.MC) and the indexed bit in the vector is one then the controller will generate a wakeup event. The exact bits used in the comparison are programmed by software in the Multicast Offset field of the Receive Control Register (RCTL.MO).

If the MAC has been configured for promiscuous mode, a multicast wakeup will occur if a broadcast packet is received. This is because a broadcast message is a special type of multicast message. Refer to 802.3, section 3.2.3.1.

| Offset | # of bytes | Field               | Value | Action  | Comment       |
|--------|------------|---------------------|-------|---------|---------------|
| 0      | 6          | Destination Address |       | Compare | See paragraph |

### 37.5.10.3.3 Broadcast

If the Broadcast Wake Up Enable bit in the Wake Up Filter Control Register (WUFC.BC) is set the controller will generate a wake up event when it receives a broadcast packet.

| Offset | # of bytes | Field               | Value  | Action  | Comment |
|--------|------------|---------------------|--------|---------|---------|
| 0      | 6          | Destination Address | FF * 6 | Compare |         |

### 37.5.10.3.4 Magic Packet

**Magic Packet Technology Details:** Once the LAN controller has been put into the Magic Packet mode, it scans all incoming frames addressed to the node for a specific data sequence, which indicates to the controller that this is a Magic Packet frame. A Magic Packet frame must also meet the basic requirements for the LAN technology chosen, such as SOURCE ADDRESS, DESTINATION ADDRESS (which may be the receiving station's IEEE address or a MULTICAST address which includes the BROADCAST address), and CRC. The specific data sequence consists of 16 duplications of the IEEE address of this node, with no breaks or interruptions. This sequence can be located anywhere within the packet, but must be preceded by a synchronization stream. The synchronization stream allows the scanning state machine to be much simpler. The synchronization stream is defined as 6 bytes of FFh. The device will also accept a BROADCAST frame, as long as the 16 duplications of the IEEE address match the address of the machine to be awakened.

The controller will expect the destination address to either:

- Be the broadcast address (FF.FF.FF.FF.FF.FF)
- Match the value in Receive Address Register 0 (RAH0, RAL0). This is initially loaded from the EEPROM but may be changed by the driver.
- Match any other address filtering enabled by the driver.

The controller will search for the contents of Receive Address Register 0 (RAH0, RAL0) as the embedded IEEE address. It will consider any non-FF byte after a series of at least 6 FFs to be the start of the IEEE address for comparison purposes. (I.E. It will catch the case of 7 FFs followed by the IEEE address). As soon as one of the first 96 bytes after a string of FFs doesn't match, it will continue to search for another set of at least 6 FFs followed by the 16 copies of the IEEE address later in the packet. Note that this definition precludes the first byte of the destination address from being FF.

A Magic Packet's destination address must match the address filtering enabled in the configuration registers with the exception that broadcast packets will be considered to match even if the Broadcast Accept bit of the Receive Control Register (RCTL.BAM) is 0. If APM Wakeup is enabled in the EEPROM, the controller will start up with the Receive Address Register 0 (RAH0, RAL0) loaded from the EEPROM. This is to permit the controller to accept packets with the matching IEEE address before the driver comes up.

| Offset  | # of bytes | Field                     | Value               | Action  | Comment   |
|---------|------------|---------------------------|---------------------|---------|---|
| 0       | 6          | Destination Address       |                     | Compare | MAC Header- processed by main address filter        |
| ...     | ...        | ...                       |                     | Skip    |   |
| Any     | 6          | Synchronizing Stream      | FF FF FF FF FF FF + | Compare |   |
| Any + 6 | 96         | 16 copies of Node Address | Node Address*16     | Compare | Compared to Receive Address Register 0 (RAH0, RAL0) |

### 37.5.10.3.5 ARP/IPv4 Request Packet

The GbE controller will support reception of ARP Request packets for wake up if the ARP bit is set in the Wake Up Filter Control Register (WUFC). Four IPv4 addresses are supported which are programmed in the IPv4 Address Table (IP4AT). A successfully matched packet must contain a broadcast MAC address, a Type of 0x0806, an ARP OP CODE of 0x01, and one of the four programmed IPv4 addresses. The GbE controller also handles ARP Request packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

| Offset     | # of bytes | Field                     | Value                        | Action  | Comment                                      |
|------------|------------|---------------------------|------------------------------|---------|--|
| 0          | 6          | Destination Address       |                              | Compare | MAC Header- processed by main address filter |
| 6          | 6          | Source Address            |                              | Skip    |  |
| 12         | S=(0/4)    | Possible VLAN Tag         | 8100h + check ID             | Check   |  |
| 12+S       | D=(0/8)    | Possible LLC/ SNAP Header | Type <= 1500 + AAAA03000000h | Check   |  |
| 12+D+S     | 2          | Type                      | 0806h                        | Compare | ARP  |
| ARP Header |            |                           |                              |         |  |
| 14+D+S     | 2          | HW Type                   | 0001h                        | Compare |  |

| Offset | # of bytes | Field                   | Value | Action  | Comment                            |
|--------|------------|-------------------------|-------|---------|------------------------------------|
| 16+D+S | 2          | Protocol Type           | 0800h | Compare |                                    |
| 18+D+S | 1          | Hardware Size           | 06h   | Compare |                                    |
| 19+D+S | 1          | Protocol Address Length | 04h   | Compare |                                    |
| 20+D+S | 2          | Operation               | 0001h | Compare |                                    |
| 22+D+S | 6          | Sender HW Address       | -     | Ignore  |                                    |
| 28+D+S | 4          | Sender IP Address       | -     | Ignore  |                                    |
| 32+D+S | 6          | Target HW Address       | -     | Ignore  |                                    |
| 38+D+S | 4          | Target IP Address       | IP4AT | Compare | May match any of 4 values in IP4AT |

### 37.5.10.3.6 Directed IPv4 Packet

The LAN controller will support reception of Directed IPv4 packets for wake up if the IPV4 bit is set in the Wake Up Filter Control Register (WUFC). Four IPv4 addresses are supported which are programmed in the IPv4 Address Table (IP4AT). A successfully matched packet must contain the station's MAC address, a Type of 0x0800, and one of the four programmed IPv4 addresses. The GbE controller also handles Directed IPv4 packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

| Offset       | # of bytes | Field                                 | Value                           | Action  | Comment                                      |
|--------------|------------|---------------------------------------|---------------------------------|---------|--|

### 37.5.10.3.7 Directed IPv6 Packet

The LAN controller will support reception of Directed IPv6 packets for wake up if the IPV6 bit is set in the Wake Up Filter Control Register (WUFC). One IPv6 address is supported and it is programmed in the IPv6 Address Table (IP6AT). A successfully matched packet must contain the station's MAC address, a Type of 0x0800, and the programmed IPv6 address. This MAC also handles Directed IPv6 packets that have VLAN tagging on both Ethernet II and Ethernet SNAP types.

| Offset     | # of bytes | Field                     | Value                        | Action  | Comment                                      |
|------------|------------|---------------------------|------------------------------|---------|--|
| 0          | 6          | Destination Address       |                              | Compare | MAC Header- processed by main address filter |
| 6          | 6          | Source Address            |                              | Ignore  |  |
| 12         | S=(0/4)    | Possible VLAN Tag         | 8100h + check ID             | Check   |  |
| 12+S       | D=(0/8)    | Possible LLC/ SNAP Header | Type <= 1500 + AAAA03000000h | Check   |  |
| 12+D+S     | 2          | Type                      | 86DDh                        | Compare | IPv6   |

| 14+D+S     | 1          | Version/ Traffic Class    | 6Xh                          | Compare | Check IPv6                                   |
| 16+D+S     | 3          | Traffic Class/Flow Label  | -                            | Ignore  |  |
| 18+D+S     | 2          | Payload Length            | -                            | Ignore  |  |
| 20+D+S     | 1          | Next Header               | IPv6 next header types       | Check   |  |

| Offset | # of bytes | Field               | Value | Action  | Comment              |
|--------|------------|---------------------|-------|---------|----------------------|
| 21+D+S | 1          | Hop Limit           | -     | Ignore  |                      |
| 22+D+S | 16         | Source Address      | -     | Ignore  |                      |
| 38+D+S | 16         | Destination Address | IP6AT | Compare | Match value in IP6AT |

#### 37.5.10.4 Wake-up Packets: Flexible Filters

Various wakeup packets are supported using two types of filters:

- Pre-defined Filters
- Flexible Filters

Each of these filters will be enabled if the corresponding bit in the Wake Up Filter Control Register (WUFC) is set to 1.

This section describes the functioning of Flexible Filters.

A total of four flexible filters are supported. Each filter is can be configured to recognize any arbitrary pattern within the first 128 byte of the packet To configure the flexible filter, the software programs the mask values into the Flexible Filter Mask Table (FFMT) and the required values into the Flexible Filter Value Table (FFVT), and the minimum packet length into the Flexible Filter Length Table (FFLT). These contain separate values for each filter. The software must also enable the filter in the Wake Up Filter Control Register (WUFC), and enable the overall wake up functionality must be enabled by setting PME\_En in the Power Management Control Status Register or the Wake Up Control Register.

Once enabled, the flexible filters will scan incoming packets for a match. If the filter encounters any byte in the packet where the mask bit is one and the byte doesn't match the byte programmed in the Flexible Filter Value Table (FFVT) then the filter will fail that packet. If the filter reaches the required length without failing the packet, it passes the packet and generates a wake up event. It will ignore any mask bits set to one beyond the required length.

The flexible filter does not have any way to automatically skip VLAN or LLC/SNAP headers. If such headers are included the offsets of the subsequent fields must be adjusted accordingly.

The following packets are listed for reference purposes only. The flexible filter could be used to filter these packets.

##### 37.5.10.4.1 IPX Diagnostic Responder Request Packet

An IPX Diagnostic Responder Request Packet must contain a valid MAC address, a Protocol Type of 0x8137, and an IPX Diagnostic Socket of 0x0456. It may include LLC/SNAP Headers and VLAN Tags. Since filtering this packet relies on the flexible filters, which use offsets specified by the operating system directly, the operating system must account for the extra offset LLC/SNAP Headers and VLAN tags.

| Offset          | # of bytes | Field                    | Value  | Action          | Comment |
|-----------------|------------|--------------------------|--------|-----------------|---------|
| 0               | 6          | Destination Address      |        | Compare         |         |
| 6               | 6          | Source Address           |        | Skip            |         |
| 12              | S=(0/4)    | Possible VLAN Tag        |        | Compare or Skip |         |
| 12+S            | D=(0/8)    | Possible LLC/SNAP Header |        | Compare or Skip |         |
| 12+D+S          | 2          | Type                     | 8137h  | Compare         | IPX     |
| IPX Header/Info |            |                          |        |                 |         |
| 14+D+S          | 16         | Some IPX Stuff           | -      | Ignore          |         |
| 30+D+S          | 2          | IPX Diagnostic Socket    | 0x0456 | Compare         |         |

#### 37.5.10.4.2 Directed IPX Packet

A valid Directed IPX Packet contain the station's MAC address, a Protocol Type of 0x8137, and an IPX Node Address that equals to the station's MAC address. It may include LLC/SNAP Headers and VLAN Tags. Since filtering this packet relies on the flexible filters, which use offsets specified by the operating system directly, the operating system must account for the extra offset LLC/SNAP Headers and VLAN tags.

| Offset          | # of bytes | Field                    | Value             | Action          | Comment |
|-----------------|------------|--------------------------|-------------------|-----------------|---------|
| 0               | 6          | Destination Address      |                   | Compare         |         |
| 6               | 6          | Source Address           |                   | Skip            |         |
| 12              | S=(0/4)    | Possible VLAN Tag        |                   | Compare or Skip |         |
| 12+S            | D=(0/8)    | Possible LLC/SNAP Header |                   | Compare or Skip |         |
| 12+D+S          | 2          | Type                     | 8137h             | Compare         | IPX     |
| IPX Header/Info |            |                          |                   |                 |         |
| 14+D+S          | 16         | Some IPX Stuff           | -                 | Ignore          |         |
| 24+D+S          | 2          | IPX Node Address         | Receive Address 0 | Compare         |         |

#### 37.5.10.4.3 IPv6 Neighbor Discovery Filter

In IPv6, a Neighbor Discovery packet is used for address resolution. A flexible filter can be used to check for a "Neighborhood Discovery Packet".

| Offset                 | # of bytes | Field                              | Value                 | Action   | Comment  |
|------------------------|------------|------------------------------------|-----------------------|----------|--|
| 0                      | 6          | Destination Address                |                       | Compare  | MAC Header - processed by main address filter, or broadcast  |
| 6                      | 6          | Source Address                     |                       | Skip     |  |
| 12                     | 4          | Possible VLAN Tag                  |                       | See text |  |
| 12+S                   | 8          | Possible LLC/SNAP Header           |                       | See text |  |
| 12+D+S                 | 2          | Type                               | 86DDh                 | Compare  | IP   |
| IPv6 Header            |            |                                    |                       |          |  |
| 14+D+S                 | 1          | Version/Traffic Class              | 6X                    | Compare  | Check IPv6   |
| 15+D+S                 | 3          | Traffic Class/Flow Label           | -                     | Ignore   |  |
| 18+D+S                 | 2          | Payload Length                     | -                     | Ignore   |  |
| 20+D+S                 | 1          | Next Header                        | 3Ah, 00h, 2Bh, or 3Ch | Check    | ICMP, or IPv6 next headers:<br>+ routing (2Bh)<br>+ dest options (3Ch)<br>+ hop-by-hop (00h)         |
| 21+D+S                 | 1          | Hop Limit                          | FFh                   | Check    |  |
| 22+D+S                 | 16         | Source IP Address                  | -                     | Ignore   |  |
| 38+D+S                 | 16         | Destination IP Address             | -                     | Ignore   |  |
| 54+D+S                 | N          | Possible IPv6 Next Headers         | -                     | Check    | Process headers to get next header. Header type must be routing, destination options, or hop-by-hop. |
| ICMP Header            |            |                                    |                       |          |  |

### 37.5.11 Serial EEPROM

The GbE controller uses an EEPROM device for storing product configuration information. The EEPROM is divided into two general regions:

- Hardware accessed - loaded by GbE controller after power-up, Unit Reset deassertion, D3>D0 transition, or software commanded EEPROM read (CTRL\_EXT.EE\_RST).
- Software accessed - used by software only. The meaning of these registers as listed here is a convention for the software only and is ignored by the controller.

#### 37.5.11.1 EEPROM Device

The EEPROM interface supports a MicroWire\* interface. It expects the EEPROM to be capable of 1MHz operation.

The EP80579 is compatible with a 4096 bit 4-wire serial EEPROM such as is compatible with a NM93C66 EEPROM. This EEPROM is accessed in 16-bit words, containing 256 words.

The EP80579 will automatically determine whether an EEPROM is connected.

*Note:* The EP80579 will ONLY detect presence of the EEPROM during power-up.

#### 37.5.11.2 Software Accesses

The MAC provides two different methods for software access to the EEPROM. It can either use the built-in controller to read the EEPROM, or access the EEPROM directly using the EEPROM's 4-wire interface.

Software can use the EEPROM Read register (EERD) to cause the GbE controller to read a word from the EEPROM that the software can then use. To do this, software writes the address to read to the Read Address (EERD.ADDR) field and simultaneously writes a 1 to the Start Read bit (EERD.START). The controller will read the word from the EEPROM, set the Read Done bit (EERD.DONE), and put the data in the Read Data field (EERD.DATA). Software can poll the EEPROM Read register until it sees the Read Done bit set, then use the data from the Read Data field. Any words read this way are not written to internal registers.

Software can also directly access the EEPROM's 4-wire interface through the EEPROM Control Register (EEC). It can use this for reads, writes, or other EEPROM operations.

To directly access the EEPROM, software should follow these steps:

- Write a 1 to the EEPROM Request bit (EEC.EE\_REQ)
- Read the EEPROM Grant bit (EEC.EE\_GNT) until it becomes 1. It will remain 0 as long as the hardware is accessing the EEPROM.
- Write or read the EEPROM using the direct access to the 4-wire interface as defined in the EEPROM Control & Data Register (EEC). The exact protocol used depends on the EEPROM placed on the board and can be found in the appropriate datasheet.
- Write a 0 to the EEPROM Request bit (EEC.EE\_REQ).

Finally, software can cause the controller to re-read the hardware accessed fields of the EEPROM (setting the MAC's internal registers appropriately) by writing a 1 to the EEPROM Reset bit of the Extended Device Control Register (CTRL\_EXT.EE\_RST).

*Note:* This will only cause the EEPROM to be re-read. The Gbe will NOT attempt to re-detect the presence of an EEPROM.

### 37.5.11.3 Signature Field

The only way the MAC has to tell if an EEPROM is present is by trying to read the EEPROM. The MAC will first read the Initialization Control Word 1. It will check the received value for bits 15 and 14. If bit 15 is 0 and bit 14 is 1, it considers the EEPROM to be present and valid and will read additional EEPROM words and program its internal registers based on the values read. Otherwise, it will ignore the values it read from the Initialization Control Word 1 and not read any other words.

### 37.5.11.4 EEPROM Map

*Note:* If any one of the GbE interfaces is disabled then the corresponding memory locations in the EEPROM for that device must be initialized to all '0's.

The following table indicates the EEPROM map to be used.

**Table 37-6. EEPROM Address Map**

| Word Offset | Used By MAC  | Upper Byte - Bits 15:8 | Lower Byte - Bits 7:0 |
|-------------|--------------|------------------------|-----------------------|
| 00h         | 0,1,2        | Init Control Word 1    |                       |

### 37.5.11.5 Hardware Accessed Words

This section describes the EEPROM words that are loaded and used by the MAC. Most of these bits are located into a configuration registers. The words will only be read and used if the signature field in the Initialization Control Word 1 field correct.

#### 37.5.11.5.1 Initialization Control Word 1

The first word read by the MAC and common for all MACs.

Table 37-7. Initialization Control Word 1

| Bit   | Bit Acronym      | Bit Description   |
|-------|------------------|---|
| 15:14 | Signature        | The Signature field is a signature of (01)b, indicating to the device that there is a valid EEPROM present. If the Signature field is not (01)b, the other bits in this word are ignored, no further EEPROM read is performed, and default values are used for the configuration space IDs.                     |
| 13:12 | Reserved         | Reserved  |
| 11    | Reserved         | Reserved. Must be set to '1'  |
| 10    | FD               | <b>Full Duplex.</b> Controls the MAC duplex setting.<br>0 = Half Duplex<br>1 = Full Duplex<br>In half-duplex mode, the EP80579's GbE transmits carrier extended packets and can receive both carrier extended packets, and packets transmitted with bursting.<br><br>This bit overrides the in register CTRL.FD |
| 9     | Reserved         | Reserved. Must be set to '1'  |
| 8:4   | Reserved         | Reserved  |
| 3     | Power Management | 0 - The Power Management Registers set is read only, and the MAC will not execute a hardware transition to D3.<br>1 - Full support for power management   |
| 2:0   | Reserved         | Reserved  |

### 37.5.11.5.2 Initialization Control Word 2

Each MAC has a unique Initialization Control Word 2.

**Table 37-8. Initialization Control Word 2**

| Bit Range | Bit Acronym     | Bit Description   |
|-----------|-----------------|---|
| 7         | APM PME# Enable | Initial value of the <i>Assert PME On APM Wakeup</i> bit in the <i>Wake Up Control Register</i> (WUC.APMPME). |
| 6:0       | Reserved        | These bits must be set to '0'   |

### 37.5.11.5.3 Initialization Control Word 3

Each MAC has a unique Initialization Control Word 3.

**Table 37-9. Initialization Control Word 3**

| Bit Range | Bit Acronym            | Bit Description  |
|-----------|------------------------|--|
| 7         | D3COLD_WAKEUP_ _ADV_EN | Configures the initial HW default value of the ADV3WUC bit in the Device Control Register (CTRL) following powerup   |
| 6:5       | Reserved               | This bit must be set to '0'  |
| 4         | RGMII/RMII             | RGMII/RMII Translation Gasket Select <ul style="list-style-type: none"> <li>• '0' - RGMII</li> <li>• '1' - RMII</li> <li>• Initializes CTRL_AUX.RGMII/RMII bit</li> </ul>  |
| 3         | Reserved               | This bit must be set to '0'  |
| 2         | APM Enable             | Initial value of <i>Advanced Power Management Wake Up Enable</i> in the <i>Wake Up Control Register</i> (WUC.APME). This bit is also used to initialize the SLU bit in the CTRL register.  |
| 1:0       | Link Mode              | Initial value of Link Mode bits of the Extended Device Control Register (CTRL_EXT.LINK_MODE), specifying which link interface and protocol is used by the MAC. <ul style="list-style-type: none"> <li>00 = MAC operates in GMII/MII mode</li> <li>01 = Reserved</li> <li>10 = Reserved</li> <li>11 = Reserved</li> </ul> |

### 37.5.11.5.4 Management Control Word

This register is unique for each MAC.

**Table 37-10. Management Control Word**

| Bit   | Bit Acronym        | Bit Description   |
|-------|--------------------|---|
| 15:13 | Reserved           | Reserved. Set to 0.   |
| 12:8  | Reserved           | Reserved. Set to 0.   |
| 7     | IPv6 Address Valid | IPv6 Address in the <i>IP Address EEPROM</i> register is valid. This is written to bit 16 of the <i>IP Address Valid</i> (IPAV[16]) register. |
| 6     | IPv4 Address Valid | IPv4 Address in the <i>IP Address EEPROM</i> register is valid. This is written to bit 0 of the <i>IP Address Valid</i> (IPAV[0]) register.   |
| 5:0   | Reserved           | Reserved. Set to 0.   |

### 37.5.11.5.5 Ethernet Address

The Ethernet Individual Address (IA) is a 6 byte field that must be unique for each adapter card, and thus unique for each MAC. The first three bytes define a group of Individual Addresses which are allocated to a specific vendor - for example, [00 AA 00] or [E9 07 00] was allocated for certain Intel products. The remaining three-bytes are allocated in manufacturing to form a unique value for each EEPROM image. These values change regularly as new products are introduced and/or allocated during in production. The value from this EEPROM field is loaded into the Receive Address Register 0 (RALO/RAHO).

For the purpose of this specification, the IA byte numbering convention is indicated below:

|         | IA Byte / Value |                 |                 |          |          |          |
|---------|-----------------|-----------------|-----------------|----------|----------|----------|
|         | 1               | 2               | 3               | 4        | 5        | 6        |
| Field   | vendor-specific | vendor-specific | vendor-specific | unique   | unique   | unique   |
| Example | E9              | 07              | 00              | variable | variable | variable |

### 37.5.11.5.6 IPv4 Address

Table 37-11. IPv4 Address

| Bit  | Name         | Bit Description   |
|------|--------------|---|
| 31:0 | IPv4 Address | The initial value of IP4AT Address Table entry 0. (IP4AT[0])<br>See the EEPROM map for an indication of how the bytes are stored. |

### 37.5.11.5.7 IPv6 Address

Table 37-12. IPv6 Address

| Bit   | Name         | Bit Description  |
|-------|--------------|--|
| 127:0 | IPv6 Address | The initial value of IPv6 Address Table entry 0. (IP6AT[0])<br>See the EEPROM map for an indication of how the bytes are stored. |

## 37.5.11.6 Software Accessed Words

### 37.5.11.6.1 Compatibility Fields

Five words in the EEPROM image are reserved for compatibility information. Hardware does not use these fields or impose any restrictions on their use.

### 37.5.11.6.2 PBA Number

Two words in the EEPROM image are reserved for PBA information. Hardware does not use these fields or impose any restrictions on their use.

### 37.5.11.6.3 Checksum Word Calculation

The Checksum word (3Fh) is used to ensure that the base EEPROM image is a valid image. The value of this word should be calculated by adding all the words (00h-3Fh), including the Checksum word itself.

*Note:* Hardware does not calculate the word 3Fh checksum during EEPROM write; it must be calculated by software independently and included in the EEPROM write data. Hardware does not compute a checksum over words 00h-3Fh during EEPROM reads in order to determine validity of the EEPROM image; this field is provided strictly for SW verification of EEPROM validity. All hardware configuration based on word 00h-3Fh content is based on the validity of the Signature field of EEPROM Initialization Control Word 1 (Signature must be 01b).

## 37.5.12 Error Handling

The overall principles and goals of error handling for the EP80579 are covered in [Chapter 5.0, "Error Handling"](#). This section covers the specifics of error handling including bus errors and soft errors for this unit.

### 37.5.12.1 CSR (Target) Accesses

The following conditions must be met for a CSR access to be considered valid:

- Command must be CSR read or CSR write
- Length must be 0 (e.g., -4 bytes)
- Byte mask must be 0x0F, 0xF0, or 0x00

If the command violates any of the above conditions then the ICR.ERR\_INTBUS condition is asserted:

- All unsupported command types (i.e. those other than CSR read or CSR write) are undefined operations and will result in indeterminate behavior by the GbE target.
- All single CSR writes are assumed to be 32-bit and will complete normally regardless of the byte mask value. Writes using an unsupported byte mask will still be flagged as an error as currently documented but will nonetheless be processed as a 32-bit write
- Read and Write burst operations (length > 0) will be completed on the push/pull buses as single operations. Reads will return 0xFFFF\_FFFF for data and will assert the push\_data\_err signal to the requestor. Write operations will discard the pull data and the requested CSR or memory write will not be performed.
- If the data source of a CSR write operation asserts the internal\_bus\_data\_error signal, then the GbE target discards the data and the write operation is not performed.

The generation of the ICR.ERR\_INTBUS condition causes the INTBUS\_ERR\_STAT register to be updated.

### 37.5.12.2 DMA Host (Master) Accesses

If the GbE is a master and receives a Push Data Error during a read transaction, then an ICR.ERR\_INTBUS condition is generated and the INTBUS\_ERR\_STAT register is updated. All transactions are terminated.

This condition is considered fatal and further Host transaction requests from the GbE unit are inhibited, until a soft reset is issued.

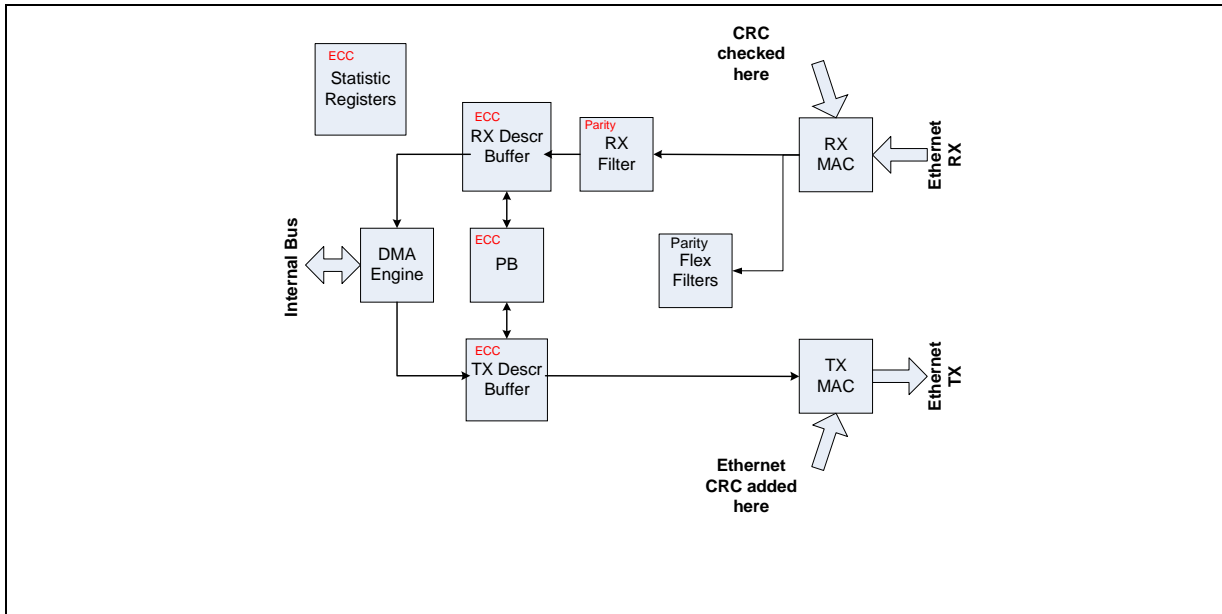

### 37.5.12.3 Internal Memories

The internal memories are protected via various means to reduce the SER associated with this unit. All memories must be scrubbed to ensure proper operation.

The GbE ECC/parity protected memories indicated in Figure 37-49 may be tested with the Memory Error Test Register (MET). The register will force an error to be written into the memory area selected with the MET.SELECT field. The MET.MASK field will be XOR'd with the ECC or parity bits to insert a parity error into the selected memory, which will cause an error when the memory is read at a later time. Errors will be reported in the appropriate bits of the three ICR registers. Functional or Error interrupt(s) may be generated if enabled.

Figure 37-49. Memory Protection in the GbE

The specifics of the memory protection for each of the memories is shown in Table 37-13, "Memory protection" on page 1419.

Table 37-13. Memory protection

| Memory              | Size     | Protection Type | Protection Bits | Description   |
|---------------------|----------|-----------------|-----------------|---|
| Statistic Registers | 64 x 32  | ECC             | 8               | 8-bit ECC code is computed on 32-bit data padded with 0s out to 64 bits for a total of 8 ECC bits (64x40)               |
| RX Filters          | 128 x 32 | Parity          | 4               | parity computed on each byte for a total of 4 parity bits (128x36)  |
| RX Flex Filters     | 128 x 36 | Parity          | 4               | parity computed on each of 4 of the Filter Value and on 4 bits of the Filter Mask for a total of 5 parity bits (128x41) |

Table 37-13. Memory protection

| Memory                   | Size     | Protection Type | Protection Bits | Description   |
|--------------------------|----------|-----------------|-----------------|---|
| DMA Tx Descriptor Buffer | 64 x 128 | ECC             | 16              | 8-bit ECC code is computed on each of the upper and lower 64-bits of the 128-bit data for a total of 16 ECC bits (64x144) |
| DMA Rx Descriptor Buffer | 64 x 128 | ECC             | 16              | 8-bit ECC code is computed on each of the upper and lower 64-bits of the 128-bit data for a total of 16 ECC bits (64x144) |
| DMA Packet Buffer        | 4K x 128 | ECC             | 16              | 8-bit ECC code is computed on each of the upper and lower 64-bits of the 128-bit data for a total of 16 ECC bits (4kx144) |

**Statistic Registers:** In the event of a multi-bit ECC error, an interrupt event will be generated in ICRx.ERR\_STAT and the GbE unit will stop all Host Transmit and Receive access to memory, as well as inhibit GbE transmit data. The GbE unit will still remain accessible through the GbE Target interface. It is a software task to detect the event, issue the soft reset to clear the ICRx.ERR\_STAT bit and decide what to do with the erroneous data from the statistics register.

**RX Filters:** In the event of an error from either the multicast filter memory or the special packets filter memory the packet will be rejected, appropriate Statistic Registers will be updated, and an ICRx.ERR\_MCFSPF event will be generated. Further GbE DMA Read/Write transactions will not be inhibited, nor will transmit traffic be inhibited.

**RX Flex Filters:** In the event of a parity error from either any of the flex filter memories the appropriate Statistic Registers will be updated, and an ICRx.ERR\_MCFSPF event will be generated. Additionally, if Wake On LAN filtering is enabled, a PME\_WAKE event will be generated.

**DMA TX Descriptor Buffer:** In the event of an ECC error, a ICRx.ERR\_TXDS event will be generated and the GbE unit will stop all Host Transmit and Receive access to memory, as well as inhibit GbE transmit data. The GbE unit will still remain accessible through the GbE Target interface. The error indicates the descriptor memory has become untrustworthy and Host accesses are stopped to avoid corruption of other interfaces. It is a software task to detect the event and issue the required soft reset for recovery.

**DMA RX Descriptor Buffer:** In the event of an ECC error, a ICRx.ERR\_RXDS event will be generated and the GbE unit will stop all Host Transmit and Receive access to memory, as well as inhibit GbE transmit data. The GbE unit will still remain accessible through the GbE Target interface. The error indicates the descriptor memory has become untrustworthy and Host accesses are stopped to avoid corruption of other interfaces. It is a software task to detect the event and issue the required soft reset for recovery.

**DMA Packet Buffer during Transmit or Receive:** In the event of an ECC error, a ICRx.ERR\_PB event will be generated and the GbE unit will stop all Host Transmit and Receive access to memory, as well as inhibit GbE transmit data. The GbE unit will still remain accessible through the GbE Target interface. The error indicates the packet buffer memory has become untrustworthy and Host accesses are stopped to avoid corruption of other interfaces. It is a software task to detect the event and issue the required soft reset for recovery.

### 37.5.13 Reset Operation

The GbE implements multiple hardware and software-initiated reset mechanisms which should be understood and distinguished:

- **SYS\_PWR\_OK Reset** - The **SYS\_PWR\_OK** pin acts as a master reset of the entire chip. It is level sensitive, and while it is 0 will hold all HW registers (state and configuration) in reset. **SYS\_PWR\_OK** is interpreted to be an indication that device power supplies are all stable and the reference clock input is stable.
- **Unit reset/RESET\_N** - This pin indicates the reset state of the internal bus. When asserted, the EP80579 will force all GbE output signals to an inactive state. Upon deassertion, the GbE will generate an internal hardware reset, clearing all states, and resetting all configuration registers to HW defaults as specified in [“Registers Overview” on page 1425](#).
- **D3->D0 transition** - This is also known as ACPI Reset. The GbE generates an internal hardware reset on the transition from D3 power state to D0, which clears all and resets nearly all configuration to HW defaults as specified in this document.
- **Soft Reset** - Software can reset the GbE by writing the [“CTRL – Device Control Register” on page 1438 \(CTRL.RST\)](#). A soft reset clears all states and resets nearly all device control registers to HW defaults as specified in [“Registers Overview” on page 1425](#). NOTE: Software must wait a minimum of 5 ms after initiating a soft-reset before accessing any CSR.
- **EEPROM Reset** - Writing a 1 to the EEPROM Reset bit of the Extended Device Control Register (CTRL\_EXT.EE\_RST) will cause the GbE to re-read the EEPROM, setting the appropriate bits in the MAC registers whose HW default values are derived from the EEPROM.

The various resets affect the following registers and logic:

**Table 37-14. GbE Reset Effects**

|             |                          | Reset Operation |            |         |                 |                     |        |       |
|-------------|--------------------------|-----------------|------------|---------|-----------------|---------------------|--------|-------|
|             |                          | PWR_Good Reset  | Unit reset | D3-> D0 | Soft (CTRL.RST) | Link (LOS deassert) | EEPROM | Notes |
| Effects to: | Enable/Disable LAN       | X               | X          |         |                 |                     |        |       |
|             | Tri-State output pins    | X               | X          |         |                 |                     |        |       |
|             | Data Path                | X               | X          | X       | X               |                     |        |       |
|             | Configuration Registers  | X               | X          | X       | X               | X                   |        | 3     |
|             | Read EEPROM              | X               | X          | X       | X               |                     | 4      |       |
|             | Wake Up Context          | X               | 1          | 1       | 1               |                     |        | 5     |
|             | Wake Up Control Register | X               |            |         |                 |                     |        |       |
|             | Wake Up Status Registers | X               |            |         |                 |                     |        |       |

1. If AUX\_POWER=0 the Wakeup Context is reset
2. N/A
3. The Configuration Registers include:
  - General Registers
  - Interrupt Registers
  - Receive Registers

- Transmit Registers
- Statistics Registers
- Diagnostic Registers

Of these registers, RAH/RAL, MTA[127:0], VFTA[127:0], TDBAH/TDBAL, and RDBAH/RDBAL registers have no default value. If the functions associated with the registers are enabled they must be programmed by software. Once programmed, their value is preserved through all resets as long as power is applied to the bE.

4. See explanation of “EEPROM Resets” above
5. The Wake Up Context is defined in the PCI Bus Power Management Interface Specifications. It includes:
  - PME\_En bit of the Power Management Control/Status Register (PMCSR)
  - PME\_Status bit of the Power Management Control/Status Register (PMCSR)
  - The shadow copies of these bits in the Wakeup Control Register are treated identically.

*Note:* In situations where the device is reset using CTRL.RST, the TX data lines will be forced to all zeros. This will cause a substantial number of symbol errors to be detected by the link partner.

### 37.5.13.1 Soft Reset

This section describes software considerations when using the Soft Reset.

A Soft Reset operation is invoked by software via the Device Control Register (CTRL.RST). The internal hardware reset is delayed until the internal bus is observed to be idle, in order to ensure that no hardware bus protocols are violated. For the next 5 msec, the GbE component is undergoing a low-level hardware reset and re-read of EEPROM in order to re-establish HW defaults. During this time, the GbE will not respond to accesses to the device for a duration of approximately 5 msec.

*Note:* Software MUST NOT access the GbE device for a minimum of 5 msec after writing the soft-reset bit. Failure to do so may result in a system hang condition. An explicit software wait of 5 milliseconds is necessary to ensure that the device has completed its reset and will respond again.

CTRL.RST self clears upon completion of the reset operation. While the above required wait interval is necessary to ensure that the reset operation is complete, a read of the Device Control Register may be done after the wait interval to confirm the completion of the reset.

### 37.5.13.2 MAC Disable

This feature allows the MAC and the I/O pins to be put into a very low-power mode. The intended usage of this feature is when the GbE will not be used in the system (no PHY connected).

When the GbE is disabled, all internal clocks are disabled and the GbE is held in reset. The device does not respond to internal bus transactions. Effectively, the unit becomes invisible to the system.

### 37.5.14 Endianness

Bytes for a receive packet arrive in the order shown from left to right: DA0 DA1 DA2 DA3 DA4 DA5 SA0 SA1 and so on. If the data were to be written to memory in the order of arrival with the first byte written to the lowest address and each subsequent

byte written at the next higher address then the data would appear in memory as shown in Table 37-15, “Long Word Little Endian, Byte Little Endian Ordering” on page 1423.

**Table 37-15. Long Word Little Endian, Byte Little Endian Ordering**

| Byte Address | Bit 63:56 | 55:48 | 47:40    | 39:32   | 31:24  | 23:16  | 15:8    | 7:0     |
|--------------|-----------|-------|----------|---------|--------|--------|---------|---------|
| 0            | SA1       | SA0   | DA5      | DA4     | DA3    | DA2    | DA1     | DA0     |
| 8            | TOS       | 45    | 00       | 08      | SA5    | SA4    | SA3     | SA2     |
| 16           | 06        | TTL   | Frag LSB | F/F MSB | ID LSB | ID MSB | Len LSB | Len MSB |
| 24           | IPDA1     | IPDA0 | IPSA3    | IPSA2   | IPSA1  | IPSA0  | HCS LSB | HCS MSB |
| 32           | PB5       | PB4   | PB3      | PB2     | PB1    | PB0    | IPDA3   | IPDA2   |

To allow flexibility in software models, two bits are provided to allow the endianness swizzling described below to be applied to either the descriptor data or the packet data or both or neither. These bits are also located in The [CTRL\\_AUX – Auxiliary Device Control/Status Register](#). The modes corresponding to these two bits is shown below:

**Table 37-16. Endianness Control for Gigabit Ethernet MACs**

| CSR value | Meaning  |
|-----------|--|
| 00        | LW Little-Endian, Byte Big-Endian (Table 37-17)    |
| 01        | LW Little-Endian, Byte Little-Endian (Table 37-18) |
| 10        | LW Big-Endian, Byte Big-Endian (Table 37-19)       |
| 11        | LW Big-Endian, Byte Little-Endian (Table 37-20)    |

**Table 37-17. Endianness Mode 0: Long Word Little Endian, Byte Big Endian**

| Byte Address | Bit 63:56 | Bit 55:48 | Bit 47:40 | Bit 39:32 | Bit 31:24 | Bit 23:16 | Bit 15:8 | Bit 7:0 |
|--------------|-----------|-----------|-----------|-----------|-----------|-----------|----------|---------|
| 0            | DA4       | DA5       | SA0       | SA1       | DA0       | DA1       | DA2      | DA3     |
| 8            | 08        | 00        | 45        | TOS       | SA2       | SA3       | SA4      | SA5     |

## 37.6 GbE Controller Register Summary

This section details the programmer-visible state inside the GbE controller. In some cases, it describes hardware structures invisible to software in order to clarify a concept.

The GbE address space is directly memory-mapped to 128 Kbyte of internal registers and memories. This register and memory space is divided into the following categories:

- General
- Receive
- Transmit
- Statistics
- Diagnostics (including packet buffer memory access)
- The external PHY registers are accessed through the MDIO interface. (For more information on MDIO, see “Global Configuration Unit”.)

### 37.6.1 Registers Overview

The Gigabit Ethernet Controller registers materialize in PCI space. For more information on the conventions the following register summaries adopt, see [Section 7.1, “Overview of Register Descriptions and Summaries”](#) on page 183.

*Note:* The completion of any CSR access will be held off (maximum estimated delay 5ms) if initiated prior to completion of HW initialization (e.g.-EEPROM read). This behavior is transparent to software.

[Table 37-21](#), [Table 37-22](#), and [Table 37-23](#) summarize the Gigabit Ethernet interface #0, #1, and #2 materializations from the PCI perspective.

**Table 37-21. Bus M, Device 0, Function 0: Summary of Gigabit Ethernet Interface Registers Mapped Through CSRBAR Memory BAR (Sheet 1 of 4)**

### 37.6.1.1 Memory-Mapped Access to Internal Registers and Memories

The internal registers and memories may be accessed as direct memory-mapped offsets from the base address register. See [Section 37.6, “GbE Controller Register Summary”](#) for the appropriate offset for each specific internal register.

### 37.6.1.2 I/O-Mapped Access to Internal Registers and Memories

To support pre-boot operation (prior to the allocation of physical memory base addresses), all internal registers and memories can be accessed using I/O operations. I/O accesses are supported only if an I/O Base Address is allocated and mapped, the BAR contains a valid (non-zero value), and I/O address decoding is enabled in the PCI/PCIX configuration.

When an I/O BAR is mapped, the I/O address range allocated opens a 32-byte “window” in the system I/O address map. Within this window, two I/O addressable register are implemented: IOADDR and IODATA. The IOADDR register is used to specify a reference to an internal register or memory and then the IODATA register is used as a “window” to the register or memory address specified by IOADDR:

**Table 37-24. I/O Mapped Registers**

| Offset      | Abbreviation | Name  | R/W | Size    |
|-------------|--------------|---|-----|---------|
| 0x00        | IOADDR       | Internal Register or Internal Memory Location Address.<br>0x00000-0x1FFFF – Internal Registers and Memories<br>0x20000-0xFFFFF – Undefined  | RW  | 4 bytes |
| 0x04        | IODATA       | Data field for reads or writes to the Internal Register or Internal Memory Location as identified by the current value in IOADDR. All 32 bits of this register are read/write-able. | RW  | 4 bytes |
| 0x08 – 0x3F | Reserved     | Reserved  | RW  | None    |

#### 37.6.1.2.1 IOADDR (I/O offset 0x00)

The IOADDR register must always be written as a DWORD access (e.g. the PCI\_CBE\_N[3:0] byte enables must all be enabled). Writes that are less than 32 bits will be ignored. Reads of any size will return a DWORD of data. However, the chipset or CPU may only return a subset of that DWORD.

For software programmers, the IN and OUT instructions must be used to cause I/O cycles to be used on the PCI bus. Because writes must be to a 32-bit quantity, the source register of the OUT instruction must be EAX (the only 32-bit register supported by the OUT command). For reads, the IN instruction can have any size target register, but it is recommended that the 32-bit EAX register be used.

Because only a particular range is addressable, the upper bits of this register are hard coded to zero. Bits 31 through 20 are not write-able and always read back as 0b.

At hardware reset (LAN\_PWR\_GOOD) or PCI Reset, this register value resets to 0x00000000. Once written, the value is retained until the next write or reset.

#### 37.6.1.2.2 IODATA (I/O offset 0x04)

The IODATA register must always be written as a DWORD access when the IOADDR register contains a value for the Internal Register and Memories (e.g. 0x00000-0x1FFFFC). In this case, writes that are less than 32 bits will be ignored.

Writes and reads to IODATA when the IOADDR register value is in an undefined range (0x20000-0x7FFFC) should not be performed. Results are indeterministic.

*Note:* There are no special software timing requirements on accesses to IOADDR or IODATA. All accesses will be immediate except when data is not readily available or acceptable. In this case, the MAC will delay the results through normal bus methods.

*Note:* Because a register/memory read or write takes two I/O cycles to complete, software must provide a guarantee that the two I/O cycles occur as an atomic operation. Otherwise, results can be non-deterministic from the software viewpoint.

### 37.6.1.2.3 Undefined I/O offsets

I/O offsets 0x08 through 0x3F are considered to reserved offsets with the I/O window. Writes within this address region may cause unpredictable behavior. Reads within this address region may return indeterminate values.

### 37.6.1.3 Register Conventions

All registers in the GbE are defined to be 32 bits and must be accessed with a DWORD transaction.

- **Reserved bit positions** — Some registers contain certain bits that are marked as “reserved”. These bits should never be written with anything other than their initial value by software (indicated in their individual descriptions). Reads from registers containing reserved bits may return indeterminate values in the reserved bit-positions unless read values are explicitly stated. When read, these reserved bits should be ignored by software.
- **Reserved and/or undefined addresses** — Any register address not explicitly declared in this specification should be considered to be reserved, and should not be written. Writing to reserved or undefined register addresses may cause indeterminate behavior. Reads from reserved or undefined configuration register addresses may return indeterminate values unless read values are explicitly stated for specific addresses.
- **Initial values** — Most registers define the initial hardware values prior to being programmed. In some cases, hardware initial values are undefined and will be listed as such via the text “undefined”, “unknown”, or “X”. Some such configuration values may need to be set by software in order for proper operation to occur; this need is dependent on the function of the bit. Other registers may cite a hardware default which is overridden by a higher-precedence operation. Operations which may supersede hardware defaults may include completion of a hardware operation (such as hardware auto-negotiation), or writing of a different register whose value is then reflected in another bit.

For all registers, partial reads and writes may cause indeterminate behavior.

## 37.6.2 General Registers: Detailed Descriptions

### 37.6.2.1 CTRL – Device Control Register

This register, as well as the [Extended Device Control Register \(CTRL\\_EXT\)](#), controls the major operational modes for the device. While software write to this register to control device settings, several bits (such as FD and SPEED) may be overridden depending on other bit settings and the resultant link configuration determined by the Auto-Negotiation resolution with the PHY. See [“Physical Layer Auto-Negotiation & Link Setup Features”](#) on page 1394 for a detailed explanation on the link configuration process.

| 26           | RST         | <p>Device Reset, also referred to as a “Soft Reset”. Normally 0, writing 1 initiates the reset. This bit is self clearing.</p> <p>CTRL.RST may be used to globally reset the entire GbE hardware. This register is provided primarily as a last-ditch software mechanism to recover from an indeterminate or suspected hung hardware state. Most registers (receive, transmit, interrupt, statistics, etc.), and state machines will be set to their power-on reset values, approximating the state following a power-on or Unit Reset. However, the <a href="#">Packet Buffer Allocation Register (PBA)</a> retains its value through a global reset.</p> <p><b>Note:</b> Software must first disable both transmit &amp; receive operation using the <a href="#">TCTL.EN</a> and <a href="#">RCTL.EN</a> register bits before asserting CTRL.RST. To ensure that the global device reset has fully completed and that the controller will respond to subsequent accesses, software must wait a minimum of 5 milliseconds after setting CTRL.RST before attempting to check if the bit has cleared or to access any other GbE device register.</p> |        | 0h              | RW                           |

| Bit Range           | Bit Acronym               | Bit Description   | Sticky   | Bit Reset Value | Bit Access |
| 31 : 25             | Rsvd                      | Reserved  |  | 0h              | RV         |
| 24                  | RMII_RX_MODE              | <p>RMII gasket receive mode select:</p> <p>0 = For proper 100mbps receive operation, after assertion of the RMII CRS_DV signal on GBE_RXCTL, the RMII gasket requires that a minimum of two di-bits of '00' appear on GBE_RXDATA[1:0] before the preamble appears.</p> <p>1 = For proper 100mbps receive operation, the RMII gasket requires that CRS_DV be asserted on GBE_RXCTL synchronously with GBE_REFCLK_RMII and on the same cycle in which the first di-bit of the preamble appears on GBE_RXDATA[1:0].</p> <p>0 is the default value of this bit and makes the RMII gasket compatible with RMII PHYs that assert CRS_DV as soon as the receive medium is non-idle, and subsequently drive '00' on RXD[1:0] until proper receive signal decoding has been achieved (per the RMII Specification, Revision 1.2). Setting this bit to a 1 makes the gasket compatible with RMII PHYs that assert CRS_DV simultaneously with the start of the preamble driven on RXD[1:0]. While this CRS_DV signalling mode does not strictly conform to the RMII specification, it is provided to allow compatibility with PHY devices that use this alternate method of asserting CRS_DV at the start of the packet.</p> <p>This bit must be set to the proper state that corresponds to the CRS_DV behavior of the attached RMII PHY, otherwise 100mbps packets cannot be properly received by the GbE.</p> <p>This bit does not affect transmit operations.</p> |  | 0h              | RW         |

Software clocks the EEPROM via toggling this bit with successive writes. |   |  | 0h                     | RW                |

This register provides software direct access to the EEPROM. Software can control the EEPROM by successive writes to this register. Data & address information is clocked into the EEPROM by software toggling the EESK bit (2) of this register with EECS set to 1. Data output from the EEPROM is latched into bit 3 of this register via the internal 62.5MHz clock and may be accessed by software via reads of this register.

| 03 : 01              | RSVD                      | <b>Reserved</b><br>Reads as 0  |                                   | 0h   | RV                |
| 00                   | START                     | Start Read<br>Writing a 1 to this bit causes the EEPROM to read a (16-bit) word at the address stored in the EE_ADDR field, storing the result in the EE_DATA field. This bit is self-clearing |                                   | 0h   | RW                |

This registers is used by software to read individual words in the EEPROM. To read a word, software writes the address to the Read Address field and simultaneously writes a 1 to the Start Read field. The GbE will read the word from the EEPROM and place it in the Read Data field, setting the Read Done filed to 1. Software can poll this register, looking for a 1 in the Read Done filed, and then using the value in the Read Data field.

When this register is used to read a word from the EEPROM, that word is not written to any of the MAC's internal registers even if it is normally a hardware accessed word.

**Note:** If SW has requested direct pin control of the EEPROM using the EEC register, an access through the EERD register mechanism may stall until the EEC control has been released. SW should ensure that EEC.EE\_REQ=0 and that EEC.EE\_GNT=0 as well before attempting to utilize EERD to access the EEPROM.

### 37.6.2.7 FCAL – Flow Control Address Low Register

Flow control packets are defined by 802.3X to be either a unique multicast address or the station address with the EtherType field indicating PAUSE. The **FCAH** and **FCAL** registers provide the value hardware compares incoming packets against to determine that it should PAUSE its output. This register contains the lower bits of the internal 48 bit Flow Control Ethernet address.

**Note:** Any packet matching the contents of {**FCAH**, **FCAL**, **FCT**} when **CTRL.RFCE** is set will be acted on by the EP80579's GbE. Whether flow control packets are passed to the software depends on the state of the **RCTL.DPF** bit and whether the packet matches any of the normal filters.

**Note:** At the time of the original implementation, the flow control multicast address was not defined and thus hardware provided programmability. Since then, the final release of the 802.3x standard has reserved the following multicast address for MAC Control Frames: 01-80-C2-00-00-01.

**Note:** This register **MUST** be written by software with the appropriate value for the MAC to behave properly.

**Table 37-31. FCAL: Flow Control Address Low Register**

### 37.6.2.8 FCAH – Flow Control Address High Register

Flow control packets are defined by 802.3X to be either a unique multicast address or the station address with the EtherType field indicating PAUSE. The FCAH and FCAL registers provide the value hardware compares incoming packets against to determine that it should PAUSE its output. This register contains the upper bits of the internal 48 bit Flow Control Ethernet address.

*Note:* Any packet matching the contents of {FCAH, FCAL, FCT} when CTRL.RFCE is set will be acted on by the EP80579's GbE. Whether flow control packets are passed to the software depends on the state of the RCTL.DPF bit and whether the packet matches any of the normal filters.

*Note:* At the time of the original implementation, the flow control multicast address was not defined and thus hardware provided programmability. Since then, the final release of the 802.3x standard has reserved the following multicast address for MAC Control Frames: 01-80-C2-00-00-01.

*Note:* This register MUST be written by software with the appropriate value for the MAC to behave properly.

**Table 37-32. FCAH: Flow Control Address High Register**

### 37.6.2.9 FCT – Flow Control Type Register

Flow control packets are defined by 802.3X to be either a unique multicast address or the station address with the EtherType field indicating PAUSE. The **FCAH** and **FCAL** registers provide the value hardware compares incoming packets against to determine that it should PAUSE its output. This register contains the type field hardware matches against to recognize a flow control packet.

**Note:** Any packet matching the contents of {**FCAH**, **FCAL**, **FCT**} when **CTRL.RFCE** is set will be acted on by the EP80579's GbE. Whether flow control packets are passed to the software depends on the state of the **RCTL.DPF** bit and whether the packet matches any of the normal filters.

**Note:** At the time of the original implementation, the flow control type field was not defined and thus hardware provided programmability. Since then, the final release of the 802.3x standard has specified the type/length value for MAC Control Frames as 88-08.

**Table 37-33. FCT: Flow Control Type Register**

|                      |  |  |               |  |                   |

### 37.6.2.11 FCTTV – Flow Control Transmit Timer Value Register

The register holds a 16-bit value in the TTV field that is inserted into a transmitted frame (either XOFF frames or any PAUSE frame value in any software transmitted packets). It counts in units of slot time, usually 64B. If software wishes to send an XON frame, it must set TTV to 0 prior to initiating the PAUSE frame.

*Note:* The EP80579’s GbE uses a fixed slot time value of 64B times

**Table 37-35. FCTTV: Flow Control Transmit Timer Value Register**

|                      |                           |   |               |  |                   |

### 37.6.2.12 PBA – Packet Buffer Allocation Register

This register sets the GbE hardware receive and transmit storage allocation ratio. The Tx allocation is calculated from the programmed Rx allocation, assuming 64KB of total Packet Buffer memory.

*Note:* Programming this register does not automatically re-load or initialize internal packet-buffer RAM pointers. The software must reset both transmit and receive operation (using the global device reset CTRL.RST bit) after changing this register in order for it to take effect. The PBA register itself will not be reset by assertion of the global reset, but will only be reset upon initial hardware power-on.

**Table 37-36. PBA: Packet Buffer Allocation Register**

| Description:         |                           |   |  |  |            |

### 37.6.3 Interrupt Registers: Detailed Descriptions

#### 37.6.3.1 ICRO – Interrupt 0 Cause Read Register

This register contains all interrupt conditions for the GbE. Whenever an interrupt causing event occurs, the corresponding interrupt bit is set in this register. See “IMS0 – Interrupt 0 Mask Set/Read Register” on page 1459 for additional details.

*Note:* All register bits clear on read. Thus, reading this register implicitly acknowledges all pending interrupt events. Writing a 1 to any bit in the register will also clear that bit. Writing a 0 to any bit will have no effect.

**Table 37-37. ICRO: Interrupt 0 Cause Read Register (Sheet 1 of 3)**

|                      |                           |   |  |                        |                   |

If using delayed interrupts (TDESC.IDE is set in the Transmit Descriptor CMD), the interrupt is delayed until after one of the delayed-timers (TIDV or TADV) expires. |                                   | 0h   | RCWC              |

### 37.6.3.2 ITR0 – Interrupt 0 Throttling Register

Software can use this register to pace (or balance) the delivery of the functional interrupt signal to the host CPU. This register provides a guaranteed inter-interrupt delay between interrupts asserted by the network controller, regardless of network traffic conditions.

**Table 37-38. ITR0: Interrupt 0 Throttling Register**

|                      |                           |  |               |  |                   |

| 31 : 16              | Rsvd                      | Reserved   |               | 0h   | RV                |
| 15 : 00              | MIII                      | <p><b>Minimum Inter-interrupt Interval.</b></p> <ul style="list-style-type: none"> <li>In RGMII mode, the interval is specified in 256ns increments.</li> <li>In RMII mode, the interval is specified in 320ns increments</li> <li>Zero disables interrupt throttling logic</li> </ul> <p>(The following example applies to RGMII mode)<br/>To independently validate configuration settings, software can use the following formula to convert the inter-interrupt interval value to the common 'interrupts/sec' performance metric:<br/> <math display="block">\text{interrupts/sec} = (256 \times 10^{-9} \text{ sec} \times \text{inter-interrupt interval})^{-1}</math>                     Inversely, inter-interrupt interval value can be calculated as:<br/> <math display="block">\text{inter-interrupt interval} = (256 \times 10^{-9} \text{ sec} \times \text{interrupts/sec})^{-1}</math>                     For example, if the interval is programmed to 500d, the network controller guarantees the CPU will not be interrupted by the network controller for 128 usec from the last interrupt. The maximum observable interrupt rate from the adapter should never exceed 7813 interrupts/sec.<br/>                     The optimal performance setting for this register is system/configuration specific. A initial suggested range is 651-5580 (28Bh - 15CCh), or, more generally, between 700 and 6000 interrupts per second.</p> |               | 0h   | RW                |

### 37.6.3.3 ICS0 – Interrupt 0 Cause Set Register

Software uses this register to set an interrupt condition. Assuming the interrupt mask is set, any bit written with a 1 triggers the corresponding interrupt, see “[IMSO – Interrupt 0 Mask Set/Read Register](#)” on page 1459 and “[ICRO – Interrupt 0 Cause Read Register](#)” on page 1454.

**Table 37-39. ICS0: Interrupt 0 Cause Set Register**

### 37.6.3.4 IMSO – Interrupt 0 Mask Set/Read Register

This register contains which interrupts are enabled. An interrupt is enabled if its corresponding mask bit is set to 1, and disabled if its corresponding mask bit is set to 0. An interrupt is generated whenever one of the bits in this register is set, and the corresponding interrupt condition occurs, see the “ICR0 – Interrupt 0 Cause Read Register” on page 1454 for interrupt conditions.

A particular interrupt may be enabled by writing a 1 to the corresponding mask bit in this register. Any bits written with a 0, are unchanged. Thus, if software desires to disable a particular interrupt condition that had been previously enabled, it must write to the [Interrupt Mask Clear Register](#) rather than writing a 0 to a bit in this register.

**Table 37-40. IMSO: Interrupt 0 Mask Set/Read Register (Sheet 1 of 2)**

### 37.6.3.5 IMCO – Interrupt 0 Mask Clear Register

Software uses this register to disable an interrupt condition that was previously enabled. Interrupts are presented to the bus interface only when the mask bit is set and the interrupt condition is active. The status of the mask bit is reflected in the [“IMS0 – Interrupt 0 Mask Set/Read Register” on page 1459](#), and the status of the cause bit is reflected in the [“ICR0 – Interrupt 0 Cause Read Register” on page 1454](#). Software disables a given interrupt by writing a 1 to the corresponding bit in this register, a 0 is ignored. A read from this register will return the current value of the Interrupt mask settings, returning the same value as a read of the IMS register.

### 37.6.3.6 ICR1 – Interrupt 1 Cause Read Register

This register contains all interrupt conditions for the GbE. Whenever an interrupt causing event occurs, the corresponding interrupt bit is set in this register. See “IMS0 – Interrupt 0 Mask Set/Read Register” on page 1459 for additional details.

*Note:* All register bits clear on read. Thus, reading this register implicitly acknowledges all pending interrupt events. Writing a 1 to any bit in the register will also clear that bit. Writing a 0 to any bit will have no effect.

**Table 37-42. ICR1: Interrupt 1Cause Read Register (Sheet 1 of 3)**

If using delayed interrupts (TDESC.IDE is set in the Transmit Descriptor CMD), the interrupt is delayed until after one of the delayed-timers (TIDV or TADV) expires. |                                   | 0h   | RCWC              |

### 37.6.3.7 ICS1 – Interrupt 1 Cause Set Register

Software uses this register to set an interrupt condition. Assuming the interrupt mask is set, any bit written with a 1 triggers the corresponding interrupt, see “IMSO – Interrupt 0 Mask Set/Read Register” on page 1459 and “ICR0 – Interrupt 0 Cause Read Register” on page 1454.

**Table 37-43. ICS1: Interrupt 0 Cause Set Register (Sheet 1 of 2)**

### 37.6.3.8 IMS1 – Interrupt 1 Mask Set/Read Register

This register contains which interrupts are enabled. An interrupt is enabled if its corresponding mask bit is set to 1, and disabled if its corresponding mask bit is set to 0. An interrupt is generated whenever one of the bits in this register is set, and the corresponding interrupt condition occurs, see the “ICRO – Interrupt 0 Cause Read Register” on page 1454 for interrupt conditions.

A particular interrupt may be enabled by writing a 1 to the corresponding mask bit in this register. Any bits written with a 0, are unchanged. Thus, if software desires to disable a particular interrupt condition that had been previously enabled, it must write to the [Interrupt Mask Clear Register](#) rather than writing a 0 to a bit in this register.

**Table 37-44. IMS1: Interrupt 1 Mask Set/Read Register (Sheet 1 of 2)**

### 37.6.3.9 IMC1 – Interrupt 1 Mask Clear Register

Software uses this register to disable an interrupt condition that was previously enabled. Interrupts are presented to the bus interface only when the mask bit is set and the interrupt condition is active. The status of the mask bit is reflected in the “[IMSO – Interrupt 0 Mask Set/Read Register](#)” on page 1459, and the status of the cause bit is reflected in the “[ICR0 – Interrupt 0 Cause Read Register](#)” on page 1454. Software disables a given interrupt by writing a 1 to the corresponding bit in this register, a 0 is ignored.

### 37.6.3.10 ICR2 – Error Interrupt Cause Read Register

This register contains all interrupt conditions for the GbE. Whenever an interrupt causing event occurs, the corresponding interrupt bit is set in this register. See “IMS0 – Interrupt 0 Mask Set/Read Register” on page 1459 for additional details.

**Note:** All register bits clear on read. Thus, reading this register implicitly acknowledges all pending interrupt events. Writing a 1 to any bit in the register will also clear that bit. Writing a 0 to any bit will have no effect.

**Table 37-46. ICR2: Error Interrupt Cause Read Register (Sheet 1 of 2)**

### 37.6.3.11 ICS2 – Error Interrupt Cause Set Register

Software uses this register to set an interrupt condition. Assuming the interrupt mask is set, any bit written with a 1 triggers the corresponding interrupt, see “IMS0 – Interrupt 0 Mask Set/Read Register” on page 1459 and “ICR0 – Interrupt 0 Cause Read Register” on page 1454.

**Table 37-47. ICS2: Error Interrupt Cause Set Register**

### 37.6.3.12 IMS2 – Error Interrupt Mask Set/Read Register

This register contains which interrupts are enabled. An interrupt is enabled if its corresponding mask bit is set to 1, and disabled if its corresponding mask bit is set to 0. An interrupt is generated whenever one of the bits in this register is set, and the corresponding interrupt condition occurs, see the “ICRO – Interrupt 0 Cause Read Register” on page 1454 for interrupt conditions.

A particular interrupt may be enabled by writing a 1 to the corresponding mask bit in this register. Any bits written with a 0, are unchanged. Thus, if software desires to disable a particular interrupt condition that had been previously enabled, it must write to the [Interrupt Mask Clear Register](#) rather than writing a 0 to a bit in this register.

**Table 37-48. IMS2: Error Interrupt Mask Set/Read Register**

|                      |                           |  |                                   |  |                   |

### 37.6.3.13 IMC2 – Error Interrupt Mask Clear Register

Software uses this register to disable an interrupt condition that was previously enabled. Interrupts are presented to the bus interface only when the mask bit is set and the interrupt condition is active. The status of the mask bit is reflected in the “[IMSO – Interrupt 0 Mask Set/Read Register](#)” on page 1459, and the status of the cause bit is reflected in the “[ICRO – Interrupt 0 Cause Read Register](#)” on page 1454. Software disables a given interrupt by writing a 1 to the corresponding bit in this register, a 0 is ignored.

**Table 37-49. IMC2: Error Interrupt Mask Clear Register**

### 37.6.4 Receive Registers: Detailed Descriptions

#### 37.6.4.1 RCTL – Receive Control Register

This register controls the types and sizes of packets received, as well as any manipulation of those received packets. The size of the receive buffers where those packets reside before they are transferred to system memory is also controlled here.

**Table 37-50. RCTL: Receive Control Register (Sheet 1 of 4)**

### 37.6.4.2 FCRTL: Flow Control Receive Threshold Low Register

This register contains the receive threshold used to determine when to send an XON packet, counting in units of bytes. The lower 3 bits must be programmed to 0 (8B granularity). Whenever hardware crosses the receive high threshold (becoming more full), and then crosses the receive low threshold, then hardware will transmits an XON frame (if enabled with FCRTL.XONE).

*Note:* Flow control reception/transmission are negotiated capabilities by the Auto-Negotiation process. When the device is manually configured, flow control operation is determined by the CTRL.RFCE & CTRL.TFCE.

**Table 37-51. FCRTL: Flow Control Receive Threshold Low Register**

### 37.6.4.3 FCRTM – Flow Control Receive Threshold High Register

This register contains the receive threshold used to determine when to send an XOFF packet. It counts in units of bytes. This value must be at least 8 bytes less than the maximum number of bytes allocated to the Receive Packet Buffer (PBA, RXA), and the lower 3 bits must be programmed to 0 (8B granularity). Whenever the receive FIFO reaches the fullness indicated by FCRTM.RTH, hardware transmits a PAUSE frame if the transmission of flow control frames is enabled.

*Note:* Flow control reception/transmission are negotiated capabilities by the Auto-Negotiation process. When the device is manually configured, flow control operation is determined by the CTRL.RFCE & CTRL.TFCE.

**Table 37-52. FCRTM: Flow Control Receive Threshold High Register**

| Description:  |                    |  |  |                 |            |

### 37.6.4.8 RDT – Receive Descriptor Tail Register

This register contains the tail pointers for the receive descriptor buffer. The register points to a 16B datum. Software writes the tail register to add receive descriptors to the hardware free list for the ring.

Table 37-57. RDT: Receive Descriptor Tail Register

|                      |                           |                         |                                   |  |                   |

### 37.6.4.9 RDTR – RX Interrupt Delay Timer (Packet Timer) Register

This register is used to delay interrupt notification for the receive descriptor ring by coalescing interrupts for multiple received packets. Delaying interrupt notification helps maximize the number of receive packets serviced by a single interrupt.

This feature operates by initiating a countdown timer upon successfully receiving each packet to system memory. If a subsequent packet is received BEFORE the timer expires, the timer is reinitialized to the programmed value and re-starts its countdown. If the timer expires due to NOT having received a subsequent packet within the programmed interval, pending receive descriptor writebacks are flushed and a receive timer interrupt is generated.

Setting the value to 0b represents no delay from a receive packet to the interrupt notification, an results in immediate interrupt notification for each received packet.

Writing this register with FPD set initiates an immediate expiration of the timer, causing a writeback of any consumed receive descriptors pending writeback, and results in a receive timer interrupt in the ICR.

Receive interrupts due to a Receive Absolute Timer (RADV) expiration cancels a pending RDTR interrupt. The RDTR countdown timer is reloaded but halted, so as to avoid generation of a spurious second interrupt after the RADV has been noted, but might be restarted by a subsequent received packet.

Table 37-58. RDTR: RX Interrupt Delay Timer (Packet Timer) Register

| Description:  |                    |   |   |                 |            |

### 37.6.4.13 RXCSUM – Receive Checksum Control Register

This register controls the receive checksum off loading features. The GbE supports the off loading of three receive checksum calculations: the Packet Checksum, the IP Header Checksum, and the TCP/UDP Checksum. Supported frame types are Ethernet II and Ethernet SNAP. This register should only be written when the receiver is not enabled (i.e., only when `RCTL.EN = 0`).

**Table 37-62. RXCSUM: Receive Checksum Control Register**

| 08            | IPOFL              | <b>IP Checksum Off load Enable.</b> This bit is used to enable the IP Checksum off-loading feature.<br>0 = IP Checksum Off load Disabled<br>1 = Hardware will calculate the IP checksum and indicate a pass/fail indication to software via the IP Checksum Error bit (IPE) in the ERROR field of the receive descriptor.   |                            | 0h                                       | RW         |
| 07 : 00       | PCSS               | <b>Packet Checksum Start.</b> This field controls the starting byte for the Packet Checksum calculation. The Packet Checksum is the one's complement over the receive packet, starting from the byte indicated by PCSS (0 corresponds to the first byte of the packet), after stripping. For example, for an Ethernet II frame encapsulated as an 802.3ac VLAN packet and with PCSS set to 14, the packet checksum would include the entire encapsulated frame, excluding the 14-byte Ethernet header (DA, SA, Type and Length) and the 4-byte VLAN tag. The Packet Checksum will not include the Ethernet CRC if the RCTL.SECRC bit is set. Software must make the required offsetting computation (to back out the bytes that should not have been included and to include the pseudo-header) prior to comparing the Packet Checksum against the TCP checksum stored in the packet. |                            | 0h                                       | RW         |

### 37.6.4.14 MTA[0-127] – 128 Multicast Table Array Registers

There is one register per 32 bits of the Multicast Address Table for a total of 128 registers (thus the MTA[127:0] designation). The size of the word array depends on the number of bits implemented in the multicast address table. Software must mask to the desired bit on reads and supply a 32-bit word on writes. Refer to “Receive Initialization” on page 1348 for details on initialization and usage.

**Table 37-63. MTA[0-127] – 128 Multicast Table Array Registers**

|                      |                            |   |                                   |  |                   |

### 37.6.4.15 RAL[0-15] – Receive Address Low Register

These registers contain the lower bits of the 48 bit Ethernet address.

**Table 37-64. RAL[0-15] - Receive Address Low Register**

|                      |                           |   |                                   |  |                   |

### 37.6.4.16 RAH[0-15] – Receive Address High Register

These registers contain the upper bits of the 48 bit Ethernet address. The complete 48b address is {RAH, RAL}. The first receive address register (RAR0) is also used for exact match pause frame checking (i.e. the destination address matches the first register). Therefore RAR0 should always be used to store the individual Ethernet MAC address of the adapter.

**Table 37-65. RAH[0-15] - Receive Address High Register**

| Description:  |                    |   |   |  |                 |            |

### 37.6.4.17 VFTA[0-127] – 128 VLAN Filter Table Array Registers

There is one register per 32 bits of the VLAN Filter Table. The size of the word array depends on the number of bits implemented in the VLAN Filter Table. Software must mask to the desired bit on reads and supply a 32-bit word on writes. The algorithm for VLAN filtering via the VFTA is identical to that used for the Multicast Table Array, refer to “Receive Initialization” on page 1348 for details on initialization and usage.

**Table 37-66. VFTA[0-127] - 128 VLAN Filter Table Array Registers**

|                      |                           |  |                                   |  |                   |

## 37.6.5 Transmit Registers: Detailed Descriptions

### 37.6.5.1 TCTL – Transmit Control Register

This register controls packet transmission. Packet collision recovery, 64B data padding, and software XOFF transmission are controlled here.

**Table 37-67. TCTL: Transmit Control Register (Sheet 1 of 2)**

| Description:  |                    |  |   |                                       |                 |            |
|---------------|--------------------|--|---|---------------------------------------|-----------------|------------|
| View          | BAR                | Bus:Device:Function  | M | Offset Start                          | Offset End      |            |
| PCI 1         | CSRBAR             | M:0:0  |   | 0400h                                 | 0403h           |            |
| PCI 2         | CSRBAR             | M:1:0  |   | 0400h                                 | 0403h           |            |
| PCI 3         | CSRBAR             | M:2:0  |   | 0400h                                 | 0403h           |            |
| Size: 32 bits | Default: 00000008h |  |   | Power Well: GbE0: Aux<br>GbE1/2: Core |                 |            |
| Bit Range     | Bit Acronym        | Bit Description  |   | Sticky                                | Bit Reset Value | Bit Access |
| 31 : 25       | Rsvd               | Reserved   |   |                                       | 0h              | RV         |
| 24            | RTLCL              | <b>Re-Transmit on Late Collision.</b> This bit configures the hardware to perform retransmission of packets when a late collision is detected. Note that the collision window is speed dependent: 64B for 10/100 Mbps and 512B for 1Gbps operation. If a late collision is detected when this bit is clear, the transmit function assumes the packet is successfully transmitted.<br><b>Note:</b> This bit is ignored in full-duplex mode.   |   |                                       | 0h              | RW         |
| 23            | PBE                | <b>Packet Burst Enable.</b> The EP80579's GbE does not support Packet Bursting for 1Gbps half-duplex transmit operation. This bit must be set to 0.  |   |                                       | 0h              | RV         |
| 22            | SWXOFF             | <b>Software XOFF Transmission.</b> When set to a 1 the device will schedule the transmission of an XOFF (PAUSE) frame using the current value of the PAUSE timer. This bit clears itself upon transmission of the XOFF frame.<br><b>Note:</b> While 802.3x flow control is only defined during full duplex operation, the sending of PAUSE frames via the SWXOFF bit is not gated by the duplex settings within the device. Software should not write a 1 to this bit while the device is configured for half duplex operation.  |   |                                       | 0h              | RW         |
| 21 : 12       | COLD               | <b>Collision Distance.</b> Wire speeds of 1Gbps result in a very short collision radius with traditional minimum packet sizes. This bit specifies the minimum number of bytes in the packet to satisfy the desired collision distance for proper CSMA/CD operation. It is important to note that the resulting packet has special characters appended to the end, not regular data characters. Hardware strips special characters for packets that go from 1 Gbps environments to 100 Mbps environments.<br><b>Note:</b> The hardware checks and pads to this value even in full-duplex operation. |   |                                       | 0h              | RW         |

The value that should be programmed into IPGT is 8. These values are recommended to assure that the minimum IPG gap is met under all synchronization conditions.</p>  |                                   | 0x8h   | RW                |

### 37.6.5.3 AIT – Adaptive IFS Throttle Register

Adaptive IFS throttles back-to-back transmissions in the transmit packet buffer and delays their transfer to the CSMA/CD transmit function. This can be used to delay the transmission of back-to-back packets on the wire. Normally, this register should be set to 0. However, if additional delay is desired between back-to-back transmits, then this register may be set with a value greater than zero.

The Adaptive IFS Throttle timer provides a similar function to the “TIPG – Transmit IPG Register” on page 1493, however, Adaptive IFS affects only the initial transmission timing, not re-transmission timing.

**Table 37-69. AIT: Adaptive IFS Throttle Register**

|                      |                           |   |  |  |                        |                   |

### 37.6.5.7 TDH – Transmit Descriptor Head Register

This register contains the head pointer for the transmit descriptor ring. It points to a 16B datum. Hardware controls this pointer. The only time that software should write to this register is after a reset (hardware reset or CTRL.RST) and before enabling the transmit function (TCTL.EN). Writing this register while the transmit function is enabled will cause indeterminate behavior.

**Table 37-73. TDH: Transmit Descriptor Head Register**

### 37.6.5.8 TDT – Transmit Descriptor Tail Register

This register contains the tail pointer for the transmit descriptor ring. It points to a 16B datum. Software writes the tail pointer to add more descriptors to the transmit ready queue. Hardware attempts to transmit all packets referenced by descriptors between head and tail.

**Table 37-74. TDT: Transmit Descriptor Tail Register**

|                      |                           |                          |                                   |  |                        |                   |

### 37.6.5.9 TIDV – Transmit Interrupt Delay Value Register

This register is used to delay interrupt notification for transmit operations by coalescing interrupts for multiple transmitted buffers. Delaying interrupt notification helps maximize the amount of transmit buffers reclaimed by a single interrupt. This feature **only** applies to transmit descriptor operations where interrupt-based reporting is requested (RS set) and the use of the timer function is requested (IDE is set).

**Table 37-75. TIDV: Transmit Interrupt Delay Value Register**

|                      |                           |  |  |  |                        |

| 21 : 16       | WTHRESH            | <p><b>Write-back Threshold.</b> This field controls the write-back of processed transmit descriptors. This threshold refers to the number of transmit descriptors in the GbE hardware buffer which are ready to be written back to host memory. In the absence of external events (explicit flushes), the write-back will occur only after more than WTHRESH descriptors are available for write-back.</p> <p>Since write-back notification of transmit descriptor completion is optional (under the control of the RS bit in the descriptor), not all processed descriptors are counted with respect to WTHRESH (any single transmit descriptor with RS=0 is consumed with no writeback notification performed). When WTHRESH is non-zero, processing a descriptor with RS=1 initiates accumulation of pending writebacks; accumulated writebacks will include even those descriptors with RS=0, in order to optimize writeback bursts.</p> <p><b>Note:</b> When WTHRESH value is set to 0, transmit descriptor writeback notification will be similar to the 82452 behavior. In accordance with WTHRESH=0, the writeback notification for a descriptor with RS=1 will occur as soon as the descriptor is processed. In addition, processed transmit descriptors are not written-back in entirety; only the descriptor status field is written back/ updated. This 82542-compatible mode is the default HW behavior.</p> |    |               | 0h                            | RW         |

| 05 : 00       | PTHRESH            | <p><b>Prefetch Threshold.</b> This field is used to control when a prefetch of descriptors will be considered. This threshold refers to the number of valid, unprocessed transmit descriptors the chip has in its GbE hardware buffer. If this number drops below PTHRESH, the algorithm will consider pre-fetching descriptors from host memory. This fetch will not happen however unless there are at least HTHRESH valid descriptors in host memory to fetch.</p>   |    |               | 0h                            | RW         |

### 37.6.5.11 TADV – Transmit Absolute Interrupt Delay Value Register

The **Transmit Absolute Interrupt Delay Value Register (TADV)** may be used to coalesce transmit interrupts, however, it may be necessary to ensure that no completed transmission remains unnoticed for too long an interval in order ensure timely release of transmit buffers. This register may be used to ensure that a transmit interrupt occurs at some predefined interval after a transmit is completed. Like the **TIDV**, the absolute transmit timer only applies to transmit descriptor operations where interrupt-based reporting is requested (RS set) and the use of the timer function is requested (IDE is set).

**Table 37-77. TADV: Transmit Absolute Interrupt Delay Value Register**

|                      |                           |   |  |                        |                   |

However, it might be necessary to ensure that no completed transmit remains unnoticed for too long an interval in order ensure timely release of transmit buffers. This register can be used to ENSURE that a transmit interrupt occurs at some predefined interval after a transmit is completed. Like the delayed-transmit timer, the absolute transmit timer ONLY applies to transmit descriptor operations where (a) interrupt-based reporting is requested (RS set) and (b) the use of the timer function is requested (IDE is set).</p> <p>This feature operates by initiating a countdown timer upon successfully transmitting the buffer. When the timer expires, a transmit-complete interrupt (ICR.TXDW) is generated. The occurrence of either an immediate (non-scheduled) or delayed transmit timer (TIDV) expiration interrupt halts the TADV timer and eliminates any spurious second interrupts.</p> <p>Setting the value to 0b disables the transmit absolute delay function. If an immediate (nonscheduled) interrupt is desired for any transmit descriptor, the descriptor IDE should be set to 0b.</p> <p><b>Note:</b> This timer ONLY causes an interrupt. It does NOT cause a writeback</p> |  | 0h                     | RW                |

### 37.6.5.12 TSPMT – TCP Segmentation Pad and Minimum Threshold Register

This register specifies fields affecting hardware behavior during TCP Segmentation operations. For normal (non TCP Segmentation) operations, the transmit DMA never begins servicing an individual data descriptor unless the transmit Packet Buffer has sufficient room to accept all of the data associated with the descriptor. However, for TCP Segmentation operations, it may be desirable to use a data descriptor which refers to a larger contiguous buffer in host memory than is actually allocated for the transmit Packet Buffer. For this case, the transmit DMA must be able to initiate smaller transfers than the entire descriptor's data length field (i.e., during TCP segmentation, the transmit DMA does not wait until the entire descriptor's data can fit in the packet buffer).

When performing TCP segmentation, the packet prototype header initially transferred by DMA is stored internally and updated as each packet of the TCP segmentation operation is composed. As data for subsequent TCP segments is DMA'd into the controller, the frame header for each segment is dynamically inserted in front of the frame payload data stream prior to being written to the packet buffer. In order to obtain the most efficient use of burst DMA operations, the transmit DMA will attempt to fetch as much data from a descriptor as possible, rather than limiting itself to bursting each data segment individually. However, to do this, sufficient packet-buffer space must be reserved to account for all headers which will be inserted into the fetched data stream, as the burst may span multiple data segments. The calculation of how much packet buffer space should be reserved is dependent on the MSS being used in the packet header, the maximum-sized data buffer pointed to by a descriptor, and the current header size. Such calculation cannot be easily calculated in hardware, and is left to software to pre-calculate for the worst-case usage.

The transmit DMA will further refrain from initiating service of a new data descriptor unless sufficient packet buffer space exists to at least fetch a full data segment or complete a partially-fetched segment. This additionally helps to reduce the number of small DMA bursts and reducing the efficiency of the host interface.

**Table 37-78. TSPMT: TCP Segmentation Pad And Minimum Threshold Register**

| <b>Bit Range</b>     | <b>Bit Acronym</b>        | <b>Bit Description</b>   | <b>Sticky</b>  | <b>Bit Reset Value</b> | <b>Bit Access</b> |
| 31 : 16              | TSPBP                     | <b>TCP Segmentation Packet Buffer Padding</b> , value is in bytes. This field allows software configuration of packet buffer space which must be reserved as “pad” for worst-case header insertion. To ensure that this value does not prevent descriptors from being serviced at all, it is necessary that the transmit packet buffer allocation should be larger than the sum of (maximum TCP HDRLEN + maximum MSS + TSPMT.TMPBP + 80 bytes).  |  | 0x0100h                | RW                |
| 15 : 00              | TSMT                      | <b>TCP Segmentation Minimum Transfer</b> , value is in bytes. The DMA will attempt to issue burst fetches for as much data as possible, and it is possible for the transmit DMA to cause the transmit packet buffer to approach fullness (less the pad specified). However, if the packet buffer empties slightly, the transmit DMA could initiate a series of small transfers.<br>To further optimize the efficiency of the transmit DMA during TCP segmentation operation, the this TSPMT.TSMT field allows software configuration of the minimum number of bytes which the DMA should attempt to transfer in a single burst operation. The transmit DMA will use this value to refrain from issuing a burst read until at least TSPMT.TSMT bytes of data from the current data descriptor can be stored in the packet buffer.<br>This check will be ignored if, after a series of DMA operations, the descriptor contains a smaller number of unfetched data bytes. To ensure that this minimum threshold does not prevent descriptors from being serviced at all, it is necessary that the transmit packet buffer allocation should be larger than the sum of (TSPMT.TSMT + TSPMT.TSPBP + 80 bytes). |  | 0x0400h                | RW                |

### 37.6.6 Statistical Registers: Detailed Descriptions

The statistics registers generally assume the presence of a system host driver which has enabled transmit and receive operations between the GbE controller and host memory. Throughout the descriptions of specific statistics registers, many require the driver to have enabled transmits enabled (**TCTL.EN=1**) or receives enabled (**RCTL.EN=1**). Some of the registers provide an indication of link activity even when the driver has transmits or receives disabled.

All statistics registers are cleared when read. It is the responsibility of software to maintain incremental count variables if statistics are intended to be monitored regularly for extended periods of time. All registers “stick” at a maximum value of 0xFFFFFFFF when reached (until cleared by reset or a read) - if accurate statistics are required, it is expected that software will query statistics at sufficient intervals to avoid reaching maximum values and failing to count values unexpectedly.

**Note:** For the receive statistics it should be noted that a packet is indicated as “received” if it passes the device’s filters and is directed towards Receive Packet Buffer memory. A packet does not have to be received all the way to the driver in order to be counted as “received”.

**Note:** Due to divergent paths between interrupt-generation and logging of relevant statistics counts, it may be possible to generate an interrupt to the system for a noteworthy event prior to the associated statistics count actually being incremented. This is extremely unlikely due to expected delays associated with the system interrupt-collection and ISR delay, but might be observed as an interrupt for which statistics values do not quite make sense. Hardware guarantees that any event noteworthy of inclusion in a statistics count will be reflected in the appropriate count within 1 usec; a small time-delay prior to read of statistics may be necessary to avoid the potential for receiving an interrupt and observing an inconsistent statistics count as part of the ISR.

#### 37.6.6.1 CRCERRS – CRC Error Count Register

This register counts the number of receive packets with CRC errors. In order for a packet to be counted in this register, it must pass MAC address filtering (Broadcast or Individual-Address/Multicast match) and must be 64B or greater (from <Destination Address> through <CRC>, inclusively) in length.

**Table 37-79. CRCERRS: CRC Error Count Register**

|                      |                           |                        |                                   |  |                        |

### 37.6.6.2 ALGNERRC – Alignment Error Count Register

This register counts the number of receive packets with alignment errors (i.e. the packet is not an integer number of bytes in length). In order for a packet to be counted in this register, it must pass MAC address filtering (Broadcast or Individual-Address/Multicast match) and must be 64B or greater (from <Destination Address> through <CRC>, inclusively) in length. This register is valid only in GMII/MII mode, during 10/100 Mbps operation.

**Table 37-80. ALGNERRC: Alignment Error Count Register**

|                      |                           |                        |                                   |  |                   |
|----------------------|---------------------------|------------------------|-----------------------------------|--|-------------------|

### 37.6.6.3 RXERRC – Receive Error Count Register

This register counts the number of packets received in which RX\_ER was asserted by the PHY. In order for a packet to be counted in this register, it must pass MAC address filtering (Broadcast or Individual-Address/Multicast match) and must be 64B or greater (from <Destination Address> through <CRC>, inclusively) in length.

**Table 37-81. RXERRC: Receive Error Count Register**

|                      |                           |                        |                                   |  |                   |

### 37.6.6.4 MPC – Missed Packet Count Register

This register counts the number of missed packets. Packets are missed when the receive FIFO has insufficient space to store the incoming packet. This could be caused because of too few buffers allocated, or because there is insufficient bandwidth on the internal bus. Events setting this counter cause the receiver overrun interrupt condition (ICR.RXO) to be set. This register does not count packets dropped due to the receiver being disabled.

*Note:* Missed packets will be included/counted in the “TPR – Total Packets Received Register” on page 1528 as well as in the Total Octets Received counter of the “TORL – Total Octets Received Low Register” on page 1525 and the “TORH – Total Octets Received High Register” on page 1526.

**Table 37-82. MPC: Missed Packet Count Register**

|                      |                           |                                   |  |  |                        |

### 37.6.6.7 MCC – Multiple Collision Count Register

This register counts the number of times that a transmit encountered more than one collision but less than 16. This register will only increment if transmits are enabled and the device is in half-duplex mode.

**Table 37-85. MCC: Multiple Collision Count Register**

|                      |                           |  |                                   |  |                        |                   |

| 31 : 00              | MCC                       | Number of times a successful transmit encountered multiple collisions. |                                   |  | 0h                     | RC                |

### 37.6.6.8 LATECOL – Late Collisions Count Register

Late collisions are collisions that occur after one slot time. This register will only increment if transmits are enabled and the device is in half-duplex mode.

**Table 37-86. LATECOL: Late Collisions Count Register**

|                      |                           |  |                                   |  |                   |

| 31 : 00              | LATECOL                   | Number of packets with late collisions |                                   | 0h   | RC                |

### 37.6.6.9 COLC – Collision Count Register

This register counts the total number of collisions seen by the transmitter. This register will only increment if transmits are enabled and the device is in half-duplex mode. This register applies to clear as well as secure traffic.

**Table 37-87. COLC: Collision Count Register**

|                      |                           |   |                                   |  |                   |
|----------------------|---------------------------|---|-----------------------------------|--|-------------------|
| <b>Description:</b>  |                           |   |                                   |  |                   |

| <b>Size:</b> 32 bits | <b>Default:</b> 00000000h |   |                                   | <b>Power Well:</b> GbE0: Aux<br>Gbe1/2:<br>Core        |                   |
| <b>Bit Range</b>     | <b>Bit Acronym</b>        | <b>Bit Description</b>                                    | <b>Sticky</b>                     | <b>Bit Reset Value</b>                                 | <b>Bit Access</b> |
| 31 : 00              | COLC                      | Total number of collisions experienced by the transmitter |                                   | 0h   | RC                |

### 37.6.6.10 DC – Defer Count Register

This register counts defer events. A defer event occurs when the transmitter cannot immediately send a packet due to the medium busy either because another device is transmitting, half-duplex deferral events, or reception of XOFF frames. This register will only increment if transmits are enabled.

Table 37-88. DC: Defer Count Register

|                      |                           |                                   |  |                        |                   |
|----------------------|---------------------------|-----------------------------------|--|------------------------|-------------------|
| <b>Description:</b>  |                           |                                   |  |                        |                   |

| <b>Size:</b> 32 bits | <b>Default:</b> 00000000h |                                   | <b>Power Well:</b> GbE0: Aux<br>Gbe1/2:<br>Core        |                        |                   |
| <b>Bit Range</b>     | <b>Bit Acronym</b>        | <b>Bit Description</b>            | <b>Sticky</b>  | <b>Bit Reset Value</b> | <b>Bit Access</b> |
| 31 : 00              | DC                        | Number of defer events.           |  | 0h                     | RC                |

### 37.6.6.11 TNCRS – Transmit with No CRS Count Register

This register counts the number of successful packet transmission in which the CRS signal from the PHY was not asserted within one slot time of start of transmission from the MAC. Start of transmission is defined as the assertion of TX\_EN to the PHY. The PHY should assert CRS during every transmission. Failure to do so may indicate that the link has failed, or the PHY has an incorrect link configuration. This register will only increment if transmits are enabled and is only valid when the device is operating at half duplex.

Table 37-89. TNCRS: Transmit with No CRS Count Register

|                      |                           |   |  |                        |                   |
|----------------------|---------------------------|---|--|------------------------|-------------------|
| <b>Description:</b>  |                           |   |  |                        |                   |
| <b>View:</b> PCI 1   | <b>BAR:</b> CSRBAR        | <b>Bus:Device:Function:</b> M:0:0                             | <b>Offset Start:</b> 4034h<br><b>Offset End:</b> 4037h |                        |                   |
| <b>View:</b> PCI 2   | <b>BAR:</b> CSRBAR        | <b>Bus:Device:Function:</b> M:1:0                             | <b>Offset Start:</b> 4034h<br><b>Offset End:</b> 4037h |                        |                   |
| <b>View:</b> PCI 3   | <b>BAR:</b> CSRBAR        | <b>Bus:Device:Function:</b> M:2:0                             | <b>Offset Start:</b> 4034h<br><b>Offset End:</b> 4037h |                        |                   |

| 31 : 00              | TNCRS                     | Number of transmissions without a CRS assertion from the PHY. |  | 0h                     | RC                |

### 37.6.6.12 CEXTERR – Carrier Extension Error Count Register

This register counts the number of packets received in which a carrier extension error was signaled by the PHY (by the encoding of 0x1F on the receive data inputs while RX\_ER is asserted to the MAC) during the carrier extended time of a packet reception. This register will only increment when the driver has receives enabled and the device is operating at 1000Mb/s.

This counter is non-functional as the receiver doesn't detect Carrier-Extend errors.

**Table 37-90. CEXTERR: Carrier Extension Error Count Register**

|                      |                           |  |   |  |                        |                   |
|----------------------|---------------------------|--|---|--|------------------------|-------------------|
| <b>Description:</b>  |                           |  |   |  |                        |                   |
| <b>View:</b> PCI 1   | <b>BAR:</b> CSRBAR        | <b>Bus:Device:Function:</b> M:0:0                          |   | <b>Offset Start:</b> 403Ch<br><b>Offset End:</b> 403Fh |                        |                   |

### 37.6.6.13 RLEC – Receive Length Error Count Register

This register counts Receive Length Error events. A length error occurs if an incoming packet passes the MAC address filtering (Broadcast or Individual-Address/Multicast match) but is undersized or oversized. Packets less than 64B are deemed as undersized; packets over 1522B are deemed oversized if RCTL.LPE=0. If RCTL.LPE=1, then an incoming packet is only considered oversized if it exceeds 16384B.

**Table 37-91. RLEC: Receive Length Error Count Register**

|                      |                           |   |   |  |                        |                   |

### 37.6.6.14 XONRXC – XON Received Count Register

This register counts the number of XON packets received. XON packets can use the global address or the station address. This register will only increment if the driver has receives enabled.

**Table 37-92. XONRXC: XON Received Count Register**

|                      |                           |                                 |                                   |  |                   |

### 37.6.6.15 XONTXC – XON Transmitted Count Register

This register counts the number of XON packets transmitted. These packets can be either hardware-initiated due to queue room availability or due to software-initiated action (using TCTL.SWXOFF). This register will only increment if transmits are enabled.

**Table 37-93. XONTXC: XON Transmitted Count Register**

### 37.6.6.18 FCRUC – FC Received Unsupported Count Register

This register counts the number of unsupported flow control frames that are received. This counter is incremented when a packet is received which matches either the reserved flow control multicast address (in [FCAH/FCAL](#)) or the MAC station address, has a matching flow control type field match (to the value in [FCT](#)), but has an incorrect opcode field. This register will only increment if the driver has receives enabled.

**Table 37-96. FCRUC: FC Received Unsupported Count Register**

|                      |                           |  |  |                        |                   |

### 37.6.6.19 PRC64 – Good Packets Received Count (64 Bytes) Register

This register counts the number of good packets (no link or CRC error) received that are exactly 64B (from <Destination Address> through <CRC>, inclusively) in length. Hardware flow-control packets are not included in this count. This register includes good regular packets received to the Receive Packet Buffer. Packets identified as Missed Packets due to Receive Packet Buffer overruns are not included in this count (refer to the [“MPC – Missed Packet Count Register”](#) on page 1507).

**Table 37-97. PRC64: Good Packets Received Count (64 Bytes) Register**

### 37.6.6.22 PRC511 – Good Packets Received Count (256-511 Bytes) Register

This register counts the number of good packets (no link or CRC error) received that are from 256B-511B (from <Destination Address> through <CRC>, inclusively) in length. This register includes good regular packets received to the Receive Packet Buffer. Packets identified as Missed Packets due to Receive Packet Buffer overruns are not included in this count (refer to the “MPC – Missed Packet Count Register” on page 1507).

**Table 37-100.PRC511 - Good Packets Received Count (256-511 Bytes) Register**

### 37.6.6.23 PRC1023 – Good Packets Received Count (512-1023 Bytes) Register

This register counts the number of good packets (no link or CRC error) received that are from 512B-1023B (from <Destination Address> through <CRC>, inclusively) in length. This register includes good regular packets received to the Receive Packet Buffer. Packets identified as Missed Packets due to Receive Packet Buffer overruns are not included in this count (refer to the “MPC – Missed Packet Count Register” on page 1507).

**Table 37-101.PRC1023: Good Packets Received Count (512-1023 Bytes) Register**

### 37.6.6.24 PRC1522 – Good Packets Received Count (1024 to Max Bytes) Register

This register counts the number of good packets (no link or CRC error) received that are from 1024B-(Max) bytes (from <Destination Address> through <CRC>, inclusively) in length. The value (Max) is dependent on the current receiver configuration (i.e., RCTL.LPE, etc.) and the type of packet being received. This register includes good regular packets received to the Receive Packet Buffer. Packets identified as Missed Packets due to Receive Packet Buffer overruns are not included in this count (refer to the “MPC – Missed Packet Count Register” on page 1507). Regular packets identified as Oversized Packets (larger than Max) are also not included in this count (refer to the “ROC – Receive Oversize Count Register” on page 1524).

*Note:* Due to changes in the standard for maximum frame size for VLAN tagged frames in 802.3, the nominal value for (Max) is 1522B length.

**Table 37-102.PRC1522: Good Packets Received Count (1024 to Max Bytes) Register**

### 37.6.6.25 GPRC – Good Packets Received Count (Total) Register

This register counts the number of good packets (no link or CRC error) received that are of any legal length. This register includes good regular packets received to the Receive Packet Buffer. Regular packets identified as Missed Packets due to Receive Packet Buffer overruns are not included in this count (refer to the “MPC – Missed Packet Count Register” on page 1507). This register should represent the sum of the Good Packets Received (Size=N) counts, and when the driver is enabled, should normally represent the total number of packets received to the driver.

**Table 37-103.GPRC: Good Packets Received Count (Total) Register**

|                      |                           |  |                                   |  |                   |

### 37.6.6.27 MPRC – Multicast Packets Received Count Register

This register counts the number of good (non-erred) multicast packets received. This register does not count multicast packets received that fail to pass the multicast address filtering, nor does it count received flow control packets. This register does not count packets counted by the “MPC – Missed Packet Count Register” on page 1507.

**Table 37-105.MPRC: Multicast Packets Received Count Register**

### 37.6.6.28 GPTC – Good Packets Transmitted Count Register

This register counts the number of good (valid) packets transmitted without error (collision, etc.). A good packet is considered one that is 64B or more in length (from <Destination Address> through <CRC>, inclusively). This count does not include flow control packets transmitted. This register will only increment when transmits are enabled by the driver.

**Table 37-106.GPTC: Good Packets Transmitted Count Register**

|                      |                           |                                    |   |  |                        |                   |

### 37.6.6.29 GORCL – Good Octets Received Count Low Register

This is the low 32b of a register that counts the number of octets received which are associated with good packets (no link or CRC errors, no flow-control packets). This counter is incremented for each good regular packet received to the Receive Packet Buffer. Regular packets dropped due to Receive Packet Buffer overruns or due to the driver's receiver being disabled are not included in this count. {GORCH,GORCL} together make up a logical 64-bit register. Each half must be accessed independently using separate 32-bit accesses. Both registers are reset when the upper 32-bit value (GORCH) is read. The register sticks at 0xFFFF\_FFFF\_FFFF\_FFFF.

**Table 37-107.GORCL: Good Octets Received Count Low Register**

|                      |                           |  |                                   |  |                        |

### 37.6.6.31 GOTCL – Good Octets Transmitted Count Low Register

This is the low 32b of a register that counts the number of octets transmitted as good packets. Good packets are considered those which are 64B or more in length (from <Destination Address> through <CRC>, inclusively), and do not encounter an error (collision, etc.) during transmission. This count does not include octets transmitted in flow control packets. This register will only increment when transmits are enabled by the driver. Octets from the <Destination Address> field through the <CRC> field are included in this count. {GOTCH,GOTCL} together make up a logical 64-bit register. Each half must be accessed independently using separate 32-bit accesses. Both registers are reset when the upper 32-bit value (GOTCH) is read. The register sticks at 0xFFFF\_FFFF\_FFFF\_FFFF.

**Table 37-109.GOTCL: Good Octets Transmitted Count Low Register**

|                      |                           |   |  |  |  |

### 37.6.6.33 RNBC – Receive No Buffers Count Register

This register counts the number of times that frames were received when there were no available buffers in host memory to store those frames (receive descriptor head and tail pointers were equal). The packet will still be received if there is space in the FIFO. This register does not increment when flow control packets are received. This register will only increment if receives are enabled.

**Table 37-111.RNBC: Receive No Buffers Count Register**

|                      |                           |  |                                   |  |                   |

### 37.6.6.36 ROC – Receive Oversize Count Register

This register counts the number of received frames that passed address filtering, and were greater than maximum size. Packets over 1522 bytes are oversized if LongPacketEnable is clear (i.e. RCTL.LPE=0). If LongPacketEnable is set, then an incoming, packet is considered oversized if it exceeds 16384 bytes. If receives are not enabled, this register will not increment. These lengths are based on bytes in the received packet from <Destination Address> through <CRC>, inclusively.

Table 37-114.ROC: Receive Oversize Count Register

|                      |                           |                                   |  |                        |                   |

### 37.6.6.37 RJC – Receive Jabber Count Register

This register counts the number of received frames that passed address filtering, and were greater than maximum size and had a bad CRC (this is slightly different from the “ROC – Receive Oversize Count Register” on page 1524). Packets over 1522B are oversized if LongPacketEnable is 0. If LongPacketEnable (LPE) is 1, then an incoming packet is considered oversized if it exceeds 16384 bytes. If receives are not enabled, this register will not increment. These lengths are based on bytes in the received packet from <Destination Address> through <CRC>, inclusively.

**Table 37-115.RJC: Receive Jabber Count Register**

|                      |                           |                                 |                                   |  |                        |

### 37.6.6.38 TORL – Total Octets Received Low Register

This is the low 32b of a register that counts the total number of octets received, including octets from both good and bad packets. Packets must first pass the MAC address filtering (Broadcast or Individual-Address/Multicast match) - packets not for this MAC are not included. Octets will be counted for all packets regardless of their length, whether they encountered errors, whether they are detected as regular packets or flow control packets, and regardless of whether they are stored successfully versus dropped from a Receive FIFO (Receive Packet Buffer). Bytes from the <Destination Address> field through the <CRC> field (inclusively) are counted. {TORH, TORL} together make up a logical 64-bit register. Each half must be accessed independently using separate 32-bit accesses. Both registers are reset when the upper 32-bit value (TORH) is read. The register sticks at 0xFFFF\_FFFF\_FFFF\_FFFF.

**Table 37-116.TORL: Total Octets Received Low Register**

|                      |                           |   |                                   |  |                   |

**37.6.6.39 TORH – Total Octets Received High Register**

This is the high 32b of a register that counts the total number of octets received, including octets from both good and bad packets. Packets must first pass the MAC address filtering (Broadcast or Individual-Address/Multicast match) - packets not for this MAC are not included. Octets will be counted for all packets regardless of their length, whether they encountered errors, whether they are detected as regular packets or flow control packets, and regardless of whether they are stored successfully versus dropped from a Receive FIFO (Receive Packet Buffer). Bytes from the <Destination Address> field through the <CRC> field (inclusively) are counted. {TORH,TORL} together make up a logical 64-bit register. Each half must be accessed independently using separate 32-bit accesses. Both registers are reset when the upper 32-bit value (TORH) is read. The register sticks at 0xFFFF\_FFFF\_FFFF\_FFFF.

**Table 37-117.TORH: Total Octets Received High Register**

### 37.6.6.40 TOTL – Total Octets Transmitted Low Register

This is the low 32b of a 64b register that counts the total number of octets in successfully transmitted packets. Octets transmitted as part of partial packet transmission (e.g. collisions in half-duplex mode) are not included. Octets will be counted for all packets regardless of their length and regardless of whether regular packets or flow-control packets. Octets from the <Destination Address> field through the <CRC> field are included in this count. {TOTL,TOTH} together make up a logical 64-bit register. Each half must be accessed independently using separate 32-bit accesses. Both registers are reset when the upper 32-bit value (TOTH) is read. The register sticks at 0xFFFF\_FFFF\_FFFF\_FFFF.

**Table 37-118. TOTL: Total Octets Transmitted Low Register**

|                      |                           |  |  |                        |                   |

### 37.6.6.44 PTC64 – Packets Transmitted Count (64 Bytes) Register

This register counts the number of packets successfully transmitted that are exactly 64B (from <Destination Address> through <CRC>, inclusively) in length. Partial packet transmissions (e.g. collisions in half-duplex mode) are not included in this count. Packet transmissions shorter than 64 bytes which may be generated due to having Short-Frame Padding (PSP) disabled are not included. This register also does not include any flow control packets transmitted.

**Table 37-122.PTC64 - Packets Transmitted Count (64 Bytes) Register**

### 37.6.6.45 PTC127 – Packets Transmitted Count (65-127 Bytes) Register

This register counts the number of packets successfully transmitted that are 65B-127B (from <Destination Address> through <CRC>, inclusively) in length. Partial packet transmissions (e.g. collisions in half-duplex mode) are not included in this count.

### 37.6.6.46 PTC255 – Packets Transmitted Count (128-255 Bytes) Register

This register counts the number of packets successfully transmitted that are 128B-255B (from <Destination Address> through <CRC>, inclusively) in length. Partial packet transmissions (e.g. collisions in half-duplex mode) are not included in this count.

**Table 37-123.PTC255: Packets Transmitted Count (128-255 Bytes) Register**

### 37.6.6.52 TSCTC – TCP Segmentation Context Transmitted Count Register

This register counts the number of TCP segmentation off load transmissions and increments once the last portion of the TCP segmentation context payload is segmented and loaded as a packet into the GbE hardware transmit buffer. Note that it is not a measurement of the number of packets sent out (covered by other registers). This register will only increment if transmits and TCP Segmentation off load are enabled.

**Table 37-129.TSCTC: TCP Segmentation Context Transmitted Count Register**

|                      |                           |   |  |  |                   |

### 37.6.6.53 TSCTFC – TCP Segmentation Context Transmit Fail Count Register

This register counts the number of TCP segmentation off load requests to the hardware that failed to transmit all data in the TCP segmentation context payload (due to the context specifying less data than the data descriptors reference). TCP Segmentation requires the context's length specification to match the total length of the supplied data descriptors, however. Therefore, this count should always be zero if TCP Segmentation is properly used.

**Table 37-130.TSCTFC: TCP Segmentation Context Transmit Fail Count Register**

| <b>View:</b> PCI 3   | <b>BAR:</b> CSRBAR        | <b>Bus:Device:Function:</b> M:2:0  | <b>Offset Start:</b> 5800h<br><b>Offset End:</b> 5803h |                        |                   |
| <b>Size:</b> 32 bits | <b>Default:</b> 00000000h |  | <b>Power Well:</b> GbE0: Aux<br>GbE1/2: Core           |                        |                   |
| <b>Bit Range</b>     | <b>Bit Acronym</b>        | <b>Bit Description</b>   | <b>Sticky</b>  | <b>Bit Reset Value</b> | <b>Bit Access</b> |
| 31 : 04              | RSVD                      | Reserved   |  | 0h                     | RO                |
| 03                   | APMPME                    | <b>Assert PME On APM Wakeup –</b><br>If it is 1, the GbE will set the PME_Status bit in the Power Management Control / Status Register (PMCSR) and assert GBE_PME_WAKE when APM Wakeup is enabled and the GbE receives a matching magic packet.<br>*Note that this bit is loaded from the EEPROM, if present |  | 0h                     | RW                |
| 02                   | PME_Status                | <b>PME_Status</b><br>This bit is set when the GbE receives a wakeup event. It is the same as the PME_Status bit in the Power Management Control / Status Register (PMCSR). Writing a “1” to this bit will clear it and clear the PME_Status bit in the PMCSR.  |  | 0h                     | RWC               |
| 01                   | PME_EN                    | <b>PME_En</b><br>This read/write bit is used by the driver to access the PME_En bit of the Power Management Control / Status Register (PMCSR) without writing to PCI configuration space.  |  | 0h                     | RW                |
| 00                   | APME                      | <b>Advance Power Management Enable -</b><br>If “1”, APM Wakeup is enabled.<br>*Note that this bit is loaded from the EEPROM, if present  |  | 0h                     | RW                |

Note: The PME\_En and PME\_Status bits are reset when PWR\_GOOD is 0. When AUX\_PWR\_PRESENT=0, this register is also reset by the deassertion (rising edge) of RESET\_N and the transition from D3 to D0. The other bits are reset on the standard internal resets.

### 37.6.7.2 WUFC – Wake Up Filter Control Register (0x05808; RW)

This register is used to enable/disable each of the pre-defined and flexible filters affecting wake up support. For most bits, a value of 1 means a wakeup for the specific event is enabled, and a value of 0 means the wakeup is disabled. For example, when MC=1, a packet containing an IA which matches the Directed Multicast Filter will generate a wakeup event.

**Table 37-132.WUFC - Wake Up Filter Control Register (0x05808; RW)**

| Description:  |                    |  |                                       |                 |            |

### 37.6.7.3 WUS – Wake Up Status Register (0x05810; RW)

This register is used to record statistics about all Wake Up packets received. If a packet matches multiple criteria than multiple bits could be set. Writing a 1 to any bit will clear that bit.

This register will not be cleared when RESET\_N is asserted. It will only be cleared when PWR\_OK is deasserted or when cleared by the driver.

Prior to re-entering a wakeup-enabled sleep state, this register should be explicitly cleared by writing with all 1's.

**Table 37-133.WUS - Wake Up Status Register (0x05810; RW)**

### 37.6.7.5 IP4AT[0-3] - (0x5840 - 0x5858; RW) – IPv4 Address Table Registers

The IPv4 Address Table is used to store the four IPv4 addresses for ARP/IPv4 Request packet and Directed IPv4 packet wake up. It has the following format:

- Address 0x5840: IPV4 ADDR0
- Address 0x5848: IPV4 ADDR1
- Address 0x5850: IPV4 ADDR2
- Address 0x5858: IPV4 ADDR3

**Table 37-135.IP4AT (0x5840 - 0x5858; RW)[0-3]: IPv4 Address Table Registers**

**Note:** This table is loaded from the EEPROM if the IP Address Valid field of the EEPROM's Management Control word is 1 and the IP Address Type field is 1 (IPv6). Otherwise, the value of this table is undefined after reset.

#### 37.6.7.10 FFLT[0-3] – Flexible Filter Length Table Registers (0x5F00 - 0x5F18; RW)

The Flexible Filter Length Table stores the minimum packet lengths required to pass each of the Flexible Filters. Any packets that are shorter than the programmed length won't pass that filter. Each Flexible Filter will consider a packet that doesn't have any mismatches up to that point to have passed the Flexible Filter when it reaches the required length. It will not check any bytes past that point:

- Address 0x5F00: FFLT\_LEN0
- Address 0x5F04: Reserved
- Address 0x5F08: FFLT\_LEN1
- Address 0x5F0C: Reserved
- Address 0x5F10: FFLT\_LEN2
- Address 0x5F14: Reserved
- Address 0x5F18: FFLT\_LEN3
- Address 0x5F1C: Reserved

**Table 37-140.FFLT[0-3] - Flexible Filter Length Table Registers (0x5F00 - 0x5F18; RW)**

*Note:* Before writing to the Flexible Filter Length Table the driver must first disable the flexible filters by writing 0's to the Flexible Filter Enable bits of the Wake Up Filter Control Register (WUFC.FLXn)

**37.6.7.11 FFMT[0-127] – Flexible Filter Mask Table Registers (0x9000 - 0x93F8; RW)**

The Flexible Filter Mask and Table is used to store the four 1-bit masks for each of the first 128 data bytes in a packet, one for each Flexible Filter. If the mask bit is 1, the corresponding Flexible Filter will compare the incoming data byte at the index of the mask bit to the data byte stored in the Flexible Filter Value Table:

**Table 37-141.Flexible Filter Mask Table**

| Address | Content           | Address | Content  |
|---------|-------------------|---------|----------|
| 0x9000  | Byte 0 Mask       | 0x9004  | Reserved |
| 0x9008  | Byte 1 Mask       | 0x900C  | Reserved |

### 37.6.8.2 MEM\_TST – Memory Error Test Register

For software testability (in order to generate an ECC or parity error in hardware), this register can be used to generate a hardware ECC or parity error in the GbE memories. The selected ECC or parity error is continuously written in to the selected memory as long as the memory is selected, at any address currently in use.

The 'Select' field allows selection of the memory that the errored data should be written to. The 'Mask' field provides an XOR mask for the ECC or parity bits of that register. Although a 16 bit mask is provided, not all registers use all bits of the Mask field. Refer to the register description below.

The ECC or Parity error will not occur until the errored location has been read.

**NOTE:**

- Single bit errors will be corrected in all but types 010 and 011, with no error indication.
- Multiple bit errors will cause a Gbe error response for all other memory types.
- A multiple bit error is caused by forcing multiple mask bits [15:8] and/or multiple bits of [7:0] for Types 100, 101, 110. Forcing one bit in [15:8] and one bit in [7:0] will not create a multiple bit error (and will therefore not produce a Gbe Error response).

**Table 37-146.MEM\_TST - Memory Error Test Register**

### 37.6.8.3 MEM\_STS – Memory Error Status Register

This register reports ECC or parity errors, for each of the memories with ECC or parity coverage. Errors will be reported in this register, regardless of whether they were induced by the MET logic or through actual hardware errors. Host write DMA transactions issued after these fatal memory errors are encountered will result in a data error asserted for every internal bus transaction. CSR target transactions, including transactions to the errored memory, will complete without error, however the memory errors will still be logged in the MES register.

If the MEM\_ERRH\_DIS bit is set (error handling is disabled), the individual memory errors can be cleared with a write to the appropriate memory error bit in this register, however the errored memory is likely to produce unexpected GbE functionality.

If the MEM\_ERRH\_DIS bit is not set (error handling is enabled) then the error bits will only be cleared by a soft reset.

**Table 37-147.MEM\_STS - Memory Error Status Register (Sheet 1 of 2)**

## 37.7 Power Management

*Note:* Power Management may be disabled via bits in the Initialization Control Word which is loaded from the EEPROM during power-up reset. Even when disabled, the Power Management register set is still present.

The following Power Management related features are supported:

- Power states of D0 & D3hot
- Support of optional D3cold for GbE0
- Power(D3) < Power(D0)
- Wake-up

### 37.7.1 Assumptions

The following assumptions apply:

- Prior to transition from D0 to the D3 state, the OS will ensure the device driver has been disabled and all pending bus transactions are complete or terminated cleanly.
- Per the PCI power Management Specification (revision 1.1, section 5.4), software “will need to perform a full re-initialization of the function including its PCI Configuration Space.” **On a transition from D3 to D0u state, all of the PCI Configuration space is reset.**
- The driver will set up the wake up filters prior to the system transitioning the GbE to D3 state.
- No wakeup capability, except APM Wakeup if enabled in the EEPROM, is required after the system puts the MAC in D3 state and then returns the MAC to D0.
- If the APMPME bit in the Wake Up Control Register (WUC.APMPME) bit is 1, it is permissible to assert GBE\_PME\_WAKE even when PME\_En is 0.
- No wakeup capability, except APM Wakeup if enabled in the EEPROM, is required after the system asserts, then deasserts RESET\_N.
- The deassertion (rising) edge of RESET\_N will put the controller in D0u state.
- The system will never deactivate the internal bus clock without asserting RESET\_N.
- Any time PWR\_OK is asserted all power supplies are stable and RESET\_N is stable.

### 37.7.2 D3cold support

If the D3Cold Wake Up Capability Advertisement Enable bit of the Device Control Register (CTRL.ADV3WUC) is set to '1', the D3Cold capability may be advertised (if 0, the capability will not be advertised). When 1, the EP80579 will then use the AUX\_PWR\_PRESENT input as an indication of whether auxiliary power is available to the GbE controller, and if AUX\_PWR\_PRESENT=1 will advertise D3cold Wake Up support in the PCI Capabilities list for that GbE controller.

If D3cold is supported, the PME\_En and PME\_Status bits of the Power Management Control/Status Register (PMCSR), as well as shadow bits in the Wake Up Control Register (WUC), are not reset by UNIT\_RESET. However, if D3cold Wake Up is not supported they will always be reset on the deassertion (falling edge) of UNIT\_RESET.

Note that AUX\_PWR\_PRESENT is level sensitive and is sampled at assertion of AUX\_PWR\_GOOD from the EEDI pin. EEDI must be pulled high to indicate that AUX\_PWR\_PRESENT is a '1'. EEDI must be pulled low to indicate that AUX\_PWR\_PRESENT is a '0'. EEDI MUST be either pulled up or down. AUX\_PWR\_PRESENT may not be left indeterminate.

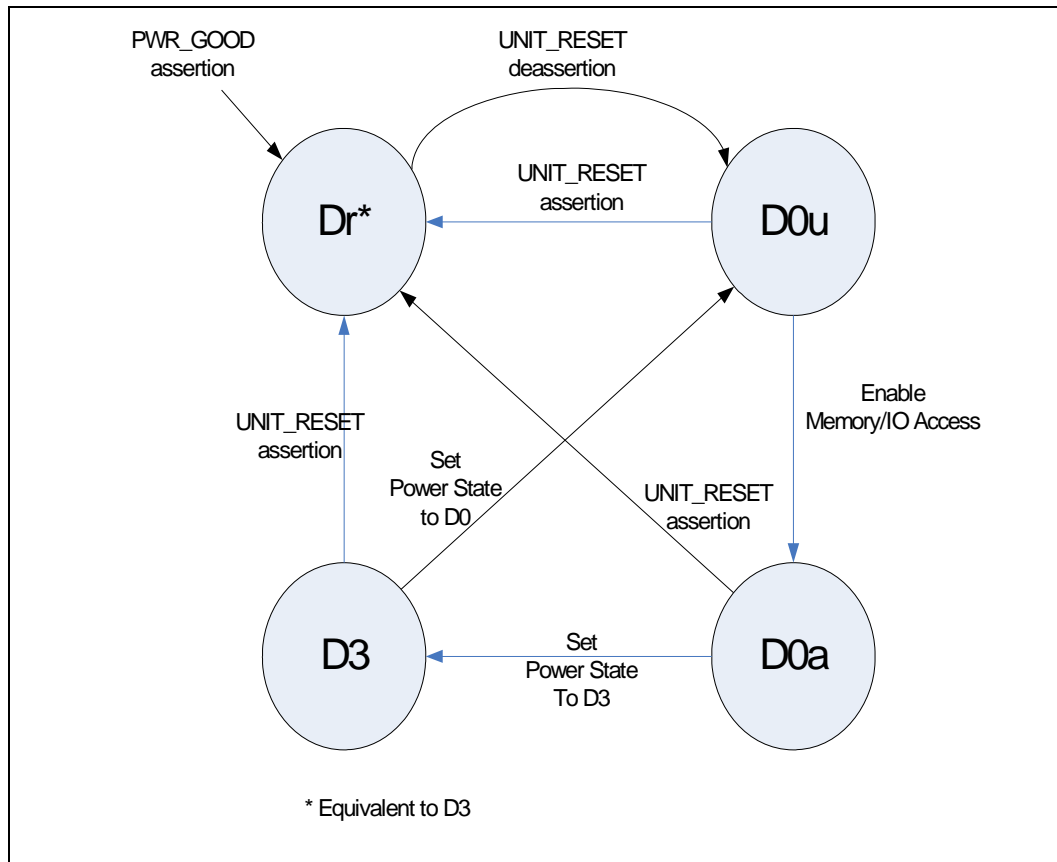

Besides the reset change and capability advertisement, the EP80579 D3cold behavior is identical to D3hot behavior (i.e. operates the same regardless of whether power is supplied from main vs. auxiliary power supplies).

### 37.7.3 Power States

The GbE Controller supports D0 and D3 power states defined in the PCI Power Management Specification. In addition, D0 is divided into two sub-states: D0u, and D0a. In addition, it supports a Dr state that is entered when UNIT\_RESET is asserted.

Figure 37-50 shows the power states and what causes a transition between them.

Figure 37-50. Power State Transitions

#### 37.7.3.1 Dr

On initial boot-up, once PWR\_GOOD is asserted the GbE controller will enter the Dr state and read the EEPROM. If the APM Enable bit in the EEPROM's Initialization Control Word 2 is set then APM Wake Up will be enabled.

Internally, the controller treats the Dr reset state equivalently to D3. Any WakeUp filter settings that were enabled before entering this reset state will be maintained.

The deassertion (falling edge) of UNIT\_RESET will cause a transition to D0u.

### 37.7.3.2 D0u State

The D0u state is a low-power state used after UNIT\_RESET is deasserted, or when coming out of D3, but before the GbE Controller is initialized.

When entering D0u the GbE Controller will disable Wake Ups, assert reset to the PHY for between 24 $\mu$ s and 1ms, and re-read the EEPROM. If the APM Mode bit in the EEPROM's Initialization Control Word 2 is set then APM Wake Up will be enabled.

**On a transition from D3 to D0u state, all of the PCI Configuration space is reset.** Per the PCI Power Management Specification (revision 1.1, section 5.4), software "will need to perform a full reinitialization of the function including its PCI Configuration Space."

Internally, D0u is treated like D3 and some internal clocks and registers are shut down. As in the Dr state, the PHY power state depends on whether PHY power-management and WakeUp are enabled.

The D0u state is exited when the system enables memory space access to the controller by writing a 1 to the Memory Access Enable bit of the PCI Command Register.

### 37.7.3.3 D0a

Once memory space is enabled all internal clocks are activated and the controller enters an active state. It can transmit and receive packets if properly configured by the driver. Any APM Wakeup previously active will remain active. The driver can deactivate APM Wakeup by writing to the Wake Up Control Register (WUC), or activate other Wake Up Filters by writing to the Wake Up Filter Control Register (WUFC).

### 37.7.3.4 D3

Prior to transition from D0 to the D3 state, the driver must ensure that controller transmit and receive operation has been disabled and all pending bus transactions are complete or terminated cleanly. If wake up capability is needed the driver should set up the appropriate wake up registers and the system should write a 1 to the PME\_En bit of the Power Management Control / Status Register (PMCSR) prior to the transition to D3.

When the system writes a '11 to the PowerState field of the Power Management Control/Status Register (PMCSR) the GbE controller will transition to D3. Any WakeUp filter settings that were enabled before entering this reset state will be maintained. Upon transitioning to D3 the controller will clear the Memory Access Enable bit of the PCI Command Register, which will disable memory access decode.

For power savings, the GbE controller shuts down some internal clocks and registers in D3 state.

To transition back to D0u, the system writes a 00 to the Power State field of the Power Management Control/Status Register (PMCSR).

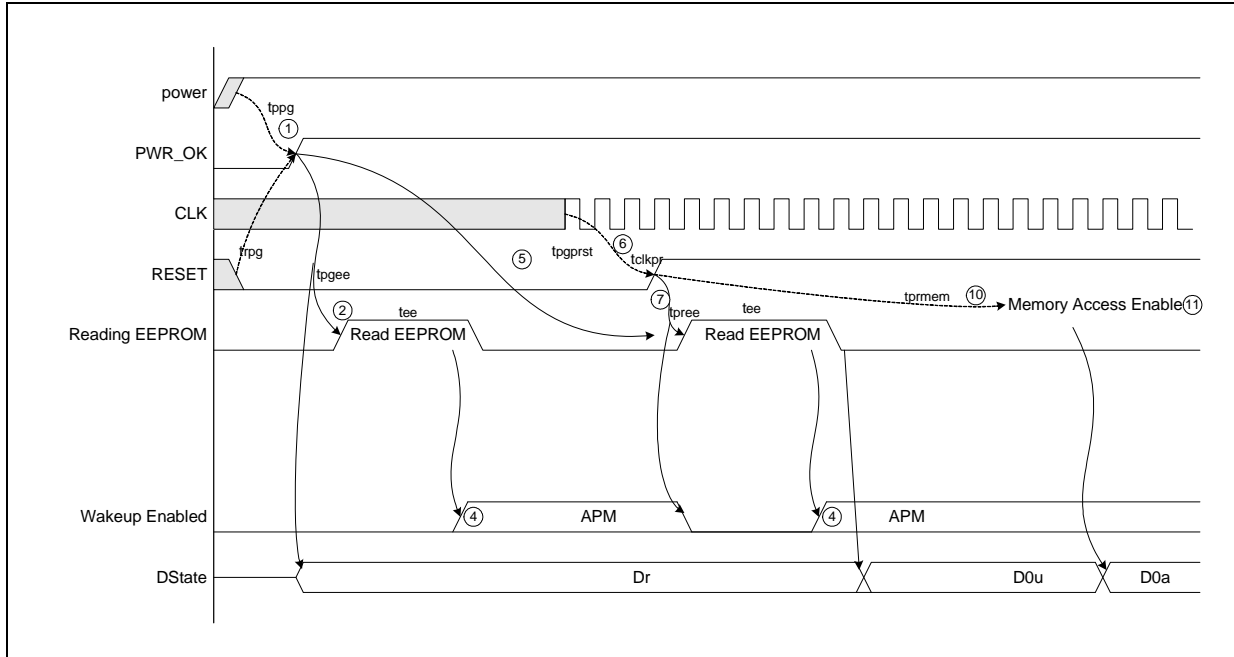

## 37.7.4 Timing of Power-State Transitions

The following sections give detailed timing for the state transitions. In the diagrams the dotted connecting lines represent the MACs' requirements, while the solid connecting lines represent the MACs' guarantees.

The timing diagrams are not to scale. The clocks edges are shown to indicate running clocks only are not used to indicate the actual number of cycles for any operation.

### 37.7.4.1 Power up (off to Dr to D0u to D0a)

Figure 37-51. Reset Deasserted after 1st EEPROM Read Completes

| Note |  |
|------|--|
| 1    | PWR_OK must not be asserted until all power supplies are good  |
| 2    | An EEPROM read is started on the rising edge of PWR_OK and RESET.  |
| 4    | APM Wakeup may be enabled based on what is read from the EEPROM.   |
| 5    | The system can delay an arbitrary time before deasserting RESET.   |
| 7    | The deassertion edge of RESET will cause the EEPROM to be re-read and Wake Up disabled.                              |
| 10   | The system can delay an arbitrary time before enabling Memory Access.  |
| 11   | Writing a 1 to the Memory Access Enable bit in the PCI Command Register will transition the MAC from D0u to D0 state |

Figure 37-52. Reset Deasserted after before EEPROM Read Completes

| Note |  |
|------|--|
| 1    | PWR_OK must not be asserted until all power supplies are good  |
| 2    | An EEPROM read is started on the rising edge of PWR_OK and RESET.  |
| 4    | APM Wakeups may be enabled based on what is read from the EEPROM.  |
| 5    | The system can delay an arbitrary time before deasserting RESET.   |
| 10   | The system can delay an arbitrary time before enabling Memory Access.  |
| 11   | Writing a 1 to the Memory Access Enable bit in the PCI Command Register will transition the MAC from D0u to D0 state |

### 37.7.4.2 Transition from D0a to D3 and Back without Reset

Figure 37-53. Transition from D0a to D3 and Back without Reset

| Note |  |
|------|--|
| 1    | Writing a 11 to the Power State field of the Power Management Control/Status Register (PMCSR) will transition the power state to D3. |
| 2    | The system can delay an arbitrary amount of time between setting D3 mode and asserting RESET.  |
| 4    | Upon assertion of RESET the MAC will go to "Dr" state.   |
| 6    | The deassertion edge of RESET will cause the EEPROM to be re-read and Wake Up disabled.  |
| 10   | The system can delay an arbitrary time before enabling memory access.  |
| 11   | Writing a 1 to the Memory Access Enable bit in the PCI Command Register will transition the MAC from D0u to D0 state                 |

### 37.7.4.3 Transition from D0a to D3 and Back with Reset

Figure 37-54. Transition from D0a to D3 and Back with Reset

| Note |  |
|------|--|
| 1    | Writing a 11 to the Power State field of the Power Management Control/Status Register (PMCSR) will transition the MAC to D3. |
| 2    | The system can delay an arbitrary amount of time between setting D3 mode and asserting RESET.                                |
| 4    | Upon assertion of RESET the MAC will go to "Dr" state.   |
| 6    | The deassertion edge of RESET will cause the EEPROM to be re-read and Wake Up disabled.                                      |
| 10   | The system can delay an arbitrary time before enabling memory access.  |
| 11   | Writing a 1 to the Memory Access Enable bit in the PCI Command Register will transition the MAC from D0u to D0 state.        |

### 37.7.4.4 Reset without Transition to D3

Figure 37-55. Reset without Transition to D3

| Note |   |
|------|---|
| 2    | Upon assertion of RESET the MAC will go to "Dr" state.  |
| 4    | The deassertion edge of RESET will cause the EEPROM to be re-read, and Wake Up disabled.                              |
| 8    | The system can delay an arbitrary time before enabling memory access.   |
| 9    | Writing a 1 to the Memory Access Enable bit in the PCI Command Register will transition the MAC from D0u to D0 state. |

### 37.7.4.5 Timing Requirements

The MAC requires the following start-up or power state transition related timing

Table 37-148. MAC Timing

| Parameter | Description                               | Min  | Max. | Notes  |
|-----------|---|------|------|--|
| tppg      | Power to PWR_OK                           | 0    | -    |  |
| trpg      | RESET stable to PWR_OK                    | 0    | -    |  |
| tpgrst    | PWR_OK assertion to RESET deassertion.    | 0    | -    |  |
| tpmem     | RESET deassertion to Memory Access Enable | 10ms | -    | The Power Management specification permits access in 10ms after exiting D3 cold. PCI 2.2 gives 225 cycles. |
| tclkpr1   | CLK stopped to RESET deassertion.         | 0ns  |      | The reset must be asserted before the rising edge of the last cycle before the clock is stopped.           |

### 37.7.4.6 Timing Guarantees

The GbE guarantees the following start-up or power state transition related timing parameters.

**Table 37-149. GbE Timing Guarantees**

| Parameter | Description                               | Min  | Max.  | Notes   |
|-----------|---|------|-------|---|
| tpgee     | PWR_OK assertion to start of EEPROM read. | 0    | 1µs   |   |
| tpree     | RESET deassertion to start of EEPROM read | 0    | 10µs  |   |
| tee       | EEPROM read duration                      | 24µs | 10ms  | The MAC must attempt to read the EEPROM to determine if an EEPROM is present, so this applies even if no EEPROM is connected. |
| td3ps     | D3 write to power reduction.              | 0    | 500ns |   |

### 37.7.5 Power Management Extended Capabilities Registers

Power Management registers are part of the capabilities linked list pointed to by the Capabilities Pointer (Cap\_Ptr) in the PCI configuration space.

All fields are reset by PWR\_GOOD. All of the fields except PME\_En and PME\_Status are reset by the deassertion (rising edge) of UNIT\_RESET. If AUX\_PWR\_PRESENT=0, the PME\_En and PME\_Status fields also reset by the deassertion (rising edge) of UNIT\_RESET.

Refer to [Section 35.6.1.17, “Offset DCh: PCID – Power Management Capability ID Register”](#) on page 1251, [Section 35.6.1.18, “Offset DDh: PCP – Power Management Next Capability Pointer Register”](#) on page 1251, [Section 35.6.1.19, “Offset DEh: PMCAP – Power Management Capability Register”](#) on page 1252, and [Section 35.6.1.20, “Offset E0h: PMCS – Power Management Control and Status Register”](#) on page 1253 for register details.

§ §

## 38.0 Global Configuration Unit

---

### 38.1 Overview

The Global Configuration Unit (GCU) implements the configuration space registers for system-level, EP80579 features. This unit also implements an MDIO interface to support the Ethernet interfaces.

### 38.2 Feature List

The following is a list of features/register sets implemented in the Global Configuration Unit:

- MDIO interface
  - Command and Status registers
  - MDIO Drive Strength register
  - MDC Drive Strength register
- RCOMP registers
  - Local Expansion bus (LEB)
  - GbE (one set for all three interfaces)
- Drive Strength registers
  - SSP Signal Group Drive Strength register
  - TDM outputs
  - CAN (one for both)

### 38.3 Usage Model

All configuration writes and reads are word accesses. Addresses to configuration reads and writes are word aligned.

#### 38.3.1 RCOMP

The RCOMP circuitry dynamically compensates the IO output drivers for variations in operating conditions due to process, temperature, voltage and PCB layout. These variations are measured through a resistive mechanism in two special IO pads. The resistive mechanism on those IO pads reference external resistors the user provides to match output driver strength to. Thus the output driver impedance can be tuned specifically to the application PCB characteristics for nominal signal transfer into the transmission lines formed by the PCB traces. The RCOMP design is nominally set to operate at 50ohms, but the user is free to set the impedance in the range 45ohms to 55ohms.

Two RCOMP pins are provided to establish the output driver impedance, one to control the drive high strength, and one to control the drive low strength. These RCOMP outputs drive into the external resistors provided by the customer. The drivers form a resistor divider and the voltages developed in these dividers are compared to a reference voltage. The RCOMP state machine independently adjusts the strength of the drivers making them stronger or weaker until the comparator signals that the voltage is greater than or less than the reference. The state machine will continue making adjustments causing the comparators to oscillate between two strength settings just above and just below the comparator trip point. Logic in the RCOMP state machine recognizes when this "dithering" between the two values has begun, and holds the strength output for the outputs fixed at one of the two settings. Note this algorithm is independently and concurrently applied to the drive high strength and to the drive low strength.

### 38.3.1.1 GbE

The GbE RCOMP controller starts operation when the GBE\_AUX\_PWR\_GOOD input is asserted. This condition indicates the power supply's are stable and it also indicates that the GBE\_REFCLK input is being driven with a 125 MHz clock. Refer to [Section 37.0, "Gigabit Ethernet Controller" on page 1341](#) for details on the GbE operation. The GBE\_REFCLK input is divided by either 4 or 16 and then used to drive the RCOMP state machine. Also present are software accessible registers that provide options to monitor/overwrite internal bias and comparator output for SV needs. See [Section 38.4.1.5, "Offset 0x00000024h: GCU\\_GBE\\_RC\\_CTRL - GCU GbE RCOMP Control Register" on page 1564](#) and [Section 38.4.1.6, "Offset 0x00000044h: GCU\\_GBE\\_RC\\_STAT - GCU GbE RCOMP Status Register" on page 1564](#).

### 38.3.1.2 LEB

The LEB RCOMP controller starts operation when the LEB comes out of reset. The RCOMP logic is clocked by the externally provided expansion bus clock. Refer to [Section 42.0, "Local Expansion Bus Controller" on page 1671](#) for details on the LEB operation. Also present are software accessible registers that provide options to monitor/overwrite internal bias and comparator output for SV needs. See [Section 38.4.1.7, "Offset 0x00000050h: GCU\\_LEB\\_RC\\_STAT - GCU Local Expansion Bus RCOMP Status Register" on page 1565](#) and [Section 38.4.1.8, "Offset 0x00000054h: GCU\\_LEB\\_RC\\_CTRL - GCU Local Expansion Bus RCOMP Control Register" on page 1566](#)

## 38.4 Register Summary

Writes to unused address space have no affect. Reads from unused address space may return indeterminate data. Neither reads nor writes cause detrimental effects on device operation unless specifically documented. Reserved bits within registers must be written with their reset value unless otherwise stated.

For more information on the conventions the following register summaries adopt, see Section 7.1, “Overview of Register Descriptions and Summaries” on page 183.

**Note:** Any programming order dependencies on configuration write values must be handled by the OS.

The Global Configuration Unit registers materialize in the PCI space.

**Table 38-1. Bus M, Device 3, Function 0: Summary of GCU Registers Mapped Through CSRBAR Memory BAR**

| Offset Start | Offset End | Register ID - Description   | Default Value |
|--------------|------------|---|---------------|
| 00000010h    | 00000013h  | “Offset 0x00000010h: MDIO_STATUS - MDIO Status Register” on page 1562                               | 00000000h     |

## 39.0 Controller Area Network - CAN

---

### 39.1 Overview

Controller Area Network (CAN) is a serial bus system used in a broad range of embedded and automation control systems. The CAN usually links two or more microcontroller-based physical devices (nodes).

CAN protocol is based on a broadcast communication mechanism. This broadcast communication is achieved by using a message-oriented transmission protocol. In this protocol, node-addresses are not defined, only messages are defined. These messages are identified by a message identifier. The message identifier has to be unique within the network and it defines not only the content, but also the priority of the message.

A high degree of system and configuration flexibility is achieved as a result of the content-oriented addressing scheme. This content-oriented addressing scheme allows for a high degree of system and configuration flexibility. It is easy to add stations to an existing CAN network without making any hardware or software modifications to the existing stations, as long as the new stations are purely receivers. This allows for modularization of the components and also permits multiple reception and the synchronization of distributed processes: data needed as information by several stations can be transmitted via the network in such a way that it is unnecessary for each station to know who the producer of the data is. This allows easy servicing and upgrading of networks, as data transmission is not based on the availability of specific types of stations.

### 39.2 Feature List

Key features are listed below:

- Conforms to ISO 11898-1 (high-speed CAN).
- Full CAN 2.0B compliance.
  - Supports CAN 2.0A.
- Supports 11-bit identifier and 29-bit identifier.
- Bit rates up to 1Mbps.
- 16 receive buffers:
  - Each buffer has its own message filter.
  - Message filter covers: ID, IDE, RTR, Data Byte (1 and 2).
  - Message buffers can be linked together to build a larger message array.
  - Automatic RTR response handler.
- Transmit path:
  - 8 transmit message holding registers with programmable priority arbitration.
  - Message abort command.
- Test and debugging support:

- Listen Only Mode.
- SRAM-based message buffer:
  - 1Odd/Even parity generation and checking.
  - Parity error reporting and parity test mode.

### 39.3 Functional Block Diagram

The block diagram for the CAN unit and its interface to other major blocks on the EP80579 is shown in [Figure 39-1](#). The figure shows only one instance of the CAN unit. There are two instances of the same CAN unit.

Figure 39-1. CAN Block Diagram

## 39.4 Usage Model

### 39.4.1 CAN Basics

CAN is an asynchronous serial bus system. The bus structure is open and linear, with equal bus nodes. A CAN bus typically consists of two or more nodes. Nodes can be added to the CAN network dynamically without interrupting the communication of other nodes. That makes it easy to add or take off bus nodes (e.g. for adding functionality to the system, error recovery or monitoring).

The CAN bus is a “wired-AND” mechanism, where recessive bits (high) are overwritten by dominant bits (low). If no nodes are driving a dominant bit, the bus stays in the recessive state (idle). The node that first drives a dominant bit becomes the master and owns the bus. One of the cheapest and most common mediums is a twisted differential wire pair. The two lines are “CAN\_H” and “CAN\_L”, which can be connected directly to the nodes via a connector. The maximum speed for the CAN bus is 1Mbps up to 40m. For bus length beyond 40 m, the bus speed must be reduced. Up to 30 nodes can be connected without extra equipment. CAN is insensitive to EMI because a differential pair will be affected in the same way.

The bit stream in a message is coded according on the Non-Return-to-Zero (NRZ) method, which means the signal level remains constant over the bit time and thus one time slot is required to represent a bit. To guarantee proper synchronization of all bus nodes, bit stuffing must be used. If five consecutive bits of the same polarity have been driven by the master, the sixth bit will be of opposite polarity, then the master will continue to transmit. Every receiver on the bus will check for the amount of bits with the same polarity, and will destuff (the sixth bit) the message.

### 39.4.2 Addressing and Bus Arbitration

The CAN protocol uses CSMA/CD with NDA (Carrier Sense Multiple Access/Collision Detection with Non-Destructive Arbitration) for bus arbitration.

A node that wants to transmit a message onto the network must first check if the CAN bus is in the “idle” state (Carrier Sense). The node then becomes the master by transmitting its message. Every other node will switch to receive mode during the Start of Frame bit, see [Figure 39-2](#). After receiving a message with no errors, all nodes sends an acknowledge, and store the message if required. If message storage is not required, the message is discarded.

If multiple nodes start their transmission simultaneously (Multiple Access), collision is avoided by the use of bitwise arbitration (Collision Detection/Non-Destructive Arbitration), and the “Wired-AND” mechanism. The node that sends out a recessive bit in its identifier field (MSB first), but reads back a dominant bit, loses arbitration and switches to receive mode. The competitive node won arbitration because it had a higher priority. This way, nodes with higher priority do not have to waste time re-sending their message. The nodes that lose arbitration will automatically attempt to re-send their message after the bus becomes “idle”.

*Note:* Different nodes cannot have similar identifiers on the same network.

Standard CAN (CAN2.0A) has an 11 bit identifier field, see [Figure 39-2](#), allowing a total of 2048 identifiers. This limitation has been improved by the Extended CAN (CAN2.0B), which has either a 11 and/or a 29 bit identifier field, resulting in a total of 536 million identifiers. See [Figure 39-2](#).

### 39.4.3 Frame Types

The CAN protocol is defined and controlled by four different frame types:

- Data Frame - Data frame from a transmitting node to receiving nodes.
- Remote Frame - Receiving node requesting the data frame with equal identifier.
- Error Frame - Transmitted by any node that detected an error.
- Overload Frame - A node can generate an overload frame under two conditions:
  - If the node detects a dominant bit during the interframe space (intermission).
  - The node is not yet ready to receive another data frame (wait states). Nodes are not allowed to generate more than 2 consecutive overload frames to delay the next transfer.
  - The CAN unit will not generate an overload frame but will respond to it if it sees one on the bus.

#### 39.4.3.1 Data Frame

A standard CAN data frame is composed of seven fields, as shown in Figure 39-2.

Figure 39-2. Standard CAN Data Frame

- Start of Frame: One dominant bit marks the beginning of Data Frames and Remote Frames. The purpose is hard synchronization for all nodes.
- Arbitration Field, consisting of:
  - 11 bit identifier
  - 1 RTR bit. This bit is used to distinguish between a Data Frame (Dominant) and a Remote Frame (Recessive).

- Control Field, consisting of:
  - Data Length Code, which is 4 bits wide
  - 2 reserved bits for future expansion
- Data Field, consisting of the data to be transmitted. The Data Field can be from 0 to 8 bytes. (MSB transferred first).
- CRC Field, consisting of:
  - CRC Sequence, which is the remainder of a polynomial division. This is a 15 bit value.
  - CRC delimiter which is one recessive bit.
- ACK Field, containing:
  - a one bit ACK SLOT  
A transmitting node drives this bit with a recessive value. All receiving nodes with comparable CRC values acknowledge with a dominant bit.
  - a one bit ACK Delimiter  
This will always be a recessive bit.
- End of Frame, which consists of seven recessive bits.

Between any frame the CAN bus must stay "idle" for at least three bit times(intermission). If no nodes wish to send a frame, the bus stays "idle".

The Extended CAN Data Frame is illustrated in [Figure 39-3](#).

Figure 39-3. Extended CAN Data Frame

*Note:* To to use both Extended and Standard Frames on the same network, it is necessary to split the 29 bit Extended identifier into one 11 bit (most significant) and one 18 bit (least significant) section. By doing this, the IDE bit can remain in the same bit position in both Standard and Extended Frames.

- Start of Frame: One dominant bit marks the beginning of both Data Frames and Remote Frames. This is for hard synchronization with all nodes.
- Arbitration Field, consisting of:
  - 11 bit identifier (most significant)
  - SRR bit, recessive
  - IDE bit, recessive to denote an Extended CAN Frame
  - Extended Identifier, 18 bits
  - 1 RTR bit. This bit is used to distinguish between a Data Frame(Dominant) and a Remote Frame (Recessive).
- Control Field, consisting of:
  - Two dominant bits
  - Data Length Code, which is 4 bits wide

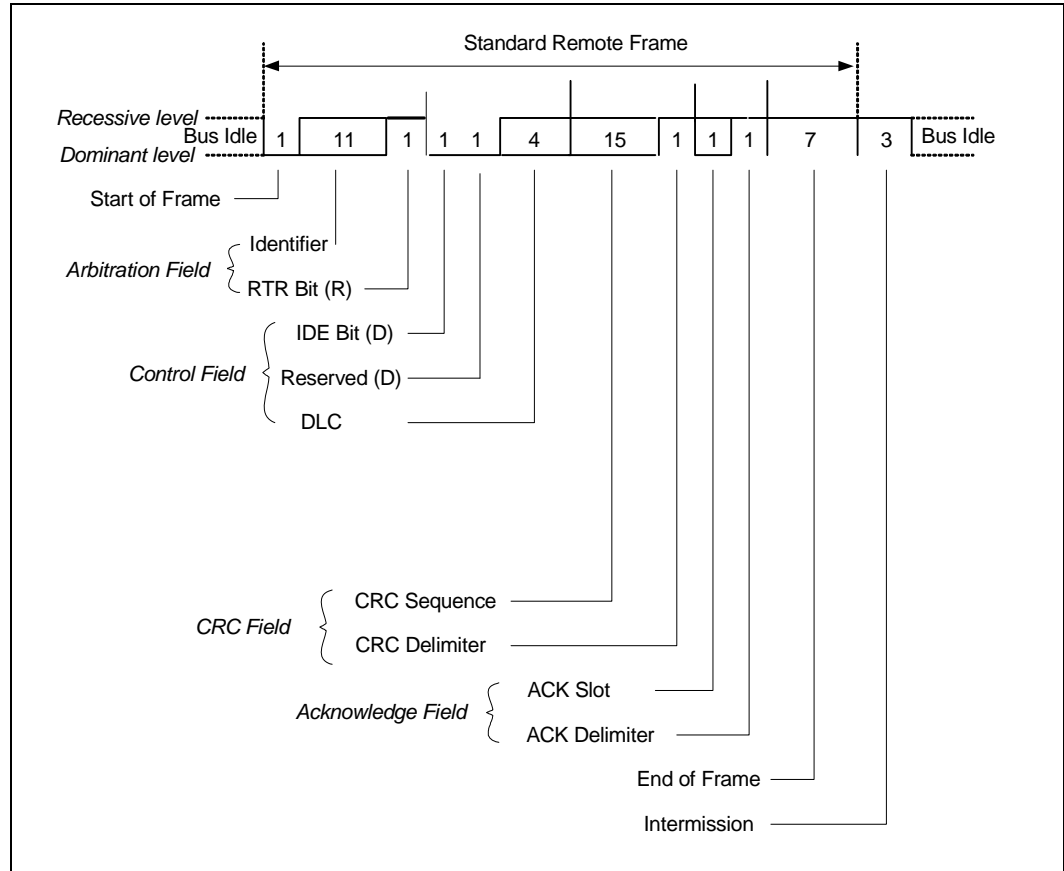

The remaining fields are similar to Standard Data Frame.

### 39.4.3.2 Remote Frame

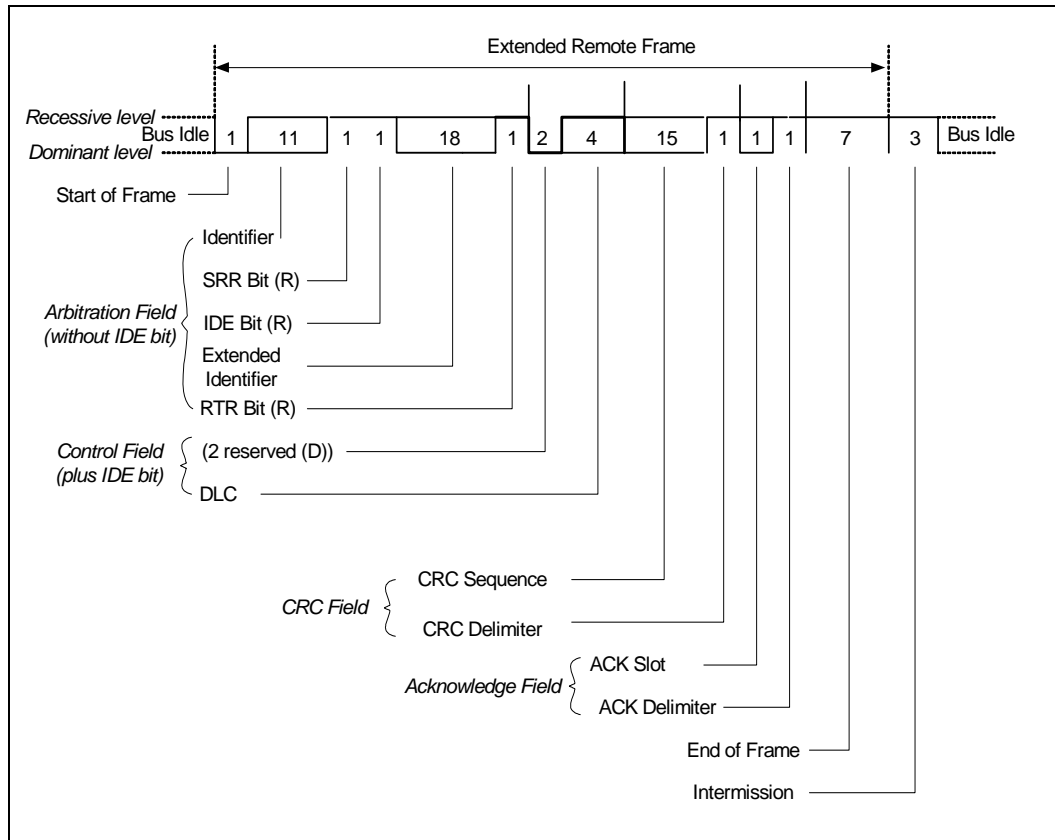

In the CAN protocol, it is also possible for a destination node to request data from a source. This can be done by transmitting a Remote Frame with an identifier that matches the identifier of the required Data Frame. This request results in a response from the source with the matching identifier, including the Data Frame. If a node were to transmit a Data Frame at the same time as a node were to send a Remote Frame with the same identifier, the Data Frame would win arbitration due to the dominant RTR bit.

Figure 39-4. Standard CAN Remote Frame

The format of an Extended Remote Frame is shown in Figure 39-5.

Figure 39-5. Extended CAN Remote Frame

### 39.4.3.3 Error Frames

CAN, as a message-oriented protocol, uses error signaling. Each network node checks each message that is transmitted on the bus for errors. When a transmitting or receiving network node detects an error, the node signals all other nodes by transmitting an error message (Error Frame). The Error Frame contains a six bit combination with the same polarity, normally as a dominant bit sequence (active error flag). All network nodes detect the error signal and cancel the segments of a message already received. Consistent data is thus ensured for all nodes of the network.

An Error Frame consists of two fields:

- Error Flag field:
  - An active Error Flag consists of six consecutive dominant bits. This violates the CAN protocol bit stuffing rule, and in turn all nodes on the network will generate error frames. The error frame field will then vary from a minimum of 6 to maximum of 12 consecutive dominant bits.
  - A passive Error Flag consists of six consecutive recessive bits, unless overwritten by dominant bits from other nodes. Unless the bus master transmits the passive Error Flag, the passive error flag will not affect any other node on the network.
- Error Delimiter field: consists of eight recessive bits and terminates the Error Frame.

When a transmitting node has transmitted an error frame to completion or has received one, it immediately attempts to transmit the previously transmitted message again with another bus arbitration process.

The error signaling mechanism ensures that the message transfer with all nodes of a network is error-free and consistent. Because error signaling takes place immediately after an error is detected, short error recovery times are guaranteed.

*Note:* The CAN protocol also provides a self-monitoring mechanism that prevents one dysfunctional node from holding the network down. The assessment of a node's statistical error rate may result in deactivation of the node.

#### 39.4.3.4 Overload Frames

An Overload Frame has the same format as an active Error Frame. The difference is when the Overload Frame is transmitted and its purpose: An Overload Frame is only permitted to transmit during Interframe Space (Intermission). Two conditions lead to the generation of an Overload Frame:

- If a node is not yet ready for any data (insert wait state).
- A node detects a dominant bit during intermission. A node may generate at most 2 consecutive Overload Frames, to delay the next Data or Remote Frame.

Overload Frames consist of two fields:

- The Overload Flag has the same format as an active Error Frame.
- The Overload Delimiter consists of eight recessive bits.

*Note:* The CAN controller will not generate overload frames. However, it will respond to overload frames when it sees one on the bus.

### 39.4.4 CAN Bit Timing

#### 39.4.4.1 Introduction

The CAN network is configured based on the bit rate. The nominal bit rate is the number of bits per second passing through the network in the absence of re synchronization. Each member of this network can implement the required timing parameters for a given bit rate using different values as long as the chosen values meet the synchronization requirements.

Oscillator drift and other issues could make the nominal configured bit rate to vary but the CAN protocol provides a mechanism to re synchronize the messages.

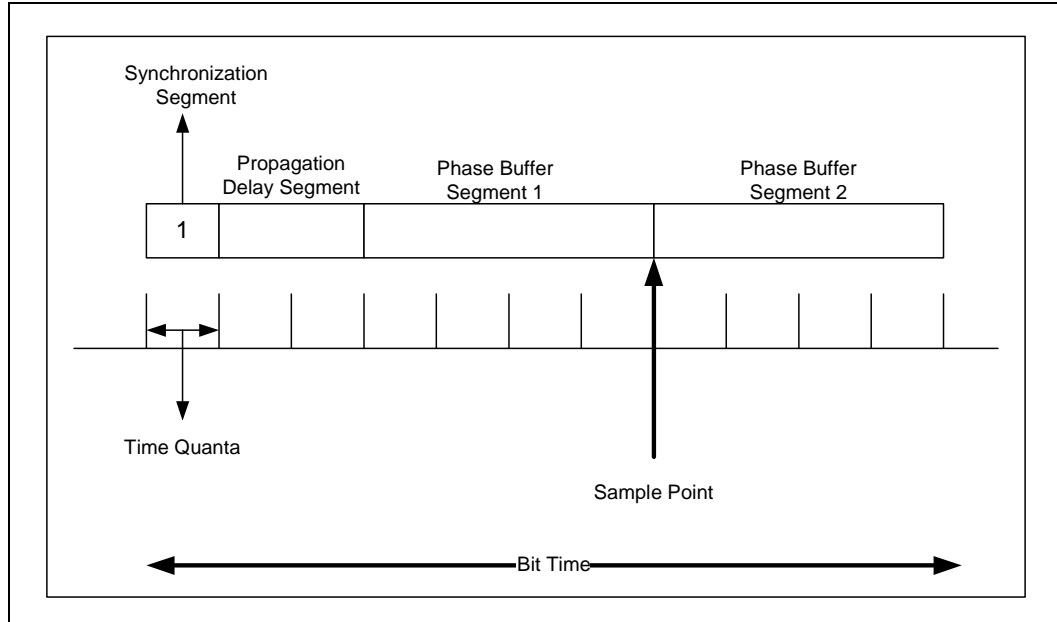

The nominal bit rate is made up of the following non-overlapping segments:

- Synchronization Segment: This is the start of the frame segment of the bit being transmitted. It is used primarily to synchronize nodes on the bus. The synchronization segment is always fixed to 1 time quanta.
- Propagation Segment: This is the time required for signals to travel in the CAN network. It includes the time required to travel from one end of the system to the other and back again. It also accounts for the CAN components to react.
- Phase Buffer Segment 1 & 2: These phase buffers exist to compensate for timing problems created by the oscillator drift and other issues. These 2 segments are adjusted in units called the Synchronization Jump Width.
- Sample Point: The sample point always occurs between the Phase 1 and Phase 2 segments. It can be set to be either single or multiple.

Each member of CAN network can use different timing parameters to achieve the same bit rate. As shown in Figure 39-6 each segment is defined in terms of time quantum (tq).

Figure 39-6. CAN Timing Parameters

The time quantum value is the basic unit of the bit time and is determined by the CAN controller system clock frequency and the bit scaler.

$$tq = \text{Bit\_Scaler} / \text{CAN clock frequency.}$$

For a given bit rate that the CAN requires, the Bit\_Scaler can be changed to meet the recommended values of phase buffer segments and synchronization jump width.

The CiA (CAN in automation) draft standard 102 version 2.0 defines the content of the physical layer and the basic characteristics of the physical medium, for communication according to the Controller Area Network protocol specification (CAN) between different types of electronic modules in general industrial applications.

The CiA recommended timing parameters for each bit rate is show in [Figure 39-7](#).

**39.4.4.2 Setting Proper Bit Rate, tseg1 and tseg2**

The CAN controller unit provides the following programmable timing parameters, which can be used to achieve CiA recommended bit rates:

- `cfg_tseg1` (Propagation Delay Segment + Phase Buffer Segment 1): This is used to compensate for edge phase errors but also consists of a propagation segment, which is used to compensate for signal delays in the network.
- `cfg_tseg2` (Phase Buffer Segment 2): This is also used for compensation of edge phase errors.
- `cfg_sjw` (Synchronization Jump Width): This defines how far the re-synchronization may move the sample point inside the limits defined by the phase buffer segments to compensate for edge phase errors.

As shown in [Figure 39-7](#), the sample point separates `tseg1` and `tseg2`, this is the point in time where the bus level is read and interpreted.

**Figure 39-7. Bit Rate and Time Settings**

The CAN unit in the EP80579 operates at a frequency of 40Mhz. Based on this frequency, the recommended timing parameter values are as show in [Table 39-2](#).

Table 39-2. CAN Recommended Bit Rate and Timing Parameters

| Bit Rate (Kbs/s) | Nominal Bit Time (us) | Number of Time Quanta Per Bit | Nominal Bit Time / CAN Controller Frequency † | Time Quantum (us) | Bit Rate Scaler Required for 40Mhz CAN Clock | cfg_tseg1 (Tseg - 1) | cfg_bitrate |
|------------------|-----------------------|-------------------------------|---|-------------------|--|----------------------|-------------|
| 1000             | 1                     | 8                             | 40  | 0.125             | 5  | 4                    | 4           |
| 800              | 1.25                  | 10                            | 50  | 0.125             | 5  | 6                    | 4           |
| 500              | 2                     | 16                            | 80  | 0.125             | 5  | 12                   | 4           |
| 250              | 4                     | 16                            | 160   | 0.250             | 10   | 12                   | 9           |
| 125              | 8                     | 16                            | 320   | 0.500             | 20   | 12                   | 19          |
| 50               | 20                    | 16                            | 800   | 1.250             | 50   | 12                   | 49          |
| 20               | 50                    | 16                            | 2000  | 3.125             | 125  | 12                   | 124         |
| 10               | 100                   | 16                            | 4000  | 6.250             | 250  | 12                   | 249         |

The bit rate scaler is chosen such that this is an integer value.

CAN Clock Frequency = 40Mhz  
cfg\_tseg2 = 1  
cfg\_sjw = 0  
Single Sampling Mode  
Synchronization Mode: Recessive to dominant only

## 39.5 Theory of Operation

### 39.5.1 Modes of Operation

The CAN unit can be used in different operating modes. By disabling transmitting data, it is possible to use the CAN in listen-only mode, enabling features such as automatic bit rate detection. The two units can be used in an on-chip loop-back mode.

Before starting the CAN controller, all CAN configuration registers must be set according to the target application.

### 39.5.2 Error Handling

The CAN protocol provides sophisticated error detection mechanisms. The following list of errors can be detected:

- Cyclic Redundancy Check (CRC) Error - The received CRC sequence did not match the calculated result.
- Acknowledge Error - The transmitter did not detect a dominant bit during ACK slot.
- Form Error - One or more illegal bits in a fixed-form bit field.
- Bit Error - The monitored bit value is different from the bit value sent.
- Stuff Error - Between Start of Frame and CRC Delimiter, 6 consecutive bits with the same polarity are detected.

An interrupt will be generated if an error is enabled and detected, see “Offset 00000000h: Int\_status - Interrupt Status Register”.

**Note:** The errors are always detected and registered in the interrupt status register. The interrupt enable register determines whether or not it gets propagated. For more information please refer to “Offset 00000000h: Int\_status - Interrupt Status Register” and “Offset 00000004h: Int\_Ebl - Interrupt Enable Register”

### 39.5.3 Send/Receive Procedure

#### 39.5.3.1 Send Procedure

Use the following procedure to send a message:

1. Write a message into one of the transmit message holding buffers. An empty buffer is indicated by a TxReq that equals zero.
2. Request transmission by setting the respective TxReq flag to '1'.
3. The TxReq flag remains set as long as the message transmit request is pending. The content of the message buffer must not change while the TxReq flag is set.
4. The internal message priority arbiter selects the message according to the chosen arbitration scheme.
5. Once the message is transmitted, the TXReq flag is set to zero and the TxMsg interrupt status is asserted.

A message can be removed from a transmit holding buffer by setting the TxAbort flag. Use the following procedure to remove the contents of a particular TxMessage buffer:

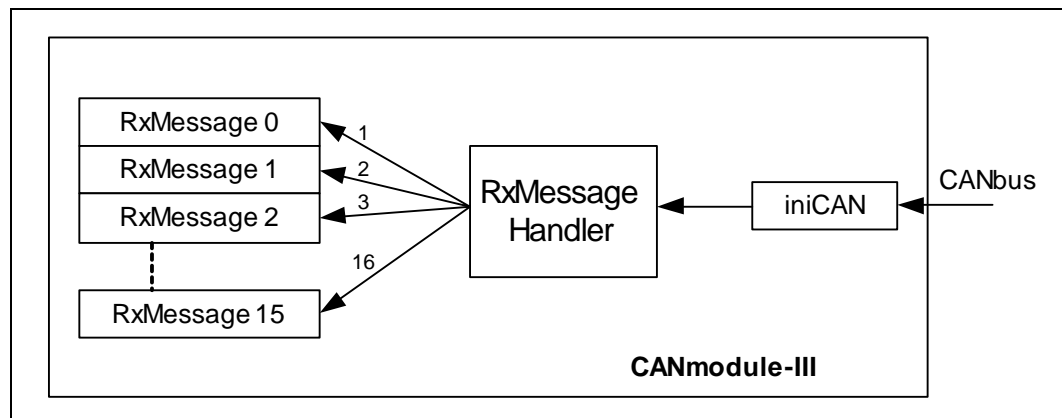

1. Set TxAbort to '1' to request the message removal.
2. The TxAbort flag remains set as long as the message abort request is pending. The flag is cleared when either the message wins arbitration (TxMsg interrupt active) or the message is removed (TxMsg interrupt inactive).

#### 39.5.3.2 Receive Procedures

The CAN unit supports 16 individual receive message buffers. Each one has its own message filter mask. Automatic reply to RTR messages is supported.

If a message is accepted in a receive buffer, its MsgAv flag is set. The message remains valid as long as MsgAv flag is set. The host CPU has to reset the MsgAv flag to enable receipt of a new message.

**Figure 39-8. Receive Message Handler**

### 39.5.3.3 Rx Message Processing

After receipt of a new message, the RxMessageHandler searches all receive buffers starting from RxMessage0 until it finds a valid buffer.

A valid buffer is indicated by:

- Receive buffer is enabled indicated by RxBufferEbl = '1'.
- Acceptance Filter of receive buffer matches incoming message.

If the RxMessageHandler finds a valid buffer that is empty, then the message is stored and the MsgAv flag is set to '1'. If the RxIntEbl flag is set, then the RxMsg flag of the interrupt controller is set. If the receive buffer already contains a message indicated by MsgAv = '1' and the Link Flag is not set, then a RxMsgLoss interrupt flag is set.

If an incoming message has its RTR flag set and the RTRreply flag is set, then the message is not stored but an RTR auto-reply is issued. See ["Offset 000000A0h: RxMessageControl\[0-15\] - Receive Message Command and Control"](#) for more details.

### 39.5.3.4 Acceptance Filter

Each receive buffer has its own acceptance filter that is used to filter incoming messages. An acceptance filter consists of an Acceptance Mask Register (AMR) and Acceptance Code Register (ACR) pair. The AMR defines which bits of the incoming CAN message have to match the respective ACR bits.

The following message fields are covered:

- ID
- IDE
- RTR
- Data byte 1 and data byte 2 (DATA[63:56])

*Note:*

Some CAN High Level Protocols such as SDS or Device Net carry additional protocol related information in the first or first two data bytes that are used for message acceptance and selection. The capability to filter on these fields provides a more efficient implementation of the protocol stack running on the CPU.

The acceptance mask register (AMR) defines whether the incoming bit is checked against the acceptance code register (ACR).

- AMR:
  - '0': The incoming bit is checked against the respective ACR. The message is not accepted when the incoming bit doesn't match the respective ACR flag.
  - '1': The incoming bit is 'don't care'.

#### Example:

The following example shows the acceptance register settings used to support receipt of a CANopen TPD01 (Transmit Process Data Object) message. In CANopen, a widely used CAN Higher Level Protocol (HLP), the ID bits are used to select the message type. The bit assignment is shown in the following table:

**Table 39-3. CAN Higher Level Protocol (HLP) Bit Assignment**

| CANopen Identifier |   |   |   |   |         |   |   |   |   |   |
|--------------------|---|---|---|---|---------|---|---|---|---|---|
| 10                 | 9 | 8 | 7 | 6 | 5       | 4 | 3 | 2 | 1 | 0 |
| Function Code      |   |   |   |   | Node-ID |   |   |   |   |   |

Identifier fields:

- Function Code: The function code for a TDPO1 message is 3h.
- Node-ID: The example uses 02h as the Node ID.
- IDE = '0': CANopen uses the short format message.
- RTR = '0': Identifies a regular message.

To accept this message, the acceptance filter settings would look like the following:

- AMR settings:
  - ID[28:18] = 0
  - ID[17:0] = all ones
  - IDE = 0
  - RTR = 0
  - DATA[63:56] = all ones
- ACR settings:
  - ID[28:18] = 182h
  - ID[17:0] = don't care
  - IDE = 0
  - RTR = 0
  - DATA[63:56] = don't care

### 39.5.3.5 RTR Auto-Reply

The CAN unit supports fully automatic answering of RTR message requests. All 16 receive buffers support this feature. If an RTR message is accepted in a receive buffer, where the RTRreply flag is set, then this buffer automatically replies to this message with the content of this receive buffer. The RTRreply\_pending flag is set when the RTR message request is received. The flag is reset when the message was sent or when the message buffer is disabled. To abort a pending RTRreply message, use the RTRabort command.

### 39.5.3.6 RxBuffer Linking

Several receive buffers may be linked together to form a receive buffer array which acts like a receiver FIFO.

The requirements are as follows:

- All buffers of the same array must have the same message filter setting (AMR and ACR are identical).
- The last buffer of an array may not have its link flag set.

When a receive buffer already contains a message (MsgAv='1') and a new message arrives for this buffer, then this message would be discarded (RxMsgLoss Interrupt). To avoid this situation, several receive buffers can be linked together. When the CAN unit receives a new message, the RxMessage handler searches for a valid receive buffer. If

one is found that is already full (MsgAv='1') and the link flag is set (BufferLink='1'), the search for a valid receive buffer is continued. If no other buffer is found, then the RxMsgLoss interrupt is set anyway.

It is possible to build several message arrays. Each of these arrays must use the same AMR and ACR.

### 39.5.4 TxMessage Registers

Eight transmit message holding buffers are provided. An internal priority arbiter selects the message according to the chosen arbitration scheme. Upon transmission of a message or message arbitration loss, the priority arbiter re-evaluates the message priority of the next message.

Figure 39-9. Message Arbitration

The priority arbiter supports round robin and fixed priority arbitration. The arbitration mode is selected using the configuration register.

- Round Robin - Buffers are served in a defined order: 0-1-2..7-0-1... A particular buffer is only selected if its TxReq flag is set. This scheme guarantees that all buffers receive the same probability to send a message.
- Fixed priority - Buffer 0 has the highest priority. With this mode, it is possible to designate buffer 0 as the buffer for error messages and it is guaranteed that they are sent first.

*Note:* RTR message requests are served before TxMessage buffers are handled (e.g. RTRreq0, ... RTRreq15, TxMessage0, TxMessage0, TxMessage1, ... TxMessage7).

See the description of the configuration register in the TxMessage0 Buffer in [“Offset 0000020h: TxMessageControl\[0-7\] - Transmit Message Control and Command”](#) for information about how to select these modes.

## 39.6 Register Summary

The default value for all registers is 0h, unless otherwise noted. All registers starting at 20h are implemented in SRAM without guaranteed reset values. It is the responsibility of either BIOS or SW to initialize these to 0.

For more information on the conventions the following register summaries adopt, see [Section 7.1, "Overview of Register Descriptions and Summaries"](#) on page 183.

The CAN registers materialize in the PCIspace.

[Table 39-4](#) and [Table 39-5](#) summarize the CAN interface #0 and #1 materializations from the PCI perspective.

**Table 39-4. Bus M, Device 4, Function 0: Summary of CAN Registers Mapped Through CSRBAR Memory BAR**

### 39.6.1 Detailed Register Descriptions

This section shows all internal registers and describes how the CAN unit can be used and programmed.

#### 39.6.1.1 Offset 00000000h: Int\_status - Interrupt Status Register

The interrupt controller contains an interrupt status and an interrupt enable register. The interrupt status register stores internal interrupt events. Once a bit is set, it remains set until it is cleared by writing a '1' to it. The interrupt enable register has no effect on the interrupt status register.

The interrupt enable register controls which particular bits from the interrupt status register are used to assert the interrupt output int\_n. int\_n is asserted if a particular interrupt status bit and the respective enable bit are set.

**Table 39-6. Offset 00000000h: Int\_Status - Interrupt Status Register**

| Description: |                    |   |                              |  |            |
|--------------|--------------------|---|------------------------------|--|------------|

### 39.6.1.3 Offset 00000008h: Buffer Status - Buffer Status Indicators

These status indicators bundle the respective flags from all RxMessage and TxMessage buffers.

**Table 39-8. Offset 00000008h: Buffer Status Indicators**

|                     |                           |                                   |                                    |  |                   |
|---------------------|---------------------------|-----------------------------------|------------------------------------|--|-------------------|
| <b>Description:</b> |                           |                                   |                                    |  |                   |
| <b>View:</b> PCI 1  | <b>BAR:</b> CSRBAR        |                                   | <b>Bus:Device:Function:</b> M: 4:0 | <b>Offset Start:</b> 00000008h<br><b>Offset End:</b> 0000000Ah |                   |
| <b>View:</b> PCI 2  | <b>BAR:</b> CSRBAR        |                                   | <b>Bus:Device:Function:</b> M: 5:0 | <b>Offset Start:</b> 00000008h<br><b>Offset End:</b> 0000000Ah |                   |
| <b>Size:</b> 32 bit | <b>Default:</b> 00000000h |                                   | <b>Power Well:</b> Core            |  |                   |
| <b>Bit Range</b>    | <b>Bit Acronym</b>        | <b>Bit Description</b>            | <b>Sticky</b>                      | <b>Bit Reset Value</b>   | <b>Bit Access</b> |
| 31 :24              | RSVD                      | Reserved, these bits are always 0 |                                    | 0h   | RO                |
| 23 :16              | TXMSG_7_0                 | TxReq pending (bits [7:0])        |                                    | 0b   | RO                |
| 15 :00              | RXMSG_15_0                | MsgAv (bits [15:0])               |                                    | 0b   | RO                |

*Note:* All flags are read only (e.g. to acknowledge a MsgAv flag, the CPU has to write to the respective RxMessage buffer).

### 39.6.1.4 Offset 0000000Ch: ErrorStatus - Error Status Indicators

Status indicators are provided to report the CAN controller error state, receive error count and transmit error count. Special flags to report error counter values equal to or in excess of 96 errors are available to indicate heavily disturbed bus situations.

**Table 39-9. Offset 0000000Ch: ErrorStatus - Error Status Indicators**

|                     |                           |   |  |                        |                   |

| 07 :00              | tx_err_cnt_7_0            | The transmitter error counter (bits [7:0]) according to the Bosch* CAN 2.0 specification. When it is greater than 255(dec), it is fixed at 255.                 |  | 0b                     | RO                |

### 39.6.1.5 Offset 0000010h: Command - Operating Modes

The CAN unit can be used in different operating modes. By disabling transmitting data, it is possible to use the CAN in listen-only mode. This allows for features such as automatic bit rate detection.

Before starting the CAN controller, all CAN controller registers have to be set according to the target application.

**Table 39-10. Offset 0000010h: Command - Operating Modes**

| Description: |                    |  |                              |  |            |
|--------------|--------------------|--|------------------------------|--|------------|
| View: PCI 1  | BAR: CSRBAR        |  | Bus:Device:Function: M: 4: 0 | Offset Start: 0000010h<br>Offset End: 0000013h |            |
| View: PCI 2  | BAR: CSRBAR        |  | Bus:Device:Function: M: 5: 0 | Offset Start: 0000010h<br>Offset End: 0000013h |            |
| Size: 32 bit | Default: 00000000h |  |                              | Power Well: Core                               |            |
| Bit Range    | Bit Acronym        | Bit Description  | Sticky                       | Bit Reset Value                                | Bit Access |
| 31 : 02      | RSVD               | Reserved, these bits are always 0  |                              | 0h   | RO         |
| 01           | listen             | Listen mode:<br>'0' = Active<br>'1' = CAN listen only: The output is held at 'R' level. The CAN is only listening  |                              | 0b   | RW         |
| 00           | run_stop           | Run/Stop mode:<br>'0' = Sets the CAN controller into stop mode. Read '0' when stopped.<br>'1' = Sets the CAN controller into run mode. Read '1' when running |                              | 0b   | RW         |

**Note:** The run/stop bit [00] can not be written from RUN mode to STOP mode while a message is pending in the TX buffer. The stalled packet can be dequeued first using the ABORT bit in the buffer prior to setting the mode to STOP. If the requirement is to retain the TX packet in the buffer, transitioning to LISTEN mode first by setting bit [1] will allow the controller to then transition to STOP mode. The packet will then remain in the buffer if the controller is transitioned back to RUN mode.

### 39.6.1.6 Offset 00000014h: Config - CAN Configuration Register

The CAN unit must be configured prior to its use. The following registers define the effective CAN data rate, CAN data synchronization, and message buffer arbitration.

*Note:* Additional information on the CAN data rate settings using time segment1 (tseg1), time segment2 (tseg2), and the bit rate are given in Section 39.4.4, “CAN Bit Timing” on page 1577.

**Table 39-11. Offset 00000014h: Config - CAN Configuration Register**

### 39.6.1.7 Offset 0000020h: TxMessageControl[0-7] - Transmit Message Control and Command

*Note:* These registers are implemented in the SRAM which does not have the capability to mask writes to reserved bits. Therefore, reserved bits in this CSR will be RW. Software should treat these bits as reserved and not change the reset value of these bits.

*Note:* These registers are implemented in SRAM which is not initialized at power-up or upon reset. So before enabling the CAN, software needs to update these CSR's with the reset values.

### 39.6.1.17 Offset 000000B8h: RxMessageAMR\_Data[0-15] - Receive Message AMR Data

*Note:* These registers are implemented in the SRAM which does not have the capability to mask writes to reserved bits. Therefore, reserved bits in this CSR will be RW. Software should treat these bits as reserved and not change the reset value of these bits.

*Note:* These registers are implemented in SRAM which is not initialized at power-up or upon reset. So before enabling the CAN, software needs to update these CSR's with the reset values.

## 40.0 SSP Serial Port

---

### 40.1 Overview

The SSP (Synchronous Serial Port) is a full-duplex synchronous serial interface. The SSP can connect to a variety of external analog-to-digital (A/D) converters, audio and telecom codecs, and many other devices that use serial protocols for transferring data. It supports National Microwire\*, Texas Instruments\* synchronous serial protocol (SSP), and Motorola\* serial peripheral interface (SPI) protocol.

The SSP operates in master mode (the attached peripheral functions as a slave), and supports serial bit rates from 7.2 Kbps to 1.84 Mbps. Serial data formats may range from 4 to 16 bits in length. Two on-chip register blocks function as independent FIFOs for data, one for each direction. The buffers are 16 entries deep x 16 bits wide.

This section describes the signal definitions and operations of the SSP functional block.

### 40.2 Feature List

A list of features is presented below:

- Supports National Microwire format.
- Supports Texas Instruments Synchronous Serial Protocol (SSP).
- Supports Motorola Serial Peripheral Interface (SPI).
- Supports serial data rates from 7.2 Kbps to 1.84 Mbps.
- Provides 32 byte FIFOs for both receive and transmit data.

### 40.3 Theory of Operation

#### 40.3.1 Endianness

The SSP uses only bits 15:0 of the internal data bus, the host must format the data into the two least significant bytes of the 32 bit internal bus transfer. The two high order bytes are ignored. The SSP unit is accessed only using dword accesses.

#### 40.3.2 Error Handling

No error handling is defined for this unit beyond the functional receiver overrun status bit (ROR) (see [Section 40.4.3.7](#)) in the SSP Status Register (see [Section 40.4.3](#)). This error condition causes the unit's interrupt to be asserted and is non-maskable.

## 40.4 Register Summary

There are five registers in the SSP block: two control, one data, one status register, and one test register.

- Control registers are used to program the baud rate, data length, frame format, data transfer mechanism, and port enabling. In addition, they permit setting the FIFO “fullness” threshold that will trigger an interrupt.
- The Data Register is mapped as one 32-bit location, which physically points to either of two 32-bit registers. One register is for WRITES, and transfers data to the Transmit FIFO; the other is for READS, and takes data from the Receive FIFO. A write cycle, will load successive words into the SSP Write Register, from the lower half 2 bytes of a 32-bit word to the Transmit FIFO. A READ cycle, will similarly take data from the SSP Read Register, and the Receive FIFO will reload it with available data bits it has stored.  
The FIFOs are independent buffers that allow full duplex operation.
- The Status Register signals the state of the FIFO buffers: whether the programmable threshold has been passed (Transmit/Receive Buffer service request), and a value showing the actual “fullness” of the FIFO. There are flag bits to indicate when the SSP is actively transmitting data, when the Transmit Buffer is not full, and when the Receive Buffer is not empty. Error bits signal overrun errors.

The SSP registers materialize in the PCI space.

Table 40-1 summarizes the SSP materialization from the PCI perspective.

#### 40.4.1.2 Data Size Select (DSS)

The 4-bit data size select (DSS) field is used to select the size of the data transmitted and received by the SSP. Data can be 4 to 16 bits in length. When data is programmed to be less than 16 bits, received data is automatically right-justified and the upper bits in the receive FIFO are zero-filled by receive logic. Transmit data should not be left-justified by the user before being placed in the transmit FIFO; transmit logic in the SSP will automatically left-justify the data sample according to the value of DSS before the sample is transmitted on **SSP\_TXD**. Although it is possible to program data sizes of 1, 2, and 3 bits, these sizes are reserved and produce unpredictable results in the SSP.

When National Microwire frame format is selected, this bit field selects the size of the received data. Note that the size of the transmitted data is always 8 bits in this mode.

#### 40.4.1.3 Frame Format (FRF)

The 2-bit frame format (FRF) field is used to select which frame format to use: Motorola SPI (FRF=00), Texas Instruments synchronous serial (FRF=01), or National Microwire (FRF=10). Note that FRF=11 is reserved and the SSP will produce unpredictable results if this value is used.

#### 40.4.1.4 External Clock Select (ECS)

The external clock select (ECS) bit selects whether the on-chip 3.6864-MHz (2.777MHz for low-power SKU) clock is used by the SSP or if an off-chip clock is supplied via **SSP\_EXTCLK**. When ECS=0, the SSP uses the on-chip 3.6864-MHz clock (2.777MHz for low-power SKU) to produce a range of serial transmission rates. When ECS=1, the SSP uses **SSP\_EXTCLK** to input a clock supplied from off-chip. The frequency of the off-chip clock can be any value up to 3.6864 MHz (2.777MHz for low-power SKU). This off-chip clock is useful when a serial transmission rate, which is not an even multiple of the internal clock, is required for synchronization with the target off-chip slave device.

#### 40.4.1.5 Synchronous Serial Port Enable (SSE)

The SSP enable (SSE) bit is used to enable and disable all SSP operations. When SSE=0, the SSP is disabled; when SSE=1, it is enabled. When the SSP is disabled, all of its clocks are powered down to minimize power consumption. Note that the SSE is the only control bit within the SSP that is reset to a known state. It is cleared to zero to ensure the SSP is disabled following a reset.

When the SSE bit is cleared during active operation, the SSP is disabled immediately, causing the current frame being transmitted to be terminated. Clearing SSE resets the SSP's FIFOs. However the SSP's control and status registers are not reset. The user must ensure these registers are properly reconfigured before re-enabling the SSP.

#### 40.4.1.6 Serial Clock Rate (SCR)

The 8-bit serial clock rate (SCR) bit-field is used to select the baud, or bit rate, of the SSP. The serial clock generator can be configured to use the internally provided 3.6864-MHz (2.777MHz for low-power SKU) clock produced by the on-chip PLL or the externally provided clock. The source clock is divided by a fixed value of 2, and then divided by the programmable SCR value (0 to 255) plus 1 to generate the serial clock (**SSP\_SCLK**). When configured to use the internal clock, a total of 256 different bit rates can be selected. The resultant clock is driven on the **SSP\_SCLK** pin and is used by the SSP's transmit logic to drive data on the **SSP\_TXD** pin, and to latch data on the **SSP\_RXD** pin. Depending on the frame format selected, each transmitted bit is driven on either the rising or falling edge of **SSP\_SCLK**, and is sampled on the opposite clock edge.

Note that the SSE bit is the only control bit that is reset to a known state, to ensure the SSP is disabled following a reset. The reset state of all other control bits is unknown and must be initialized before enabling the SSP.

## 40.4.2 SSP Control Register 1

### 40.4.2.1 Offset 04h: SSCR1 - SSP Control Register 1 Details

The SSP Control Register 1 (SSCR1) contains nine bit fields that control various SSP functions.

#### 40.4.2.2 Receive FIFO Interrupt Enable (RIE)

The Receive FIFO Interrupt Enable (RIE) bit is used to mask or enable the Receive FIFO service request interrupt. When RIE=0, the interrupt is masked and the state of the Receive FIFO Service Request (RFS) bit within the SSP Status Register is ignored by the interrupt controller. When RIE=1, the interrupt is enabled and whenever RFS is set to one, an interrupt request is made to the interrupt controller. Note that programming RIE=0 does not affect the current state of RFS or the receive FIFO logic's ability to set and clear RFS, it only blocks the generation of the interrupt request.

#### 40.4.2.3 Transmit FIFO Interrupt Enable (TIE)

The Transmit FIFO Interrupt Enable (TIE) bit is used to mask or enable the transmit FIFO service request interrupt. When TIE=0, the interrupt is masked and the state of the Transmit FIFO Service Request (TFS) bit within the SSP Status Register is ignored by the interrupt controller. When TIE=1, the interrupt is enabled, and whenever TFS is set to one an interrupt request is made to the interrupt controller. Note that programming TIE=0 does not affect the current state of TFS or the transmit FIFO logic's ability to set and clear TFS, it only blocks the generation of the interrupt request.

#### 40.4.2.4 Loop Back Mode (LBM)

The loop back mode (LBM) bit is used to enable and disable the ability of the SSP transmit and receive logic to communicate. When LBM=0, the SSP operates normally. The transmit and receive data paths are independent and communicate via their respective pins. When LBM=1, the output of the transmit serial shifter is directly connected to the input of the receive serial shifter internally.

Loop back mode is only valid for SSP and SPI modes, Microwire mode does not support loop back mode testing because the bus protocol is half-duplex.

*Note:* While in loopback mode, the data will continue to be driven on the transmit pins.

#### 40.4.2.5 Serial Clock Polarity (SPO)

The serial clock (**SSP\_SCLK**) polarity bit (SPO) selects the polarity of the inactive state of the **SSP\_SCLK** pin when Motorola SPI format is selected (FRF=00). For SPO=0, the **SSP\_SCLK** is held low in the inactive or idle state when the SSP is not transmitting/receiving data. For SPO=1, the **SSP\_SCLK** is held high during the inactive/idle state. The programmed setting of the SPO alone does not determine which **SSP\_SCLK** edge is used to transmit or receive data. The SPO setting in combination with the **SSP\_SCLK** phase bit (SPH) determines this. Note that the SPO is ignored for all data frame formats except for the Motorola SPI format (FRF=00).

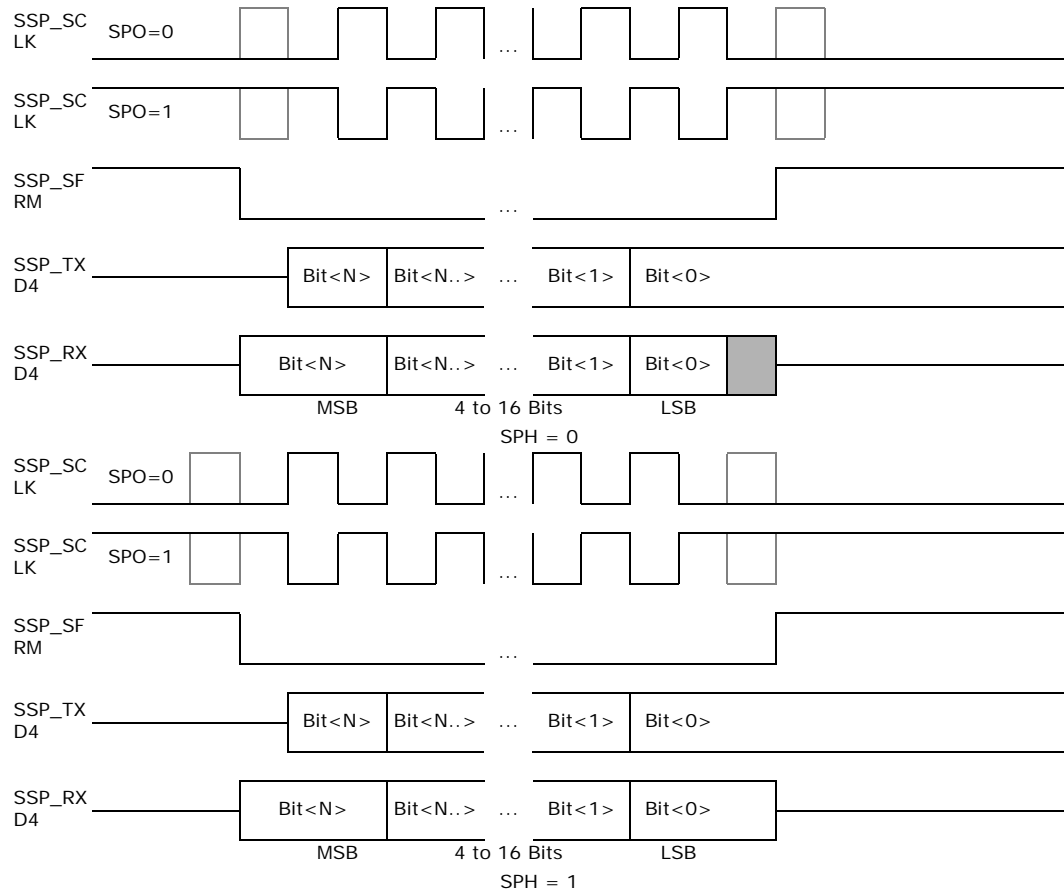

#### 40.4.2.6 Serial Clock Phase (SPH)

The serial clock (**SSP\_SCLK**) phase bit (SPH) determines the phase relationship between the **SSP\_SCLK** and the serial frame (**SSP\_SFRM**) pins when the Motorola SPI format is selected (FRF=00). When SPH=0, **SSP\_SCLK** remains in its inactive/idle state (as determined by the SPO setting) for one full cycle after **SSP\_SFRM** is asserted low at the beginning of a frame. **SSP\_SCLK** continues to transition for the rest of the frame and is then held in its inactive state for one-half of an **SSP\_SCLK** period before **SSP\_SFRM** is de-asserted high at the end of the frame. When SPH=1, **SSP\_SCLK** remains in its inactive/idle state (as determined by the SPO setting) for one-half cycle after **SSP\_SFRM** is asserted low at the beginning of a frame. **SSP\_SCLK** continues to transition for the rest of the frame and is then held in its inactive state for one full **SSP\_SCLK** period before **SSP\_SFRM** is de-asserted high at the end of the frame. The combination of the SPO and SPH settings determines when **SSP\_SCLK** is active during the assertion of **SSP\_SFRM** and which **SSP\_SCLK** edge is used to transmit and receive data on the **SSP\_TXD** and **SSP\_RXD** pins. When SPO and SPH are programmed to the same value (both 0 or both 1), transmit data is driven on the falling edge of **SSP\_SCLK** and receive data is latched on the rising edge of **SSP\_SCLK**. When SPO and SPH are programmed to opposite values (one 0 and the other 1), transmit data is driven on the rising edge of **SSP\_SCLK** and receive data is latched on the falling edge of **SSP\_SCLK**. Note that the SPH is ignored for all data frame formats except for the Motorola SPI format (FRF=00).

Table 40-4 shows the pin timing for all four programming combinations of SPO and SPH. Note that SPO inverts the polarity of the **SSP\_SCLK** signal and SPH determines the phase relationship between **SSP\_SCLK** and **SSP\_SFRM**, shifting the **SSP\_SCLK** signal one-half phase to the left or right during the assertion of **SSP\_SFRM**.

**Table 40-4. Motorola\* SPI Frame Formats for SPO and SPH Programming**

**40.4.2.7 National Microwire\* Data Size (MWDS)**

This bit sets the size of data in the Microwire format. If '1', a 16 bits data size is chosen for the Microwire format, otherwise, an 8-bit data size.

**40.4.2.8 Transmit FIFO Interrupt Threshold (TFT)**

This 4-bit value sets the level at or below which the FIFO controller triggers a service interrupt.

**40.4.2.9 Receive FIFO Interrupt Threshold (RFT)**

This 4-bit value sets the level at or above which the FIFO controller triggers a service interrupt.

**40.4.2.10 Enable FIFO Write/Read Function (EFWR)**

This bit enables a special functional mode for the SSP. When EFWR = 0, the SSP operates in the normal mode described in this document. When EFWR = 1, the SSP enters a mode in which whenever the CPU reads or writes to the SSP Data register, it actually reads and writes exclusively to either the Transmit FIFO or the Receive FIFO depending on the programmed state of the Select FIFO for EFWR (STRF) bit. In this special mode, data will not be transmitted on the TXD pin and data input on the RXD

pin will not be stored. This mode can be used to test, through software, whether or not the Transmit FIFO or the Receive FIFO operates properly as a first-in-first-out memory stack.

*Note:* When this mode is enabled, a write followed immediately by a read to the RX or TX FIFOs may not return the correct read data. Since this is a test mode, a delay should be inserted between the write and read transactions so that the data is guaranteed to be read back correctly.

#### 40.4.2.11 Select FIFO for Enable FIFO Write/Read (STRF)

This bit selects whether the Transmit or Receive FIFO is enabled for write/read.

### 40.4.3 SSP Status Register

#### 40.4.3.1 Offset 08h: SSSR - SSP Status Register Details

The SSP status register (SSSR) contains bits that signal overrun errors as well as the transmit and receive FIFO service requests. Each of these hardware-detected events signal an interrupt request to the interrupt controller. The status register also contains flags that indicate when the SSP is actively transmitting characters, when the transmit FIFO is not full, and when the receive FIFO is not empty (no interrupt generated).

Bits that cause an interrupt will signal the request as long as the bit is set. Once the bit is cleared, the interrupt is cleared. Read/write bits are called status bits, read-only bits are called flags. Status bits are referred to as “sticky” (once set by hardware, must be cleared by software). Writing a 1 to a sticky status bit clears it, writing a 0 has no effect. Read-only flags are set and cleared by hardware; writes have no effect. Additionally some bits that cause interrupts have corresponding mask bits in the control registers and are indicated in the section headings that follow.

#### 40.4.3.2 Transmit FIFO Not Full Flag (TNF) (Read-Only, Non-Interruptible)

The transmit FIFO not full flag (TNF) is a read-only bit that is set whenever the transmit FIFO contains one or more entries that do not contain valid data. TNF is cleared when the FIFO is completely full. This bit can be polled when using programmed I/O to fill the transmit FIFO over its half-way mark. This bit does not request an interrupt.

#### 40.4.3.3 Receive FIFO Not Empty Flag (RNE) (Read-Only, Non-Interruptible)

The receive FIFO not empty flag (RNE) is a read-only bit that is set whenever the receive FIFO contains one or more entries of valid data and is cleared when it no longer contains any valid data. This bit can be polled when using programmed I/O to remove remaining bytes of data from the receive FIFO since CPU interrupt requests are only made when the Receive FIFO Threshold has been met or exceeded. This bit does not request an interrupt.

#### 40.4.3.4 SSP Busy Flag (BSY) (Read-Only, Non-Interruptible)

The SSP busy (BSY) flag is a read-only bit that is set when the SSP is actively transmitting and/or receiving data and is cleared when the SSP is idle or disabled (SSE=0). This bit does not request an interrupt.

#### 40.4.3.5 Transmit FIFO Service Request Flag (TFS) (Read-Only, Maskable Interrupt)

The Transmit FIFO service request flag (TFS) is a read-only bit that is set when the transmit FIFO is nearly empty and requires service to prevent an underrun. TFS is set any time the transmit FIFO has the same or fewer entries of valid data than indicated by the Transmit FIFO Threshold and it is cleared when it has more entries of valid data than the threshold value. When the TFS bit is set, an interrupt request is made unless the transmit FIFO interrupt request enable (TIE) bit is cleared. After the CPU fills the FIFO such that it exceeds the threshold, the TFS flag (and the service request and/or interrupt) is automatically cleared.

#### 40.4.3.6 Receive FIFO Service Request Flag (RFS) (Read-Only, Maskable Interrupt)

The receive FIFO service request flag (RFS) is a read-only bit that is set when the receive FIFO is nearly filled and requires service to prevent an overrun. RFS is set any time the receive FIFO has the same or more entries of valid data than indicated by the Receive FIFO Threshold and it is cleared when it has fewer entries than the threshold value. When the RFS bit is set, an interrupt request is made unless the receive FIFO interrupt request enable (RIE) bit is cleared. After the CPU reads the FIFO such that it has fewer entries than the RFT value, the RFS flag (and the service request and/or interrupt) is automatically cleared.

#### 40.4.3.7 Receiver Overrun Status (ROR) (Read/Write, Non-Maskable Interrupt)

The receiver overrun status bit (ROR) is a read/write bit that is set when the receive logic attempts to place data into the receive FIFO after it has been completely filled. Each time a new piece of data is received, the set signal to the ROR bit is asserted and the newly received data is discarded. This process is repeated for each new piece of data received until at least one empty FIFO entry exists. When the ROR bit is set, an interrupt request is made. Writing 1 to this bit resets ROR status and its interrupt request.

#### 40.4.3.8 Transmit FIFO Level

This 4-bit value shows how many valid entries are currently in the Transmit FIFO.

#### 40.4.3.9 Receive FIFO Level

This 4-bit value shows how many valid entries are currently in the Receive FIFO.

The following bit table shows the bit locations corresponding to the status and flag bits within the SSP status register. All bits are read-only except ROR, which is read/write. Writes to TNF, RNE, BSY, TFS, and RFS have no effect. The reset state of ROR is unknown and must be initialized before enabling the SSP. Note that writes to reserved bits are ignored and reads to those bits return zeros.

### 40.4.4 SSP Interrupt Test Register

#### 40.4.4.1 Offset 0Ch: SSITR - SSP Interrupt Test Register Details

Writing '1' to the corresponding bit position to the SSP Interrupt Test register generates an interrupt strobe signal to the Interrupt Controller for test purposes.

*Note:* SSITR functionality is available even when the SSP is disabled.

### 40.4.5 SSP Data Register

#### 40.4.5.1 Offset 10h: SSSDR - SSP Data Register Details

The SSP Data Register (SSDR) is a block of 32-bit locations that can be accessed by 32-bit data transfers. Transfers can be from 1 to 8 words. The SSSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO.

As the register is accessed by the system, FIFO control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted WRITE to a full Transmit FIFO). Status bits are available to show the system whether either buffer is full, above/below a programmable threshold, or empty.

For outbound data transfers (WRITE from system to SSP peripheral), the register may be loaded (written) by the system processor anytime the register is empty.

When a data size of less than 16-bits is selected, the user should not left-justify data written to the transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data less than 16-bits is automatically right-justified in the receive buffer. When the SSP is programmed for National Microwire frame format, the default size for transmit data is 8-bits (the most significant byte is ignored), the receive data size is controlled by the programmer using the DSS field in SSCR0.

The following table shows the location of the SSP data register. Note that both FIFOs are cleared when the block is reset or by writing a zero to SSE (SSP disabled).

|                              |            |                       |           |           |           |           |           |           |           |           |           |           |           |           |           |                             |                    |           |           |           |           |          |                 |          |          |          |          |          |          |          |          |

## 41.0 IEEE 1588 Time Synchronization Hardware Assist

---

### 41.1 Overview

This document describes the hardware-assist logic developed to achieve time synchronization on Ethernet and CAN.

In a distributed control system containing multiple clocks, individual clocks tend to drift apart. Some kind of correction mechanism is necessary to synchronize the individual clocks to maintain global time, which is accurate to some requisite clock resolution. For this purpose, you can use the IEEE 1588 standard, which defines a precision clock synchronization protocol for networked measurement and control systems. The IEEE standard defines several messages that you can use to exchange timing information. The hardware assist logic, required to achieve precision clock synchronization using the IEEE 1588 standard, is left to the implementation.

The time synchronization logic monitors the internal MII and GMII signals on the Gigabit Ethernet controller. Only Gigabit port 0 and port 1 are supported. The interrupt signals from CAN will also be monitored to allow CAN traffic to be time-stamped as well.

An interrupt signal to the host processor is generated by the 1588 Time Sync block when any of the following conditions occur and are enabled:

- Target Time expiration
- Auxiliary Target Time expiration
- Auxiliary Master Mode snapshot is taken
- Auxiliary Slave Mode snapshot is taken
- Pulse Per Second signal assertion

The System Time, Target Time and Aux Target Time registers are all 64 bits wide. When the system time is greater than or equal to the target time, the target time expiration condition will set. An interrupt enable mask must be set to allow the target time interrupt to pass to the core. The Aux Target Time register works the same as the Target Time register.

### 41.2 Feature List

A list of features is presented below:

- Supports IEEE1588-2008.
- Supports user-defined messages.
- Supports detection of IEEE 1588 messages for both receive and transmit directions.
- Supports Ethernet MII and GMII.
- Supports CAN 2.0B.
- Provides external signals to signify if a snapshot was taken.
- Provides external control over taking snapshots.

- Supports 15 ns resolution on the 1066 MHz and 1200 MHz SKUs.
- Supports 20 ns resolution on the 600MHz SKUs.
- Provides a Pulse Per Second output.

### 41.2.1 Signal Descriptions

- **Auxiliary Slave Mode Snapshot** – An active high level on this input causes a snapshot of system time to be captured in the ASMS register. Refer to [“Auxiliary Snapshots” on page 4765](#) for usage and restrictions.
- **Auxiliary Master Mode Snapshot** – An active high level on this input causes a snapshot of system time to be captured in the AMMS register. Refer to [“Auxiliary Snapshots” on page 4765](#) for usage and restrictions.
- **Test Mode Data** – This signal will reflect bits of the internal System Timer depending on the setting of internal control bits in the TS\_Test register.
- **Pulse Per Second Output** - This signal is asserted high when a match occurs between the Compare register and lower 32 bits of system time. Clearing of this signal is under firmware control. The register and pin can be used to create a pulse per second event.
- **Snapshot Taken Outputs** – These 2 signals will each pulse high for eight (8) pclk whenever a timestamp has been taken on the selected channel. (either TX or RX). The channel that is monitored is determined by the control bits in the TS\_Test Register.

### 41.3 Functional Block Diagram

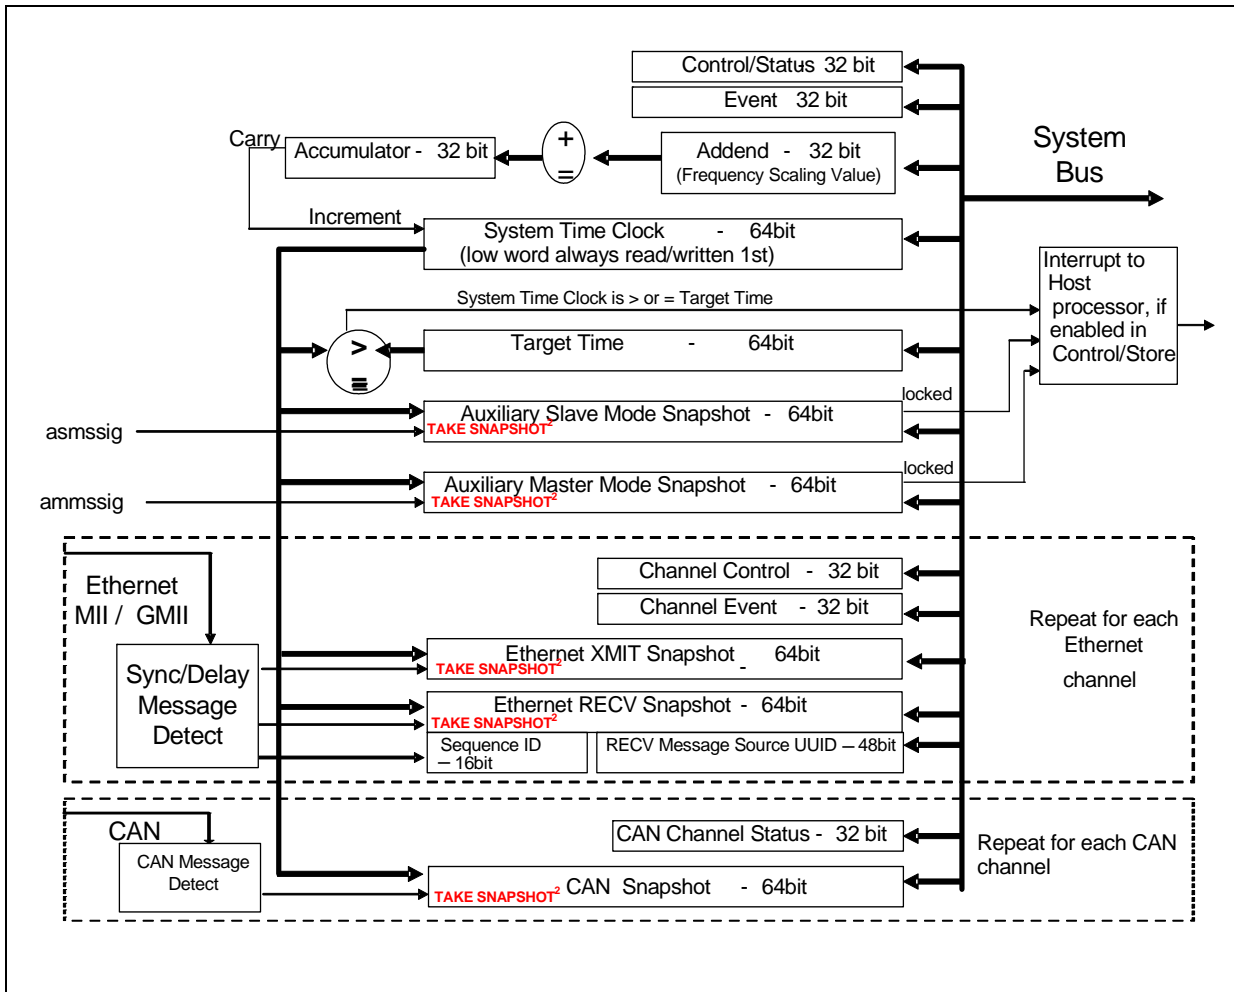

A programming model is shown in [Figure 41-1](#), showing registers and interconnections.

*Note:* If the functional block is the Master, the XMIT snapshot holds the “SYNC” message time and the RECV snapshot holds the DELAY” message time. If the unit is the Slave, the XMIT snapshot holds the “DELAY” message time and the RECV snapshot holds the “SYNC” message time.

*Note:* “Take snapshot” = Synch, edge detect, and lock, until reset by writing a “1” to the corresponding bit in the event register.

Figure 41-1. Programming Model

## 41.4 Usage Model

### 41.4.1 Channel Mapping

Ten channels are supported which are mapped to the Ethernet and CAN interfaces as shown in the table below:

Table 41-1. Channel Mapping to Interfaces

| Channel            | Interface Being Monitored | Notes                                   |
|--------------------|---------------------------|---|
| Ethernet Channel 0 | N/A                       | Reserved for future use                 |
| Ethernet Channel 1 | N/A                       | Reserved for future use                 |
| Ethernet Channel 2 | N/A                       | Reserved for future use                 |
| Ethernet Channel 3 | Gbe 0 GMII/MII            | Both GMII and MII modes supported       |
| Ethernet Channel 4 | Gbe 1 GMII/MII            | Both GMII and MII modes supported       |
| Ethernet Channel 5 | N/A                       | Reserved for future use                 |
| Ethernet Channel 6 | N/A                       | Reserved for future use                 |
| Ethernet Channel 7 | N/A                       | Reserved for future use                 |
| CAN Channel 0      | CAN 0                     | Supports simple timestamping of packets |
| CAN Channel 1      | CAN 1                     | Supports simple timestamping of packets |

## 41.5 Functional Description

### 41.5.1 IEEE 1588 Overview

A simplified view of an example 1588 Network topology is shown in [Figure 41-2, "Example Network Topology" on page 1623](#). Each device in an IEEE 1588 enabled network may have one or more ports each of which is defined to be a master or a slave port. Each slave synchronizes its internal clock to that of the master. Each master-enabled port may also act as a slave. The specific hierarchy of the network is determined dynamically.

There are five basic types of Precision Time Protocol (PTP) devices:

- Ordinary clock.
- Boundary clock.
- End-to-end transparent clock.
- Peer-to-peer transparent clock.
- Management node.

An **ordinary clock** communicates with the network via a single physical port. This interface is used to send and receive PTP messages, which are time stamped based on the value of the local clock. The ordinary clock can be the grandmaster clock in a system or it can be a slave clock in the master-slave hierarchy.

The **boundary clock** typically has several physical ports. Each port of a boundary clock is similar to the port of an ordinary clock, but the local clock is now common to all the ports. Each port of the boundary clock terminates all messages related to synchronization and establishing the master-slave hierarchy.

The **end-to-end transparent clock** forwards all messages just as a normal switch, router or repeater. However for PTP-event messages, the time the message takes to traverse the switch is measured and appended to the forwarded event messages.

The **peer-to-peer transparent clock** is similar to the end-to-end transparent clock however, it also measures peer-to-peer link delays in addition to the internal message traversal time.

A **management node** is a PTP device that is physically connected to the network and provides an user interface to the PTP management messages. It will not be discussed further here

**Figure 41-2. Example Network Topology**

The operation of a PTP enabled network is divided into two stages, Initialization and time synchronization.

#### 41.5.1.1 Initialization

At the initialization stage every master enabled node starts by sending Sync packets that include the clock parameters of its clock. These parameters include the source of the clock, the accuracy of the clock, it's variance, etc. Upon reception of a Sync packet, a node compares the received clock parameters to its own and if the received parameters are better, then this node moves to Slave state and stops sending Sync packets. When in slave state the node continuously compares the incoming packet to its currently chosen master and if the new clock parameters are better then the master selection is transferred to this master clock. Eventually the best master clock is chosen. Every node has a defined time-out interval in which if no Sync packet was received from its chosen master clock it moves back to master state and starts sending Sync packets until a new best master clock (BMC) is chosen.

#### 41.5.1.2 Time Synchronization

The time synchronization stage is different to master and slave nodes. If a node is at master state it should periodically send a Sync packet which is time stamped by hardware on the TX path (as close as possible to the PHY). After the Sync packet is sent, a Follow\_Up packet is sent which includes the value of the timestamp captured from the Sync packet. In addition the master should timestamp Delay\_Req packets on its RX path and return to the slave that sent it the timestamp value using a Delay\_Response packet. A node in Slave state should timestamp every incoming Sync packet and if it came from its selected master keep this value for time offset calculation. In addition it should periodically send Delay\_Req packets in order to

calculate the path delay from its master. Every sent Delay\_Req packet sent by the slave is time stamped and kept. With the value received from the master with Delay\_Response packet the slave can now calculate the path delay from the master to the slave.

The implementation of this protocol is typically distributed between hardware and software.

The HW responsibilities are:

- Identify the packets that require time stamping.
- Time stamp the packets on both RX and TX paths.
- Store the time stamp value for SW.
- Keep the system time in HW and give a time adjustment service to the SW.
- Maintain auxiliary features related to the system time.

The SW responsibilities are:

- BMC protocol execution which means defining the node state (master or slave) and selection of the master clock if in slave state.
- Read time stamps from HW and generate PTP packets.
- Calculate the time offset and adjust the system time using HW mechanism for that.
- Enable configuration and usage of the auxiliary features.

#### 41.5.1.2.1 Protocol for Ordinary and Boundary Clocks

The synchronization protocol flow and the offset calculation for an ordinary or boundary clock model are described in [Figure 41-3](#).

Figure 41-3. Clock Synchronization

Table 41-2. Clock Synchronization Protocol Flow

| Action  | Responsibility | Node Type |
|---|----------------|-----------|
| Generate a Sync Packet  | SW             | Master    |
| Timestamp the Sync packet and store the value in registers (T1)   | HW             | Master    |
| Timestamp the incoming Sync packet; store the value in a register (T2); and record the sourceID and sequenceID in registers | HW             | Slave     |
| Read the timestamp register (T1) and put the value in a Follow_Up packet and send it.                                       | SW             | Master    |
| Note the timestamp (T1) from the received Follow-up message   | SW             | Slave     |
| Generate a Delay_Req packet and send it   | SW             | Slave     |
| Timestamp the outgoing Delay_Req packet and store in register (T3)  | HW             | Slave     |
| Timestamp incoming Delay_Req message; store value (T4); record sourceID and sequenceID in registers                         | HW             | Master    |
| Read timestamp (T4) from register and send back to slave using a Delay_Response packet                                      | SW             | Master    |
| Note the timestamp (T4) from received Delay_Resp packet and calculate the time offset using T1, T2, T3, and T4              | SW             | Slave     |

41.5.1.2.2 Protocol for Transparent Switches

The synchronization protocol flow through a transparent switch is described in Figure 41-4.

Table 41-3. Transparent Clock Synchronization Protocol Flow

| Action   | Responsibility | Node Type          |
|--|----------------|--------------------|
| <b>Sync Packet</b>   |                |                    |
| Generate a Sync Packet   | SW             | Master             |
| Timestamp the Sync packet and store the value in registers (T1)  | HW             | Master             |
| Timestamp the incoming Sync packet; store the value in a register (T2); and record the sourceID and sequenceID in registers  | HW             | Transparent Switch |
| Forward the received Sync Packet to the slave  | SW             | Transparent Switch |
| Timestamp the Sync packet and store the value in registers (T2a)   | HW             | Transparent Switch |
| Timestamp the incoming Sync packet; store the value in a register (T3); and record the sourceID and sequenceID in registers  | HW             | Slave              |
| <b>Follow_Up Packet</b>  |                |                    |
| Read the timestamp register (T1) and put the value in a Follow_Up packet and send it.  | SW             | Master             |
| Forward the received Follow_Up packet, first appending the Residence Time (RC2) of the previous Sync packet. RC2 being the delay between receiving the Sync packet (T2) and transmitting the sync packet (T2a)                     | SW             | Transparent Switch |
| Note the timestamp (T1) and the residence time (RC2) from the received Follow-up message   | SW             | Slave              |
| <b>Delay_Req Packet</b>  |                |                    |
| Generate a Delay_Req packet and send it  | SW             | Slave              |
| Timestamp the outgoing Delay_Req packet and store in register (T4)   | HW             | Slave              |
| Timestamp incoming Delay_Req message; store value (T5); record sourceID and sequenceID in registers  | HW             | Transparent Switch |
| Forward the received Delay_Req Packet to the master  | SW             | Transparent Switch |
| Timestamp the outgoing Delay_Req packet and store the value in registers (T5a)   | HW             | Transparent Switch |
| Timestamp incoming Delay_Req message; store value (T6); record sourceID and sequenceID in registers  | HW             | Master             |
| <b>Delay_Response Packet</b>   |                |                    |
| Read timestamp (T6) from register and send back to slave using a Delay_Response packet   | SW             | Master             |
| Forward the received Delay_Response packet, first appending the Residence Time (RC5) of the previous Delay_Req packet. RC5 being the delay between receiving the Delay_Req packet (T5) and transmitting the Delay_Req packet (T5a) | SW             | Transparent Switch |
| Note the timestamp (T6) and the residence time RC5 from received Delay_Resp packet and calculate the time offset using T1, RC2, T3, T4, RC5 and T6   | SW             | Slave              |

Figure 41-4. Transparent Clock Switch Protocol Flow

### 41.5.1.3 PTP Message Formats

The time sync implementation supports both IEEE1588 V1 and IEEE1588-2008 PTP messages. The format for each of these is shown in Table 41-4.

When a PTP message containing packet is recognized, the PTP version is checked. If it is V1 PTP message then the control field contains the message type. The message type decoding is shown in Table 41-5 and Table 41-6.

**Table 41-4. IEEE1588 Version 1 and IEEE1588-2008 PTP Message Formats**

| Offset in bytes | V1 Fields                       | IEEE1588-2008 Fields                 |
|-----------------|---------------------------------|--------------------------------------|
| 0               | VersionPTP                      | Transport Specific/messageId         |
| 1               |                                 | Reserved (4 bits)/VersionPTP(4 bits) |
| 2               | VersionNetwork                  | MessageLength                        |
| 3               |                                 |                                      |

### 41.5.2 Time Stamping Operation

Time stamping means that the current value in the system time register is captured in a second register, generally called a snapshot register.

The time stamping will occur when the appropriate conditions exist such as an auxiliary input is received or when a particular type of message is transmitted or received by the channel. Once a timestamp of system time is taken and locked, a unique indication for the snapshot is set in the appropriate Event register. No further timestamps of that

type can be received until the snapshot indication is cleared by firmware. Thus, the setting of the indication is a lockout of further snapshots of a particular type until firmware takes action (unless the traffic analyzer lock inhibit feature is enabled).

#### 41.5.2.1 Sync Messages

The SW for the master channel sends a Sync message periodically over the network at 1-, 2-, 8-, 16-, or 64-second intervals.

If the channel is a master, the Time Sync logic will monitor the interface and detect when a Sync message has been transmitted. When a Sync message is detected and the XMIT\_Snapshot is not locked out, the message is time stamped and the current system time is captured in the XMIT\_Snapshot register. If the message is transmitted with no errors, the XMIT\_Snapshot is locked.

If the channel is a slave, the Time Sync logic will monitor the interface and detect when a Sync message has been received. When the Sync message is detected and the RECV\_Snapshot is not locked out, the message is time stamped and the current system time is captured in the RECV\_Snapshot register. If the message is received with no errors, the RECV\_Snapshot is locked.

When the snapshot of the Sync message has occurred, an indication asserts in the TS\_Channel\_Event register and remains set until firmware explicitly writes a '1' back to that bit. Until the Sync message snapshot indication is cleared, no further Sync messages will be time stamped. Locking can be inhibited by setting the TS\_Channel\_Control register appropriately.

#### 41.5.2.2 Follow-up Messages

The Time Sync logic performs no action related to Follow-up messages. It is the responsibility of the SW for the Master to read the XMIT\_Snapshot register and send the Follow-up message containing this timestamp.

#### 41.5.2.3 Delay\_Req Message

Slave channels transmit a Delay\_Req message to the master in response to receiving a Sync message.

If the channel is a master, the Time Sync logic will monitor the interface and detect when a Delay\_Req message has been received. When the message is detected and the RECV\_Snapshot is not locked out, the message is time stamped and the current system time is captured in the RECV\_Snapshot register. If the message is received with no errors, the RECV\_Snapshot is locked.

If the channel is a slave, the Time Sync logic will monitor the interface and detect when a Delay\_Req message has been transmitted. When the message is detected and the XMIT\_Snapshot is not locked out, the message is time stamped and the current system time is captured in the XMIT\_Snapshot register. If the message is transmitted with no errors, the XMIT\_Snapshot is locked.

When the snapshot for the Delay\_Req message has occurred, an indication asserts in the TS\_Channel\_Event register and remains set until firmware explicitly writes a '1' back to that bit. Until the Delay\_Req message snapshot indication is cleared, no further Delay\_Req messages will be time stamped. This is important to note since multiple slave channels may try to send Delay\_Req messages simultaneously. Locking can be inhibited by setting the TS\_Channel\_Control register appropriately.

#### 41.5.2.4 Delay\_Response Messages

The Time Sync logic performs no action related to Delay\_Response messages. It is the responsibility of the SW for the Master to read the RECV\_Snapshot register and send the Delay\_Response message containing this timestamp.

#### 41.5.2.5 Error Handling

The time synchronization hardware depends on software for filtering appropriate IEEE-1588 packets. When the software receives a Sync or Delay Request message, it interrogates the 1588 hardware for time snapshot information. However before using this data, the software must do several reasonableness checks on the data. This is due to the possibility of lost messages, the limited 1588 queue size of 1 entry, the possibility of multiple domains (the 1588 hardware only supports 1 domain), the asynchronous nature of the software clearing the timestamp lock with respect to possible incoming messages, and other similar events. Therefore the hardware includes some mechanisms to assist the software filtering, such as the capture of the UUID and Sequence Count.

When a time sync message is received by software that is expected to have an associated timestamp, the software should perform the following checks:

1. Compare snapshot UUID to UUID in received 1588 packet.
2. Compare snapshot Sequence Count to Sequence Count in received 1588 packet.
3. Verify that timestamp is different than last timestamp.

If any of these tests fail, the software should clear the lock and discard the information.

### 41.5.3 IEEE1588 over Ethernet

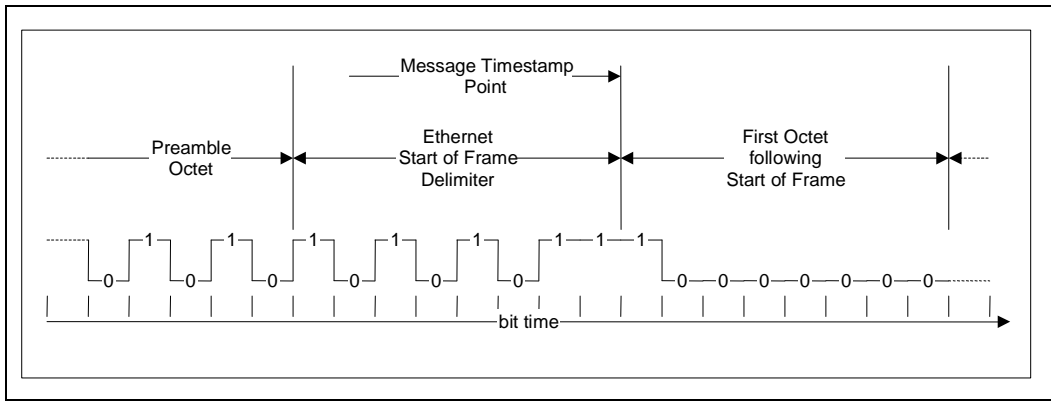

#### 41.5.3.1 Timestamping Mechanism

Per the 1588 specification, synchronized time is referenced to the end of the “start of frame delimiter” (SFD) as shown [Figure 41-5](#).

The time sync hardware captures the system time immediately upon detection of the SFD. The timestamp point is immediately after the SFD. This timestamp is stored in the snapshot register and is frozen in the snapshot register when the last nibble of the frame CRC is transmitted or received and the overall message is detected with no errors. If an errored frame is detected (TX\_ERR or RX\_ERR are asserted) then the frame/message will be ignored.

Due to PHY and synchronization delays, the actual timestamp will be slightly later than the desired reference point. However, allowing for 1  $pclk$  synchronization jitter, this is a fixed delay, easily nulled out in the software portion of the algorithm. This fixed delay is dependent on the 10/100/1000 MHz selection at the PHY. Therefore, a constant can be subtracted from the snapshot to compensate for PHY and synchronization delays to arrive at the IEEE-1588 specified time stamp point.

Figure 41-5. Time Stamp Reference Point

### 41.5.3.2 PTP Message Detection in Ethernet Frames

IEEE1588 PTP messages may be detected within three types of ethernet frames.

- L4 UDP frames where the port is of the type “EventPort”
- L2 Ethernet frames where the EtherType is defined to be “IEEE1588”
- A user defined frame in which configurable offsets, masks and compare values can be defined by the user via registers. This mode is provided to facilitate usage with a custom or otherwise non-IEEE1588 compliant system.

The specific decoding to identify a PTP containing frame is shown in [Table 41-7](#).

Table 41-7. PTP Frame Identification

| Field   | Field Size | L4  | L2  | User Defined                |
|---|------------|---|---|-----------------------------|
| <b>Ethernet Header</b>                                |            |   |   |                             |
| Dest MAC Address                                      | 6          | x   | x   | x                           |
| Source MAC Address                                    | 6          | x   | x   | x                           |
| EtherType   | 2          | 0x0800<br>--- OR ---<br>0x8100 (indicates tagged frame) | Programmable value (default = 0x88f7 IEEE1588)<br>--- OR ---<br>0x8100 for tagged frame | Programmable mask and value |
| <b>VLAN Header</b>                                    |            |   |   |                             |

When the mode of operation is "Locked", the timestamp taken after the SFD is frozen in the snapshot registers and will not be updated until the software reset it.

When the mode of operation is not "Locked", Each message is time stamped at the reception of a start of frame delimiter (SFD), however the snapshot registers will be overwritten with the arrival of a subsequent PTP message.

#### 41.5.4 IEEE1588 over CAN

The time synchronization logic supports a hardware assist implementation for a CAN network (e.g. DeviceNet). The 1588 protocol operates over a CAN network in much the same way as it does over Ethernet, using the same time synchronization messages identified earlier. However, the CAN protocol requires that these relatively lengthy messages are broken into much smaller frames. This fragmentation prevents one device from utilizing excessive bandwidth and maintains real time access to the network for all devices.

Since the CAN protocol breaks up 1588 messages into small frames and the frames do not carry 1588 specific identifiers, it is not practical to identify the 1588 Sync and Delay Request messages in hardware. Therefore, the hardware merely captures a timestamp into a holding register at the appropriate point in each and every frame that is transmitted or received. The software has the responsibility to log the captured timestamp as part of each frame, as the software processes the transmit done interrupt (at the completion of a sent frame) or the received frame ready interrupt (at the availability of a received frame).

This hardware assisted approach eliminates the potential for variable software interrupt service times from introducing jitter in the time snapshot and provides improved accuracy over a software-only approach. However, it does require significant software support. For example, when using 1588 hardware support for CAN, the multiple message buffers and screeners of the normal CAN block cannot be used in a continually over-writing updating mode without processor intervention. This is due to the fact that the software must read and save the time snapshot before the next message is sent or received. Therefore, when 1588 hardware support is used, software will only be able to effectively use 1 screener/buffer and must guarantee that all CAN frame interrupts are

serviced, which may come as often as the minimum frame size. These requirements should be easily met since CAN is a half duplex protocol operating at a relatively low baud rate.

When a CAN packet is received or transmitted, the interrupt signal from the CAN device will assert and cause a snapshot of system time to be captured in the `TS_CanSnapLo` and `TS_CanSnapHi` registers. The `TS_CanSnapLo` register contains the lower 32 bits of the time value, and the `TS_CanSnapHi` register contains the upper 32 bits. The interrupt signal from the CAN must be enabled to assert on receive and transmit completion of each packet in order to capture snapshots for CAN packets. It is up to the firmware to assemble the packets into messages and determine which packet's snapshot is the appropriate one for the entire message. There is one pair of CAN snapshot registers (low and high) for each CAN device.

Therefore, for each CAN device, the assertion of the CAN interrupt signal when a frame transmit or receive is completed will capture the system time in a 64-bit snapshot register for that CAN device. Each frame that is received or transmitted will have a snapshot taken. Firmware will process the frames as part of the overall message evaluation, identify valid time sync messages, and determine the appropriate snapshot to utilize. Two CAN channels are currently supported.

*Note:* In order to Timestamp CAN activity the following assumptions must be valid.

- The CAN interrupts from the CAN controller MUST be serviced by Software before the next CAN frame is detected. The initial assertion of the interrupt signal will initiate a time snapshot of the first frame but no further snapshots will be taken and no 1588 overflow will be set on any subsequent frames. However, this condition is detected, not by the 1588 block but by the CAN controller itself. The primary detection of a missed CAN interrupt is still (and always was) an overrun condition in the CAN controller.
- In 1588 mode, it is expected that only one of the 16 available CAN receive buffers will be enabled and used. The relatively slow speed of the CAN channel makes this an acceptable trade-off between hardware and performance. When a frame is received, the CAN controller sets the buffer's `MsgAv` bit. If another frame is received and no receive buffers are available (as would be the case if only one buffer was enabled and its `MsgAv` bit was set from a previous frame not yet serviced), the `RxMsgLost` flag is set in the CAN IP. Thus the software would recognize this overflow condition by the `RxMsgLost` flag when it finally got around to servicing the interrupt.

#### 41.5.5 Auxiliary Snapshots

Time stamps may also be taken based on externally provided signals (`asmssig` and/or `ammssig`). These time stamps are recorded in the auxiliary snapshot registers.

When the signal is asserted the hardware will take a timestamp and set the lock. Software may then be notified via interrupt (if so configured) and it will read the appropriate register. If the software clears the lock before the signal is de-asserted, then a second, redundant snapshot event will be generated.

*Note:* Hardware filtering and edge-detection were considered but not implemented because the signal quality from the master could be bad enough to cause spurious locks. For example, cables to a GPS could be a kilometer or more in length and the type of cable could be a factor as well. The firmware handles the filtering and MUST not clear the lock until after the master has negated the snapshot input.

### 41.5.6 Target Time Expiration

A system time that is greater than or equal to the target time sets the target time expiration condition and generates an interrupt if enabled.

Two independent target times are supported.

Refer to Section 41.6.1.11, "Offset 0028h: TS\_TrgtLo - Target Time Low Register" and Section 41.6.1.12, "Offset 002Ch: TS\_TrgtHi - Target Time High Register".

Also, Section 41.6.1.28, "Offset 01F0h: TS\_Aux\_TrgtLo - Auxiliary Target Time Low Register" and Section 41.6.1.29, "Offset 01F4h: TS\_Aux\_TrgtHi -Auxiliary Target Time High Register"

### 41.5.7 System Time

The system timer is derived from the source clock through a frequency divider. The frequency divider is based on the value in the Addend register. Once every system clock cycle the value in the Addend register is added to the value in the Accumulator register. When the accumulator register rolls over, the system timer is incremented.

A single SourceClock is provided from which the desired SystemClock can be derived via a frequency divider. The frequency divider is implemented by using the Addend register. Once every SourceClock cycle the value in the Addend register is added to the value in the Accumulator register. When the accumulator register rolls over, the system timer is incremented. Thus, the system timer is incremented once every SystemClock period.

The value in the Addend register represents the frequency compensation value. This value is determined as follows:

$$\text{FreqDivisionRatio} = \text{FreqOscillator} / \text{FreqClock}$$

The equation for the frequency compensation value utilizes the precision of the accumulator and the FreqDivisionRatio. Since the accumulator is 32 bits, the following equation applies:

$$\text{FreqCompensationValue} = 2^{32} / \text{FreqDivisionRatio}$$

The hexadecimal representation of the FreqCompensationValue is the value that is written to the Addend register. The following table gives examples of addend values based on a 66.67 MHz FreqOscillator:

Table 41-9. Addend Values

| FreqOscillator <sup>1</sup> | FreqClock | FreqDivisionRatio | FreqCompensationValue |
|-----------------------------|-----------|-------------------|-----------------------|
| 66.67 MHz                   | 40 MHz    | 1.67              | 0x994B1D20            |
| 66.67 MHz                   | 50 MHz    | 1.33              | 0xC07B301E            |
| 66.67 MHz                   | 60 MHz    | 1.11              | 0xE6A17102            |

1. 50 MHz for 600 MHz IA-32 core and 66.67 MHz for 1066 MHz/1200 MHz IA-32 core.

### 41.5.8 Interrupts

An level sensitive interrupt signal to the processor is generated when any of the following conditions occur and are enabled:

- Auxiliary Master Mode snapshot is taken
- Auxiliary Slave Mode snapshot is taken
- Target time expiration.
- Auxiliary Target Time expiration
- Pulse per Second assertion

An interrupt enable mask must be set to allow any of the interrupts to pass to the core.

### 41.5.9 Reset

There are two types of reset:

- Power-on reset
- MMR write to soft reset register to initiate a channel

Each channel may be independently reset by SW by writing to the channel's control register.

If the GMII interface changes clock speeds (1000Mbps down to 100/10 Mbps), SW must initiate a soft reset to the corresponding channel.

## 41.6 Register Summary

Writes to unused address space will have no affect. Reads to unused address space may return indeterminate data. Neither situation should cause detrimental effects on device operation unless specifically documented. Reserved bits within registers must be written with their reset value unless otherwise stated.

For more information on the conventions the following register summaries adopt, see [Section 7.1, "Overview of Register Descriptions and Summaries" on page 183.](#)

The IEEE 1588 Hardware Assist registers materialize in the PCI space

[Table 41-10](#) summarizes the IEEE 1588 TSYNC materialization from the PCI perspective.

| 5 : 5                | atp                   | <b>Auxiliary Target Time Interrupt Pending.</b> This bit is the Auxiliary Target Time interrupt pending indication. When this bit is set, it indicates that the Auxiliary Target Time interrupt condition has occurred, which means that the System Time value has reached the 64-bit Auxiliary Target Time register value. If <b>atm</b> in the Time Sync Control register is set, the interrupt will be passed to the Host processor. To clear this condition and also the interrupt to the Host if no other sources are driving it, the firmware must write a '1' to the <b>atp</b> bit. To prevent an immediate reoccurrence of the auxiliary target time interrupt, the processor should first write a new value to the Auxiliary Target Time register and then clear the condition. This bit is set at power-up since both the System Time and the Auxiliary Target Time are reset at power-up to 0x0000000000000000. |                                     |                         | 1  | RWC        |
| 4 : 4                | pps                   | <b>PPS Match.</b> This event bit sets when the lower 32 bits of the system time register is equal to the 1PPS Compare register. When this signal is asserted high, an interrupt will be generated to the Host on the ts_intreq if the ppsm bit in the Time Sync Control register is also set. This signal also drives the ts_pps output pin of the TimeSync block. The user will clear pps by writing a '1' to it.  |                                     |                         | 0h   | RWC        |

| 31 : 0   | TS_PPS_Compare            | <p><b>The PPS Compare register</b> is a 32-bit register that contains a value that will be compared against the lower 32 bits of system time. The value placed in this register defines the value of the lower 32 bits of system time required to generate a 1 pulse per second signal to an external scope. When the two values are equal, the pin ts_pps is asserted</p> <p>Concurrently, the state of the signal is visible as the pps bit in the TS_Event register. The pps signal can also interrupt the Host if the ppsm bit in the TS_Channel register is set. It is the firmware's responsibility to calculate the new compare value for the next pulse per second and update this register accordingly. The bits of this register are set at reset in order to prevent ts_pps from asserting right after reset.</p> |                                     | FFFFFFFFh               | RW   |
| <b>Note:</b> The PPS output controlled by this compare register is independent of the TM bit in the TS_TEST register |                           |  |                                     |                         |  |

| 31 : 0               | RawSystemTime_High    | This register contains the upper 32 bits of system time. When you want to read or write the system time, this register typically first accesses the RawSystemTime_Low Register. This register pair contains the raw system timer value, and no latching of system time occurs when the lower half is read. Time could increment between the reading of the lower 32 bits in the RawSystemTime_Low register and the reading of this register. |                                    |                         | 0000h  | RO         |

| <b>Size:</b> 32 bits | <b>Default:</b> 0000h |  |                                     | <b>Power Well:</b> Core |  |
| Bit Range            | Bit Acronym           | Bit Description  | Sticky                              | Bit Reset Value         | Bit Access   |
| 31 : 0               | SystemTime_Low        | <p>The system timer is a loadable up-counter, and reflects the local time in the module. While the system timer is 64 bits wide, the lower 32 bits reside in this register. The system timer is clocked by the module system clock and incremented when the Accumulator register rolls over.</p> <p>To read the entire system time value, the user must read this location first. Reading this location captures the upper 32 bits of the system time in a temporary register, which is accessed when the user reads the SystemTime_High Register next.</p> <p>Likewise, the SystemTime_Low Register must be written first when the user wants to write a new 64-bit value to system time. The data written to this register is captured in a holding register. When the user writes to the SystemTime_High Register, all 64 bits are then written to the system timer. Updating the system time with a direct write has precedence over increments to the system time based on an Accumulator rollover.</p> |                                     | 0000h                   | RW   |

## 42.0 Local Expansion Bus Controller

---

### 42.1 Overview

The Expansion bus controller provides an interface from to external Expansion target devices.

The Expansion bus controller includes a 25-bit address bus and a 16-bit wide data path. The expansion bus supports Intel multiplexed, Intel non-multiplexed, Intel StrataFlash® technology, Intel StrataFlash® Synchronous Memory, Micron\* Flow-Through ZBT, Motorola\* multiplexed, Motorola non-multiplexed, and Texas Instruments\* Host Port Interface (HPI) target devices.

Byte-wide devices may also be used by programming the channel connection for 8-bit operation. For TI DSPs that support an internal bus width of 32 bits, the multiplexed HPI-8 or HPI-16 interface can be used to complete these transfers.

### 42.2 Feature List

- Outbound transfers (the EP80579 integrated processor is the master to an external target device).
- Eight programmable target chip selects.
- Twenty five bits of address; sixteen bits of data.
- Supports Intel mode and Motorola\* mode bus cycles.
- Supports Intel StrataFlash® technology.
- Supports 66-MHz Intel StrataFlash® Synchronous Memory (16-bit only).
- Supports 16-bit Micron Flow-Through ZBT (Zero bus turnaround) SRAMS.
- Supports 8-bit and 16-bit Texas Instruments HPI specifications.
- Multiplexed or non-multiplexed address / data buses for Intel/Motorola\*/HPI bus cycles.
- Supports even and odd parity generation and calculation for Intel/Motorola\*/Micron\* ZBT modes.
- Maximum clock input frequency of 80 MHz.
- Minimum input clock frequency of 33MHz.

## 42.3 Block Diagram

Figure 42-1. Expansion Bus Controller

## 42.4 Theory of Operation

The Expansion bus controller supports outbound transfers that are initiated by the EP80579 that target Expansion bus slaves. The Expansion data bus is 16 bits wide and the address bus is 25 bits wide.

Since the Expansion bus controller has only 1 outbound transaction queue, outbound accesses all complete in order.

### 42.4.1 Outbound Transfers

For outbound data transfers, the Expansion bus controller occupies up to 256 Mbytes of address space in the EP80579's memory map (refer to signal EX\_ADDR [24:0] in [Table 48-24, "Expansion Bus Signals"](#)) and contains a 1-deep address queue, an 8-word write data fifo, and an 8-word read data FIFO. Eight chip selects are supported to allow up to eight independent external devices to be connected. The address space for each chip select is up to 32 Mbytes.

An external clock input, EX\_CLK, is required to operate the Expansion interface. The maximum clock frequency supported by the Expansion bus controller is 80 MHz. The clock input is provided to allow a wide variety of different peripherals to be connected to the Expansion interface. To provide a glue-less interface to a wide variety of devices, the Expansion bus controller supplies eight chip selects to a 16-bit wide external bus, which can be configured as Intel, Synchronous Intel, Micron ZBT, Motorola, or HPI-style controls. The signaling characteristics and timing for each chip select is individually programmable.

For Synchronous Intel StrataFlash Memory, the Expansion bus controller only supports single word asynchronous page-mode read and synchronous burst-mode read (1-8 words). It does not support page mode read mode or single word latched asynchronous read mode. When configuring a Synchronous Intel StrataFlash Memory, wait polarity must be programmed to active low, data hold programmed to one clock, wait delay be deasserted with valid data and clock edge programmed to rising edge. For 16-bit Synchronous Intel devices, the burst length must be programmed to 16-word bursts. The latency count must be programmed to the appropriate value that is defined in the specific Synchronous Intel StrataFlash Memory specification.

The Expansion Bus interface signals need to be connected based upon the device type (Intel, Synchronous Intel, Micron ZBT, Motorola, or HPI-style control signals) and a sample mapping of the pins are shown in Table 42-1.

**Table 42-1. Example Expansion Bus Pin Mappings to Target Devices**

| Pin            | Intel StrataFlash® 28F128J3A | Synchronous Intel StrataFlash 28F256K3 | Motorola* MCM6946 | Micron* ZBT MT55L128L36 F1 | TI * HPI TMS320UC540 9 |

The EX\_IOWAIT\_N signal is available to be shared by the devices attached to chip 0 through 7, when the chip selects are configured in Intel or Motorola mode of operation. The EX\_IOWAIT\_N signal allows an external device to hold off completion of the read or write phase of a transaction until the external device is ready to complete the transaction.

Similarly, EX\_RDY[3:0] are provided for chip selects 7 through 4, respectively. The EX\_RDY[3:0] signals are used to hold off data transfers when chip selects 7 through 4 are configured in HPI mode. For example when chip select 5 is configured in HPI mode of operation, chip select 5 will no longer respond to the EX\_IOWAIT\_N signal and will only respond to the EX\_RDY\_N[1]. All other chip selects will respond to the EX\_IOWAIT\_N signal. Chip selects 7 through 4 are the only chip selects that can be configured in HPI mode of operation.

#### 42.4.1.1 Chip Select Address Allocation

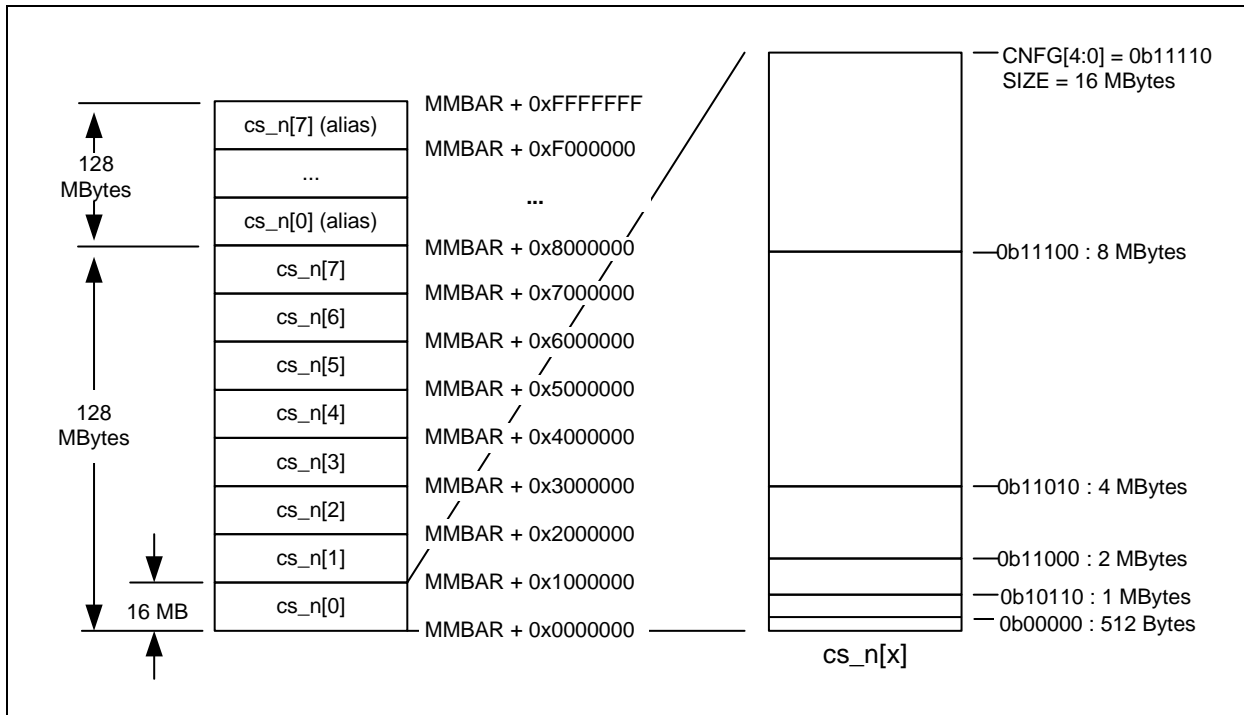

The Expansion bus controller occupies up to 256 Mbytes of address space in the EP80579 memory map. The Expansion bus controller uses bits 27:0, from the internal bus, to determine how to translate the internal bus address to the Expansion Bus Address. If there are no 32 MByte devices programmed (i.e., All eight EXP\_TIMING\_CS registers bit 9 equal 0), the lower 24 bits of the internal bus address are translated to the lower 24 bits of the Expansion Bus address, EX\_ADDR [23:0]. EX\_ADDR[24] will always be zero. Bits 26:24 of the internal bus are used to decode one of eight chip-

select regions implemented by the Expansion bus, each region being 16 Mbytes. Address bit 27 is not used and will currently alias each chip select region as shown on the left side of Figure 42-2.

The right side of Figure 42-2 shows the implementation of bit 13:10 of the each Timing

**Figure 42-2. Chip Select Address Allocation When There Are no 32-MByte Devices Programmed**

and Control (EXP\_TIMING\_CS) Register. A Timing and Control (EXP\_TIMING\_CS) Register is implemented for each of the eight chip selects. Each chip select defines a base region size of 512 bytes with the actual size of the region given by the formula shown in Figure 42-3. If the address is outside of the programmed region, the Expansion bus controller responds with an error.

**Figure 42-3. Expansion Bus Memory Sizing**

Region Size =  $2^{(9+CNFG[4:1])} + 16 * CNFG[0]$

For Examples of how to use this feature:

If bits 13:9 of Timing and Control (EXP\_TIMING\_CS0) Register 0 = "00000" an address space of  $2^9 = 512$  Bytes is defined for chip select 0 (EX\_CS0\_N).

If bits 13:9 of Timing and Control (EXP\_TIMING\_CS1) Register 1 = "10000" an address space of  $2^{17} = 128K$ Bytes is defined for chip select 1 (EX\_CS1\_N).

If bits 13:9 of Timing and Control (EXP\_TIMING\_CS2) Register 2 = "11110" an address space of  $2^{24} = 16M$ bytes is defined for chip select 2 (EX\_CS2\_N).

If bits 13:9 of Timing and Control (EXP\_TIMING\_CS7) Register 7 = "00001" an address space of  $2^{25} = 32M$ bytes is defined for chip select 7 (EX\_CS7\_N).

If there is a 32-MByte device programmed in any of the eight EXP\_CS\_TIMING registers, a different memory map is used as shown in Figure 42-4. The lower 25 bits of the internal bus address are translated to the lower 25 bits of the Expansion Bus address, EX\_ADDR [24:0]. Bits 27:25 of the internal bus are used to decode one of eight chip-select regions implemented by the Expansion bus, each region being 32 Mbyte. If a design has 16-MByte or smaller devices on all of the chip selects, one of the EXP\_CS\_TIMING register could be programmed to a 32-Mbyte device so the Expansion bus address mapping will not change if that design switches to 32-Mbyte device sometime in the future. The Expansion bus controller will still work with the smaller device, however an error response will not be generated if there is an access outside the device window for that device.

#### 42.4.1.2 Address and Data Byte Steering

Figure 42-4. Chip Select Address Allocation when a 32 Mbyte device is programmed

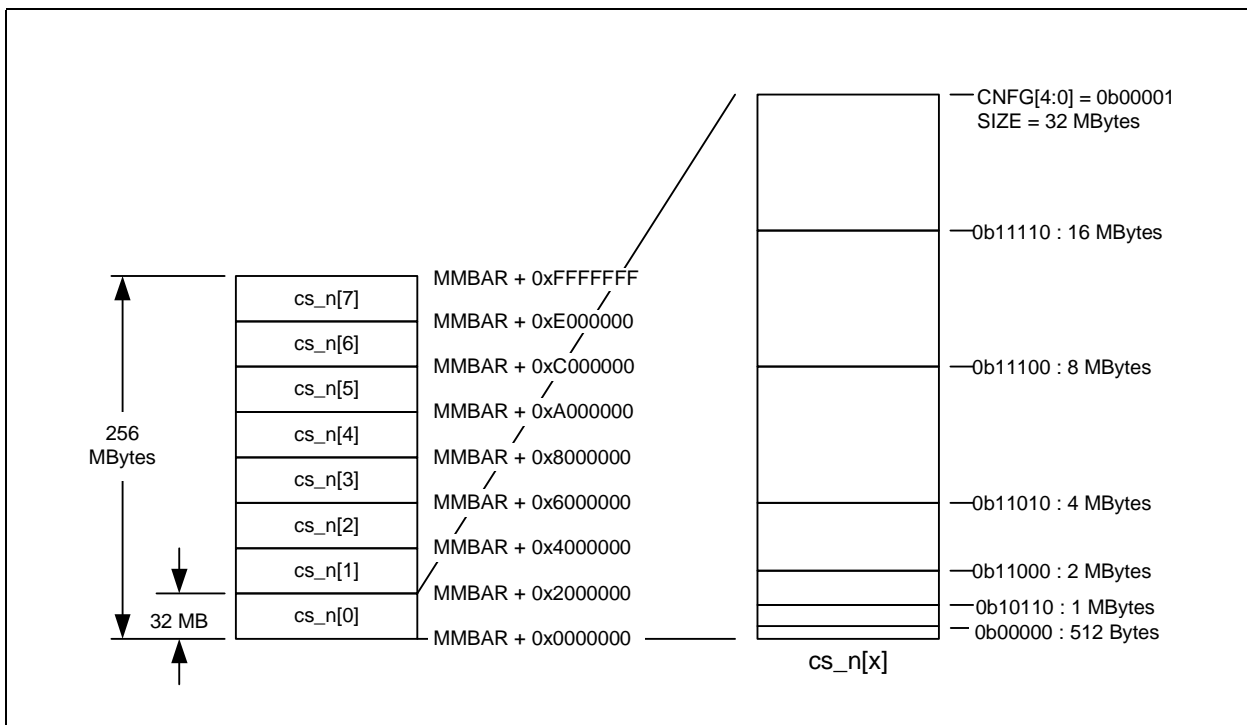

Table 42-2 shows the address and data mapping from the internal bus to the Expansion Bus. This table applies to Intel, Synchronous Intel, Micron ZBT and Motorola defined cycles only. For 32-bit read operations to a byte/halfword wide interface, multiple bytes are collected and then transferred as a complete 32-bit word. This pattern occurs as shown below for any allowable sub-length read access. Four and eight word reads are also supported and generate multiple accesses to the target device. Four and eight word reads to Synchronous Intel, only generate one burst access to the device. Byte enables are generated for both reads and writes and are valid the same cycles (T1-T4 phases) as EX\_ADDR is valid. Byte write devices (devices that need EX\_BE\_N asserted in the same exact cycles that EX\_WR\_N is asserted) are not supported. The internal bus is always big endian format; the Expansion bus is big endian as well. The data byte steering for each cycle type is showing in Table 42-2.

For 8-bit devices, EX\_DATA[31:8] must not toggle to conserve power. Similarly, for 16-bit devices, EX\_DATA[31:16] must not toggle. For sub-word writes to 32-bit devices, EX\_DATA must not toggle for byte enables not asserted.

### 42.4.1.3 Expansion Bus Interface Configuration

Table 42-2. Expansion Bus Address and Data Byte Steering (Sheet 1 of 2)

| Internal Bus Cycle | Device Width Connected to Expansion Bus (8-bit or 16-bit) | Internal Address Value (Internal _ADDR[1:0]) | Expansion Bus Address Value (EX_ADDR[1:0]) | Data Location Translation Between Expansion Data Bus and Internal Data Bus |

There are eight registers called the Timing and Control (EXP\_TIMING\_CS) Registers that define the operating mode for each chip select. When designing with the Expansion Bus Interface, placing the devices on the correct chip selects is required.

Chip Select 0 through 7 can be configured to operate with devices that require an Intel, Synchronous Intel, Micron ZBT or Motorola Micro-Processor style bus accesses. These chip selects can be configured to operate in a multiplexed or a simplex mode of operation for either Intel- or Motorola-style bus accesses. Additionally, Chip Select 4 through 7 can be configured to generate Texas Instruments HPI-style bus accesses. The mode of operation (Intel, Motorola, TI HPI, or Synchronous Intel, Micron ZBT) is set by bits 15, 14, and 8 of each Timing and Control (EXP\_TIMING\_CS) Register. [Table 42-6 on page 1698](#) shows the possible settings for the Cycle Type selection using bits 15, 14, and 8 of the Timing and Control (EXP\_TIMING\_CS) Register.

Once the cycle type has been determined, the mode of operation must be set. There are two configurable modes of operation for each chip select, multiplexed and non-multiplexed. Bit 4 of the Timing and Control (EXP\_TIMING\_CS) Registers is used to select this mode. If bit 4 of the Timing and Control (EXP\_TIMING\_CS) Register is set to logic 1, the access mode for that Chip Select is multiplexed. Likewise, if bit 4 of the Timing and Control (EXP\_TIMING\_CS) Register is cleared to logic 0, the access mode for that Chip Select is non-multiplexed. For Synchronous Intel, Micron ZBT memories bit 4 must be programmed to logic 0. Multiplexed and non-multiplexed can imply different operations depending upon the Cycle Type that is selected.

The size of the data bus for each device connected to the Expansion bus must be configured. The data bus size is selected on a per-chip-select basis, allowing the most flexibility when connecting devices to the Expansion bus. There are two valid selections that can be configured for each data bus size, 8-bit or 16-bit. Bit 0 of each Timing and Control (EXP\_TIMING\_CS) Register is used to select the data bus size on a per-chip-select basis.

Each chip select can be independently enabled or disabled by setting a value in bit 31 of each Timing and Control (EXP\_TIMING\_CS) Register. Clearing bit 31 of the Timing and Control (EXP\_TIMING\_CS) Register to logic 0 disables the corresponding chip select. Setting bit 31 of the Timing and Control (EXP\_TIMING\_CS) Register to logic 1 enables the corresponding chip select. Accesses to chip selects that are disabled result in an error response.

Split transfers are supported for all read transfer types and controlled by setting bit 3 (SPLT\_EN) of the Timing and Control (EXP\_TIMING\_CS) Register. Setting bit 3 of each Timing and Control (EXP\_TIMING\_CS) Register to logic 1 enables split transfers for accesses to the corresponding chip select. Clearing bit 3 of each Timing and Control (EXP\_TIMING\_CS) Register to logic 0 disables split transfers for accesses to the corresponding chip select. Enabling split transactions allows for more efficient utilization of the internal bus, especially for slow external expansion bus devices. For higher performance devices with low read latencies, disabling split transactions may provide better performance.

Each chip select region has the ability to be write-protected by setting bit 1 of each Timing and Control (EXP\_TIMING\_CS) Register. When bit 1 of Timing and Control (EXP\_TIMING\_CS) Register is cleared to logic 0, writes to a specified chip select region results in an error response. When bit 1 of Timing and Control (EXP\_TIMING\_CS) Register is set to logic 1, writes are allowed to a specified chip select region. Chip select 0 will be write-protected after reset.

For chip selects 4 through 7 configured in HPI mode of operation, there is an associated ready bit (EX\_RDY [3:0]). The ready bit is only used when the mode of operation is set to Texas Instruments HPI mode. The ready bits are used to hold off the host processor when the given DSP is not ready to complete the transfer. However, the polarity of this ready bit can vary based upon the DSP that is selected. Bit 5 of each Timing and Control (EXP\_TIMING\_CS) Register allows the polarity used by each ready bit to be independently set. When bit 5 of the Timing and Control (EXP\_TIMING\_CS) Register is cleared to logic 0, the ready bit is cleared to respond to an active low signal (logic 0). When bit 5 of the Timing and Control (EXP\_TIMING\_CS) Register is set to logic 1, the ready bit is set to respond to an active high signal (logic 1).

One final set of parameters that may be set prior to using Expansion Bus Interface Chip Select 1 through Chip Select 8. After boot up, these parameters may be adjusted for Chip Select 0 as well. These five parameters are the timing extension parameters for each phase of an Expansion Bus access.

There are five phases to every Expansion Bus access:

- T1 – Address Timing
- T2 – Setup/Chip Select Timing

- T3 – Strobe Timing
- T4 – Hold Timing
- T5 – Recovery Phase

For Synchronous Intel mode, the T1, T2, T3, T4, T5 timing parameters are only used for writes. For Synchronous Intel reads, the Expansion bus controller uses the Count value programmed in the EXP\_SYNCINTEL\_COUNT register to determine how many cycles before data is valid (based on the timing parameters for a specific device) For Micron ZBT devices, the timing parameters must be programmed to all zero since reads and writes are synchronous.

The Expansion-bus address is used to present the 25 bits of the address [24:0] used for the Expansion bus access accompanied by an address latch enable output signal, EX\_ALE for multiplexed devices. The address phase normally lasts two clock cycles in multiplexed mode. The address phase may be extended by one to three clock cycles using the T1 - Address Timing parameter, bits 29:28 in the Timing and Control (EXP\_TIMING\_CS) Register for the particular Chip Select. When the address phase T1 is extended, the ALE pulse is extended and always deasserts one cycle prior to the end of the T1 phase. The lower address bits are placed onto the data bus (i.e for a 16 bit data bus, EX\_DATA contains EX\_ADDR[15:0]) along with EX\_ADDR[24:0] signals during the first cycle of the address phase. During the second cycle of the address phase, the data bus now will output data when attempting to complete a write or tri-state when attempting to complete a read. The address signals will retain their state.

For Synchronous Intel and Micron ZBT devices, EX\_ALE acts as the address valid signal (ADV#) and is logic 0 during the address phase and logic 1 during the continuation of a burst or IDLE cycle.

Due to the fact that, in HPI mode of operation, it is possible to begin an access to a busy device (EX\_RDY is false), special consideration must be taken with programming the T1 – Address Timing parameter when using the chip select in HPI mode. The T1 – Address Timing parameter must be set to a minimum of two additional cycles (T1 must equal to 0x2). Programming the T1 – Address Timing parameter to this value ensures that the asynchronous EX\_RDY input is sampled and available to the controlling hardware logic before beginning the new HPI access over the Expansion bus.

The chip-select signal is presented for one Expansion bus phase before the Strobe Phase. The chip select will be presented for the remainder of the Expansion bus cycles (setup, strobe, and hold phases).

The Setup/Chip Select Timing phase may also be extended by one to three clock cycles, using bits 27:26 of the Timing and Control (EXP\_TIMING\_CS) Register, T2 – Setup/Chip Select Timing parameter. In HPI mode of operation, T2 is defined as the time required by the external DSP device to drive EX\_RDY false for the current access plus the time required by the Expansion bus controller to sample and synchronize the EX\_RDY signal. The T2 – Setup/Chip Select Timing parameter must have a minimum value of two additional cycles (T2 >= 0x2). Programming the T2 – Setup/Chip Select Timing parameter to be three clock cycles in length ensures that when the Strobe Phase, T3, begins, the Strobe Phase will be able to sample the EX\_RDY signal and exit the Strobe Phase at the proper time.

The Strobe Phase of an Expansion-bus access is when the read or write strobe is applied. The 25 Expansion Bus Interface Address bits are maintained in non-multiplexed mode or the Expansion Bus Interface Data bus is switched from address to data when configured in multiplexed mode during the Strobe Phase.

The Strobe Phase may be extended from one to 15 clock cycles, as defined by programming bits 25:22 of the Timing and Control (EXP\_TIMING\_CS) Register, T3 – Strobe Timing parameter. In HPI mode of operation, the T3 – Strobe Timing parameter

must have a minimum value of one additional cycle ( $T3 \geq 0x1$ ). Programming the T3 – Strobe Timing parameter to be two clock cycles in length ensures that any data sent to the DSP is captured regardless of when the EX\_RDY signal is asserted by the DSP.

The Hold Phase of an Expansion-bus access is provided to allow a hold time for data to remain valid after the data strobe has transitioned to an invalid state. During a write access, the Hold Phase provides hold time for data written to an external device on the Expansion bus, after the strobe pulse has completed.

During a read access, the Hold Phase allows an external device time to release the bus after driving data back to the controller. The Hold Phase may be extended one to three clock cycles, using bits 21:20 of the Timing and Control (EXP\_TIMING\_CS) Register, T4 – Hold Timing parameter. In HPI mode of operation, the Hold Phase is defined the same as described for the Intel and Motorola modes of operation, but must be set to a minimum value of one additional cycle ( $T4 \geq 0x1$ ).

After the address and chip select is de-asserted, the Expansion bus controller can be programmed to wait a number of clocks before starting the next Expansion Bus access. This action is referred to as the Recovery Phase. The Recovery Phase is may be extended one to 15 clock cycles using bits 19:16 of the Timing and Control (EXP\_TIMING\_CS) Register, T5 – Recovery Timing parameter. In HPI mode of operation, the Recovery Phase is defined the same as described for the Intel and Motorola modes of operation.

#### 42.4.1.4 Using I/O Wait

The EX\_IOWAIT\_N signal is available to be shared by devices attached to chip selects 0 through chip select 7, when configured in Intel or Motorola modes of operation. The shared device will assert EX\_IOWAIT\_N in the T2 phase of a read or write transaction. During idle cycles, the board is responsible for ensuring that EX\_IOWAIT\_N is pulled-up. Additionally, EX\_IOWAIT\_N must always be pulled high during Micron ZBT, Intel Synchronous Mode, and HPI cycles. The Expansion bus controller will ignore EX\_IOWAIT\_N for Synchronous Intel mode transfers and use the EXP\_SYNCINTEL\_COUNT register for the wait state generation.

When an external device asserts EX\_IOWAIT\_N before the first cycle of a Strobe phase of a read or write transaction, the Expansion bus controller will hold in the Strobe phase until the EX\_IOWAIT\_N signal returns to an inactive state. Since there is a synchronizer cell on EX\_IOWAIT\_N, the external device must assert EX\_IOWAIT\_N three cycles before the deassertion of EX\_WR\_N/EX\_RD\_N. This implies that the value programmed in the T2 and T3 phase cannot both be equal to zero. After EX\_IOWAIT\_N is deasserted the Expansion bus controller will only transition to the T4 - Hold state after the T3 counter reaches zero.

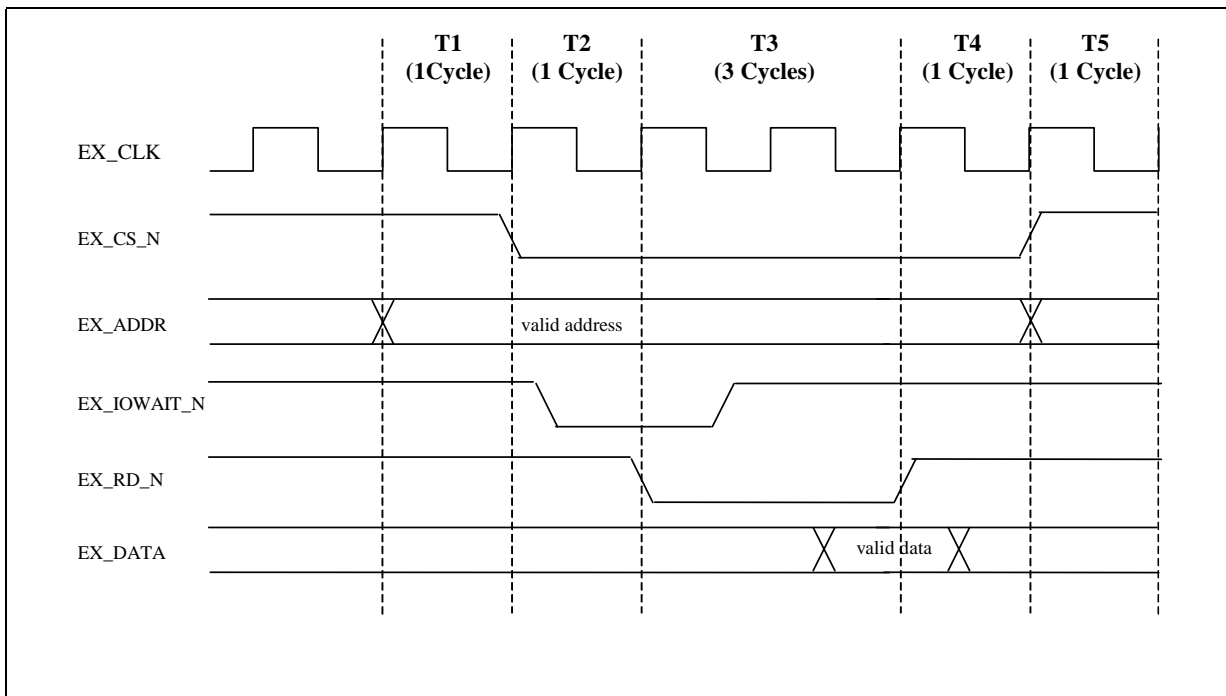

Operation of EX\_RDY signals is the same as the EX\_IOWAIT\_N signal, but is defined primarily for the 'C54xx family of DSPs. In addition, the EX\_RDY signals will hold the current access in the Address Phase if detected during that phase. This event can happen if a busy DSP memory access is started before the previous access completes. [Figure 42-5](#) shows the operation of the EX\_IOWAIT\_N signal.

Notice that the access is an Intel Style Simplex Read access. The data strobe phase is set to a value to last three clock cycles. The data is returned from the peripheral device prior to the three clocks and the peripheral device de-asserts EX\_IOWAIT\_N. The data strobe phase terminates after two clocks even though the strobe phase was configured to pulse for three clocks.

Figure 42-5. Expansion Bus I/O Wait Operation

#### 42.4.1.5 Parity

The Expansion bus controller generates even or odd parity for each byte written to EX\_DATA and compares parity for each byte read on EX\_DATA, if PAR\_EN is set in each EXP\_TIMING\_CS register. EX\_PARITY is transferred in the same clock cycle in which EX\_DATA is transferred. If a read transfer results in a parity mismatch on EX\_PARITY, the target address is logged in the EXP\_PARITY\_STATUS and OutErrorSts is set. Exp\_parity\_error will be asserted by the Expansion bus controller during a parity error and an interrupt will be generated if enabled in the interrupt controller. Exp\_parity\_error will remain asserted until software clears EXP\_PARITY\_STATUS register.

Even parity is defined as the number of 1's on EX\_DATA[7:0] and EX\_PARITY[0] must be an even number. For example, if EX\_DATA[7:0] = 0x25, EX\_PARITY[0] must be 1, since there are 3 bits set on 0x25 and there needs to be an even number of 1s. Parity for the second byte of EX\_DATA is generated on EX\_PARITY[1].

If PAR\_EN is cleared for a particular device, the Expansion bus controller doesn't generate or compare parity and EX\_PARITY should not toggle to conserve power. Odd parity can be enabled by setting OddPar in the EXP\_MST\_CONTROL register and is equivalent to the inverted value of even parity.

#### 42.4.1.6 Special Design Knowledge for Using HPI mode

The Expansion bus controller supports a number of the 8-bit and 16-bit versions of the Texas Instruments Host Port Interface\* (HPI) standards. This flexibility allows the TMS320C54xx family of Digital Signals Processors (DSP) to seamlessly interface to the Expansion Bus.

However, there are some special things to note when using the Expansion Bus in HPI mode of operation. These features are shown in the following tables. There are also some restrictions on the timing parameters and these are outlined in Section 42.4.1.3, "Expansion Bus Interface Configuration" on page 1676.

The Expansion-bus address-pins bits 0, 1, 2, 22, and 23 are multiplexed with special function signal pins for HPI as shown in Table 42-3.

Table 42-3. Multiplexed Output Pins for HPI Operation

| HPI Control Signal | Output Signal Pin |
|--------------------|-------------------|
| EX_HBIL            | EX_ADDR [0]       |
| EX_HCNTL [1:0]     | EX_ADDR [2:1]     |
| EX_HCSEL [1:0]     | EX_ADDR [23:22]   |

The byte identification signal, EX\_HBIL, is used to determine the byte transfer order. (EX\_HBIL is driven low for the first byte of the transfer and driven high for the second byte.)

The byte order bit (BOB) in the HPIC register (contained in the DSP) — within the HPI device — is used to determine the placement for the two bytes of the transfer. Please consult the datasheet of the specific DSP being connected to determine the order of the transferred bytes.

When operating in HPI mode, bits 13:10 in the Timing and Control (EXP\_TIMING\_CS) Registers are ignored.

When operating in HPI-16, non-multiplexed mode, the Expansion bus address bus provides direct accesses to the DSP memory space. The data associated with this address will be read or written from the location specified by the value contained on the Expansion Bus address bits. The signals EX\_HCNTL [1:0] are multiplexed onto the EX\_ADDR [2:1] pins. When communicating to a multiplexed HPI interface, the EX\_HCNTL [1:0] signals are used to select one of four internal registers used for interfacing to the DSP. The EX\_HCNTL [1:0] mapping is described in the Table 42-4.

Table 42-4. HPI HCNTL Control Signal Decoding

| hcntl[1:0] | Required Access   |
|------------|---|
| 00         | Read / write control register (HPIC)  |
| 01         | Read / write data register (HPID)<br>HPI-8:<br>Post-increment HPIA on reads, pre-increment on writes.<br>HPI-16:<br>Post-increment HPIA on reads and writes |
| 10         | Read / write address register (HPIA)  |
| 11         | Read / write data register (HPID)   |

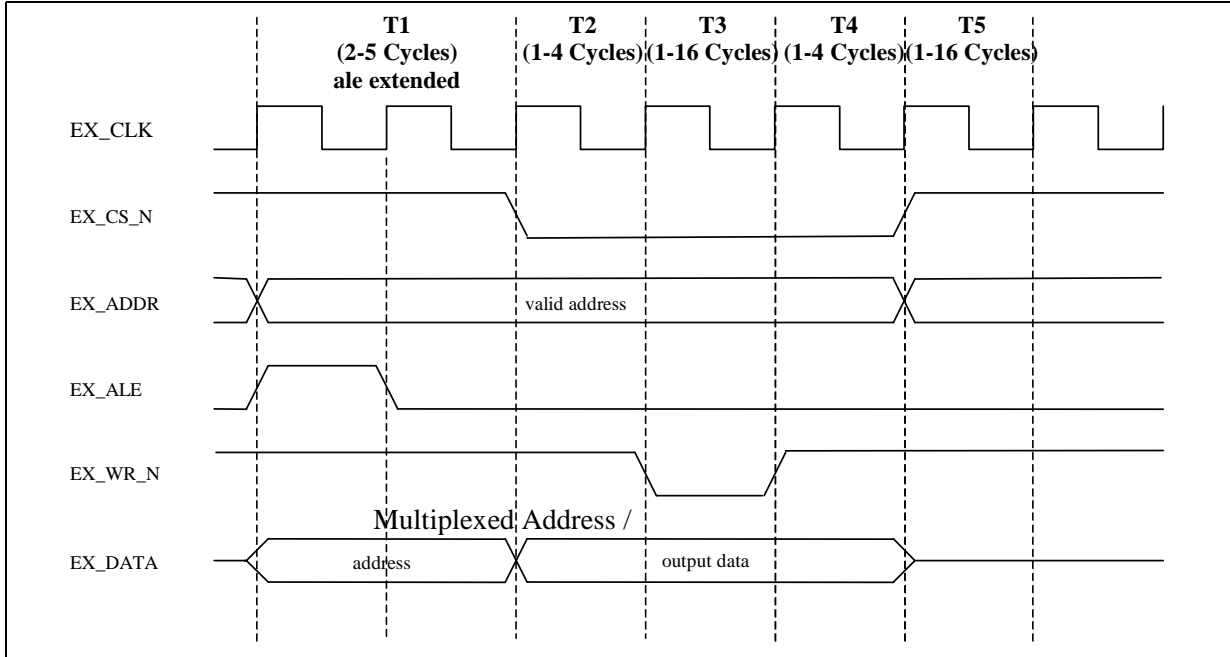

### 42.4.1.7 Expansion Bus Outbound Timing Diagrams

The STATE signal that is shown in some of the following timing diagrams is the internal state of the Expansion bus controller.

42.4.1.7.1 Intel, Multiplexed-Mode Write Access

Figure 42-6. Expansion-Bus Write (Intel, Multiplexed Mode)

42.4.1.7.2 Intel, Multiplexed-Mode Read Access

Figure 42-7. Expansion-Bus Read (Intel, Multiplexed Mode)

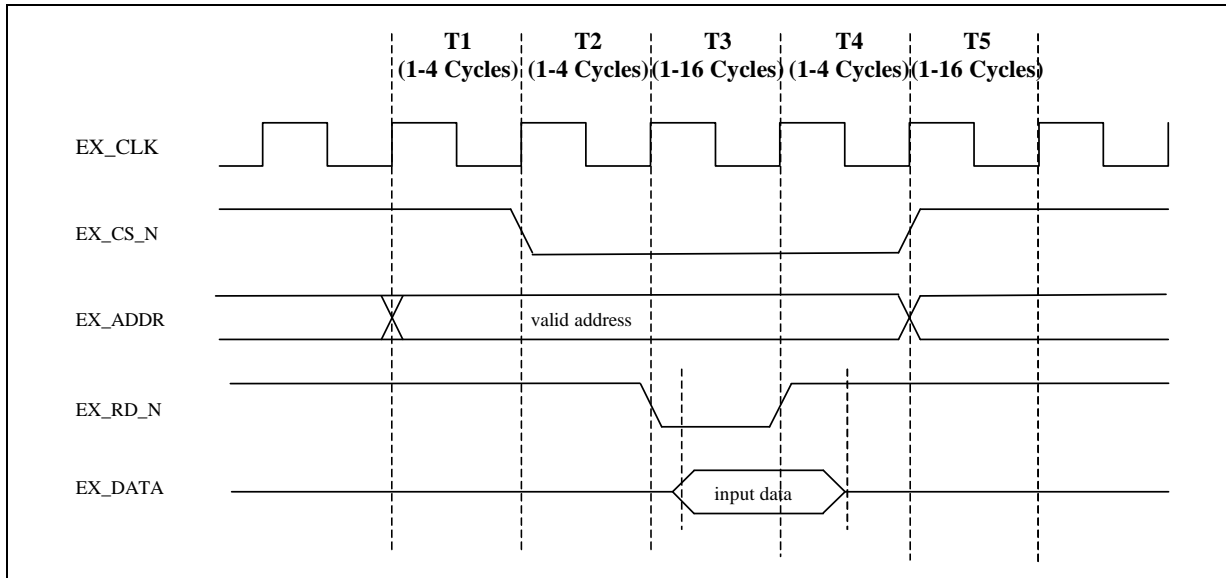

### 42.4.1.7.3 Intel-Simplex-Mode and Synchronous Intel Write Access

Figure 42-8. Expansion-Bus Write (Intel-Simplex Mode, Synchronous Intel)

### 42.4.1.7.4 Intel, Simplex-Mode Read Access

Figure 42-9. Expansion-Bus Read (Intel, Simplex Mode)

42.4.1.7.5 Synchronous Intel 8-word Read Access

Figure 42-10. Intel Synchronous 8-word Read

The above timing diagram shows an 8-word read to a Synchronous Intel device such as Synchronous Intel StrataFlash. Depending on the EX\_CLK period, the latency count bits in the Intel Synchronous Device read configuration register needs to be programmed appropriately based on the timing parameters for the specific device. The Expansion bus controller will always wait in cycles 1 and 2, regardless of EX\_IOWAIT\_N. The device will then assert EX\_IOWAIT\_N for several cycles and deassert EX\_IOWAIT\_N when its ready to transfer data. After the device deasserts EX\_IOWAIT\_N, it will transfer the remaining words until all 8 words are transferred. The Expansion bus controller and Synchronous Intel device both support wrapping for 8-word reads, therefore ADDR0 is not always aligned to an 8-word boundary. The STATE signal shows the internal Expansion bus state.

### 42.4.1.7.6 Synchronous Intel 1-word Read Access

Figure 42-11. Intel Synchronous One-Word Read

42.4.1.7.7 Micron\* ZBT Write/Read/Write Access

Figure 42-12. Micron\* ZBT Write/Read/Write

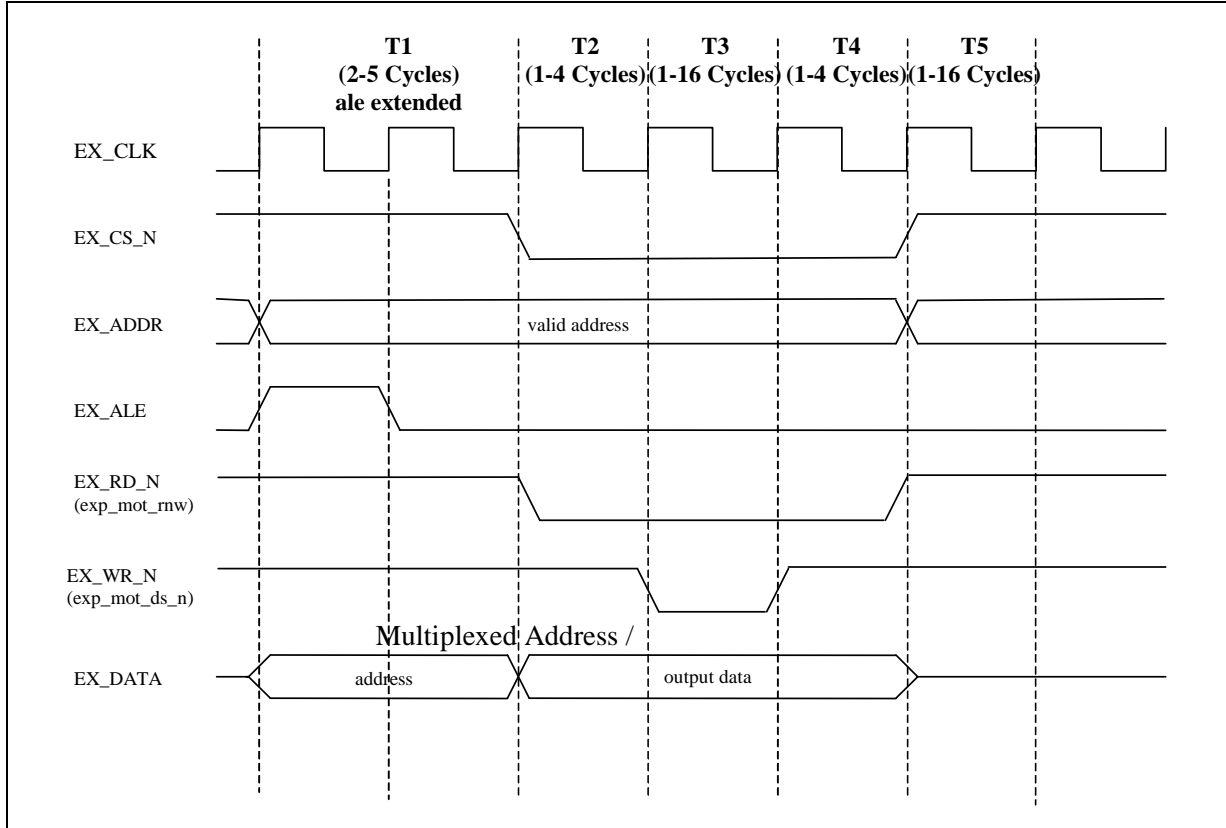

Figure 42-12 shows a write to a Micron ZBT device followed by a read and then followed by another read. The device will never assert EX\_IOWAIT\_N for this mode.

### 42.4.1.7.8 Motorola\*, Multiplexed-Mode Write Access

42.5 Register Summary

Accesses to Expansion bus registers are only via 32-bit transfers. Other sized accesses result in unpredictable operation. Accesses to all reserved bits must be written with zero unless otherwise specified. All reserved address spaces must not be read. All writes to reserved address spaces results in unpredictable operation.

For more information on the conventions the following register summaries adopt, see [Section 7.1, "Overview of Register Descriptions and Summaries" on page 183.](#)

The Local Expansion Bus registers materialize in the PCI space.

[Table 42-5](#) summarizes the Local Expansion Bus materialization from the PCI perspective.

**Table 42-5. Bus M, Device 8, Function 0: Summary of Local Expansion Bus Registers Mapped Through CSRBAR PCI Memory BAR"**

## 42.5.1 Timing and Control Registers

### 42.5.1.1 EXP\_TIMING\_CS0 - Expansion Bus Timing Register

The EXP\_TIMING\_CS registers may only be written if there is not an outstanding Expansion bus transaction. Software must ensure that all outstanding Expansion bus transfers are complete before changing the EXP\_TIMING\_CS registers.

**Table 42-6. EXP\_TIMING\_CS0 - Expansion Bus Timing Register**

### 42.5.1.2 EXP\_TIMING\_CS[1-7] - Expansion Bus Timing Registers

The EXP\_TIMING\_CS registers may only be written if there is not an outstanding Expansion bus transaction. Software must ensure that all outstanding Expansion bus transfers are complete before changing the EXP\_TIMING\_CS registers.

Table 42-7. EXP\_TIMING\_CS[1-7] - Expansion Bus Timing Registers (Sheet 1 of 2)

00000004h - EXP\_TIMING\_CS1  
00000008h - EXP\_TIMING\_CS2  
0000000Ch - EXP\_TIMING\_CS3  
00000010h - EXP\_TIMING\_CS4  
00000014h - EXP\_TIMING\_CS5  
00000018h - EXP\_TIMING\_CS6  
0000001Ch - EXP\_TIMING\_CS7

## 42.5.2 Configuration and Status Registers

### 42.5.2.1 EXP\_CNFG0 - Configuration Register 0

At power up or whenever RESET\_IN\_N is asserted, the Expansion-bus address outputs are switched to inputs and the states of the bits are captured and stored in Configuration Register 0. This occurs when RESET\_OUT\_N is deasserted.

Only bits EX\_ADDR[23:21] are used.

These configuration bits are made available to the system as outputs from the Expansion bus controller block. The bits are read-only.

**Table 42-8. EXP\_CNFG0 -Configuration Register 0**

| <b>Description:</b> Defines the reset-time configuration straps. |                           |  |  |                 |            |
|--|---------------------------|--|--|-----------------|------------|
| <b>View:</b> PCI   | <b>BAR:</b> CSRBAR        | <b>Bus:Device:Function:</b> M:8:0  | <b>Offset Start:</b> 00000020h<br><b>Offset End:</b> 00000020h |                 |            |
| <b>Size:</b> 32 bit  | <b>Default:</b> 00000040h |  | <b>Power Well:</b> Core  |                 |            |
| Bit Range  | Bit Acronym               | Bit Description  | Sticky   | Bit Reset Value | Bit Access |
| 31 : 24  | RSVD                      | Reserved   |  | 0h              | RO         |
| 23 : 21  | LEB_SIZE                  | These bits are initialized from EX_ADDR[23:21] at reset using the reset-time strapping mechanism described above. This field always contains the value read from the straps at reset and is <b>not</b> updated in the event BIOS overrides the value of LEB_SIZE.<br>The effect of these bits is defined in <a href="#">Table 35-159, "MMBAR ADDR Field Behavior"</a> on page 1325   |  | X               | RO         |

| 10   | EXIOW                     | 1 = EX_IOWAIT_N is sampled during the read/write Expansion bus cycles as defined in <a href="#">Section 42.4.1.4, "Using I/O Wait"</a> on page 1680 for Chip Select 0.<br>0 = EX_IOWAIT_N is ignored for read and write cycles to Chip select 0 if EXP_TIMING_CS0 is configured to Intel mode. Typically, IOWAIT_CS0 must be pulled down to Vss when attaching a Synchronous Intel StrataFlash on Chip select 0 since the default mode for EXP_TIMING_CS0 is Intel mode and EX_IOWAIT_N is an unknown value for Synchronous Intel StrataFlash. If the board does not connect the Synchronous Intel StrataFlash WAIT pin to EX_WAIT_N (and the board guarantees EX_IOWAIT_N is pulled up), the value of IOWAIT_CS0 is a don't care since EX_IOWAIT_N will not be asserted. When EXP_TIMING_CS0 is reconfigured to Intel Synchronous mode during boot-up (for Synchronous Intel chips), the Expansion bus controller ignores EX_IOWAIT_N during read and write cycles since the WAIT functionality is determined from the EXP_SYNCINTEL_COUNT and EXP_TIMING_CS registers. |  | 0h              | RO         |

## 42.5.2.2 EXP\_PARITY\_STATUS - Expansion Bus Parity Status Register

Table 42-9. EXP\_PARITY\_STATUS - Expansion Bus Parity Status Register

| <b>Description:</b> Specifies the parity error status. |                           |  |                                   |  |            |
|--|---------------------------|--|-----------------------------------|--|------------|
| <b>View:</b> PCI                                       | <b>BAR:</b> CSRBAR        |  | <b>Bus:Device:Function:</b> M:8:0 | <b>Offset Start:</b> 00000120h<br><b>Offset End:</b> 00000123h |            |
| <b>Size:</b> 32 bit                                    | <b>Default:</b> 00000000h |  |                                   | <b>Power Well:</b> Core  |            |
| Bit Range  | Bit Acronym               | Bit Description  | Sticky                            | Bit Reset Value  | Bit Access |
| 31 : 02  | ErrorAddr                 | Address corresponding to the parity error<br>For Outbound transactions, the derivation of this address is as follows: <ul style="list-style-type: none"> <li>ErrorAddr = Internal_Bus_ADDR[31:5] &amp; EX_ADDR[4:2]</li> </ul> Internal_BusInternal_BusInternal_BusInternal_BusIf multiple parity errors occur (eg- multiple parity errors within a multi-word transfer/burst; or additional parity errors detected on subsequent transactions), then ErrorAddr contains the address of the first parity error. After receiving a parity error, the ErrorAddr is locked until OutErrorSts is cleared by software.<br>If another parity error occurs prior to the interrupt and EXP_PARITY_STATUS being cleared, then the subsequent parity errors will not be trapped nor will the address be logged. As a result, only the first errored transaction will be dropped, but the subsequent (errored) transaction(s) will be completed.<br>Note: ErrorAddr will not be unlocked until the current transaction is complete. |                                   | 0h   | RO         |
| 01   | RSVD                      | Reserved   |                                   | 0h   | RWC        |
| 00   | OutErrorSts               | A parity error occurred on an outbound read. This bit will not get set unless PAR_EN is set in the EXP_TIMING_CS for which the parity error has occurred.  |                                   | 0h   | RWC        |

OutErrorSts is generated to forms exp\_parity\_error which is routed to the Interrupt Controller and can generate interrupts to the processor core. In the event of multiple outbound parity errors, there is a race condition between when software performs a write to clear the EXP\_PARITY\_STATUS register and setting the InErrorSts/OutErrorSts error bit in hardware.

If the software clears the error bit before another parity error, the EXP\_PARITY\_STATUS register will be set again. However if software clears the error bit on or after another parity error, the EXP\_PARITY\_STATUS register will be cleared.

## 42.6 Performance Estimation

The bandwidth that can be supported on the expansion bus depends on the latencies through the system and the nature of the protocol on the expansion bus. All latencies are dependent on whether the transaction is read or write.

Each specific protocol supported by the expansion has its own set of timing parameters as described by the number cycles required for T1, T2, T3, T4 and T5. The reader is referred to [Section 42.4, "Theory of Operation"](#) for explanation of these parameters. Additionally, the number of wait states required contributes additional cycles required for a given transaction and will reduce the bandwidth.

Estimated system latencies expressed in terms of Expansion Bus clock cycles are shown in [Table 42-10](#).

The estimated bandwidth for a given platform configuration is determined as:

$$BW \text{ (Mbit/s)} = \text{TransactionSize} * \text{LEB\_Freq} / \text{TotalLatency}$$

where:

- TransactionSize is size of the transaction expressed in bits
- LEB\_Freq is the frequency of the external clock being used to clock the Expansion bus
- TotalLatency is the sum of:
  - SytemLatency + T1 + T2 + T3 + T4 + T5 + Wait States

*Note:* The appropriate values for these latencies must be used depending on whether the transaction is a read or a write.

*Note:* This estimate applies to a single, serialized request at the entry to the AIOC (PCI-to-PCI Bus M Bridge) onto the expansion bus

**Table 42-10. LEB Performance Calculation - Estimated AIOC Latencies**

| AIOC Internal Bus (MHz) | LEB (MHz) | AIOC Latency Read (LEB cycles) | AIOC Latency Write (LEB cycles) |
|-------------------------|-----------|--------------------------------|---------------------------------|
| 400                     | 80        | 31                             | 27                              |
| 533                     | 80        | 24                             | 21                              |
| 800                     | 80        | 22                             | 19                              |
|                         |           |                                |                                 |
| 400                     | 66        | 26                             | 22                              |
| 533                     | 66        | 19                             | 17                              |
| 800                     | 66        | 17                             | 15                              |

*Note:* Note: The system is assumed to be otherwise quiescent. No competing traffic on the internal buses is considered.

*Note:* These latencies comprehend only those from the time an IA initiated transaction is received at the AIOC to the time the AIOC completes the transaction. No IA, FSB, MCH, software, etc latencies are included.

[Table 42-11](#) provides example estimates for various platform configurations.

**Table 42-11. Outbound Performance Estimation Examples**

|                         | Example A<br>Write | Example A<br>Read | Example B<br>Write | Example B<br>Read | Example C<br>Write | Example C<br>Read |
|-------------------------|--------------------|-------------------|--------------------|-------------------|--------------------|-------------------|
| Expansion Bus (MHz)     | 80                 | 80                | 80                 | 80                | 80                 | 80                |
| AIOC Internal Bus (MHz) | 400                | 400               | 533                | 533               | 800                | 800               |
| Transaction Size(bits)  | 32                 | 32                | 32                 | 32                | 32                 | 32                |
|                         |                    |                   |                    |                   |                    |                   |
| AIOC Latency            | 27                 | 31                | 21                 | 24                | 19                 | 22                |
|                         |                    |                   |                    |                   |                    |                   |
| Wait states             | 0                  | 0                 | 0                  | 0                 | 0                  | 0                 |
| T1                      | 1                  | 1                 | 1                  | 1                 | 1                  | 1                 |
| T2                      | 2                  | 3                 | 2                  | 3                 | 2                  | 3                 |
| T3                      | 1                  | 2                 | 1                  | 2                 | 1                  | 2                 |
| T4                      | 1                  | 1                 | 1                  | 1                 | 1                  | 1                 |
| T5                      | 1                  | 1                 | 1                  | 1                 | 1                  | 1                 |
|                         |                    |                   |                    |                   |                    |                   |
| Total Latency           | 33                 | 39                | 27                 | 32                | 25                 | 30                |
|                         |                    |                   |                    |                   |                    |                   |
| Mbits/s                 | 77                 | 66                | 95                 | 80                | 102                | 85                |

*Note:* These examples assume 0 wait states introduced by the external LEB device. The latency of the attached device must be taken into account for specific applications.

## 43.0 Global Design for Test Features

---

### 43.1 JTAG

#### 43.1.1 JTAG Functions Overview

The JTAG functionality, has the following attributes.

- The JTAG TAP controller is compliant with the *IEEE 1149.1 Specification*.
- The JTAG block supports the TAP controllers in IA-32 core and IMCH.
- The JTAG block supports the IO Boundary Scan Requirement implementing all the mandatory and some optional instructions from the IEEE 1149.1 specification.

#### 43.1.2 EP80579 TAP Controllers

The JTAG Test Access Port (TAP) controller requires 4 **input** pins: Test Reset (**TRST#**, active Low), Test Clock (**TCK**), Test Mode Select (**TMS**) and the serial Test Data In (**TDI**). TMS controls tSoChe TAP state transitions. The TAP has one **output** pin, the serial Test Data Out (**TDO**).

##### 43.1.2.1 IA-32 Core

There are two JTAG Test Access Port (TAP) controllers: one in the IA-32 core, and one “master” TAP in the MCH. The IA-32 Core TAP is present as a result of the SoC integration and performs no JTAG functions besides BYPASS and IDCODE.

##### 43.1.2.2 MCH TAP Extension

The TAP controller in the IMCH (in the CMI), is the master. It executes all of the IEEE 1149/1 compliant JTAG and Boundary Scan functions in the EP80579.

Serial TAPs have the issue that they have a BYPASS register length >1. This is not desirable from a IEEE 1149.1 compliance standpoint. To get around this, two BSDLs are published, one each for the IMCH and IA-32 core. The IMCH TAP acts as the master TAP, supporting the public instructions for customer usage. The IA-32 core TAP's public Boundary Scan instructions, while still supported and available, do not perform any meaningful function since the IA-32 core's TAP does not control any IO pins directly. The appropriate Boundary Scan functionality is performed by the corresponding instructions in the IMCH TAP controller. Both TAPs support the BYPASS and IDCODE instructions. This is summarized in [Table 43-1](#).

Table 43-1. EP80579 TAPs Public Instructions

| Public Instruction | MCH TAP Controller                                  | VmC TAP Controller                                       |
|--------------------|---|--|
| <b>BYPASS</b>      | Supported   | Supported  |
| <b>IDCODE</b>      | EP80579 IDCODE; unique per EP80579 silicon stepping | IA-32 core IDCODE; fixed for all products using the core |
| <b>EXTEST</b>      | Boundary Scan for EP80579 IOs                       | Implemented, but not connected to any IO pads            |

### 43.1.3 EP80579 JTAG ID Codes

On account of the multiple TAPs, the EP80579 supports and displays multiple IDCODEs. This is described below in [Table 43-2](#).

Table 43-2. EP80579 TAP IDCode Values

| JTAG TAP Controller      | IDCode        | Comments  |
|--------------------------|---------------|---|
| <b>IMCH</b><br>(EP80579) | 32'h0E66_0013 | The 4 MSBs are incremented for each EP80579 silicon stepping (major or minor) |
| <b>IA-32 Core</b>        | 32'h0B36_0013 | Fixed for all products and steppings using this core                          |

### 43.1.4 Special Requirements and Limitations

The JTAG implementation has the following requirements for proper JTAG operation.

- For proper boundary scan operation, the following GbE reset pins need to be in the specified states: **SYS\_PWR\_OK = 1** and **AUX\_PWR\_GOOD = 1**. This requirement is true even if the GbE units are disabled. These additional non-JTAG pins must be automatically driven to the proper values by the platform's power-up devices when the EP80579 is powered up for boundary scan testing.
- Several high-speed interfaces and critical system reset and power related pins have been removed from the Boundary Scan chain. These are documented in [Section 43.2.1, "JTAG Boundary Scan"](#).

### 43.1.5 JTAG Instructions Summary: MCH

The table in this section summarizes the EP80579-specific JTAG instructions implemented in the MCH section of the chip.

The JTAG instructions are classified as follows:

- **Public:** These instructions are available to anyone.

Table 43-3. JTAG Instructions Summary for MCH

| Opcode (8'Hxx) | Instruction | Register Size | Type     | Special Impltn. | Section                            | Description                     |
|----------------|-------------|---------------|----------|-----------------|------------------------------------|---------------------------------|
| 00             | EXTEST      | 884           | Public   | -               | <a href="#">Section 45.2.1.1.1</a> | Boundary Scan -- Extest         |
| 01             | SAMPPRE     | 884           | Public   | -               | <a href="#">Section 45.2.1.1.2</a> | Boundary Scan -- Sample Preload |
| 02             | IDCODE      | 32            | Public   | -               | <a href="#">Section 45.2.1.1.3</a> | IDCode                          |
| 03             |             |               | reserved |                 |                                    | not implemented                 |
| 05-07          |             |               | Reserved |                 |                                    | Not implemented                 |
| 08             | HIGHZ       | 0             | Public   | -               | <a href="#">Section 45.2.1.1.4</a> | Boundary Scan -- HighZ          |
| 09             |             |               | Reserved |                 |                                    | Not implemented                 |
| FF             | BYPASS      | 0             | Public   | -               | <a href="#">Section 45.2.1.1.5</a> | Bypass                          |
| 16-1B          |             |               | reserved |                 |                                    | Not implemented                 |
| 43-46          |             |               | Reserved |                 |                                    | Not implemented                 |
| 6C-6F          |             |               | Reserved |                 |                                    | Not implemented                 |

## 43.2 I/O Testing

The EP80579 implements JTAG Boundary Scan to allow testing of the I/O pins.

### 43.2.1 JTAG Boundary Scan

The EP80579 implements *IEEE 1149.1 compliant JTAG Boundary Scan (BScan)* on all its interfaces with the exception noted below.

The three high-speed interfaces, PCIe, SATA and USB2 did not implement JTAG BScan. These are tested with an XOR chain that covers the AFEs of all 3 interfaces ([Section 46.2.3, "XOR Chains"](#)). In addition, several compliance pins were excluded from the BScan chain to ensure proper functionality. These are listed in [Table 43-4](#). The Boundary Scan Chain is defined in the EP80579 BSDL file.

#### 43.2.1.1 Pins Excluded from Boundary Scan Chain

Several critical compliance pins were excluded from the Boundary Scan chain. These are listed below in [Table 43-4](#).

**Table 43-4. Compliance Pins Excluded from Boundary Scan Chain**

| Interface  | Excluded Pin(s)  |
|------------|--|
| RTC        | RTCX1, RTCX2, RTEST_N  |
| ICH Misc   | INTVRMEN   |
| Power Mgmt | PWROK, RSMRST_N  |
| SMBus      | INTRUDER_N   |
| CRU        | CLKS100, CLKP100, CLKN100                                      |
| LEB        | EXRCMP, EXRCMN   |
| DDR        | D_RCOMPX, D_DDRRCRES[2:0], D_DRVCRES, D_SLEWCRES               |
| VC signal  | XXTHRMDA_OUT, XXTHRMDA_IN, XXTPCD_OUT, XXTPCL_OUT, XXHFPLL_OUT |
| GBE        | GBE_RCOMPP, GBE_RCOMPN, SYS_PWR_OK, GBE_AUX_PWR_GOOD           |

§ §

## 44.0 IA-32 Core

The testability features supported by the IA-32 core integrated into Intel® EP80579 Integrated Processor are described in this section.

### 44.1 JTAG

The IA-32 core TAP (Test Access Port) complies with the IEEE 1149.1 (“JTAG”) test architecture standard. The TAP implements an instruction set of 6 functions as follows:

- SAMPLE/PRELOAD
- EXTEST
- CLAMP
- HIGHZ
- IDCODE
- BYPASS

#### 44.1.1 Usage

There are seven 1149.1-defined public instructions implemented in the IA-32 core TAP. These instructions are described in [Table 44-1](#). These instructions select from among three different TAP data registers — the boundary scan, device ID, and bypass registers.

**Table 44-1. 1149.1 Public Instructions in the IA-32 Core TAP**

| TAP Instruction (op-code) | Function during StopClk | Data Register Selected | Action during... |                            |                  |                           |
|---------------------------|-------------------------|------------------------|------------------|----------------------------|------------------|---------------------------|
|                           |                         |                        | RT/IDLE          | Capture-DR                 | Shift-DR         | Update-DR                 |
| SAMPLE/PRELOAD (0000001)  | Yes                     | Boundary scan          | —                | Sample all IA-32 core pins | Shift bscan reg  | Update bscan reg. outputs |
| EXTEST (0000000)          | Yes                     | Boundary scan          | —                | Sample all IA-32 core pins | Shift bscan reg  | Update IA-32 core outputs |
| CLAMP (0000100)           | Yes                     | Bypass                 | —                | Reset bypass reg           | Shift bypass reg | —                         |
| HIGHZ (0001000)           | Yes                     | Bypass                 | —                | Reset bypass reg           | Shift bypass reg | —                         |
| IDCODE (0000010)          | Yes                     | Device ID              | —                | Load IA-32 core ID code    | Shift ID reg     | —                         |
| BYPASS (1111111)          | Yes                     | Bypass                 | —                | Reset bypass reg           | Shift bypass reg | —                         |

The operation of these instructions is summarized as follows:

- **SAMPLE/PRELOAD:** This is the Boundary scan command. The IA-32 core operates normally. IA-32 core pins are sampled into the boundary scan register on CaptureDr, shifted out on ShiftDr.
- **EXTEST:** Same as SAMPLE, except the IA-32 core outputs are driven directly from the boundary scan register (so that the external pins wiggle as you shift the results out).
- **CLAMP:** The IA-32 core outputs are driven directly from the previously-loaded value in the boundary scan register; the 1-bit TAP bypass register is connected between TDI and TDO.
- **HIGHZ:** All outputs of the IA-32 core are driven to their high-impedance state.
- **IDCODE:** The IA-32 core operates normally; the Device ID register is read using this TAP instruction. The IDCODE returned contains the fields described in Table 44-2.
- **BYPASS:** The IA-32 core operates normally; TAP pins TDI and TDO access the 1-bit bypass register.

Table 44-2. Device ID Register Bit-fields

| Field Name                     | Bit Position(s) | Value   | Function   |
|--------------------------------|-----------------|---|--|
| Version Number                 | 31-28           | xxxx<br>(0000 for A-0)  | What version of IA-32 core this unit is. Should increment with each stepping |
| Part Number                    | 27-12           | 1011001101100000<br>(Request Number 101100)<br>(Product 11011)<br>(End User/Market 00000) | Number chosen by Intel to describe what part this is.                        |
| Manufacturer Identity          | 11-1            | 00000001001   | Identity code that uniquely identifies Intel.                                |
| Device ID register implemented | 0               | 1   | Must always be a 1 if the Device ID register exists.                         |

#### 44.1.1.1 Description

Full details of the operation of these public instructions can be found in the 1149.1 standard. Please note that the op-codes for the public instructions are an Intel standard and do not vary from processor to processor.

The contents of the Device ID register are shown in Table 44-2. Note that the Version Number changes for each stepping. The rest of the fields do not change during the life of the product. IA-32 core IDCODE value is xB360013h, where x represent the stepping number (x=0000 for A-0).

## 45.0 IMCH Design for Test

### 45.1 IMCH Design for Test Features

#### 45.1.1 Features

The IMCH includes a number of Design For Test features. These features are described in this section.

### 45.2 JTAG

#### 45.2.1 IMCH JTAG Instructions

Table 45-1 below lists the JTAG chains, their public or private designation, the chain length, and a short descriptive name. The chains are described in more detail in later sections.

Due to the nature of the JTAG design in EP80579, there are two operating modes in which the instructions below are accessible. In the default serial mode (i.e. MCH JTAG + IA-32 core JTAG), the TDI value represents the full input instruction required.

**Table 45-1. IMCH JTAG Instructions**

| Mnemonic | Parallel Mode IR | Hex | Serial Mode IR   | Hex  | Public | Chain Length | Description    |
|----------|------------------|-----|------------------|------|--------|--------------|----------------|
| ExTest   | 00000000         | 00  | 0000000011111111 | 007F | Public | 884          | Extest         |
| SampPre  | 00000001         | 01  | 0000000111111111 | 00FF | Public | 884          | Sample Preload |
| IDCode   | 00000010         | 02  | 0000001011111111 | 017F | Public | 32           | IDCode         |
| HighZ    | 00001000         | 08  | 0000100011111111 | 047F | Public | 0            | HighZ          |
| ByPass   | 11111111         | FF  | 1111111111111111 | 7FFF | Public | 0            | Bypass         |

#### 45.2.1.1 JTAG Chain Details

Descriptions follow for the JTAG chain.

##### 45.2.1.1.1 ExTest

The ExTest instruction allows circuitry or wiring external to the devices to be tested. Output boundary scan register cells are used to apply stimulus, while boundary scan cells at the input pins are used to capture data. I/O cells can be used for either purpose, depending on the value set in the corresponding output enable cell.

Note that some signals are prevented from driving out during ExTest: xxpwrzd, xxrstinn, and xxextintrnn.

#### 45.2.1.1.2 Sample/Preload

The Sample/Preload instruction is used to allow scanning of the boundary scan register without causing interference to the normal operation of the device. Two functions can be performed by use of the Sample/Preload instruction.

Sample - allows a snapshot of the data flowing into and out of the device to be taken without affecting the normal operation of the device.

Preload - allows an initial pattern to be placed into the boundary scan register cells. This allows initial known data to be present prior to the selection of another boundary scan test operation.

#### 45.2.1.1.3 IDCode

This instruction is used to determine the manufacturer, part number, and revision level of the device being accessed. This instruction selects only the device identification register to be connected for serial access between TDI and TDO in the Shift-DR controller state. When this instruction is selected, the operation of the test logic shall have no effect on the operation of the on-chip system logic. Reading the IDCode returns a single value.

The ID consists of 6 fields. The first field is for the version and stepping of the device. The Part Number field contains 3 fields. Field #1 is the product category, and for a server, has a value of "000 100" binary. Field #2 is product type and is "01 000" for the IMCH. Field #3 is an assigned chronological value within a product type. The Manufacturer ID is "000 0000 1001" for Intel as assigned by IEEE. The last field is filled by a binary "1".

Table 45-2. JTAG Device Identification Register Field Designations

| Version/<br>Stepping | Part Number |          |          | Manufacturer ID | Hardwired<br>'1' |
|----------------------|-------------|----------|----------|-----------------|------------------|
|                      | Field #1    | Field #2 | Field #3 |                 |                  |
| 4 bits               | 6 bits      | 5 bits   | 5 bits   | 11 bits         | 1 bit            |

The JTAG 32-bit ID contains information in order to uniquely identify a component, and its manufacturer. Note that this ID does not uniquely distinguish between devices of a given component type. This ID does not contain a device serial number. The fields as defined are shown in the table below.

The revision codes must be changed to match chip specification.

#### 45.2.1.1.4 HighZ

The HIGHZ instruction is used to force all outputs of the device (except TDO) into a high impedance state. This instruction shall select the Bypass Register to be connected between TDI and TDO in the Shift-DR controller state.

#### 45.2.1.1.5 Bypass

The BYPASS command selects the Bypass Register to be connected for serial access between TDI and TDO pins of the device. The Bypass Register is a single bit register and is used to provide a minimum-length serial path through the device. This allows more rapid movement of test data to and from other components in the system.

### 45.3 High Speed I/O Testing

There is a single XOR chain which connects PCIe pads, along with USB and SATA pads. The definition for this is located in the ICH XOR Chain section ([Section 46.2.3, "XOR Chains"](#)).

§ §

## 46.0 ICH Design for Test

---

### 46.1 JTAG

The IICH in the EP80579 does not have a JTAG interface.

### 46.2 I/O Test Mode

#### 46.2.1 Test Mode Entry Methods

Non-functional test modes are dedicated test modes where the chip is not operating in its normal manner. This test mode includes Boundary scan. Functional test modes are features built into the existing functional modes that allow the IICH to be optimally tested and/or margined in its normal operating mode.

##### 46.2.1.1 Non-Functional Test Mode Entry

This section covers the Non-functional Test Mode entry methods.

###### 46.2.1.1.1 Serial Test Mode (STM) Entry

The Non-functional test mode is activated with the Serial Test Mode Entry. This method uses a single test pin (DFXTEST#) to write to a test-mode command register or to read from a test-mode status register.

DFXTEST\_N pin on EP80579 is shared between IICH and IMCH. By default it works as DFXTEST\_N pin for IICH and if JTAG\_INSTR\_0x73 is set in the MCH, then it acts as TESTNN pin for IMCH.

The protocol for this serial test mode entry is based on PCICLK and is depicted in [Table 46-1](#). For either a read or a write, an 18-bit serial command field is fed into the test pin, prefaced with a '0' as the start bit (the idle condition of the test pin must be a logic-high). For a write, the 18-bit command field is followed by 32 bits of write data, which is fed into the appropriate test-mode command register. For a read, the 18-bit command field is followed by one clock of turn-around, followed by the test-pin driving out 32 bits of read data. [Figure 46-1](#) and [Figure 46-2](#) demonstrate the timing of the Serial Test Mode Entry read and write cycles. It is important that test modes are not activated until after the entire data field has been written. It is also important that if a register is read, that its value is sampled at the end of the turn-around cycle. All serial values are put out MSB-first.

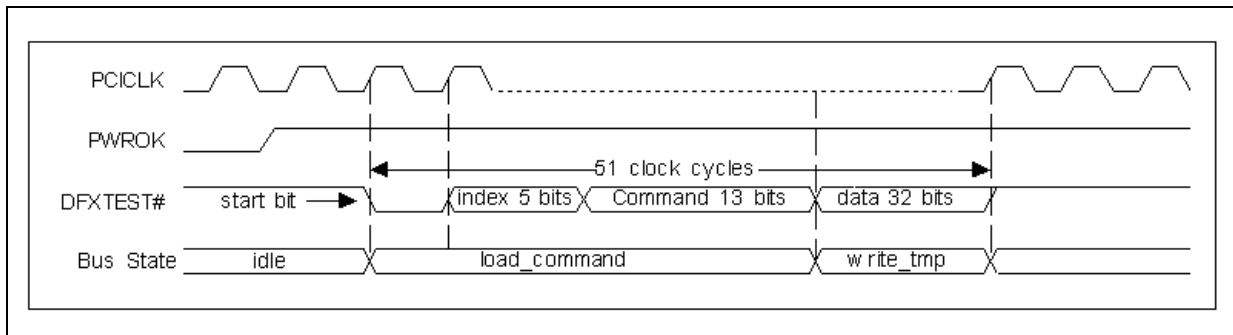

All STM accessible registers are implemented as STICKY registers.

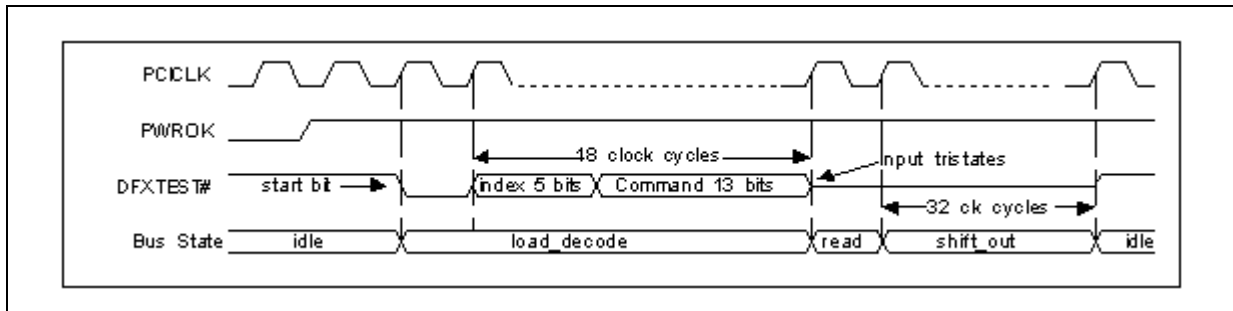

**Table 46-1. Serial Test Mode Entry Command Field**

| Bit Field | Default and Access      | Description   |
|-----------|-------------------------|---|
| [17:13]   | 00000b – Write-Only     | Register Index (31-0)                                   |
| [12:11]   | 00b – Write-Only        | Read/Write Enable (11 – Write 01 – Read, x0 – Reserved) |
| [10:0]    | 000000000b – Write-Only | Reserved  |

**Figure 46-1. Serial Test Mode Entry for Write**

**Figure 46-2. Serial Test Mode Entry for Read**

## 46.2.2 Test Mode Registers

### 46.2.2.1 TEST0 - Test Control Register 0

Table 46-2. Test Control Register 0

| Description: |   |  |        |                                    |            |

### 46.2.3 XOR Chains

XOR Chains are used to validate connectivity of high speed IO pins when JTAG control is unavailable. This technique chains together pins in a serial fashion, with an XOR gate between each pin, effectively creating a single multi-input XOR gate. By toggling the pins individually or in combination, the connectivity of the pins at the platform level, and the functionality of the I/O driver itself can be validated.

There is only one XOR chain in to cover the AFEs of PCI express, SATA and USB. This mode can be entered by setting bit 8 of test control register 0.

**Table 46-3. XOR Chains**

| XOR Chain Order | Comments                           |
|-----------------|------------------------------------|
| PEA0_Rn[6]      | First pin / input pin to XOR chain |
| PEA0_Rp[6]      |                                    |
| PEA0_Tp[6]      |                                    |
| PEA0_Tn[6]      |                                    |
| PEA0_Rn[7]      |                                    |
| PEA0_Rp[7]      |                                    |
| PEA0_Tp[7]      |                                    |
| PEA0_Tn[7]      |                                    |
| PEA0_Rn[4]      |                                    |
| PEA0_Rp[4]      |                                    |
| PEA0_Tp[4]      |                                    |
| PEA0_Tn[4]      |                                    |
| PEA0_Rn[5]      |                                    |
| PEA0_Rp[5]      |                                    |
| PEA0_Tp[5]      |                                    |
| PEA0_Tn[5]      |                                    |
| PEA_RCOMPO      |                                    |
| PEA_ICOMPO      |                                    |
| PEA0_Rn[2]      |                                    |
| PEA0_Rp[2]      |                                    |
| PEA0_Tp[2]      |                                    |
| PEA0_Tn[2]      |                                    |
| PEA0_Rn[3]      |                                    |
| PEA0_Rp[3]      |                                    |
| PEA0_Tp[3]      |                                    |
| PEA0_Tn[3]      |                                    |
| PEA0_Rn[0]      |                                    |
| PEA0_Rp[0]      |                                    |
| PEA0_Tp[0]      |                                    |
| PEA0_Tn[0]      |                                    |
| PEA0_Rn[1]      |                                    |
| PEA0_Rp[1]      |                                    |

| PEAO_Tp[1]      |                      |
| PEAO_Tn[1]      |                      |
| SATA_RBIAS      |                      |
| SATA_RBIASSENSE |                      |
| SATA_RXn0       |                      |
| SATA_RXp0       |                      |
| SATA_TXn0       |                      |
| SATA_TXp0       |                      |
| SATA_RXn1       |                      |
| SATA_RXp1       |                      |
| SATA_TXn1       |                      |
| SATA_TXp1       |                      |
| USBn0           |                      |
| USBp0           |                      |
| USBn1           |                      |
| USBp1           |                      |
| RI_N            | XOR Chain Output pin |

These signals listed below enable the XOR test mode for PCI express AFE and need to be connected to dt\_xor signal:

- input\_comp\_oxoren
- input\_iol0\_oxoren0
- input\_iol0\_oxoren1
- input\_iol1\_oxoren0
- input\_iol1\_oxoren
- input\_iou0\_oxoren0
- input\_iou0\_oxoren1
- input\_iou1\_oxoren0
- input\_iou1\_oxoren1

## **47.0 SKUs, Power Savings and Pre-Boot Firmware**

---

### **47.1 Overview**

This section provides an overview of the various EP80579 SKUs. The SKUs are designed to optimize cost, performance, temperature environment (industrial temperature support) and power consumption. Several options allow designers to further reduce power consumption by disabling functional units that may not be utilized by the target application.

### **47.2 SKUs, Strap Options and Pre-Boot Firmware Programmable Configuration Modes**

#### **47.2.1 SKU Features**

Table 47-1 outlines the various SKUs available.

Table 47-1. Base Features of EP80579 SKUs

| SKU Overview                   |  |                 |                 |                 |  |                 |                 |                 |

| WDT                            | Yes  |                 |                 |                 |  |                 |                 |                 |
| RTC                            | Yes  |                 |                 |                 |  |                 |                 |                 |
| 36x GPIO                       | Yes  |                 |                 |                 |  |                 |                 |                 |
| 2x CAN                         | Yes  |                 |                 |                 |  |                 |                 |                 |
| IEEE 1588-2008 Hardware Assist | Yes  |                 |                 |                 |  |                 |                 |                 |
| Local Exp Bus                  | Yes  |                 |                 |                 |  |                 |                 |                 |
| SSP                            | Yes  |                 |                 |                 |  |                 |                 |                 |
| †                              | Intel recommends using the SPI for Pre-boot firmware due to the reduced availability of LPC FWH. |                 |                 |                 |  |                 |                 |                 |
| ‡                              | Feature must be enabled with the EP80579 software. Refer to the EP80579 software documentation.  |                 |                 |                 |  |                 |                 |                 |

## 47.2.2 DDR2 Frequencies Supported by the EP80579

Supported DDR2 frequencies are based on the SKU and the Tolapai operating frequency. Table 47-2 lists the supported DDR2 frequencies. The supported frequencies are defined as frequency blocks. The DDR2 interface is defined as a function of the SKUs shown in Table 47-1, “Base Features of EP80579 SKUs”.

**Table 47-2. IA-32 Core Internal Bus and DDR2 Frequencies**

| IA-32 Core [MHz] | Internal Quad Pump FSB [MHz] | DDR2 Supported Frequencies (MHz) |
|------------------|------------------------------|----------------------------------|
| 1,200            | 533                          | 400, 533, 667, 800               |
| 1,066            | 533                          | 400, 533, 667, 800               |
| 600              | 400                          | 400, 533, 667                    |

## 47.2.3 Strap Options (Platform-based Configuration)

The Tolapai provides an external pull-down strap pin (V\_SEL) that allows the platform to select IA-32 core frequency. The value of V\_SEL determines the operating point (frequency and voltage) of the IA-32 core in conjunction with the value of the Tolapai output pin, BSEL.

BSEL is derived from the IA-32 core BSEL output and indicates the fixed FSB frequency. The V\_SEL pin is driven by the Tolapai to a default value corresponding to the SKU shown in Table 47-1, “Base Features of EP80579 SKUs” on page 1730, but may be strapped low by the platform to override the SKU value; this causes the IA-32 core to operate at the lowest gear ratio (multiplier applied to the FSB frequency to obtain the IA-32 core frequency) and voltage combination corresponding to the SKU's FSB frequency. Table 47-3 shows the Tolapai strap options:

**Table 47-3. Tolapai Strap Options**

| SKU ID | Manufacturing Frequency SKU (FSB/Intel Architecture MHz) | BSEL Value <sup>1</sup> | V_SEL Value | Operating Frequency (FSB/IA-32 Core MHz) | IA-32 Core Voltage |
|--------|--|-------------------------|-------------|--|--------------------|
| 5/6    | 533/1200   | 1                       | 1           | 533/1200                                 | 1.30V              |
|        | 533/1200   | 1                       | 0           | 533/1066                                 | 1.30V              |
| 3/4/7  | 533/1066   | 1                       | 0           | 533/1066                                 | 1.30V              |
| --     | --   | 0                       | 1           | Reserved                                 | --                 |
| 1/2/8  | 400/600  | 0                       | 0           | 400/600                                  | 1.0V               |

**Notes:**

- The BSEL output to the clock generator on the board assumes that '0' indicates 400 MHz FSB and '1' indicates 533 MHz FSB.

#### 47.2.4 Pre-Boot Firmware Programmable SKU Options

Pre-boot firmware programmable SKU options allow certain features to be disabled. This is helpful when downgrading a part for power savings.

- Power Savings: Software (pre-boot firmware) can disable interface device to save power.

Table 47-4 lists the pre-boot firmware programmable features:

**Table 47-4. EP80579 Pre-Boot Firmware Programmable Options**

| Pre-Boot Firmware Programmable Features <sup>1</sup> |
|--|
| Accelerator Services Unit (ASU)                      |
| Security Services Unit (SSU)                         |
| Gigabit Ethernet (per port)                          |
| CAN 0/1  |
| IEEE 1588-2008 Hardware Assist                       |
| SSP  |
| USB  |
| PCI Express* (per controller)                        |
| SATA (per port)                                      |

**Notes:**

1. Refer to the EP80579 software and the, Intel® EP80579 Integrated Processor product line Firmware Writer's Guide.

§ §

## 48.0 Package Specifications

This chapter provides EP80579 package specifications.

### 48.1 Package Introduction

The EP80579 is offered in a 1,088 ball, Flip-Chip Ball Grid Array (FCBGA) package with Lead-free only (RoHS 5/6 compliant) for commercial and industrial applications.

### 48.2 Functional Signal Definitions

Table 48-1 provides the legend for interpreting the Type field that appears throughout the tables in this section.

**Table 48-1. Signal Type Definitions**

| Symbol    | Description  |
|-----------|--|
| #         | Active low signal  |
| I         | Input pin only   |
| O         | Output pin only  |
| I/O       | Pin can be either an input or output                                   |
| OD        | Open Drain pin   |
| PWR       | Power pin  |
| GND       | Ground pin   |
| Reservedn | Pin must be connected as described, where n is the reserved pin number |
| NCn       | No Connection, where n is the NC pin number                            |

### 48.3 JTAG Boundary Scan Chain (BSC) and XOR Chain

The EP80579 implements a consistent, IEEE 1149.1 compliant JTAG Boundary Scan Chain (BSC) for most interfaces (See Section 48.4, "Signal Pin Descriptions" for the interfaces and signals) enabling a low-cost manufacturing test for boards. The interfaces include the IICH interfaces. The BSC cell is defined in the Boundary Scan Description Language (BSDL) documentation and the boundary scan is initiated by the JTAG entry in the IMCH side.

Three high-speed interfaces, PCI Express\*, SATA and USB, are not implemented in the JTAG boundary scan. These interfaces are in an XOR Chain to validate connectivity of high speed IO pins when JTAG control is unavailable (See Table 48-2, "XOR Chain Elements" and Section 48.4, "Signal Pin Descriptions" for the interfaces and signals). XOR chain mode is initiated by the serial test mode entry of the IICH side. The XOR chain provides the sequence of elements that include first element and XOR output (last element) to allow the reader to know the chain starting and ending points. This

technique chains together pins in a serial fashion, with an XOR gate between each pin, effectively creating a single multi-input XOR gate. By toggling the pins individually or in combination, the connectivity of the pins are validated at the output pin.

*Note:* A test point must be placed on the board for each of these XOR pins.

**Table 48-2. XOR Chain Elements**

| XOR chain elements           | XOR chain elements | XOR chain elements |
|------------------------------|--------------------|--------------------|
| PEA0_Rn[6] -> First Elements | PEA_RCOMPO         | PEA0_Tn[1]         |
| PEA0_Rp[6]                   | PEA_ICOMPO         | SATA_RBIASP        |
| PEA0_Tp[6]                   | PEA0_Rn[2]         | SATA_RBIASN        |
| PEA0_Tn[6]                   | PEA0_Rp[2]         | SATA_RXn0          |
| PEA0_Rn[7]                   | PEA0_Tp[2]         | SATA_RXp0          |
| PEA0_Rp[7]                   | PEA0_Tn[2]         | SATA_TXn0          |
| PEA0_Tp[7]                   | PEA0_Rn[3]         | SATA_TXp0          |
| PEA0_Tn[7]                   | PEA0_Rp[3]         | SATA_RXn1          |
| PEA0_Rn[4]                   | PEA0_Tp[3]         | SATA_RXp1          |
| PEA0_Rp[4]                   | PEA0_Tn[3]         | SATA_TXn1          |
| PEA0_Tp[4]                   | PEA0_Rn[0]         | SATA_TXp1          |
| PEA0_Tn[4]                   | PEA0_Rp[0]         | USBn0              |
| PEA0_Rn[5]                   | PEA0_Tp[0]         | USBp0              |
| PEA0_Rp[5]                   | PEA0_Tn[0]         | USBn1              |
| PEA0_Tp[5]                   | PEA0_Rn[1]         | USBp1              |

## 48.4 Signal Pin Descriptions

This section provides I/O signal definitions. The signals are categorized into one of several blocks:

- IA-32 core
- IMCH
- IICH
- AIOC
- Miscellaneous
- Power

In each block, there are specific functional group interfaces. [Table 48-3](#) summarizes the signal pin tables that appear throughout this section.

Table 48-3. Signal Pin Description References

| Block      | Interface   | Table Reference             |
|------------|---|-----------------------------|
| IA-32 Core | Thermal Diode                                     | Table 48-4                  |
|            | Global Clock CRU                                  | Table 48-5                  |
|            | Sideband Miscellaneous Signals                    | Table 48-6                  |
| IMCH       | IMCH Clock/Reset                                  | Table 48-7                  |
|            | DDR2 Interface                                    | Table 48-8                  |
|            | PCI Express* Interface                            | Table 48-9                  |

|            | Local Expansion Bus (LEB) Interface               | Table 48-24                 |
|            | Synchronous Serial Port (SSP) Interface           | Table 48-25                 |
|            | IEEE 1588-2008 Hardware Assist Interface          | Table 48-26                 |
| Misc.      | JTAG  | Table 48-27                 |
|            | Miscellaneous Signals                             | Table 48-28                 |
|            | Reserved  | Table 48-29                 |
|            | No Connect  | Table 48-30                 |
| Power      | Power and Ground                                  | Table 48-31                 |

The tables in this section list the signal pins associated with each interface and signal group on the EP80579. Some of the pins provide either normal mode or alternate mode. The Signal column provides the name of the signal that is associated with a pin in a particular mode.

## 48.4.1 IA-32 Core

### 48.4.1.1 Thermal Diode

Table 48-4. IA-32 Core Thermal Signals

| Signal Name | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode                 |
|-------------|---------|-----------|------------|------------------------------|---------|--|
| THERMDC     | Analog  | O         | 1          |                              |         | IA-32 core Thermal Diode: Thermal Diode Cathode (Input). |
| THERMDA     | Analog  | I         | 1          |                              |         | IA-32 core Thermal Diode: Thermal Diode Anode (output).  |
| TOTAL       |         |           | 2          |                              |         |  |

### 48.4.1.2 Global Clock CRU

Table 48-5. Global Clock and Reset (CRU) Signals

| Signal Name | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode                           |
|-------------|---------|-----------|------------|------------------------------|---------|--|
| CLKP100     | LVDS    | I         | 1          |                              |         | CRU Clock (Differential) Positive side of the 100Mhz clock input.  |
| CLKN100     | LVDS    | I         | 1          |                              |         | CRU Clock (Differential): Negative side of the 100Mhz clock input. |
| TOTAL       |         |           | 2          |                              |         |  |

### 48.4.1.3 Sideband Miscellaneous Signals

Table 48-6. Sideband Miscellaneous Signals (Sheet 1 of 2)

| Signal Name  | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|--------------|-------------|-----------|------------|------------------------------|---------|--|
| CPUSLP_OUT#  | LVTTTL,3.3V | O         | 1          |                              | BSC     | CPU Sleep: This EP80579 output signal is made visible to the platform for debug purposes only. This internal EP80579 signal places the processor into a state that saves substantial power compared to the Stop-Grant state. When EP80579 is in this state, it will not recognize snoops or interrupts. The processor will recognize only assertion of the CPURST# signal, and deassertion of CPUSLP_OUT# while in Sleep state. If CPUSLP_OUT# is deasserted, the processor exits Sleep state and returns to Stop-Grant state, restarting its internal clock signals to the bus and processor core units.  |
| INIT33V_OUT# | LVTTTL,3.3V | O         | 1          |                              | BSC     | CPU Initialization: This 3.3V EP80579 output signal is made visible to the platform to reset the Firmware Hub. Internal EP80579 signal that when asserted, resets integer registers inside the processor without affecting its internal caches or floating-point registers. The processor then begins execution at the power-on Reset vector configured during power-on configuration. The processor continues to handle snoop requests during INIT33V_OUT# assertion. INIT33V_OUT# is an asynchronous signal. However, to ensure recognition of this signal following an Input/Output Write instruction, it must be valid along with the TRDY# assertion of the corresponding Input/Output Write bus transaction. |
| NMI          | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | Non-Maskable Interrupt: NMI is used to force a non-maskable interrupt to the processor, if configured. The processor detects an NMI as a rising edge on NMI. NMI is reset by setting the corresponding NMI source enable/disable bit in the NMI Status and Control Register (I/O Register 61h), except when an external platform agent is driving the NMI pin.   |
| SMI_OUT#     | LVTTTL,3.3V | O         | 1          |                              | BSC     | System Management Interrupt: This EP80579 output signal is made visible to the platform for debug purposes only. This internal EP80579 signal is active low output synchronous to PCICLK that is asserted in response to one of many enabled hardware or software events. On accepting a System Management Interrupt, the processor saves the current state and enter System Management mode (SMM). An SMI Acknowledge transaction is issued, and the processor begins program execution from the SMM handler.   |

Table 48-6. Sideband Miscellaneous Signals (Sheet 2 of 2)

| Signal Name  | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|--------------|-------------|-----------|------------|------------------------------|---------|---|
| STPCLK_OUT#  | LVTTTL,3.3V | O         | 1          |                              | BSC     | Stop Clock Request: This EP80579 output signal is made visible to the platform for debug purposes only. This internal EP80579 signal is an active-low output synchronous to PCICLK that is asserted in response to one of many hardware or software events. When the processor samples STPCLK_OUT# asserted, it causes the processor to enter a low power Stop-Grant state. The processor issues a Stop-Grant Acknowledge transaction, and stops providing internal clock signals to all processor core units except the CPU FSB and CPU APIC units. The processor continues to snoop bus transactions and service interrupts while in Stop-Grant state. When STPCLK_OUT# is deasserted, the processor restarts its internal clock to all units and resumes execution. The assertion of STPCLK_OUT# has no effect on the bus clock; STPCLK_OUT# is an asynchronous CPU input generated by the EP80579 IICH. |
| RCIN#        | LVTTTL,3.3V | I         | 1          |                              | BSC     | Keyboard Controller Reset Processor: The keyboard controller can generate INIT_N to the processor. This saves the external OR gate of other sources of INIT_N. When the EP80579 detects the assertion of this signal, INIT_N is generated for 16 PCICLK clocks.<br><br>The EP80579 will ignore RCIN# assertion during transitions to the S3, S4 and S5 states.  |
| A20GATE      | LVTTTL,3.3V | I         | 1          |                              | BSC     | A20 Gate: A signal from the keyboard controller. Acts as an alternative method to force the A20M_N signal active. Saves the external OR gate needed with various other chipsets.  |
| CPURST#      | LVTTTL,3.3V | O         | 1          |                              | BSC     | Processor Bus Reset: The IMCH asserts CPURST# while RSTIN# is asserted and for approximately 1 ms after RSTIN# is deasserted. The CPURST# allows the processors to begin execution in a known state.<br><br>This EP80579 signal is for the use by the debug tool purpose.   |
| CPUPWRGD_OUT | LVTTTL,3.3V | OD O      | 1          | 10K Up                       | BSC     | CPUPWRGD is an open drain signal, this signal requires an external pull-up resistor. This EP80579 output signal is made externally visible to the platform for debug purposes only. CPUPWRGD monitors an internal EP80579 signal connected directly from the IICH to the processor and represents a logical AND of PWROK and VRMPWRGD signals. This signal also must be driven high throughout Boundary Scan operation.   |
| IERR#        | LVTTTL,3.3V | O         | 1          |                              | BSC     | IERR (Internal Error) is asserted by a processor as the result of an internal error. Assertion of IERR is usually accompanied by a SHUTDOWN transaction on the FSB. This transaction may optionally be converted to an external error signal (e.g., NMI) by the EP80579. The processor will keep IERR asserted until the assertion of INIT33V_OUT# or the EP80579 is reset using SYS_RESET#. For termination requirements please refer to the platform design guides.   |
| TOTAL        |             |           | 10         |                              |         |   |

## 48.4.2 Integrated Memory Controller Hub (IMCH)

### 48.4.2.1 IMCH Reset

Table 48-7. IMCH Reset Signals

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|-------------|-------------|-----------|------------|------------------------------|---------|---|
| RSTIN#      | LVTTTL,3.3V | I         | 1          |                              | BSC     | IMCH Reset Input: This input must be connected to PLTRST#.  |
| PWRGD       | LVTTTL,3.3V | I         | 1          |                              | BSC     | IMCH Power Good: Asynchronously resets the entire IMCH component, including "sticky" bits. Driven by platform logic to indicate all board power supplies are valid. |
| TOTAL       |             |           | 2          |                              |         |   |

### 48.4.2.2 DDR2 SDRAM

Table 48-8. DDR2 Interface Signals (Sheet 1 of 2)

| Signal Name  | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|--------------|---------|-----------|------------|------------------------------|---------|---|
| DDR_CK[5:0]  | SSTL_18 | O         | 6          |                              | BSC     | DDR Channel Command Clock (Differential): The positive side of the command clocks used by the DDR DRAMs to latch the DDR_A[14:0], DDR_BA[2:0], DDR_RAS#, DDR_CAS#, DDR_WE#, DDR_CKE[1:0], and DDR_CS[1:0]# signals. |
| DDR_CK[5:0]# | SSTL_18 | O         | 6          |                              | BSC     | DDR Channel Command Clock (Differential): The negative side of the differential command clock (see DDR_CK[5:0]).  |
| DDR_CS[1:0]# | SSTL_18 | O         | 2          |                              | BSC     | DDR Channel Chip Select: Used to indicate to which DRAM device cycles are targeted.   |
| DDR_RAS#     | SSTL_18 | O         | 1          |                              | BSC     | DDR Channel Row Address Strobe: Used to indicate a valid row address and open a row   |
| DDR_CAS#     | SSTL_18 | O         | 1          |                              | BSC     | DDR Channel Column Address Strobe: Used to indicate a valid column address and initiate a transaction.  |
| DDR_WE#      | SSTL_18 | O         | 1          |                              | BSC     | DDR Channel Write Enable: Used to indicate a write cycle.   |
| DDR_DM[8:0]  | SSTL_18 | O         | 9          |                              | BSC     | DDR Channel Data Mask: Data mask for write data.  |
| DDR_BA[2:0]  | SSTL_18 | O         | 3          |                              | BSC     | DDR Channel Bank Address: The DDR bank address signals. These signals are outputs of the IMCH and select which bank within a row is selected.   |
| DDR_A[14:0]  | SSTL_18 | O         | 15         |                              | BSC     | DDR Channel Memory Address: The DDR memory address signals.   |
| DDR_DQ[63:0] | SSTL_18 | I/O       | 64         |                              | BSC     | DDR Channel Data Bus: The DDR data bus provides the data to/from the DRAM devices.  |
| DDR_ECC[7:0] | SSTL_18 | I/O       | 8          |                              | BSC     | DDR Channel ECC Bits: ECC bits for the data on the interface.   |

Table 48-8. DDR2 Interface Signals (Sheet 2 of 2)

| Signal Name   | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|---------------|---------|-----------|------------|------------------------------|---------|--|
| DDR_DQS[8:0]  | SSTL_18 | I/O       | 9          |                              | BSC     | DDR Channel Data Strobes (Differential): The positive side of the data strobe. Each data strobe is used to strobe a set of four or eight data signals (depending on whether x4 or x8 DRAM devices are used). |
| DDR_DQS[8:0]# | SSTL_18 | I/O       | 9          |                              | BSC     | DDR Channel Data Strobes (Differential): The negative side of the data strobe (see D_DQS[8:0]).  |
| DDR_CKE[1:0]  | SSTL_18 | O         | 2          |                              | BSC     | DDR Channel Clock Enable: Independent per-DIMM-slot clock enables used by the controller during the initialization sequence.   |
| DDR_ODT0      | SSTL_18 | I/O       | 1          |                              | BSC     | DDR Compensation: On-die termination configuration.  |
| DDR_ODT1      | SSTL_18 | I/O       | 1          |                              | BSC     | DDR Compensation: On-die termination configuration.  |
| DDR_RCOMPX    | Analog  | I         | 1          |                              |         | DDR Compensation: CMD/CK/ADD pin slewrate control.   |
| DDR_CRES[2:0] | Analog  | I/O       | 3          |                              |         | DDR Compensation: Resistive compensation I/O's   |
| DDR_DRVCRES   | Analog  | I/O       | 1          |                              |         | DDR Compensation   |
| DDR_SLEWCRES  | Analog  | I/O       | 1          |                              |         | DDR Compensation: DQ/DQS/DM pin slewrate control.  |
| TOTAL         |         |           | 144        |                              |         |  |

## 48.4.2.3 PCI Express\*

Table 48-9. PCI Express Interface Signals (Sheet 1 of 4)

| Signal Name | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|-------------|---------|-----------|------------|------------------------------|---------|---|
| PEAO_Tp[0]  | LV Diff | O         | 1          |                              | XOR     | <p>PCI Express Interface Port A Transmit Data Pair (Differential): The positive side of the PCI Express Port A transmit data pair. These signals are an output (Tx) from the EP80579's perspective, and must be connected to the input (receive or Rx) signals of the other PCI Express device.</p> <p>The signals for this 1x8 interface can be trained to 2x4 or 2x1 ports. | SERIRQ      | LVTTTL,3.3V | I         | 1          | 10K Up (in PIRQ mode)        | BSC     | Serial Interrupt Request: This pin implements the serial interrupt protocol.<br>This signal is not 5V tolerant. It is 3.3 V tolerant. |
| TOTAL       |             |           | 1          |                              |         |   |

#### 48.4.3.3 Serial Peripheral Interface (SPI)<sup>1</sup>

Table 48-13. SPI Interface Signals

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode |
|-------------|-------------|-----------|------------|------------------------------|---------|--|
| SPI_SCLK    | LVTTTL,3.3V | O         | 1          |                              | BSC     | Serial bit-rate Clock                    |
| SPI_CS#     | LVTTTL,3.3V | O         | 1          |                              | BSC     | CS for Slave                             |
| SPI_MOSI    | LVTTTL,3.3V | O         | 1          |                              | BSC     | Master data out/Slave In                 |
| SPI_MISO    | LVTTTL,3.3V | I         | 1          |                              | BSC     | Master data in/Slave out                 |
| TOTAL       |             |           | 4          |                              |         |  |

#### 48.4.3.4 Low Pin Count (LPC) Interface

Table 48-14. LPC and FWH Interface Signals (Sheet 1 of 2)

| Signal Name   | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|---------------|-------------|-----------|------------|------------------------------|---------|---|
| LAD[3:0]      | LVTTTL,3.3V | I/O       | 4          |                              | BSC     | LPC Multiplexed Command, Address, Data<br>LAD[3:0] may be used as Firmware Hub [3:0] signals.                           |
| LFRAME#       | LVTTTL,3.3V | O         | 1          |                              | BSC     | LPC Frame: LFRAME# Indicates the start of an LPC cycle, or an abort.<br>LFRAME# may be used as Firmware Hub [4] signal. |
| GP41_LDRQ[1]# |             |           |            |                              |         | See GPIO interface.   |

1. Intel recommends using the SPI for Pre-boot firmware due to the reduced availability of LPC FWH.

Table 48-14. LPC and FWH Interface Signals (Sheet 2 of 2)

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|-------------|-------------|-----------|------------|------------------------------|---------|--|
| LDRQ[0]#    | LVTTTL,3.3V | I         | 1          |                              | BSC     | LPC Serial DMA/Master Request Input Bit 0: Used by LPC devices, such as Super I/O chips, to request DMA or bus master access. This signal is typically connected to external Super I/O device. |
| PCICLK      | LVTTTL,3.3V | I         | 1          |                              | BSC     | LPC clock. PCI clock used for the LPC bus (up to 33Mhz)  |
| TOTAL       |             |           | 7          |                              |         |  |

### 48.4.3.5 SMBus

Table 48-15. SMBus Interface Signals

| Signal Name    | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|----------------|-------------|-----------|------------|------------------------------|---------|---|
| SMBDATA        | LVTTTL,3.3V | OD I/O    | 1          | 8.2K Up                      | BSC     | SMBus Data: SMBus data signal. An external pull-up is required.   |
| SMBCLK         | LVTTTL,3.3V | OD I/O    | 1          | 8.2K Up                      | BSC     | SMBus Clock: SMBus clock signal. An external pull-up is required.   |
| GP11_SMBALERT# |             |           |            |                              |         | See GPIO interface.   |
| INTRUDER#      | LVTTTL,3.3V | I         | 1          |                              |         | SMBus Intruder Detect: Detects if the system case has been opened. Can be set to disables the system if the box is detected open. This input signal is in the RTC well. This pin's status is readable, so it can be used like a GPI if the Intruder switch is not needed. |
| SMLINK[1:0]    | LVTTTL,3.3V | OD I/O    | 2          | 8.2K Up                      | BSC     | SMBus System Management Link: SMBus link to optional external system management ASIC or LAN controller. External pull-ups are required.<br><br>Note that SMLINK[0] corresponds to an SMBus Clock signal, and SMLINK[1] corresponds to an SMBus Data signal.               |
| SMBSDA         | LVTTTL,3.3V | OD I/O    | 1          | 8.2K Up                      | BSC     | SMBus Data: Data signal for the IMCH SMBus interface. An external pull-up is required.  |
| SMBSCL         | LVTTTL,3.3V | OD I/O    | 1          | 8.2K Up                      | BSC     | SMBus Clock: Clock signal for the IMCH SMBus interface. An external pull-up is required.  |
| TOTAL          |             |           | 7          |                              |         |   |

### 48.4.3.6 UART Interface

Table 48-16. UART Signals (Sheet 1 of 3)

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|-------------|-------------|-----------|------------|------------------------------|---------|--|
| SIU_CTS1#   | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 1 Clear to Send: Active low, this pin indicates that data can be exchanged between UART port 1 and the external interface. This pin has no effect on the transmitter.</p> <p>Note: This pin could be used as Modem Status Input whose condition can be tested by the processor by reading bit 4 (CTS) of the Modem Status register (MSR). Bit 4 is the compliment of the CTS# signal. Bit0 (DCTS) of the MSR indicates whether the CTS# input has changed state since the previous reading of the MSR. When the CTS bit of the MSR changes state an interrupt is generated if the Modem Status Interrupt is enabled.</p>                  |
| SIU_CTS2#   | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 2 Clear to Send. Refer to UART Port 1 Clear to Send (SIU_CTS1#) for more information.</p>   |
| SIU_DCD1#   | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 1 Data Carrier Detect: Active low, this pin indicates that data carrier has been detected by the external agent for UART port 1.</p> <p>Note: This pin is Modem Status Input which condition can be tested by the processor by reading bit 7 (DCD) of the Modem Status Register (MSR). Bit 7 is complement of the DCD# signal. Bit 3 (DDCD) of the MSR indicates whether the DCD# input has changed state since the previous reading of the MSR. When the DCD bin of the MSR changes state an interrupt is generated if the Modem Status Interrupt is enabled.</p>  |
| SIU_DCD2#   | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 2 Data Carrier Detect. Refer to UART Port 1 Data Carrier Detect (SIU_DCD1) for more information.</p>  |
| SIU_DSR1#   | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 1 Data Set Ready: Active low, this pin indicates that the external agent is ready to communicate with UART port 1. This pin has no effect on the transmitter.</p> <p>Note: This pin could be used as Modem Status Input whose condition can be tested by the processor by reading bit 5 (DSR) of the Modem status register (MSR). Bit 5 is the complement of the DSR# signal. Bit 1 (DDSR) of the Modem status register (MSR) indicates whether the DSR# input has changed state since the previous reading of the MSR. When the DSR bin of the MSR changes state an interrupt is generated if the Modem Status Interrupt is enabled.</p> |
| SIU_DSR2#   | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 2 Data Set Ready. Refer to UART Port 1 Data Set Ready for more information.</p>   |

Table 48-16. UART Signals (Sheet 2 of 3)

| Signal Name | IO Type    | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|-------------|------------|-----------|------------|------------------------------|---------|--|
| SIU_DTR1#   | LVTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 1 Data Terminal Ready: When low, this pin informs the modem or data set that the UART port 1 is ready to establish a communication link. The DTR# output signal can be set to an active low by programming the DTR (bit 0) of the Modem Control Register to a logic '1'. A Reset operation sets this signal to its inactive state (logic '1'). LOOP mode operation holds this signal in its inactive state.</p> <p>SIW Configuration Port Address Select Strap: This strap selects the IO address for the SIW configuration port.</p> <p>The EP80579 interprets the strap as follows:<br/>           0 = IO Addresses 20Eh and 20Fh<br/>           1 = IO Addresses 04Eh and 04Fh (default)</p> |
| SIU_DTR2#   | LVTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 2 Data Terminal Ready. Refer to UART Port 1 Data Terminal Ready (SIU_DTR1#) for more information.</p> <p>Note: Do not drive this signal low until the CPURST# signal is de-asserted.</p>  |
| SIU_RI1#    | LVTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 1 Ring Indicator: Active low, this pin indicates that a telephone ringing signal has been received by the external agent for UART port 1.</p> <p>Note: This pin is Modem Status Input whose condition can be tested by the processor by reading bit 6 (RI) of the MSR. Bit 6 is the complement of the RI# signal. Bit 2 (TERI) of the MSR indicates whether the RI# input has transitioned back to an inactive state. When the RI bit of the MSR changes from a 1 to 0 an interrupt is generated if the Modem Status Interrupt is enabled.</p>  |
| SIU_RI2#    | LVTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 2 Ring Indicator. Refer to UART Port 1 Ring Indicator (SIU_RI1#) for more information.</p>  |
| SIU_RTS1#   | LVTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 1 Request To Send: When low this pin informs the modem or data set that UART port 1 is wants to send data on an established communication link. The RTS# output signal can be set to an active low by programming the RTS (bit 1) of the Modem Control Register to a logic '1'. A Reset operation sets this signal to its inactive state (logic '1'). LOOP mode operation holds this signal in its inactive state.</p> <p>Note: Do not drive this signal low until the CPURST# signal is de-asserted.</p>   |
| SIU_RTS2#   | LVTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 2 Request to Send. Refer to UART Port 1 Request to Send (SIU_RTS1#) for more information.</p> <p>Note: Do not drive this signal low until the CPURST# signal is de-asserted.</p>  |
| SIU_RXD1    | LVTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 1 Serial Data Input: Serial data input form device pin to the receive port for UART port 1.</p>   |
| SIU_RXD2    | LVTTL,3.3V | I/O       | 1          |                              | BSC     | <p>UART Port 2 Serial Data Input: Serial data input form device pin to the receive port for UART port 2.</p>   |

Table 48-16. UART Signals (Sheet 3 of 3)

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|-------------|-------------|-----------|------------|------------------------------|---------|---|
| SIU_TXD1    | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | UART Port 1 Serial Data Output: Serial data output to the communication peripheral/modem or data set for UART port 1. Upon reset, the TXD pins will be set to MARKING condition (logic '1' state).  |
| SIU_TXD2    | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | UART Port 2 Serial Data Output: Serial data output to the communication peripheral/modem or data set for UART port 2. Upon reset, the TXD pins will be set to MARKING condition (logic '1' state).<br><br>GPIO IRQ Strap: This strap selects the interrupt capabilities of some GPIO pins on the EP80579 .<br><br>The EP80579 interprets this strap as follows:<br>0 = GPIO IRQ capability enabled.<br>1 = GPIO IRQ capability disabled (default) |
| UART_CLK    | LVTTTL,3.3V | I         | 1          |                              | BSC     | UART CLock: Input clock to the SIU. This clock is passed to the baud clock generation logic for the UART in the SIU. The clock can run at either 14.7456, 33, or 48 MHz.  |
| TOTAL       |             |           | 17         |                              |         |   |

#### 48.4.3.7 Serial ATA (SATA) Interface

Table 48-17. Serial ATA Interface Signals (Sheet 1 of 2)

| Signal Name  | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|--------------|---------|-----------|------------|------------------------------|---------|---|
| SATA_TXp0    | LV Diff | O         | 1          |                              | XOR     | Serial ATA Interface Port 0 Transmit Data Pair (Differential): The positive side of the port 0 transmit data pair.                |
| SATA_TXn0    | LV Diff | O         | 1          |                              | XOR     | Serial ATA Interface Port 0 Transmit Data Pair (Differential): The negative side of the port 0 transmit data pair.                |
| SATA_RXp0    | LV Diff | I         | 1          |                              | XOR     | Serial ATA Interface Port 0 Receive Data Pair (Differential): The positive side of the port 0 receive data pair.                  |
| SATA_RXn0    | LV Diff | I         | 1          |                              | XOR     | Serial ATA Interface Port 0 Receive Data Pair (Differential): The negative side of the port 0 receive data pair.                  |
| SATA_CLKREFn | CMOS    | I         | 1          |                              |         | Serial ATA Reference Clock (Differential): The negative side of the 100MHz clock input from the clock generator for the SATA PLL. |
| SATA_CLKREFp | CMOS    | I         | 1          |                              |         | Serial ATA Reference Clock (Differential): The positive side of the 100MHz clock input from the clock generator for the SATA PLL. |
| SATA_TXp1    | LV Diff | O         | 1          |                              | XOR     | Serial ATA Interface Port 1 Transmit Data Pair (Differential): The positive side of the port 1 transmit data pair.                |

Table 48-17. Serial ATA Interface Signals (Sheet 2 of 2)

| Signal Name  | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|--------------|-------------|-----------|------------|------------------------------|---------|---|
| SATA_TXn1    | LV Diff     | O         | 1          |                              | XOR     | Serial ATA Interface Port 1 Transmit Data Pair (Differential): The negative side of the port 1 transmit data pair.  |
| SATA_RXp1    | LV Diff     | I         | 1          |                              | XOR     | Serial ATA Interface Port 1 Receive Data Pair (Differential): The positive side of the port 1 receive data pair.  |
| SATA_RXn1    | LV Diff     | I         | 1          |                              | XOR     | Serial ATA Interface Port 1 Receive Data Pair (Differential): The negative side of the port 1 receive data pair.  |
| SATA_RBIAS   | Analog      | I         | 1          |                              | XOR     | Serial ATA Resistor Bias (Positive): Analog connection point for an external bias resistor.   |
| SATA_RBIAS#  | Analog      | I         | 1          |                              | XOR     | Serial ATA Resistor Bias (Negative): Analog connection point for an external bias resistor.   |
| GP26_SATA0GP |             |           |            |                              |         | See GPIO interface.   |
| GP29_SATA1GP |             |           |            |                              |         | See GPIO interface.   |
| SATALED#     | LVTTTL,3.3V | OD O      | 1          | 220 to 10K Ohms              | BSC     | Serial ATA LED: This is an open-collector/open-drain output signal driven during SATA command activity. It is to be connected to external circuitry that can provide the current to drive a platform LED. When active, the LED is on. When tristated, the LED is off. An external pull-up resistor is required. |
| TOTAL        |             |           | 13         |                              |         |   |

### 48.4.3.8 Universal Serial Bus (USB) Interface

Table 48-18. USB Interface Signals

| Signal Name | IO Type    | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|-------------|------------|-----------|------------|------------------------------|---------|---|
| USBp0       | LV Diff    | I/O       | 1          |                              | XOR     | USB Port 0 Signal (Differential): The positive side of the differential pair that is used to transmit Data/Address/Command signals for USB port 0.<br><br>Note: External resistors are not required on these signals. The chip integrates the 15 K-ohm pull-down and provides an output driver impedance of 45 ohm which requires no external series resistor.  |
| USBn0       | LV Diff    | I/O       | 1          |                              | XOR     | USB Port 0 Signal (Differential): The negative side of the differential pair that is used to transmit Data/Address/Command signals for USB port 0 (see USBp0).  |
| USBp1       | LV Diff    | I/O       | 1          |                              | XOR     | USB Port 1 Signal (Differential): The positive side of the differential pair that are used to transmit Data/Address/Command signals for USB port 0.<br><br>Note: External resistors are not required on these signals. The chip integrates the 15 K-ohm pull-down and provides an output driver impedance of 45 ohm which requires no external series resistor. |
| USBn1       | LV Diff    | I/O       | 1          |                              | XOR     | USB Port 1 Signal (Differential): The negative side of the differential pair that is used to transmit Data/Address/Command signals for USB port 0 (see USBp1).  |
| OC[1]#      | LVTTL,3.3V | I         | 1          | 10K Up                       | BSC     | USB Port 1 Overcurrent Indicator: This signal sets corresponding bits in the USB controller to indicate that an overcurrent condition has occurred on USB Port 1.   |
| OC[0]#      | LVTTL,3.3V | I         | 1          | 10K Up                       | BSC     | USB Port 0 Overcurrent Indicator: This signal sets corresponding bits in the USB controller to indicate that an overcurrent condition has occurred on USB Port 0.   |
| USB_RBIASp  | Analog     | O         | 1          |                              |         | USB Controller Resistor Bias (Positive): Analog connection point for an external resistor. Used to set transmit currents and internal load resistors.   |
| USB_RBIASn  | Analog     | I         | 1          |                              |         | USB Controller Resistor Bias (Negative): Analog connection point for an external resistor. Used to set transmit currents and internal load resistors.   |
| CLK48       | LVTTL,3.3V | I         | 1          |                              |         | USB Controller Reference Clock: 48MHz reference clock for the USB controller.   |
| TOTAL       |            |           | 9          |                              |         |   |

### 48.4.3.9 Power Management Interface

Table 48-19. Power Management Interface Signals (Sheet 1 of 2)

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|-------------|-------------|-----------|------------|------------------------------|---------|--|
| PLTRST#     | LVTTTL,3.3V | O         | 1          |                              | BSC     | Platform Reset: The EP80579 asserts PLTRST# to reset devices that reside on the PCI bus. The IICH asserts PLTRST# during power-up and when a hard reset sequence is initiated through the 0CF9h register. PLTRST# is driven inactive a minimum of 1 ms after both PWROK and VRMPWRGD are driven high. PLTRST# is driven for a minimum of 1 ms when initiated through the 0CF9h register.<br><br>Note: PLTRST# is in the 3.3V VCCPSUS well.   |
| PROCHOT#    | LVTTTL,3.3V | O         | 1          |                              | BSC     | Processor Hot Thermal Alarm: This signal will go active when the processor temperature monitoring sensor detects that the processor has reached its maximum safe operating temperature. This indicates that the processor Thermal Control Circuit has been activated, if enabled.  |
| THRMTRIP#   | LVTTTL,3.3V | OD I/O    | 1          | 10K (maximum) Up             | BSC     | Thermal Trip: The processor protects itself from catastrophic overheating by use of an internal thermal sensor. This sensor is set well above the normal operating temperature to ensure that there are no false trips. When low, indicates that a thermal trip on behalf of the processor has occurred, and corrective action will be taken (immediately transitions the EP80579 to a S5 state). This is an open-drain signal which optionally allows the platform to force an S5 transition. |
| SLP_S3#     | LVTTTL,3.3V | O         | 1          |                              | BSC     | S3 Sleep Control: SLP_S3# is for power plane control. This signal shuts off power to all non-critical systems when in S3 (Suspend To RAM), S4 (Suspend to Disk), or S5 (Soft Off) states.  |
| SLP_S4#     | LVTTTL,3.3V | O         | 1          |                              | BSC     | S4 Sleep Control: SLP_S4# is for power plane control. This signal shuts power to all non-critical systems when in the S4 (Suspend to Disk) or S5 (Soft Off) state.<br><br>Note: This pin must be used to control the DRAM power to use the EP80579 's DRAM power-cycling feature.  |
| SLP_S5#     | LVTTTL,3.3V | O         | 1          |                              | BSC     | S5 Sleep Control: SLP_S5# is for power plane control. This signal is used to shut power off to all non-critical systems when in the S5 (Soft Off) states.  |
| PWROK       | LVTTTL,3.3V | I         | 1          |                              |         | Power OK: When asserted, PWROK is an indication that core power has been stable for at least 99ms and PCICLK has been toggling cleanly for at least 1 ms. PWROK can be driven asynchronously. When PWROK is low, PLTRST# is asserted.<br><br>Note that it is required that the core power has been valid for 99ms prior to PWROK assertion in order to comply with the 100ms PCI 2.3 Specification on PLTRST# deassertion.   |

Table 48-19. Power Management Interface Signals (Sheet 2 of 2)

| Signal Name | IO Type      | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR        | Signal Description Normal/Alternate Mode   |
|-------------|--------------|-----------|------------|------------------------------|----------------|--|
| PWRBTN#     | LVTTTL, 3.3V | I         | 1          |                              | BSC            | Power Button: Causes SMI or SCI to indicate to system request to go to a sleep state. If already in sleep state, will cause a wake event. If PWRBTN# is pressed for four seconds, will cause unconditional transition (power button override) to the S5 state. Override will occur even if the system is in the S3 or S4 state.<br><br>This signal has an internal pullup resistor and has an internal 16 ms de-bounce on the input. |
| RI#         | LVTTTL, 3.3V | I         | 1          |                              | BSC/XOR output | Ring Indicate: From the modem interface. Can be enabled as a wake event and is preserved during power failures.  |
| SYS_RESET#  | LVTTTL, 3.3V | I         | 1          |                              | BSC            | System Reset: This pin forces an internal reset after being debounced. The EP80579 will reset immediately if the SMBus is idle; otherwise, it will wait up to 25 ms $\pm$ 2 ms for the SMBus to idle before forcing a reset on the system.   |
| RSMRST#     | LVTTTL, 3.3V | I         | 1          |                              |                | Resume Well Reset: Used for resetting the resume well. An external RC circuit is required to guarantee that the resume well power is valid prior to RSMRST# going high.  |
| SUS_STAT#   | LVTTTL, 3.3V | O         | 1          |                              | BSC            | Suspend Status: This signal is asserted to indicate that the system will be entering a low power state soon. This can be monitored by devices with memory that need to switch from normal refresh to suspend refresh mode. It can also be used by other peripherals as an indication that they must isolate their outputs that may be going to powered-off planes.<br><br>This signal is called LPCPD# on the LPC I/F.               |
| SUSCLK      | LVTTTL, 3.3V | O         | 1          |                              | BSC            | Suspend Clock: Output of the RTC clock generator circuit (32.768 kHz). SUSCLK will have a duty cycle that can be as low as 30% or as high as 70%.  |
| VRMPWRGD    | LVTTTL, 3.3V | I         | 1          |                              | BSC            | Voltage Regulator Power Good: This is the processor's VRM Power Good, and will save an external AND gate. This signal is internally ANDed with the ATX power supply's PWROK signal. Traditionally, this AND gate has been external to the chipset.   |
| TOTAL       |              |           | 14         |                              |                |  |

### 48.4.3.10 IICH Miscellaneous Signals

Table 48-20. IICH Miscellaneous Signals

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|-------------|-------------|-----------|------------|------------------------------|---------|--|
| CLK14       | LVTTTL,3.3V | I         | 1          |                              | BSC     | Timer Oscillator Clock: Used for 8254 timers and HPET (High Precision Event Timer). Runs at 14.31818 MHz. This clock stops (and should be low) during S3 and S5 state. CLK14 must be accurate to within 500ppm over 100usecs (and longer periods) in order to meet HPET accuracy requirements.   |
| PE_HPINTR#  | LVTTTL,3.3V | I         | 1          | 10K to 100K Up               | BSC     | IMCH PCI Express Hot-plug Controller Interrupt: Input pin to hot-plug controller on PCI Express bus. Not 5V tolerant.<br><br>Note: Because PCI Express Hot Plug is not supported in the EP80579, this pin must be pulled up to 3.3V through a 10K to 100K pull-up resistor.  |
| BSEL        | LVTTTL,3.3V | O         | 1          |                              | BSC     | IA FSB Frequency Select: The CPU Select (BSEL) encodings are used at power-on to specify the frequency mode of the FSB PLL circuitry.<br><br>The EP80579 interprets BSEL as follows:<br>0 = 400MHz FSB<br>1 = 533MHz FSB<br><br>BSEL is driven by the on-die CPU based on its configuration.   |
| V_SEL       | LVTTTL,3.3V | I/OD      | 1          | 10K Up                       | BSC     | IA Voltage Select: The voltage select encodings are used in conjunction with BSEL at power-on to specify the operating voltage of the IA CPU. This signal is a 3.3V OD output with an external pullup.<br><br>The EP80579 interprets V_SEL as follows when BSEL is 0 (400MHz FSB):<br>0 = 1.00V IA core voltage VCCVC<br>1 = Reserved<br>and as follows when BSEL is 1 (533MHz FSB):<br>0 = 1.30V IA core voltage VCCVC<br>1 = 1.30V IA core voltage VCCVC<br><br>The voltage supply for these pins must be valid before the Voltage Regulator can supply VCCVC to the processor. The V_SEL pin is needed to support the processor voltage specification variations defined above. The VR must supply the voltage that is requested by the pins. |
| WDT_TOUT#   | LVTTTL,3.3V | O         | 1          |                              | BSC     | Watchdog Timer Output Signal: The signal is driven low when the main 35-bit down counter reaches zero during the second stage. The WDT_TOUT_CNF bit in the WDT Lock register determines if the output is to change from the previous state if another time out occurs, or WDT_TOUT_N is driven low until the system is reset or power is cycled.   |
| TOTAL       |             |           | 5          |                              |         |  |

## 48.4.4 Acceleration and I/O Complex (AI OC)

### 48.4.4.1 Controller Area Network (CAN) Bus

Table 48-21. Controller Area Network Bus Signals

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|-------------|-------------|-----------|------------|------------------------------|---------|--|
| CNORXD      | LVTTTL,3.3V | I         | 1          |                              | BSC     | CAN Bus Channel 0: Receive data signal. Connect to the respective RxD of the external driver.  |
| CNOTXD      | LVTTTL,3.3V | O         | 1          |                              | BSC     | CAN Bus Channel 0: Transmit data signal. Connect to the respective TxD of the external driver. |
| CNOTXEN     | LVTTTL,3.3V | O         | 1          |                              | BSC     | CAN Bus Channel 0: Data enable signal.   |
| CN1RXD      | LVTTTL,3.3V | I         | 1          |                              | BSC     | CAN Bus Channel 1: Receive data signal. Connect to the respective RxD of the external driver.  |
| CN1TXD      | LVTTTL,3.3V | O         | 1          |                              | BSC     | CAN Bus Channel 1: Transmit data signal. Connect to the respective TxD of the external driver. |
| CN1TXEN     | LVTTTL,3.3V | O         | 1          |                              | BSC     | CAN Bus Channel 1: Data enable signal.   |
| TOTAL       |             |           | 6          |                              |         |  |

### 48.4.4.2 Gigabit Ethernet (GbE) Interface

Table 48-22. Gigabit Ethernet Interface Signals (Sheet 1 of 4)

| Signal Name      | IO Type  | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|------------------|----------|-----------|------------|------------------------------|---------|--|
| GBE0_TxCLK       | 2.5VCMOS | O         | 1          |                              | BSC     | Gigabit Ethernet Controller Port 0 Transmit Clock: Transmit clock for GbE port 0. The interpretation of this signal depends on the interface mode that the controller is operating in.<br><br>For RGMII this signal is the Transmit Clock, it is disabled for RMII.  |
| GBE0_TxCTL       | 2.5VCMOS | O         | 1          |                              | BSC     | Gigabit Ethernet Controller Port 0 Transmit Control: Transmit control for GbE port 0. The interpretation of this signal depends on the interface mode that the controller is operating in.<br><br>For RGMII and RMII, this signal is the Transmit Control and Transmit Enable, respectively.   |
| GBE0_TxDATA[3:0] | 2.5VCMOS | O         | 4          |                              | BSC     | Gigabit Ethernet Controller Port 0 Transmit Control: Transmit control for GbE port 0. The interpretation of these signals depends on the interface mode that the controller is operating in.<br><br>For RGMII,<br>GBE0_TxDATA[3:0] - Transmit Data<br>and for RMII,<br>GBE0_TxDATA[3:2] - Disabled<br>GBE0_TxDATA[1:0] - Transmit Data                       |
| GBE0_RxCLK       | 2.5VCMOS | I         | 1          |                              | BSC     | Gigabit Ethernet Controller Port 0 Receive Clock: Receive clock for GbE port 0. The interpretation of this signal depends on the interface mode that the controller is operating in.<br><br>For RGMII this signal is the Receive Clock, it is disabled for RMII. The GBE0_RxCLK's can be tied to GND as they are not required in RMII mode – only in RGMII.  |
| GBE0_RxCTL       | 2.5VCMOS | I         | 1          |                              | BSC     | Gigabit Ethernet Controller Port 0 Receive Control: Receive control for GbE port 0. The interpretation of this signal depends on the interface mode that the controller is operating in.<br><br>For RGMII and RMII, this signal is the Receive Control and Carrier Sense/Receive Data Valid, respectively.   |
| GBE0_RxDATA[3:0] | 2.5VCMOS | I         | 4          |                              | BSC     | Gigabit Ethernet Controller Port 0 Receive Data: Receive data for GbE port 0. The interpretation of these signals depends on the interface mode that the controller is operating in.<br><br>For RGMII,<br>GBE0_RxDATA[3:0] - Receive Data<br>and for RMII,<br>GBE0_RxDATA[3] - Receive Error<br>GBE0_RxDATA[2] - Disabled<br>GBE0_RxDATA[1:0] - Receive Data |

Table 48-22. Gigabit Ethernet Interface Signals (Sheet 2 of 4)

| Signal Name      | IO Type  | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|------------------|----------|-----------|------------|------------------------------|---------|---|
| GBE1_TxCLK       | 2.5VCMOS | O         | 1          |                              | BSC     | Gigabit Ethernet Controller Port 1 Transmit Clock: Transmit clock for GbE port 1. See GBE0_TxCLK.     |

Table 48-22. Gigabit Ethernet Interface Signals (Sheet 3 of 4)

| Signal Name     | IO Type  | Direction | Ball Count | External Pull-Up/Down [Ohms]                     | BSC/XOR | Signal Description Normal/Alternate Mode  |
|-----------------|----------|-----------|------------|--|---------|---|
| GBE_REFCLK      | 2.5VCMOS | I         | 1          |  | BSC     | <p>Gigabit Ethernet Controller Reference Clock: 50MHz or 125MHz (depend on mode) reference clock for the GbE Controller.</p> <p>In RGMII mode or mixed mode (RGMII and RMII), the frequency of this clock must be 125MHz regardless of the individual port transmit and receive rates and this clock must always be present.</p> <p>In RMII mode (all ports only), there are two clocks required. The GBE_REFCLK_RMII is required as per the RMII spec. The GBE_REFCLK is also required for the RCOMP controller and the retrieval of the port information from the EEPROM. In RMII mode (all ports only), the GBE_REFCLK can be either 50Mhz or 125Mhz. If both clock are the same frequency, connecting GBE_REFCLK and GBE_REFCLK_RMII to the same source will work fine.</p> |
| GBE_REFCLK_RMII | 2.5VCMOS | I         | 1          |  | BSC     | <p>Gigabit Ethernet Controller RMII Reference Clock: 50Mhz reference clock for the GbE Controller in RMII Mode. The frequency of this clock is 50MHz regardless of the individual port transmit / receive rates and must always be present.</p>   |
| GBE_RCOMP       | Analog   | I/O       | 1          | 50 Down (to VSS)                                 |         | <p>Gigabit Ethernet Controller Compensation: Off-die reference resistor to which the output driver pull up output impedance is matched (nominally 50 ohms to ground).</p>   |
| GBE_RCOMP       | Analog   | I/O       | 1          | 50 Up (to VCCSUS25)                              |         | <p>Gigabit Ethernet Controller Compensation: Off-die reference resistor to which the output driver pull down output impedance is matched (nominally 50 ohms to VCCSUS25).</p>   |
| EEDI            | 2.5VCMOS | O         | 1          | 10K Up (if AUX_PWR_PRESENT), otherwise 4.7K Down | BSC     | <p>Gigabit Ethernet Controller EEPROM Input Data: LVTTTL data output to serial EEPROM.</p> <p>This pin is also sampled at an edge of GBE_AUX_PWR_GOOD to indicate the presence of the auxiliary power supply for GbE0.</p> <p>Gigabit Ethernet Controller aux_pwr Strap: This strap indicates if an auxiliary supply is being used for GbE0.</p> <p>The EP80579 interprets the strap as follows:<br/>           0 = No aux_pwr mode (i.e., auxiliary supply is not used).<br/>           1 = aux_pwr mode support (i.e., auxiliary supply is used)</p>  |
| EEDO            | 2.5VCMOS | I         | 1          |  | BSC     | <p>Gigabit Ethernet Controller EEPROM Output Data.</p>  |
| EECS            | 2.5VCMOS | O         | 1          |  | BSC     | <p>Gigabit Ethernet Controller EEPROM Chip Select: chip select to enable the EEPROM device.</p>   |
| EESK            | 2.5VCMOS | O         | 1          |  | BSC     | <p>Gigabit Ethernet Controller EEPROM Shift Clock: clock for the EEPROM interface, frequency is ~1MHz.</p>  |

Table 48-22. Gigabit Ethernet Interface Signals (Sheet 4 of 4)

| Signal Name      | IO Type  | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|------------------|----------|-----------|------------|------------------------------|---------|--|
| GBE_PME_WAKE     | 2.5VCMOS | OD O      | 1          |                              | BSC     | Gigabit Ethernet Controller Wake: This active low signal is used by the GbE's to signal that a PME event has occurred. It is the wired OR of all three Gigabit Ethernet Controllers on the EP80579 .   |
| SYS_PWR_OK       | 2.5VCMOS | I         | 1          |                              |         | Gigabit Ethernet Controller: This is the PWR_GOOD signal used by GbEs supplied by primary core power. This signal indicates that all chip power supplies are on and stable. This signal should be asserted once core power is stable.  |
| GBE_AUX_PWR_GOOD | 2.5VCMOS | I         | 1          |                              |         | Gigabit Ethernet Controller Power Good: Input signifying that the GbE Port 0 and miscellaneous support IO power supplies are on and stable (this is the PWR_GOOD signal which is pinned out for GbE Port 0 only). When an auxiliary power supply is used for GbE Port 0, this signal should be asserted once that auxiliary power is stable. If Core power is used for GbE Port 0 then this pin should be tied to the core Power OK signal SYS_PWR_OK. |
| TOTAL            |          |           | 49         |                              |         |  |

### 48.4.4.3 Time Division Multiplexing (TDM) Interface

Table 48-23. TDM Interface Signals<sup>a,b</sup>

| Signal Name  | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode    |

| Rx_DATA_IN1  | LVTTTL,3.3V | I         | 1          |                              | BSC     | TDM Interface Port 1: Receive data input.   |
| Rx_CLK2      | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | TDM Interface Port 2: Receive clock.        |
| Tx_CLK2      | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | TDM Interface Port 2: Transmit clock.       |
| Tx_FRAME2    | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | TDM Interface Port 2: Transmit frame.       |
| Tx_DATA_OUT2 | LVTTTL,3.3V | O         | 1          |                              | BSC     | TDM Interface Port 2: Transmit data output. |
| Rx_FRAME2    | LVTTTL,3.3V | I/O       | 1          |                              | BSC     | TDM Interface Port 2: Receive frame.        |
| Rx_DATA_IN2  | LVTTTL,3.3V | I         | 1          |                              | BSC     | TDM Interface Port 2: Receive data input.   |
| TOTAL        |             |           | 18         |                              |         |   |

- a. Feature must be enabled with the EP80579 software. Refer to the software for the Intel® EP80579 Integrated Processor product line.
- b. Certain SKUs may not contain this feature. For complete information about product features, see Section 47.2.1, “SKU Features” .

#### 48.4.4.4 Local Expansion Bus (LEB) Interface

Table 48-24. Expansion Bus Signals (Sheet 1 of 3)

| Signal Name   | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|---------------|-------------|-----------|------------|------------------------------|---------|---|
| EX_ALE        | LVTTTL,3.3V | O         | 1          |                              | BSC     | Expansion Bus Address Latch Enable/Advance/LD#: Address latch enable signal for the Expansion bus.<br><br>EXALE has pull-ups enabled when PLL_LOCK is deasserted. These pull-ups are disabled when PLL_LOCK is asserted and the EP80579 drives the signal based upon grant. EXALE is driven by the EP80579.   |
| EX_ADDR[24:0] | LVTTTL,3.3V | IO        | 25         |                              | BSC     | Expansion Bus Address: The 25-bit address bus for the Expansion Bus.<br><br>EXADx has pull-ups enabled when PLL_LOCK is deasserted to allow sampling of configuration bits that select the address space size (see strapping discussion).<br><br>These pull-ups are disabled when PLL_LOCK is asserted and the EP80579 drives the signal based upon grant. EXADx driven by the EP80579.<br><br>Expansion Bus Memory Size Strap: This strap selects the size of the memory space that the Expansion Bus claims for its MMIO region. Bits 23, 22, and 21 encode the size. The EP80579 interprets the value of the EXAD[23:21] pins as follows:<br>000b - 0MB (i.e., Expansion bus disabled)<br>001b - 32MB<br>010b - 64MB<br>011b - 128MB<br>1XXb - 256MB<br><br>Note: Expansion Bus Memory Size should be configured by strapping or by Pre-boot Firmware to determine LEB_SIZE. |
| EX_BE[1:0]#   | LVTTTL,3.3V | IO        | 2          |                              | BSC     | Expansion Bus Byte Enable: Byte enables for the 16-bit data bus in the Expansion Bus.<br><br>EXBEx has pull-ups enabled when PLL_LOCK is deasserted. These pull-ups are disabled when PLL_LOCK is asserted and the EP80579 drives the signal based upon grant. EXBEx is driven by EP80579.<br><br>These signals are active-low.   |
| EX_CLK        | LVTTTL,3.3V | I         | 1          |                              | BSC     | Expansion Bus Clock: EXCLK is always an input. May be driven from a GPIO clock or from an external clock source.<br><br>Maximum Frequency: 80MHz<br>Minimum Frequency: 33MHz  |

Table 48-24. Expansion Bus Signals (Sheet 2 of 3)

| Signal Name    | IO Type    | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|----------------|------------|-----------|------------|------------------------------|---------|---|
| EX_CS[7:0]#    | LVTTL,3.3V | IO        | 8          |                              | BSC     | Expansion Bus Target Chip Selects: Chip selects to select Expansion Bus devices.<br><br>EXCS has pull-ups enabled when PLL_LOCK is deasserted. These pull-ups are disabled when PLL_LOCK is asserted and the EP80579 drives the signal based upon grant. EXCS is driven by the EP80579.<br><br>These signals are active-low.              |
| EX_DATA[15:0]  | LVTTL,3.3V | IO        | 16         |                              | BSC     | Expansion Bus Data: The 16-bit data bus for the Expansion bus.<br><br>EXDA has pull-ups enabled when PLL_LOCK is deasserted. These pull-ups are disabled when PLL_LOCK is asserted and the EP80579 drives the signal based upon grant. EXDA is driven by the EP80579 during outbound writes, and inbound reads, and when the bus is idle. |
| EX_IOWAIT#     | LVTTL,3.3V | I         | 1          |                              | BSC     | Expansion bus Target Wait #. EX_IOWAIT_N is always an input.<br>Reset value is driven from the board.<br><br>This signal is active-low.   |
| EX_PARITY[1:0] | LVTTL,3.3V | IO        | 2          |                              | BSC     | Expansion Bus Parity: Parity bits for the two bytes on the data bus.<br>EXPAR0 = Parity for EXDA[7:0]<br>EXPAR1 = Parity for EXDA[15:8]<br><br>EXPARx has pull-ups enabled when PLL_LOCK is deasserted. These pull-ups are disabled when PLL_LOCK is asserted. EXPARx is driven with the same timing as EXDAX.                            |
| EX_RD#         | LVTTL,3.3V | IO        | 1          |                              | BSC     | Expansion Bus Read: Read signal for the Expansion Bus.<br><br>EXRDN has pull-ups enabled when PLL_LOCK is deasserted. These pull-ups are disabled when PLL_LOCK is asserted and the EP80579 drives the signal based upon grant. EXRDN is driven by the EP80579.<br><br>This signal is active-low.   |
| EX_RDY[3:0]#   | LVTTL,3.3V | I         | 4          |                              | BSC     | Expansion Bus HPI Ready: HPI ready signal for the Expansion Bus. EXRDYx are always inputs.<br>EXRDY0 = Ready signal for Chip Select #4<br>EXRDY1 = Ready signal for Chip Select #5<br>EXRDY2 = Ready signal for Chip Select #6<br>EXRDY3 = Ready signal for Chip Select #7<br><br>This signal is active-low.                              |
| EX_BURST       | LVTTL,3.3V | I         | 1          |                              | BSC     | Expansion Bus Burst Size: Burst size signal.<br>EX_BURST is an input in normal operation.   |
| EX_WR#         | LVTTL,3.3V | IO        | 1          |                              | BSC     | Expansion Bus Write: Write signal.<br><br>This signal is active-low.  |

Table 48-24. Expansion Bus Signals (Sheet 3 of 3)

| Signal Name | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|-------------|---------|-----------|------------|------------------------------|---------|--|
| EX_RCOMP    | Analog  | IO        | 1          | 50 Down                      |         | Expansion Bus Compensation: Resistive compensation, controls the drive high strength of EX outputs. Connect to a 50 pulldown resistor.                       |
| EX_RCOMP    | Analog  | IO        | 1          | 50 Up (to VCC3P3)            |         | Expansion Bus Compensation: Resistive compensation, controls the drive low strength of the EX outputs. Connect to a 50 pullup resistor, pulled up to VCC3P3. |
| TOTAL       |         |           | 65         |                              |         |  |

### 48.4.4.5 Synchronous Serial Port (SSP) Interface

Table 48-25. SSP Interface Signals

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|-------------|-------------|-----------|------------|------------------------------|---------|--|
| SSP_SCLK    | LVTTTL,3.3V | O         | 1          |                              | BSC     | SSP Interface Clock: Serial bit-rate clock (1.84MHz maximum frequency). This is the bit-rate clock, driven from the SSP port to the peripheral. Normally, it toggles only when data is actively being transmitted. |
| SSP_SFRM    | LVTTTL,3.3V | O         | 1          |                              | BSC     | SSP Interface Frame Indicator: This is the framing signal and indicates the beginning and the end of a serialized data word.   |
| SSP_TXD     | LVTTTL,3.3V | O         | 1          |                              | BSC     | SSP Interface Transmit Data: This is the transmit (i.e., outbound) serialized data lines. The word length and MSB/LSB orientation are a function of the selected serial data format.                               |
| SSP_RXD     | LVTTTL,3.3V | I         | 1          |                              | BSC     | SSP Interface Receive Data: This is the receive (i.e., inbound) serialized data lines. The word length and MSB/LSB orientation are a function of the selected serial data format.                                  |
| SSP_EXTCLK  | LVTTTL,3.3V | I         | 1          |                              | BSC     | SSP Interface External Clock: This clock can be selected to replace the internally-generated clock that is used to generate the serial bit-rate clock (SSPCLK).  |
| TOTAL       |             |           | 5          |                              |         |  |

### 48.4.4.6 IEEE 1588-2008 Hardware Assist Interface

Table 48-26. IEEE 1588-2008 Hardware Assist Interface Signals (Sheet 1 of 2)

| Signal Name        | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|--------------------|-------------|-----------|------------|------------------------------|---------|--|
| 1588_TESTMODE_DATA | LVTTTL,3.3V | O         | 1          |                              | BSC     | IEEE 1588-2008 Hardware Assist Test Output: This signal will reflect bits of the internal System Timer depending on the setting of internal control bits in the 1588_Test register.  |
| 1588_PPS           | LVTTTL,3.3V | O         | 1          |                              | BSC     | IEEE 1588-2008 Hardware Assist Pulse Per Second Output - This signal is asserted high when a match occurs between the Compare register and lower 32 bits of system time. Clearing of this signal is under firmware control. The register and pin can be used to create a pulse per second event. |
| ASMSSIG            | LVTTTL,3.3V | I         | 1          |                              | BSC     | IEEE 1588-2008 Hardware Assist Auxiliary Slave Mode Snapshot: An active high level on this input causes a snapshot of system time to be captured in the ASMS register.   |
| AMMSSIG            | LVTTTL,3.3V | I         | 1          |                              | BSC     | IEEE 1588-2008 Hardware Assist Auxiliary Master Mode Snapshot: An active high level on this input causes a snapshot of system time to be captured in the AMMS register.  |

Table 48-26. IEEE 1588-2008 Hardware Assist Interface Signals (Sheet 2 of 2)

| Signal Name  | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|--------------|-------------|-----------|------------|------------------------------|---------|--|
| 1588_RX_SNAP | LVTTTL,3.3V | O         | 1          |                              | BSC     | IEEE 1588-2008 Hardware Assist Receive Snapshot Taken Output: This signal will pulse high for eight pclk's whenever a timestamp has been taken on the receive channel. The receive channel that is monitored is determined by the control bits in the TS_Test Register.    |
| 1588_TX_SNAP | LVTTTL,3.3V | O         | 1          |                              | BSC     | IEEE 1588-2008 Hardware Assist Transmit Snapshot Taken Output: This signal will pulse high for eight pclk's whenever a timestamp has been taken on the transmit channel. The transmit channel that is monitored is determined by the control bits in the TS_Test Register. |
| TOTAL        |             |           | 6          |                              |         |  |

## 48.4.5 Miscellaneous

### 48.4.5.1 JTAG

Table 48-27. JTAG Interface Signals

| Signal Name   | IO Type       | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode  |
|---------------|---------------|-----------|------------|------------------------------|---------|---|
| TMS           | LVC MOS, 1.2V | I         | 1          |                              |         | Test Interface: Test Mode Select. Input in normal operation.  |
| TDI           | LVC MOS, 1.2V | I         | 1          |                              |         | Test Interface: Test Data In. Input in normal operation.  |
| TDO           | LVC MOS, 1.2V | OD O      | 1          |                              |         | Test Interface: Test Data Out   |
| TCK           | LVC MOS, 1.2V | I         | 1          |                              |         | Test Interface: Test Clock. Input in normal operation.  |
| TRST#         | LVC MOS, 1.2V | I         | 1          |                              |         | Test Interface: Test Reset. Input in normal operation.  |
| BPM0          | SSTL_18       | OD I/O    | 1          |                              | BSC     | ITP debug interface   |
| BPM1          | SSTL_18       | OD I/O    | 1          |                              | BSC     | ITP debug interface   |
| BPM2          | SSTL_18       | OD I/O    | 1          |                              | BSC     | ITP debug interface   |
| BPM3          | SSTL_18       | OD I/O    | 1          |                              | BSC     | ITP debug interface   |
| BPM3_IN       | LVC MOS, 1.2V | I         | 1          |                              | BSC     | ITP Debug Interface: IA-32 core breakpoint monitor. Should be a NC (no-connect, left floating) if not used. |
| BPM4_PRDY_OUT | LVTTTL,3.3V   | OD O      | 1          | 50 Ohm Pullup to 1.2v        | BSC     | ITP Debug Interface: IA-32 core PRDY. Open drain output.  |
| BPM5_PREQ_IN  | LVC MOS, 1.2V | I         | 1          |                              | BSC     | ITP Debug Interface: IA-32 core PREQ. Should be a NC (no-connect, left floating) if not used.               |
| TOTAL         |               |           | 12         |                              |         |   |

### 48.4.5.2 Miscellaneous Signals

Table 48-28. Miscellaneous Signals

| Signal Name | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode   |
|-------------|-------------|-----------|------------|------------------------------|---------|--|
| PME#        | LVTTTL,3.3V | I/OD      | 1          |                              | BSC     | <p>PCI Power Management Event: Driven by PCI peripherals to wake the system from low-power states S3, S4 and S5. It can also cause an SCI from the S0 state. Note that in some cases the EP80579 may drive PME# active (low) due to an internal wake event. It will not drive PME# high (but it may be pulled up using the internal pull-up resistor).</p> <p>PME# is in the 3.3V VCCPSUS power plane and has an internal pull-up resistor.</p>  |
| PCIRST#     | LVTTTL,3.3V | O         | 1          |                              | BSC     | <p>PCI Reset: This is the Secondary parallel PCI Bus reset signal. It is a logical OR of the primary interface PLTRST# signal and the state of the Secondary Bus Reset bit.</p> <p>Note: PCIRST# is in the 3.3V VCCPSUS well.</p>  |
| SPKR        | LVTTTL,3.3V | O         | 1          |                              | BSC     | <p>Speaker: The SPKR signal is the output of counter 2 and is internally "ANDed" with Port 061h bit 1 to provide Speaker Data Enable. This signal drives an external speaker driver device, which in turn drives the system speaker. Upon PLTRST#, its output state is 0.</p> <p>This signal has a weak internal pull-down resistor.</p> <p>SPKR is sampled at platform reset as a functional strap.</p> <p>No Reboot Strap: This strap controls the re-boot behavior of timeouts in the TCO timer. The EP80579 interprets the strap as follows:<br/>           0 = Reboot on second timeout of TCO timer (default).<br/>           1 = No re-boot on second timeout of TCO timer.</p> |
| TOTAL       |             |           | 3          |                              |         |  |

### 48.4.5.3 Reserved

Table 48-29. Reserved Pin List (Sheet 1 of 2)

| Signal Name | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode                             |
|-------------|---------|-----------|------------|------------------------------|---------|--|
| Reserved0   |         |           | 1          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown. |
| Reserved1   |         |           | 1          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown. |
| Reserved2   |         |           | 1          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown. |

Table 48-29. Reserved Pin List (Sheet 2 of 2)

| Signal Name   | IO Type     | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode                              |
|---------------|-------------|-----------|------------|------------------------------|---------|---|
| Reserved3     |             |           | 1          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown.  |
| Reserved4     |             |           | 1          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown.  |
| Reserved5     |             |           | 1          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown.  |
| Reserved6     |             |           | 1          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown.  |
| Reserved7     |             |           | 1          |                              | BSC     | Reserved: This signal must be connected to VSS.                       |
| Reserved8     |             |           | 1          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown.  |
| Reserved9     |             |           | 1          |                              | BSC     | Reserved: This signal must be connected to VSS.                       |
| Reserved10    |             |           | 1          | 10K Up                       | BSC     | Reserved: Must have external pull-up to VCCPSUS.                      |
| Reserved11    |             |           | 1          |                              | BSC     | Reserved: This pin must be tied low (VSS) externally on the platform. |
| Reserved12-14 |             |           | 3          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown.  |
| Reserved15    |             |           | 1          |                              | BSC     | Reserved: This signal must be connected to VSS.                       |
| Reserved16    | LVTTTL,3.3V | I         | 1          | 10K Up                       | BSC     | Reserved: This signal must be connected to a 10K-ohm pull-up to 3.3V. |
| Reserved17    | LV          | I/O       | 1          |                              | BSC     | Reserved: This signal must be connected to VSS.                       |
| Reserved18    | LVTTTL,3.3V | I         | 1          | 10K Down                     | BSC     | Reserved: This signal must be connected to VSS via 10K-ohm pulldown.  |
| Reserved19-20 | LVTTTL,3.3V | I         | 2          | 10K Up                       | BSC     | Reserved: This signal must be connected to a 10K-ohm pull-up to 3.3V. |
| TOTAL         |             |           | 21         |                              |         |   |

#### 48.4.5.4 No Connect

Table 48-30. No Connect Pin List (Sheet 1 of 2)

| Signal Name | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode |
|-------------|---------|-----------|------------|------------------------------|---------|--|
| NC_SUS_TWO  |         |           | 1          |                              | BSC     | No Connect                               |
| NC_TWO      |         |           | 1          |                              | BSC     | No Connect                               |
| NC7         |         |           | 1          |                              | BSC     | No Connect                               |
| NC9         |         |           | 1          |                              | BSC     | No Connect                               |
| NC10        |         |           | 1          |                              | BSC     | No Connect                               |
| NC11        |         |           | 1          |                              | BSC     | No Connect                               |

Table 48-30. No Connect Pin List (Sheet 2 of 2)

| Signal Name | IO Type | Direction | Ball Count | External Pull-Up/Down [Ohms] | BSC/XOR | Signal Description Normal/Alternate Mode                             |
|-------------|---------|-----------|------------|------------------------------|---------|--|
| NC12        |         |           | 1          |                              |         | No connect.  |
| NC13        |         |           | 1          |                              |         | No connect.  |
| NC14        |         |           | 1          |                              |         | No connect.  |
| NC15        |         |           | 1          |                              |         | No connect.  |
| NC16        |         |           | 1          |                              |         | No connect.  |
| NC17        |         |           | 1          |                              |         | No Connect   |
| NC18        |         |           | 1          |                              |         | No Connect   |
| NC19        |         |           | 1          |                              |         | No Connect   |
| NC20        |         |           | 1          |                              |         | No Connect   |
| NC21        |         |           | 1          |                              |         | No Connect   |

### 48.4.6 Power

Table 48-31. Power and Ground Summary Pin List (Sheet 1 of 2)

| Signal Name   | Signal Description Normal/Alternate Mode   | Ball Count |
|---------------|--|------------|
| VCCAUSB12     | 1.2V power supply for USB interface. Analog Power.   | 3          |
| VCC           | 1.2V power supply  | 85         |
| VCC18         | 1.8V power supply for DDR circuitry. IO Power.   | 20         |
| VCCTMP18      | 1.8V power supply for the Thermal Sensor. This supply can be optionally shut off in S3 sustain mode. | 1          |
| VCCUSB12      | 1.2V power supply for USB interface. Digital Power.  | 7          |
| VCC1P2_USBSUS | 1.2V sustain supply for core logic in USB interface.   | 1          |
| VCC33         | 3.3V power supply  | 15         |

Table 48-31. Power and Ground Summary Pin List (Sheet 2 of 2)

| Signal Name   | Signal Description Normal/Alternate Mode   | Ball Count |
|---------------|--|------------|
| VCCGBE33      | 3.3V power supply for Gigabit Ethernet interfaces.   | 1          |
| VCCSATA33     | 3.3V power supply for SATA interface.  | 1          |
| VCC50         | 5.0V power supply  | 7          |
| VCC50_SUS     | 5.0V power supply for 5.0V tolerance in sustain well   | 1          |
| VCCA[1]       | 1.20V power supply for IA-32 core. Minimum voltage is 1.20V-5%, even in low-power applications.  | 1          |
| VCCA[2]       | 1.20V power supply for IA-32 core. Minimum voltage is 1.20V-5%, even in low-power applications.  | 1          |
| VCCABG3P3_USB | 3.3V power supply for USB interface. Analog Bandgap Power.   | 1          |
| VCCABGP033    | 3.3V power supply for PCI Express circuitry. Analog Bandgap Power.   | 1          |
| VCCAHPLL      | Analog 1.2V supply for CRU circuitry (CRU PLL and REFCLK inputs).  | 1          |
| VCCAPE        | 1.2V power supply for PCI Express circuitry. Analog Power.   | 12         |
| VCCAPE0PLL12  | 1.2V power supply for PCI Express circuitry. PLL Digital Power.  | 2          |
| VCCAPLL       | 1.2V power supply for SATA interface.  | 1          |
| VCCARX        | 1.2V power supply for SATA interface. Analog receiver power.   | 3          |
| VCCASATABG3P3 | 3.3V power supply for SATA interface. Analog Bandgap power.  | 1          |
| VCCATX        | 1.2V power supply for SATA interface. Analog transmitter power.  | 3          |
| VCCVC         | 1.30V or 1.00V CPU power supply for IA-32 core. This supply is 1.30V for 1200MHz, 1.30V for 1066MHz, and 1.00V for 600MHz (see V_SEL signal description in the ICH Miscellaneous signals).   | 1          |
| VCC25         | 2.5V power supply for Gigabit Ethernet interfaces.   | 4          |
| VCCSUS25      | 2.5V sustain power supply for Gigabit Ethernet interfaces.   | 4          |
| VCCPRTC       | 3.3V power supply for the RTC (this supply can drop to 2.0V if all other planes are shut off). This power is not expected to be shut off unless the RTC battery is removed or drained.<br>Note: Implementations must not attempt to clear CMOS by using a jumper to pull VCCPRTC low. Clearing CMOS can be done by using a jumper on RTEST_N or GPI. | 1          |
| VCCPSUS       | 3.3V sustain supply for IO logic   | 3          |
| VCCGBEPSUS    | 3.3V sustain supply for IO logic for Gigabit Ethernet interfaces.  | 1          |
| VCCRPE        | 1.2V power supply for PCI Express circuitry. Digital Receiver Power.   | 8          |
| VCCSATA       | 1.2V power supply for SATA interface.  | 2          |
| VCCSUS1       | 1.2V sustain supply for core logic   | 4          |
| VCCVC         | 1.30V or 1.00V CPU power supply for IA-32 core. This supply is 1.30V for 1200MHz, 1.30V for 1066MHz, and 1.00V for 600MHz (see V_SEL signal description in the ICH Miscellaneous signals).   | 45         |
| VSS           | Ground   | 292        |
| VSSA          | Analog Ground  | 1          |
| VTTDDR        | 0.9V power supply for DDR circuitry. Terminal Voltage.   | 14         |
| TOTAL         |  | 549        |

## 48.5 Flip-Chip Ball Grid Array (FCBGA) Package Dimensions

The FCBGA package is shown in the following illustrations:

- Figure 48-1, “FCBGA Package — Top and Side Views” on page 1775

- [Figure 48-2, “FCBGA Package — Front and Detail Views” on page 1776](#)
- [Figure 48-3, “FCBGA Package — Bottom View” on page 1777](#)

## 49.0 Electrical Specifications

This chapter provides electrical specifications for the EP80579 interfaces.

The information contained in this chapter is divided into the following sections:

| Section Title                                      | Section Link                    |
|--|---------------------------------|
| Absolute Maximum Ratings                           | <a href="#">Section 49.1</a>    |

| JTAG   | <a href="#">Section 49.5.23</a> |

## 49.1 Absolute Maximum Ratings

Absolute maximum ratings are limits beyond which may cause permanent damage to the device or affect device reliability. Stressing the device beyond the “absolute maximum ratings” may cause permanent damage.

These are stress ratings only. Operate all supplies within the stated nominal operating voltage described in Table 49-6, “Operating Conditions Power Supply Rails” on page 1823.

Absolute maximum ratings are not the normal operating conditions of the device. All voltages are specified with respect to GND unless otherwise specified.

Table 49-1. Absolute Maximum Ratings

| Parameter  | Maximum Rating  | Notes |
|--|-----------------|-------|
| Operating Temperature                                      | 0° C to 70° C   |       |
| Operating Temperature (Industrial)                         | -40° C to 85° C |       |
| Storage Temperature  | -10° C to 45° C | 1     |
| Supply Voltage IA-32 core 600 MHz SKU (1.0V nominal)       | 1.03V           |       |
| Supply Voltage IA-32 core 1066/1200 MHz SKU (1.3V nominal) | 1.326V          |       |
| Supply Voltage DDR2 (1.8V nominal)                         | 1.89V           |       |
| Supply Voltage I/O (1.2V nominal)                          | 1.26V           |       |
| Supply Voltage I/O (2.5V nominal)                          | 2.62V           |       |
| Supply Voltage I/O (3.3V nominal)                          | 3.46V           |       |
| Supply Voltage I/O (5.0V nominal)                          | 5.25V           |       |

**Note:**

- The component storage temperature range (Pre-Board Assembly) is -45°C to 75°C for short-term exposure and -10°C to 45°C for sustained exposure. Consistent with industry practice, Intel does not specify storage conditions beyond component level (e.g. board or system level). In addition to this storage temperature specification, compliance to the latest IPC/JEDEC J-STD-033B.1 joint industry standard is required for all Surface Mount Devices (SMDs). This document governs handling, packing, shipping and use of moisture/reflow sensitive SMDs.

### 49.1.1 Input and I/O Pin Undershoot and Overshoot Specifications

The following tables provide Input and I/O pin undershoot and overshoot specifications:

- Table 49-2: applies to PCI, JTAG, SATA, CRU (15 pins) Input and I/O pin groups
- Table 49-3: applies to DDR2 Input and I/O pin group
- Table 49-4: applies to GbE Input and I/O pin group
- Table 49-5: applies to Input and I/O pin groups RTC, SPI, USB, TDM, LEB, CAN, SSP, IEEE 1588-2008, ICH Miscellaneous, IICH, SMBus, UART, LPC, GPIO, Sideband Miscellaneous, IMCH, PMI, and Miscellaneous

Table 49-2. Undershoot and Overshoot for PCI, JTAG, SATA and CRU Signal Groups

| VUS <sup>a</sup> | VOS <sup>b</sup> | PW <sup>c</sup> | Signal Group <sup>d</sup>  |
|------------------|------------------|-----------------|--|

| -0.8             | 1.8              | 8.47E-11        |  |

- a. VUS (Voltage UnderShoot) - Values of Vpeak (peak undershoot voltage) for the maximum Pulse Width specified.
- b. VOS (Voltage OverShoot) - Values of Vpeak (peak overshoot voltage) for the maximum Pulse Width specified.
- c. PW (Pulse Width) - Maximum Pulse Width allowed for a given Vpeak value (undershoot or overshoot), such that the reliability specifications of the device are not exceeded.
- d. Values provided in this table apply to Input and I/O pins in signal groups: PCI, JTAG, SATA, and CRU (15 pins). For more details, follow the table links provided.

Table 49-3. Undershoot and Overshoot for DDR2 Signal Group

- a. VUS (Voltage UnderShoot) - Values of Vpeak (peak undershoot voltage) for the maximum Pulse Width specified.
- b. VOS (Voltage OverShoot) - Values of Vpeak (peak overshoot voltage) for the maximum Pulse Width specified.
- c. PW (Pulse Width) - Maximum Pulse Width allowed for a given Vpeak value (undershoot or overshoot), such that the reliability specifications of the device are not exceeded.
- d. Values provided in this table apply to Input and I/O pins in signal groups: RTC, SPI, USB, TDM, LEBus, CAN, SSP, IEEE 1588-2008, ICH Miscellaneous, IICH, SMBus, UART, LPC, GPIO, Sideband Miscellaneous, IMCH, PMI, and Miscellaneous. For more details, follow the table links provided.

## 49.2 Power Characteristics

### 49.2.1 Power Supply Requirements

This section describes areas related to the EP80579's power, including:

- Description of power supply requirements
- Power wells and platform expectations for connecting the power wells
- Power planes

Table 49-6 and Table 49-7 defines the power supply requirements for each power rail.

*Note:* Further details for the EP80579 power supply rails are provided in Section 6-3, "EP80579 Power Supply Pins"

**Table 49-6. Operating Conditions Power Supply Rails (Sheet 1 of 2)**

| Well/Voltage Rail      | Symbol       | Supply Types   | Tolerance +/-   | Min   | Nominal | Max   | Unit | Notes |  |
|------------------------|--------------|--|---|-------|---------|-------|------|-------|--|
| <b>Core</b>            |              |  |   |       |         |       |      |       |  |
| 1.0 V (IA-32 core)     | VCCVC        | Core power, Freq @ 600 MHz   | 2%  | 0.98  | 1.00    | 1.02  | V    |       |  |
| 1.3 V (IA-32 core)     | VCCVC        | Core power, Freq @ 1066 MHz  | 2%  | 1.274 | 1.30    | 1.326 | V    |       |  |
| 1.3 V (IA-32 core)     | VCCVC        | Core power, Freq @ 1200 MHz  | 2%  | 1.274 | 1.30    | 1.326 | V    |       |  |

| 3.3 VRTC                 | ICCRTC <sup>1</sup> | RTC Current, on VCCPRTC  | 6      |     |   | µA   |

**Notes:**

- ICCRTC nominal data is taken with VccPRTC at 3.0V while the system is under battery power and at room temperature. This is shown to provide an estimated battery life. Maximum value of ICCRTC is 2mA while operating under full power.

## 49.3 Clocks

### 49.3.1 External Clock Requirements

External clocks are supplied to the internal PLLs as the reference clock and to the other I/O devices. The EP80579 has internal PLLs that use the reference clock to generate the internal clocks. Table 49-9 shows the external clocks that must be supplied for the EP80579 and its external interfaces.

**Table 49-9. Platform External/Internal Clock Interface**

| Clock Domain  | Frequency            | Source   |
|---------------|----------------------|----------|
| DDR2          | 200/266/320/400 MHz  | Internal |
| GbE           | 2.5, 25, 125 MHz     | External |
| CRU Clock     | 100/133 MHz          | External |
| PCI Express*  | 100 MHz              | External |
| Serial ATA    | 100 MHz              | External |
| USB2          | 48 MHz               | External |
| UART          | 48/14.7456 MHz       | External |
| LPC           | 33 MHz               | External |
| Expansion Bus | 33/80 MHz            | External |
| CLK14         | 14.31818 MHz         | External |
| TDM           | 512 kHz to 8.192 MHz | External |
| SSP           | 3.864 MHz            | External |
| RTC           | 32.768 KHz           | External |
| SUSCLK        | 32.768 KHz           | Internal |
| SMBus         | 10-100 KHz           | External |
| SPI           | 17.86 MHz            | Internal |

## **49.4 Power and Reset Sequencing**

The details for power and reset sequencing are described in [Chapter 6.0, “EP80579 Power Sequencing and Reset Sequence”](#)

## 49.5 AC/DC Characteristics

### 49.5.1 Power Management

This section describes the electrical characteristics of the Power Management interface.

#### 49.5.1.1 Power Management Signal List

Refer to Table 48-19, “Power Management Interface Signals” on page 1756 for the power management signal description.

##### 49.5.1.1.1 Power Management DC Characteristics

**Table 49-10. Power Management DC Input Characteristics**

| Symbol     | Parameter             | Conditions                | Min | Typical | Max | Units   | Notes |
|------------|-----------------------|---------------------------|-----|---------|-----|---------|-------|
| $V_{IH}$   | Input voltage high    | -                         | 2.0 | -       | -   | V       | 2     |
| $V_{IL}$   | Input voltage low     | -                         | -   | -       | 0.8 | V       | 2     |
| $I_{leak}$ | Input Leakage Current | $0 < V_{IN} < V_{cc3\_3}$ | -   | -       | 10  | $\mu A$ | -     |
| $C_{IN}$   | Input-pin capacitance | -                         | -   | -       | 10  | pf      | 1     |

**Notes:**

- 1.
2.  $V_{IH}$  and  $V_{IL}$  for PWRBTN# is guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-11. Power Management DC Output Characteristics**

| Symbol   | Parameter                      | Conditions       | Min | Typical | Max | Units | Notes   |
|----------|--------------------------------|------------------|-----|---------|-----|-------|---------|
| $V_{OH}$ | Output voltage high            | $I_{out} = -6mA$ | 2.0 | -       | -   | V     | 3, 2, 3 |
| $V_{OL}$ | Output voltage low             | $I_{out} = 6mA$  | -   | -       | 0.4 | V     | -       |
| $I_{OH}$ | Output current at high voltage | $V_{OH} = 2.4$   | -12 | -27     | -48 | mA    | -       |
| $I_{OL}$ | Output current at low voltage  | $V_{OL} = 0.8$   | 12  | 18      | 26  | mA    | -       |

**Notes:**

- 1.
2.  $V_{OH}$  and  $V_{OL}$  for PWRBTN# is guaranteed by design. These values are typical values seen for this process, but not measured during production testing.
3.  $V_{OH}$  spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

### 49.5.1.2 Power Management AC Characteristics

The following table and diagrams illustrate the sequencing that occurs for supported power state transitions. For more detail, see [Section 27.6, “Sleep States”](#).

**Table 49-12. Power Sequencing Signal Timings (Sheet 1 of 2)**

| Sym          | Parameter   | Min         | Max | Units  | Notes | Fig #      |
|--------------|---|-------------|-----|--------|-------|------------|
| t204         | VccSus supplies active to RSMRST# inactive  | 10          | –   | ms     | 7     | 49-1       |
| t214         | Vcc supplies active to PWROK, VRMPWRGD active   | 99          | –   | ms     | 11    | 49-1, 49-3 |
| t215         | Vcc active to STPCLK# and CPUSLP# inactive  | –           | 50  | ns     | -     | 49-1, 49-3 |
| t217         | PWROK and VRMPWRGD/ CPU_VRD_PWR_GD active and SYS_RESET# inactive to SUS_STAT# inactive and Processor I/F signals latched to strap value. | 32          | 38  | RTCCLK | 1     | 49-1, 49-3 |
| t218         | SUS_STAT# inactive to PLTRST# and PCIRST# inactive  | 2           | 3   | RTCCLK |       | 49-1, 49-3 |
| t230         | VccSus active to SLP_S5#, SLP_S4#, SLP_S3#, SUS_STAT#, PLTRST# and PCIRST# active   | –           | 50  | ns     | -     | 49-1       |
| t231<br>t232 | RSMRST# inactive to SUSCLK running, SLP_S5# inactive  | –           | 110 | ms     | 2     | 49-1       |
| t233         | SLP_S5# inactive to SLP_S4# inactive  | See Note 10 |     |        | 10    | 49-1       |
| t234         | SLP_S4# inactive to SLP_S3# inactive  | 1           | 2   | RTCCLK | 1     | 49-1       |
| t271         | S1 Wake Event to CPUSLP# inactive   | 1           | 25  | PCICLK | 8     | 49-2       |
|              | SUSCLK duty cycle   | 30          | 70  | %      | 9     |            |
| t280         | STPCLK# active to NSI Message   | 0           |     | PCICLK | 3     | 49-2, 49-3 |
| t281         | NSI Message to CPUSLP# active   | 60          | 63  | PCICLK | 8     | 49-2       |
| t283         | NSI Message to SUS_STAT# active   | 2           |     | RTCCLK | 1     | 49-3       |
| t284         | SUS_STAT# active to PLTRST#, PCIRST# active   | 7           | 17  | RTCCLK | 1     | 49-3       |
| t287         | PLTRST#, PCIRST# active to SLP_S3# active   | 1           | 2   | RTCCLK | 1     | 49-3       |
| t289         | SLP_S3# active to PWROK, VRMPWRGD/ CPU_VRD_PWR_GD inactive  | 0           |     | ms     | 4     | 49-3       |
| t291         | SLP_S3# active to SLP_S4# active  | 1           | 2   | RTCCLK | 1     | 49-3       |
| t294         | PWROK, VRMPWRGD/ CPU_VRD_PWR_GD inactive to Vcc supplies inactive   | 20          |     | ns     | 6     | 49-3       |
| t295         | SLP_S4# active to SLP_S5# active  | 1           | 2   | RTCCLK | 1, 5  | 49-3       |
| t296         | Wake Event to SLP_S5# inactive  | 1           | 10  | RTCCLK | 1     | 49-3       |

**Notes:**

- These transitions are clocked off the internal RTC. 1 RTC clock is approximately 32 μs.
- If there is no RTC battery in the system, so VCCPRTC and the VCCPSUS supplies come up together, the delay from RTCRST# and an inactive RSMRST# prior to SUSCLK toggling may be as much as 2.5 s.
- STPCLK# assertion triggers the processor to send a stop grant acknowledge cycle.
- The EP80579 has no maximum timing requirement for this transition. It is up to the system designer to determine if the SLP\_S3#, SLP\_S4# and SLP\_S5# signals are used to control the power planes.
- If the transition to S5 is due to Power Button Override, SLP\_S3#, SLP\_S4# and SLP\_S5# are asserted together similar to timing t287 (PCIRST# active to SLP\_S3# active).
- VCC in diagram represents all core well supplies that are powered off in S3 state.
- VCCSus in diagram represents all sustainable supplies as identified in the Suspend power well.
- These transitions are clocked off the 33MHz PCICLK. 1 PCICLK is approximately 30ns.
- SUSCLK is an output of the RTC generator (32.768 KHz), has a duty cycle that can be as low as 30% or as high as 70%.
- The Min/Max times depend on the programming of the “SLP\_S4# Minimum Assertion Width” and the “SLP\_S4# Assertion Stretch Enable bits. Note that this does not apply for synchronous SMI’s.
- The relationship that the active edge of SYS\_PWR\_OK (platform signal connected to PWROK, PWRGD, and SYS\_PWR\_OK pins) has to the active edge of VRMPWRGD/ CPU\_VRD\_PWR\_GD in [Figure 6-1](#) must be observed.

Table 49-12. Power Sequencing Signal Timings (Sheet 2 of 2)

| Sym  | Parameter                                   | Min         | Max               | Units  | Notes | Fig # |
|------|---|-------------|-------------------|--------|-------|-------|
| t297 | SLP_S5# inactive to SLP_S4# inactive        | See Note 10 |                   |        | 10    | 49-3  |
| t298 | SLP_S4# inactive to SLP_S3# inactive        | 1           | 2                 | RTCCLK | 1     | 49-3  |
| t299 | S4 to SLP_S4# inactive                      | See Note 10 |                   |        | 10    | 49-3  |
| t300 | S3 Wake Event to SLP_S3# inactive (S3 Wake) | 0           | Small as possible | ms     | 1     | 49-3  |
| t301 | CPUSLP# inactive to STPCLK# inactive        | 8           |                   | PCICLK | -     | 49-2  |

**Notes:**

- These transitions are clocked off the internal RTC. 1 RTC clock is approximately 32  $\mu$ s.
- If there is no RTC battery in the system, so VCCPRTC and the VCCPSUS supplies come up together, the delay from RTCRST# and an inactive RSMRST# prior to SUSCLK toggling may be as much as 2.5 s.
- STPCLK# assertion triggers the processor to send a stop grant acknowledge cycle.
- The EP80579 has no maximum timing requirement for this transition. It is up to the system designer to determine if the SLP\_S3#, SLP\_S4# and SLP\_S5# signals are used to control the power planes.
- If the transition to S5 is due to Power Button Override, SLP\_S3#, SLP\_S4# and SLP\_S5# are asserted together similar to timing t287 (PCIRST# active to SLP\_S3# active).
- VCC in diagram represents all core well supplies that are powered off in S3 state.
- VCCSUS in diagram represents all sustainable supplies as identified in the Suspend power well.
- These transitions are clocked off the 33MHz PCICLK. 1 PCICLK is approximately 30ns.
- SUSCLK is an output of the RTC generator (32.768 KHz), has a duty cycle that can be as low as 30% or as high as 70%.
- The Min/Max times depend on the programming of the "SLP\_S4# Minimum Assertion Width" and the "SLP\_S4# Assertion Stretch Enable bits. Note that this does not apply for synchronous SMI's.
- The relationship that the active edge of SYS\_PWR\_OK (platform signal connected to PWROK, PWRGD, and SYS\_PWR\_OK pins) has to the active edge of VRMPWRGD/ CPU\_VRD\_PWR\_GD in [Figure 6-1](#) must be observed.

49.5.1.2.1 Power Management Timing Diagrams

Figure 49-1. G3 (Mechanical Off) to S0 Timings

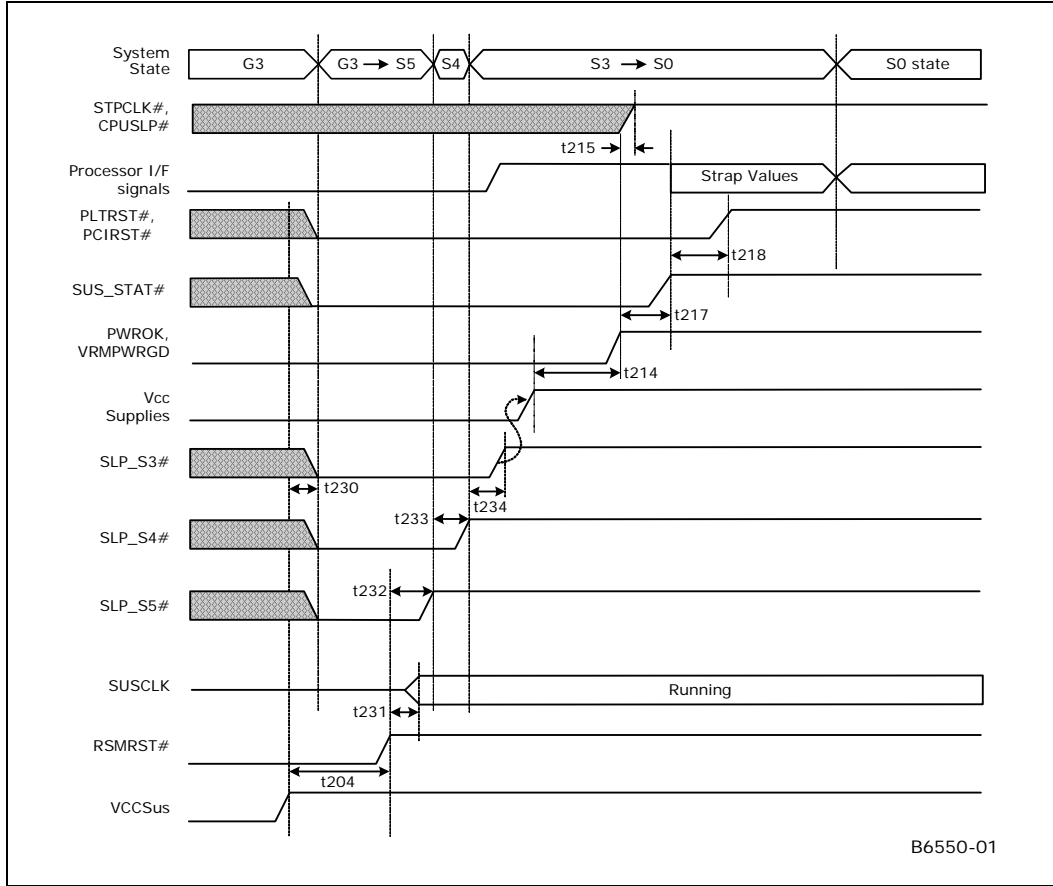

Figure 49-2. S0 to S1 to S0 Timing

Figure 49-3. S0 to S5 to S0 Timings, S3<sub>COLD</sub>

49.5.1.2.2 Power Management Miscellaneous Timing Diagrams

Refer to Section 6.1.3, “EP80579 Power Sequencing and Reset Sequence” for additional timing requirements related to power management signals.

## 49.5.2 DDR2

The EP80579 provides an integrated memory controller for direct-connection to a single channel of DDR2 with 400, 533, 640 and 800 MT/s unbuffered or registered memory devices, with a maximum support of up to two ranks.

The electrical specifications of the EP80579's DDR2 interface is compatible to the JEDEC\* Standard DDR2 SDRAM Specification, JESD79-2B, January 2005. The AC & DC operating conditions are included in Chapter 5 of the JEDEC specification. Refer to the subsections that follow for the electrical characteristics of the EP80579 DDR2 interface.

### 49.5.2.1 DDR2 Signal List

For DDR2 pin descriptions, refer to Table 48-8, "DDR2 Interface Signals" on page 1739.

### 49.5.2.2 DDR2 DC Characteristics

Table 49-13. DDR2 DC Input Characteristics

| Signal Group  | Symbol               | Parameter  | Min            | Nom | Max            | Unit | Notes |
|---------------|----------------------|--|----------------|-----|----------------|------|-------|
| DDR2 SSTL I/O | V <sub>IL</sub> (DC) | Input Low Voltage (DC)   | -              | -   | DDR_VREF - 150 | mV   | 1, 2  |
|               | V <sub>IH</sub> (DC) | Input High Voltage (DC)  | DDR_VREF + 150 | -   | -              | mV   | 1, 2  |
|               | I <sub>Leak</sub>    | Input Leakage Current (0 < V <sub>in</sub> < V <sub>cc18</sub> ) | -20            | -   | +20            | µA   | 1     |

**Notes:**

1. Refer to the JESD-79-2 and SSTL-18 Specification for further details.
2. These input voltages apply only when the signals are inputs to the EP80579. When the signals are inputs to the SDRAM, the SDRAM input voltage specifications apply.

Table 49-14. DDR2 DC Output Characteristics (Sheet 1 of 2)

| Signal Group     | Symbol           | Parameter           | Min            | Nom | Max            | Unit    | Notes      |
|------------------|------------------|---------------------|----------------|-----|----------------|---------|------------|
| DDR2 Output      | I <sub>OH</sub>  | Output High Current | -              | -   | -11.0          | mA      | 1, 2, 3    |
|                  | I <sub>OL</sub>  | Output Low Current  | -              | -   | 11.0           | mA      | 1, 2, 3, 4 |
|                  | V <sub>OL</sub>  | Output Low Voltage  | 0.0            | -   | DDR_VREF - 575 | mV      | 1, 2       |
|                  | V <sub>OH</sub>  | Output High Voltage | DDR_VREF + 575 | -   | -              | mV      | 1, 2       |
|                  | C <sub>Pin</sub> | Pin Capacitance     | 2.0            | -   | 2.5            | pF      | 1, 5       |
| S <sub>out</sub> | Output Slew Rate | 2.2                 | -              | 3.2 | V/ns           | 1, 6, 7 |            |

**Notes:**

1. Refer to the JESD-79-2 and SSTL-18 Specification for further details.
2. DDR2 DC parameters are specified with a 43 ohm test load to V<sub>dd</sub>/2 and with up to 22 ohm resistive compensation (RCOMP). Guaranteed by design. These values are typical values seen for this process, but not measured during production testing
3. I<sub>OH</sub>=0mA at V<sub>OH</sub> of 0.99\*V<sub>CC</sub>; I<sub>OL</sub>=0mA at V<sub>OL</sub> of 0.01\*V<sub>CC</sub>
4. For open drain outputs, I<sub>OL</sub>, MIN=3mA
5. Guaranteed by design.
6. Slew rate measured from vil(ac) to vih(ac)
7. The absolute value of the slew rate as measured from DC to DC is equal to or greater than the slew rate as measured from AC to AC. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing

Table 49-14. DDR2 DC Output Characteristics (Sheet 2 of 2)

| Signal Group | Symbol           | Parameter                | Min                      | Nom                      | Max                      | Unit | Notes |
|--------------|------------------|--------------------------|--------------------------|--------------------------|--------------------------|------|-------|
|              | R <sub>out</sub> | Output Impedance         | 20.0                     | -                        | 40.0                     | Ohms | 1     |
|              | DDR_VREF         | DDR2 Reference Voltage   | 0.49 x V <sub>CC18</sub> | 0.50 x V <sub>CC18</sub> | 0.51 x V <sub>CC18</sub> | V    | 1     |
| VTTDDR       | DDR_VTT          | DDR2 Termination Voltage | DDR_VREF - 40            | DDR_VREF                 | DDR_VREF + 40            | mV   | 1     |
| VCC18        | DDR_VDD          | DDR2 Supply Voltage      | 1.71                     | 1.80                     | 1.89                     | V    | 1     |

**Notes:**

1. Refer to the JESD-79-2 and SSTL-18 Specification for further details.
2. DDR2 DC parameters are specified with a 43 ohm test load to V<sub>dd</sub>/2 and with up to 22 ohm resistive compensation (R<sub>COMP</sub>). Guaranteed by design. These values are typical values seen for this process, but not measured during production testing
3. I<sub>OH</sub>=0mA at V<sub>OH</sub> of 0.99\*V<sub>CC</sub>; I<sub>OL</sub>=0mA at V<sub>OL</sub> of 0.01\*V<sub>CC</sub>
4. For open drain outputs, I<sub>OL</sub>, MIN=3mA
5. Guaranteed by design.
6. Slew rate measured from vil(ac) to vih(ac)
7. The absolute value of the slew rate as measured from DC to DC is equal to or greater than the slew rate as measured from AC to AC. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing

## 49.5.2.3 DDR2 AC Characteristics

Table 49-15. DDR2 Differential Input/Output AC Levels

| Signal Group     | Symbol       | Parameter                                 | Min               | Max               | Unit | Notes |
|------------------|--------------|---|-------------------|-------------------|------|-------|
| DDR2<br>SSTL I/O | $V_{IL(AC)}$ | Input Low Voltage (AC)                    | -                 | DDR_VREF<br>- 200 | mV   | 1, 2  |
|                  | $V_{IH(AC)}$ | Input High Voltage (AC)                   | DDR_VREF +<br>200 | -                 | mV   | 1, 2  |
|                  | $V_{ID}$     | AC Differential Input<br>Voltage          | 400               | -                 | mV   |       |
|                  | $V_{IX}$     | Differential cross point<br>input voltage | DDR_VREF -<br>100 | DDR_VREF<br>+ 100 | mV   | 1, 3  |

**Notes:**

1. Refer to the JESD-79-2 and SSTL-18 Specification for further details.
2. These input voltages apply only when the signals are inputs to the EP80579. When the signals are inputs to the SDRAM, the SDRAM input voltage specifications apply.
3. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing

Table 49-16. DDR2-400 Interface AC Characteristics

| Symbol  | Parameter   | Min           | Max           | Unit | Figures | Notes   |
|---|---|---------------|---------------|------|---------|---------|
| <b>System Memory Clock Timings</b>                      |   |               |               |      |         |         |
| $T_{CK}$  | DDR_CK[5:0] Period  | 5             | -             | ns   | 49-9    |         |
| $T_{CH}$  | DDR_CK[5:0] High Time   | 2.25          | -             | ns   | 49-11   |         |
| $T_{CL}$  | DDR_CK[5:0] Low Time  | 2.25          | -             | ns   | 49-12   |         |
| tJIT  | DDR_CK[5:0] Cycle to Cycle Jitter   | -             | 225           | ps   |         | 6       |
| tSKEW_CK-CK   | Skew between any two system memory differential clock pairs (DDR_CK[5:0]/DDR_CK[5:0]#)                | -             | $0.06T_{CK}$  | ps   | 49-10   | 6       |
|   | DDR_CK[x] to DDR_CK[y]#<br>(where x does not equal y)   |               | $0.25T_{CK}$  | ps   | 49-10   | 6       |
| tSKEW_CK-DQS  | Skew between any system memory clock pair and any system memory strobe                                | $-0.25T_{CK}$ | $+0.25T_{CK}$ | ps   | 49-13   | 6       |
| <b>System Memory Command and Control Signal Timings</b> |   |               |               |      |         |         |
| tCVB  | DDR_RAS#, DDR_CAS#, DDR_WE#, DDR_A[14:0], DDR_BA[2:0], DDR_CS[1:0]# Valid Before DDR_CK Rising Edge   | 1.94          | -             | ns   | 49-8    |         |
| tCVA  | DDR_RAS#, DDR_CAS#, DDR_WE#, DDR_A[14:0], DDR_BA[2:0], DDR_CS[1:0]# Valid After DDR_CK Rising Edge    | 1.94          | -             | ns   | 49-8    |         |
| <b>System Memory Data and Strobe Signal Timings</b>     |   |               |               |      |         |         |
| tDVB  | DDR_DQ[63:0], DDR_ECC[7:0], DDR_DM[8:0] Valid Before the corresponding DDR_DQS and DDR_DQS_L Crossing | 0.828         | -             | ns   | 49-5    | 6       |
| tDVA  | DDR_DQ[63:0], DDR_ECC[7:0], DDR_DM[8:0] Valid Before the corresponding DDR_DQS and DDR_DQS_L Crossing | 0.828         | -             | ns   | 49-5    | 6       |
| tDOPW   | DDR_DQ[63:0], DDR_ECC[7:0] Output Valid Pulse Width   | 2.25          | -             | ns   | -       | 3, 6    |
| tSU_DQS   | DDR_DQ and DDR_ECC Input Setup Time to DQS Crossing   | -0.897        | -             | ns   | 49-4    | 1, 2, 6 |
| tHD_DQS   | DDR_DQ and DDR_ECC Input Hold Time After DQS Crossing   | +1.60         | -             | ns   | 49-4    | 1, 6    |
| tWPRE   | DDR_DQS Write Preamble Duration   | 1.75 (nom)    | -             | ns   | 49-6    |         |
| tWPST   | DDR_DQS Write Postamble Duration  | 2.00 (nom)    | -             | ns   | 49-7    |         |

**Notes:**

1. Data to Strobe read setup and Data from strobe read hold minimum requirements specified are determined with the DQS Delay programmed for a 90 degree phase shift.
2. Refer to Figure 49-4. Negative minimum setup time at the EP80579 pins is correct – the DQS crossing at the EP80579 pins is expected to arrive before data becomes valid. Data is latched by a delayed copy of DQS (see Note 1), which nominally centers the strobe within the data valid window. Refer to the DDR2 Specification for further details.
3. TDOPW defines the minimum time a given data bit is guaranteed valid at the pin. Note that this is greater than the sum of minimum TDVA and TDVB, since strobe-to-data alignment uncertainty subtracts from those times.
4. AC timings are specified into a 25 ohm test load (for DQ and DQS) or 50 ohm test load (for other signals) terminated to  $V_{dd}/2$
5. This specification applies for writes only; that is, when the IMCH is driving the strobes as well as the clocks. Refer to the JEDEC specification for an explanation of strobe to clock timing for DDR2 reads.
6. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing

Table 49-17. DDR2-533 Interface AC Characteristics

| Symbol  | Parameter   | Min                  | Max                  | Unit | Figures | Notes   |
|---|---|----------------------|----------------------|------|---------|---------|
| <b>System Memory Clock Timings</b>                      |   |                      |                      |      |         |         |

| t <sub>DOPW</sub>                                       | DDR_DQ[63:0], DDR_ECC[7:0] Output Valid Pulse Width   | 1.70                 | -                    | ns   | -       | 3, 6    |
| t <sub>SU_DQS</sub>                                     | DDR_DQ and DDR_ECC Input Setup Time to DQS Crossing   | -0.594               | -                    | ns   | 49-4    | 1, 2, 6 |
| t <sub>HD_DQS</sub>                                     | DDR_DQ and DDR_ECC Input Hold Time After DQS Crossing   | +1.281               | -                    | ns   | 49-4    | 1, 6    |
| t <sub>WPRE</sub>                                       | DDR_DQS Write Preamble Duration   | 1.31 (nom)           | -                    | ns   | 49-6    |         |
| t <sub>WPST</sub>                                       | DDR_DQS Write Postamble Duration  | 1.50 (nom)           | -                    | ns   | 49-7    |         |

**Notes:**

1. Data to Strobe read setup and Data from strobe read hold minimum requirements specified are determined with the DQS Delay programmed for a 90 degree phase shift.
2. Refer to Figure 49-5. Negative minimum setup time at the EP80579 pins is correct – the DQS crossing at the EP80579 pins is expected to arrive before data becomes valid. Data is latched by a delayed copy of DQS (see Note 1), which nominally centers the strobe within the data valid window. Refer to the DDR2 Specification for further details.
3. TDOPW defines the minimum time a given data bit is guaranteed valid at the pin. Note that this is greater than the sum of minimum TDVA and TDVB, since strobe-to-data alignment uncertainty subtracts from those times.
4. AC timings are specified into a 25 ohm test load (for DQ and DQS) or 50 ohm test load (for other signals) terminated to V<sub>dd</sub>/2
5. This specification applies for writes only; that is, when the IMCH is driving the strobes as well as the clocks. Refer to the JEDEC specification for an explanation of strobe to clock timing for DDR2 reads.
6. Guaranteed by design.

Table 49-18. DDR2-667 Interface AC Characteristics

| Symbol  | Parameter   | Min                  | Max                  | Unit | Figures | Notes   |
|---|---|----------------------|----------------------|------|---------|---------|
| <b>System Memory Clock Timings</b>                      |   |                      |                      |      |         |         |

**Notes:**

1. Data to Strobe read setup and Data from strobe read hold minimum requirements specified are determined with the DQS Delay programmed for a 90 degree phase shift.
2. Refer to Figure 49-5. Negative minimum setup time at the EP80579 pins is correct – the DQS crossing at the EP80579 pins is expected to arrive before data becomes valid. Data is latched by a delayed copy of DQS (see Note 1), which nominally centers the strobe within the data valid window. Refer to the DDR2 Specification for further details.
3. TDOPW defines the minimum time a given data bit is guaranteed valid at the pin. Note that this is greater than the sum of minimum TDVA and TDVB, since strobe-to-data alignment uncertainty subtracts from those times.
4. AC timings are specified into a 25 ohm test load (for DQ and DQS) or 50 ohm test load (for other signals) terminated to V<sub>dd</sub>/2
5. This specification applies for writes only; that is, when the IMCH is driving the strobes as well as the clocks. Refer to the JEDEC specification for an explanation of strobe to clock timing for DDR2 reads.
6. Guaranteed by design.

### 49.5.3 PCI Express\*

This section describes the electrical characteristics of the PCI Express\* interface.

The PCI Express\* interface signals are driven by transceivers designed specifically for high-speed serial communication. All PCI Express\* signals are fully differential and operate in a current mode, rather than a voltage mode. These interfaces support A/C coupling to facilitate communication across independent power supply domains and signal at a rate well above the flight time of the interface. The nominal supply voltage for the PCI Express\* interfaces is 1.2V, although receivers must tolerate up to 1.6V peak-to-peak across differential pairs as required by the *PCI Express\* Interface Specification*.

This section describes the electrical characteristics of the PCI Express\* interface.

#### 49.5.3.1 PCI Express\* Signal List

For PCI Express\* pin description refer to [Table 48-9, "PCI Express Interface Signals"](#) on page 1741.

#### 49.5.3.2 PCI Express\* Differential Transmitter and Receiver Specifications

This electrical specifications of the PCI Express\* Differential Transmitter and Receiver in the EP80579 are compliant with the *PCI Express\* Base Specification, Rev. 1.1* (<http://www.pcisig.com>). Refer to the specification subsections that follow for more information:

- Section 4.3 Electrical Sub-Block of *PCI Express\* Base Specification, Rev. 1.1*:
  - Section 4.3.1 Electrical Sub-Block Requirements
  - Section 4.3.2 Electrical Signal Specifications
  - Section 4.3.3 Differential Transmitter (Tx) Output Specifications
  - Section 4.3.4 Differential Receiver (Rx) Input Specifications
    - Section 4.3.3.1 Tx Compliance Eye Diagrams
    - Section 4.3.3.1 Rx Compliance Eye Diagrams

Table 49-20. PCI Express\* Differential Receiver (RX) Specifications

| Symbol                                   | Parameter  | Min    | Nom | Max    | Unit | Figures | Notes |

| T <sub>RX-IDLE-DET-DIFF-ENTERTIME</sub>  | Unexpected Electrical Idle Enter Detect Threshold Integration Time           | -      | -   | 10     | ms   | -       |       |
| L <sub>RX-SKEW</sub>                     | Total Skew   | -      | -   | 20     | ns   | -       |       |

**Notes:**

- Specified at the measurement point and measured over any 250 consecutive UIs. The test load in Figure 49-14 (not the EP80579 itself) must be used as the Rx device when taking measurements (also refer to the Receiver Compliance Eye Diagram as shown in Figure 49-15). If the clocks to the Rx and Tx are not derived from the same clock chip the Tx UI must be used as a reference for the eye diagram.
- Impedance during all LTSSM states. When transitioning from a Fundamental Reset to Detect (the initial state of the LTSSM) there is a 5ms transition time before Receiver termination values must be met on all un-configured Lanes of a Port.
- The Rx DC Common Mode Impedance that exists when no power is present or Fundamental Reset is asserted. This helps ensure that the Receiver Detect circuit does not falsely assume a Receiver is powered on when it is not. This term must be measured at 300mV above the Rx ground.
- PCI-Express mVdiff p-p = PEA0\_Xp[x] - PEA0\_Xn[x]
- No test load is necessarily associated with this value.
- Specified at the measurement point and measured over any 250 consecutive UIs. The test load in Figure 49-14 and measured over any 250 consecutive Unit Intervals. Also refer to the Receiver Compliance Eye Diagram as shown in Figure 49-15. That is, the receiver device must be replaced with 50 Ω terminations to ground on each half of the signal pair for the purpose of measuring this parameter. If the clocks to the Rx and Tx are not derived from the same clock chip the Tx UI must be used as a reference for the eye diagram.
- A TRX-EYE = 0.40 UI provides for a total sum of 0.60 UI deterministic and random jitter budget for the transmitter and interconnect collected any 250 consecutive UIs. The TRX-EYE-MEDIAN-to-MAX-JITTER specification ensures a jitter distribution in which the median and the maximum deviation from the median is less than half of the total.6 UI jitter budget collected over any 250 consecutive Tx UIs. It must be noted that the median is not the same as the mean. The jitter median describes the point in time where the number of jitter points on either side is approximately equal as opposed to the averaged time value. If the clocks to the Rx and Tx are not derived from the same clock chip, the appropriate average Tx UI must be used as the reference for the eye diagram.
- The receiver input impedance shall result in a differential return loss greater than or equal to 15 dB and a common mode return loss greater than or equal to 6 dB over a frequency range of 50 MHz to 1.25 GHz. This input impedance requirement applies to all valid input levels. The reference impedance for return loss measurements for is 50 Ω to ground for both the D+ and D- line (for example, as measured by a Vector Network Analyzer with 50 Ω probes – see Figure 49-15). Note that the series capacitors CTX is optional for the return loss measurement.

Table 49-21. PCI Express\* Differential Transmitter (TX) Specifications (Sheet 1 of 2)

| Symbol                                      | Parameter  | Min    | Nom  | Max          | Unit       | Figures | Notes |

**Notes:**

- Specified at the measurement point into a timing and voltage compliance test load as shown in Figure 49-14 and measured over any 250 consecutive Unit Intervals. Also refer to the Transmitter Compliance Eye Diagram as shown in Figure 49-15.
- The allowed DC Common Mode voltage under any conditions. Refer to Section 4.3.1.8 in the *PCI-Express\* Specification* for further details.
- Static skew between any two Transmitter Lanes within a single link
- The allowed current when any output is shorted to ground.
- PCI-Express mVdiff p-p = PEx\_Xp[x] - PEx\_Xn[x]
- Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.
- No test load is necessarily associated with this value.
- Specified at the measurement point into a timing and voltage compliance test load as shown in Figure 49-14 and measured over any 250 consecutive Unit Intervals. Also refer to the Transmitter Compliance Eye Diagram as shown in Figure 49-16.
- A TTX-EYE = 0.70 UI provides for a total sum of deterministic and random jitter budget of TTX-JITTER-MAX = 0.30 UI for the transmitter collected over any 250 consecutive Tx UIs. The TTX-EYE-MEDIAN-to-MAX-JITTER specification ensures a jitter distribution in which the median and the maximum deviation from the median is less than half of the total Tx jitter budget collected over any 250 consecutive Tx UIs. Note that the median is not the same as the mean. The jitter median describes the point in time where the number of jitter points on either side is approximately equal, as opposed to the average value.
- The transmitter input impedance shall result in a differential return loss greater than or equal to 12 dB and a common mode return loss greater than 6 dB over a frequency range of 50 MHz to 1.25 GHz. This input impedance requirement applies to all valid input levels. The reference impedance for return loss measurements is 50 Ω to ground for both the D+ and D- line (for example, as measured by a Vector Network Analyzer with 50 Ω probes – see Figure 49-16). Note that the series capacitors CTX is optional for the return loss measurement.
- Measured between 20–80% at Transmitter package pins into a test load as shown in Figure 49-16 for both VTX-D+ and VTX-D-.
- Refer to Section 4.3.1.8 in the *PCI-Express\* Specification* for further details.

Table 49-21. PCI Express\* Differential Transmitter (TX) Specifications (Sheet 2 of 2)

| Symbol                                  | Parameter  | Min | Nom | Max | Unit | Figures | Notes |
|---|--|-----|-----|-----|------|---------|-------|
| V <sub>TX-CM-DC-ACTIVE-IDLE-DELTA</sub> | Absolute Delta of DC Common Mode Voltage During LO and Electrical Idle                             | 0   |     | 100 | mV   | -       | 8     |
| V <sub>TX-CM-DC-LINE-DELTA</sub>        | Absolute Delta of DC Common Mode Voltage between D+ and D-   | 0   |     | 20  | mV   |         | 8     |
| V <sub>TX-IDLE-DIFFp</sub>              | Electrical Idle Differential Peak Output Voltage   | 0   |     | 20  | mV   |         | 8     |
| V <sub>TX-RCV-DETECT</sub>              | The amount of voltage change allowed during Receiver Detection                                     |     |     | 600 | mV   |         | 12    |
| T <sub>TX-IDLE-MIN</sub>                | Minimum time spent in Electrical Idle  | 50  |     |     | UI   |         |       |
| T <sub>TX-IDLE-SET-TO-IDLE</sub>        | Maximum time to transition to a valid Electrical Idle after sending an Electrical Idle ordered set |     |     | 20  | UI   |         |       |
| T <sub>TX-IDLE-TO-DIFF-DATA</sub>       | Maximum time to transition to valid Tx Specification after leaving an Electrical Idle condition    |     |     | 20  | UI   |         |       |
| T <sub>TX-IDLE-RCV-DETECT-MAX</sub>     | Maximum time spent in electrical Idle before initiating a receiver detect sequence                 |     |     | 100 | ms   |         | 12    |
| RL <sub>TX-DIFF</sub>                   | Differential Return Loss   | 10  |     |     | dB   |         | 10    |
| RL <sub>TX-CM</sub>                     | Common Mode Return Loss  | 6   |     |     | dB   |         | 10    |
| T <sub>crosslink</sub>                  | Crosslink Random Timeout   | 0   |     | 1   | ms   |         |       |

**Notes:**

- Specified at the measurement point into a timing and voltage compliance test load as shown in [Figure 49-14](#) and measured over any 250 consecutive Unit Intervals. Also refer to the Transmitter Compliance Eye Diagram as shown in [Figure 49-15](#).
- The allowed DC Common Mode voltage under any conditions. Refer to Section 4.3.1.8 in the *PCI-Express\* Specification* for further details.
- Static skew between any two Transmitter Lanes within a single link
- The allowed current when any output is shorted to ground.
- PCI-Express mVdiff p-p = PEx\_Xp[x] - PEx\_Xn[x]
- Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.
- No test load is necessarily associated with this value.
- Specified at the measurement point into a timing and voltage compliance test load as shown in [Figure 49-14](#) and measured over any 250 consecutive Unit Intervals. Also refer to the Transmitter Compliance Eye Diagram as shown in [Figure 49-16](#).
- A TTX-EYE = 0.70 UI provides for a total sum of deterministic and random jitter budget of TTX-JITTER-MAX = 0.30 UI for the transmitter collected over any 250 consecutive Tx UIs. The TTX-EYE-MEDIAN-to-MAX-JITTER specification ensures a jitter distribution in which the median and the maximum deviation from the median is less than half of the total Tx jitter budget collected over any 250 consecutive Tx UIs. Note that the median is not the same as the mean. The jitter median describes the point in time where the number of jitter points on either side is approximately equal, as opposed to the average value.
- The transmitter input impedance shall result in a differential return loss greater than or equal to 12 dB and a common mode return loss greater than 6 dB over a frequency range of 50 MHz to 1.25 GHz. This input impedance requirement applies to all valid input levels. The reference impedance for return loss measurements is 50 Ω to ground for both the D+ and D- line (for example, as measured by a Vector Network Analyzer with 50 Ω probes – see [Figure 49-16](#)). Note that the series capacitors CTX is optional for the return loss measurement.
- Measured between 20–80% at Transmitter package pins into a test load as shown in [Figure 49-16](#) for both VTX-D+ and VTX-D-.
- Refer to Section 4.3.1.8 in the *PCI-Express\* Specification* for further details.

### 49.5.3.3 PCI Express\* Clock Specifications

Table 49-22. PCI Express\* Clock DC Specifications

| Symbol                  | Parameter                | Min   | Nom   | Max   | Unit | Notes      |
|-------------------------|--------------------------|---|-------|---|------|------------|
| V <sub>IL</sub>         | Input Low Voltage        | -0.150  | 0     | 0.150   | V    | 1          |
| V <sub>IH</sub>         | Input High Voltage       | 0.660   | 0.710 | 0.850   | V    | 1          |
| V <sub>CROSS(abs)</sub> | Absolute Crossing Point  | 0.250   |       | 0.550   | V    | 1, 2, 6    |
| V <sub>CROSS(rel)</sub> | Relative Crossing Point  | 0.250 + 0.5<br>x (V <sub>Havg</sub><br>- 0.710) |       | 0.550 + 0.5<br>x (V <sub>Havg</sub><br>- 0.710) | V    | 1, 3, 6, 7 |
| ΔV <sub>CROSS</sub>     | Range of Crossing Points |   |       | 0.140   | V    | 1          |
| V <sub>RBM</sub>        | Ringback Margin          | 0.200   |       |   | V    | 1, 4       |
| V <sub>TR</sub>         | Threshold Region         | V <sub>CROSS</sub><br>- 0.100                   |       | V <sub>CROSS</sub><br>+ 0.100                   | V    | 1, 5       |

**Notes:**

1. Refer to Figure 49-17 and Figure 49-18.
2. Crossing voltage is defined as the instantaneous voltage when the rising edge of PEA\_CLKp is equal to the falling edge of PEA\_CLKn.
3. V<sub>Havg</sub> is the statistical average of the V<sub>H</sub> measured by the oscilloscope.
4. Ringback Margin is defined as the absolute voltage difference between the maximum Rising Edge Ringback and the maximum Falling Edge Ringback.
5. Threshold Region is defined as a region entered around the crossing point voltage in which the differential receiver switches. It includes input threshold hysteresis.
6. The crossing point must meet the absolute and relative crossing point specifications simultaneously.
7. V<sub>Havg</sub> can be measured directly using “Vtop” on Agilent\* scopes and “High” on Tektronix\* scopes.

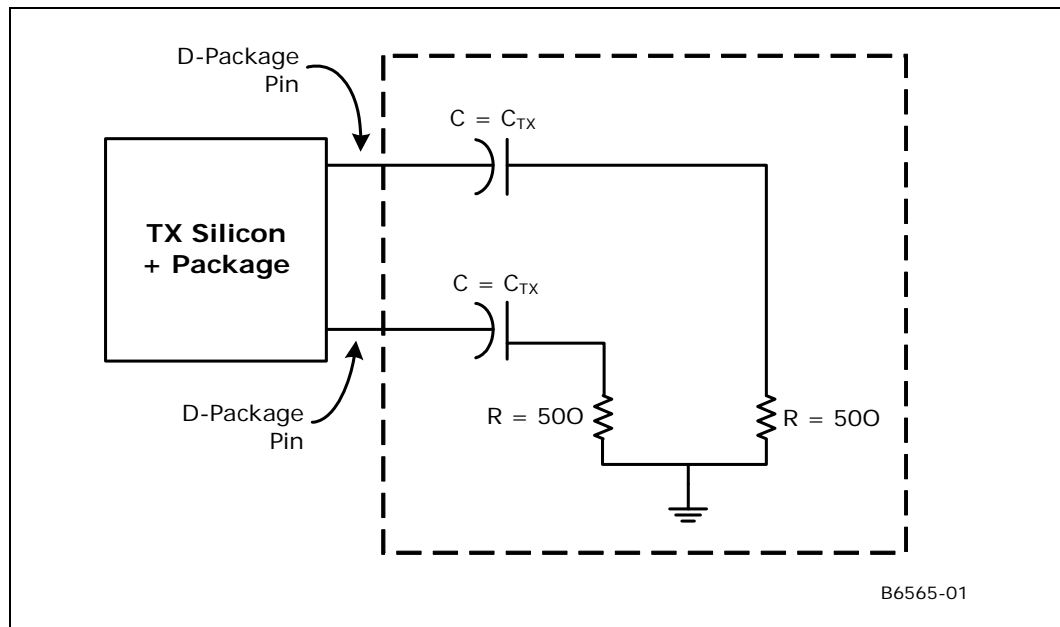

Table 49-23. PCI Express\* Clock Timings

| Symbol                | Parameter                   | Min   | Typical | Max | Units | Figure | Notes |
|-----------------------|-----------------------------|-------|---------|-----|-------|--------|-------|
|                       | PEA_CLK Frequency           |       | 100     |     | MHz   |        |       |
|                       | Clock Tolerance             | 300   |         | 300 | ppm   |        |       |
| T <sub>p</sub>        | PEA_CLK Period              | 9.872 |         |     | ns    | 49-17  |       |
| T <sub>ccjitter</sub> | Cycle to Cycle Jitter       |       |         | 125 | ps    |        |       |
|                       | Duty Cycle                  | 45    |         | 55  | %     |        |       |
| T <sub>5</sub>        | PEA_CLK Rise Time           | 175   |         | 700 | ps    | 49-17  |       |
| ΔT <sub>rise</sub>    | PEA_CLK Rise Time variation |       |         | 125 | ps    |        |       |
| T <sub>6</sub>        | PEA_CLK Fall Time           | 175   |         | 700 | ps    | 49-17  |       |
| ΔT <sub>fall</sub>    | PEA_CLK Fall Time variation |       |         | 125 | ps    |        |       |
|                       | PEA_CLK Slew Rate           | 0.5   |         | 1.6 | V/ns  |        | 1, 2  |
|                       | Rise/Fall Matching          |       |         | 20  | %     |        |       |

**Notes:**

1. Rise/fall times and slew rates are measured single ended between 245 mV and 455 mV of the clock swing.
2. Slew rate specifications apply to both rising and falling edges.

## 49.5.4 Serial ATA (SATA)

The EP80579 has an integrated SATA host controller that supports independent DMA operation on two ports and supports data transfer rates of up to 3.0 Gb/s (300 MB/s). This technology consists of a receiver and transmitter.

The EP80579 SATA ports support Gen1 Electrical Specifications for “Short” Backplane and External Desktop Applications running at 1.5Gbp/s. These are defined on page 12 of the *Serial ATA II: Electrical Specification Revision 1.0 26-May 2004*. The EP80579 silicon and platform supports SATA hot plug. Use of an interlock switch is optional. While SATA controllers commonly provide hot plug functionality, SATA cable assemblies are not standardized, especially the SATA power cable. To support SATA hot plug, any EP80579 platform needs to support a SATA 15-pin power connector interface with a hot plug compatible SATA HDD.

The EP80579 supports the *Serial ATA Specification, Revision 1.0a*. The EP80579 also supports several optional sections of the *Serial ATA II: Extensions to Serial ATA 1.0 Specification, Revision 1.0* (AHCI support is required for some elements).

This section describes the electrical characteristics of the SATA interface.

### 49.5.4.1 SATA Signal List

For SATA pin descriptions, refer to [Table 48-17, “Serial ATA Interface Signals” on page 1753](#).

### 49.5.4.2 SATA DC Characteristics

**Table 49-24. SATA DC Input Characteristics (SATA\_RX[P,N])**

| Symbol             | Parameter             | Conditions | Gen 1 m | Gen 2 m | Units      | Notes |
|--------------------|-----------------------|------------|---------|---------|------------|-------|
| V <sub>MIN10</sub> | Minimum Input Voltage |            | 240     | 240     | mVdiff p-p | 1     |
| V <sub>MAX10</sub> | Maximum Input Voltage |            | 600     | 750     | mVdiff p-p | 1     |

**Notes:**

- SATA Vdiff, tx (V<sub>MAX</sub>/MIN10) is measured at the SATA connector on the transmit side (generally, the motherboard connector), where SATA mVdiff p-p = |SATA[x]TXP/RXP - SATA[x]TXN/RXN|

**Table 49-25. SATA DC Input Characteristics (GPIO and SATALED#)**

| Symbol            | Parameter             | Conditions                               | Min | Typical | Max | Units | Notes |
|-------------------|-----------------------|--|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high    | -  | 2.0 | -       | -   | V     | -     |
| V <sub>IL</sub>   | Input voltage low     | -  | -   | -       | 0.8 | V     | -     |
| I <sub>leak</sub> | Input Leakage Current | 0 < V <sub>IN</sub> < V <sub>cc3_3</sub> | -   | -       | 10  | µA    | -     |
| C <sub>IN</sub>   | Input-pin capacitance | -  | -   | -       | 10  | pf    | 1     |

**Notes:**

- Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

### 49.5.4.3 SATA DC Output Characteristics

Table 49-26. SATA DC Output Characteristics (SATA\_TX(P,N))

| Symbol             | Parameter              | Conditions | Gen 1 m | Gen 2 m | Units      | Note |
|--------------------|------------------------|------------|---------|---------|------------|------|
| V <sub>OMIN8</sub> | Minimum Output Voltage |            | 400     | 400     | mVdiff p-p | 1    |
| V <sub>OMAX8</sub> | Maximum Output Voltage |            | 600     | 700     | mVdiff p-p | 1    |

**Notes:**

1. SATA Vdiff, Tx (VOMAX/MIN8) is measured at the SATA connector on the transmit side closest to the IICH (generally, the motherboard connector), where SATA mV diff p-p = |SATAxTXP - SATAxTXN

Table 49-27. SATA DC Output Characteristics (SATALED#)

| Symbol          | Parameter                      | Conditions              | Min | Typical | Max | Units |
|-----------------|--------------------------------|-------------------------|-----|---------|-----|-------|
| V <sub>OH</sub> | Output voltage high            | I <sub>out</sub> = -6mA | 2.4 | -       |     | V     |
| V <sub>OL</sub> | Output voltage low             | I <sub>out</sub> = 6mA  | -   | -       | 0.4 | V     |
| I <sub>OH</sub> | Output current at high voltage | V <sub>OH</sub> = 2.4   | -   | -       | -6  | mA    |
| I <sub>OL</sub> | Output current at low voltage  | V <sub>OL</sub> = 0.8   | 2   | -       | -   | mA    |

### 49.5.4.3.1 SATA\_CLK

The 100MHz Serial ATA Reference Clock (SATACLKP, SATACLKN) is the main clock for the SATA interface. The reference clock is used by the SATA PLL to generate the clocks of the SATA interface and is implemented on the system as a ground-terminated, low-voltage differential signal pair driven by the system clock chip.

Table 49-28. SATA DC Clock Specifications (SATA\_CLKN, SATA\_CLKP)

| Symbol                  | Parameter               | Conditions | Min    | Typical | Max   | Units |
|-------------------------|-------------------------|------------|--------|---------|-------|-------|
| V <sub>IL12</sub>       | Input Low Voltage       |            | -0.150 |         | 0.150 | V     |
| V <sub>IH12</sub>       | Input High Voltage      |            | 0.660  |         | 0.850 | V     |
| V <sub>cross(abs)</sub> | Absolute Crossing Point |            | 0.250  |         | 0.550 | V     |

### 49.5.4.4 SATA LED

The SATALED# output is driven whenever the BSY bit is set in any SATA port. The SATALED# is an active-low open-collector output. When SATALED# is low, the LED is active. When SATALED# is high, the LED is inactive.

#### 49.5.4.5 SATA AC Characteristics

**Table 49-29. SATA Clock (SATA\_CLKp, SATA\_CLKn)**

| Parameter | Min   | Typical | Max     | Units |
|-----------|-------|---------|---------|-------|
| Period    | 9.997 | -       | 10.0533 | ns    |
| Rise time | 175   | -       | 700     | ps    |
| Fall time | 175   | -       | 700     | ps    |

**Table 49-30. SATA Interface Timings**

| Symbol | Parameter                           | Min    | Typical  | Max    | Units | Notes |
|--------|-------------------------------------|--------|----------|--------|-------|-------|
| UI     | Gen1 Operating Data Period          | 666.43 | 666.6667 | 670.12 | ps    | 5     |
| UI     | Gen2 Operating Data Period (3 Gbps) | 333.21 | 333.3333 | 335.06 | ps    | 5     |
|        | Rise Time (Gen1)                    | 0.10   | -        | 0.41   | UI    | 1, 5  |
|        | Fall Time (Gen1)                    | 0.10   | -        | 0.41   | UI    | 2, 5  |
|        | Rise Time (Gen2)                    | 0.20   | 0.3      | 0.41   | UI    | 1, 5  |
|        | Fall Time (Gen2)                    | 0.20   | 0.3      | 0.41   | UI    | 2, 5  |
|        | Tx differential skew                | -      | -        | 20     | ps    |       |
|        | COMRESET                            | 310.4  | 320      | 329.6  | ns    | 3     |
|        | COMWAKE transmit spacing            | 103.5  | 106.7    | 109.9  | ns    | 3     |
|        | OOB Operating Data period           | 646.67 | -        | 686.67 | ns    | 4     |

**Notes:**

1. 20% - 80% at transmitter
2. 80% - 20% at transmitter
3. As measured from 100 mV differential cross points of last and first edges of burst.
4. Operating data period during Out-Of-Band burst transmissions
5. Unit Interval (UI). Equal to the time required to transmit one bit.

### 49.5.5 Universal Serial Bus (USB)

The EP80579 has (2) Universal Serial Bus 2.0 interface that can be configured as master, but not as a slave interface.

The USB interface supports both USB 1.1 and USB 2.0 signaling. USB1.1 has a low-speed mode (1.5 Mbps) and a full-speed mode (12 Mbps). USB 2.0 works at high speed LVDS mode with a data rate of 480 Mbps. The driver operates in voltage mode for USB 1.1 and current mode for USB 2.0. The receiver can detect single-ended/differential-ended classical signals as well as high speed LVDS signals.

This section describes the electrical characteristics of the USB interface.

#### 49.5.5.1 USB Signal List

For USB pin description refer to [Table 48-18, "USB Interface Signals"](#) on page 1755.

## 49.5.5.2 USB DC Characteristics

### 49.5.5.2.1 USB Transceiver DC Characteristics

The DC electrical specifications of the USB Transceivers in the EP80579 (USBp0, USBn0, USBp1, USBn1) are compliant with the USB v2.0 specification from April 27, 2000 (refer to Section 7.3.2 Bus Timing/Electrical Characteristics for more information).

External resistors are not required on USBp0, USBn0, USBp1 and USBn1. The chip integrates the 15 K $\Omega$  pull-down and provides an output driver impedance of 45 Ohm, which requires no external series resistor.

### 49.5.5.2.2 USB LVTTTL Inputs DC Characteristics

The DC electrical specifications for the LVTTTL inputs are described in [Table 49-31](#).

**Table 49-31. USB Overcurrent Indicators DC Input (OC[1:0])**

| Symbol     | Parameter             | Conditions                | Min  | Typical | Max                 | Units   | Notes |
|------------|-----------------------|---------------------------|------|---------|---------------------|---------|-------|
| $V_{IH}$   | Input voltage high    | -                         | 2.0  | -       | $V_{CC3\_3} + 0.3V$ | V       | -     |
| $V_{IL}$   | Input voltage low     | -                         | -0.4 | -       | 0.8                 | V       | -     |
| $I_{leak}$ | Input Leakage Current | $0 < V_{IN} < V_{CC3\_3}$ | -    | -       | 10                  | $\mu A$ | -     |
| $C_{IN}$   | Input-pin capacitance | -                         | -    | -       | 10                  | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

49.5.5.2.3 USB LV Differential DC Characteristics

The DC electrical specifications for the LV Differential signals are described in Table 49-32.

Table 49-32. USB LV Differential DC Characteristics (USBn[1:0], USBp[1:0])

| Symbol              | Parameter   | Min                      | Max                      | Unit | I <sub>OL</sub> /I <sub>OH</sub> | Notes   |
|---------------------|---|--------------------------|--------------------------|------|----------------------------------|---------|
| V <sub>DI</sub>     | Input Differential Input Sensitivity              | 0.2                      |                          | V    |                                  | 1, 2, 4 |
| V <sub>CM</sub>     | Input Differential Common Mode Range              | 0.8                      | 2.5                      | V    |                                  | 1, 2, 3 |
| V <sub>SE</sub>     | Input Single-Ended Receiver Threshold             | 0.8                      | 2.0                      | V    |                                  | 1, 2    |
| V <sub>CRS</sub>    | Output Signal Crossover Voltage                   | 1.3                      | 2.0                      | V    |                                  | 2       |
| V <sub>HSSQ</sub>   | Input HS Squelch Detection Threshold              | 100                      | 150                      | mV   |                                  | 1       |
| V <sub>HSDSC</sub>  | Input HS Disconnect Detection Threshold           | 525                      | 625                      | mV   |                                  | 1       |
| V <sub>HSCM</sub>   | Input HS Data Signaling Common Mode Voltage Range | -50                      | 500                      | mV   |                                  | 1       |
| V <sub>HSOI</sub>   | Output HS Idle Level                              | -10.0                    | 10.0                     | mV   |                                  | 1       |
| V <sub>HSOH</sub>   | Output HS Data Signaling High                     | 360                      | 440                      | mV   |                                  | 1       |
| V <sub>HSOL</sub>   | Output HS Data Signaling Low                      | -10.0                    | 10.0                     | mV   |                                  | 1       |
| V <sub>CHIRPJ</sub> | Output Chirp J Level                              | 700                      | 1100                     | mV   |                                  | 1       |
| V <sub>CHIRPK</sub> | Output Chirp K Level                              | -900                     | -500                     | mV   |                                  | 1       |
| V <sub>OL6</sub>    | Output Low Voltage                                |                          | 0.4                      | V    | 5 mA                             | 2       |
| V <sub>OH6</sub>    | Output High Voltage                               | V <sub>CC3_3</sub> - 0.5 |                          | V    | -2 mA                            | 2       |
| V <sub>IL4</sub>    | Input Low Voltage                                 | -0.5                     | 0.3(V <sub>CC3_3</sub> ) | V    |                                  |         |
| V <sub>IH4</sub>    | Input High Voltage                                | 0.5(V <sub>CC3_3</sub> ) | V <sub>CC3_3</sub> + 0.5 | V    |                                  |         |

Notes:

1. Applies to High-speed USB 2.0
2. Applies to Low-speed and Full-speed
3. Includes VDI range
4. VDI = USBp[X] - USBn[X]

#### 49.5.5.2.4 USB Clock (CLK48) DC Input Specifications

The DC electrical specifications for the clock input are described in Table 49-33.

**Table 49-33. USB Clock (CLK48) DC Input Specifications**

| Symbol     | Parameter             | Conditions    | Min  | Typical | Max                 | Units   | Notes |
|------------|-----------------------|---------------|------|---------|---------------------|---------|-------|
| $V_{IH}$   | Input voltage high    | -             | 2.0  | -       | $V_{CC3\_3} + 0.3V$ | V       | -     |
| $V_{IL}$   | Input voltage low     | -             | -0.4 | -       | 0.8                 | V       | -     |
| $I_{leak}$ | Input Leakage Current | $V_{IN}=3.3V$ | -    | -       | 60                  | $\mu A$ | -     |
| $C_{IN}$   | Input-pin capacitance | -             | -    | -       | 10                  | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

#### 49.5.5.3 USB AC Characteristics

##### 49.5.5.3.1 USB Transceiver AC Specifications

The AC electrical specifications of the USB transceivers in the EP80579 are compliant with the *USB v2.0 specification from April 27, 2000*.

##### 49.5.5.3.2 Transceiver Timing Waveforms

The timing waveform specifications of the USB Transceivers in the EP80579 are compliant with the *USB v2.0 specification from April 27, 2000*.

#### 49.5.5.4 USB AC Specifications

**Table 49-34. USB Input Clock (CLK48) AC Specifications**

| Parameters          | Min | Typical | Max | Units | Figure |
|---------------------|-----|---------|-----|-------|--------|
| Operating Frequency |     | 48      |     | MHz   | -      |
| Frequency Tolerance |     |         | 100 | ppm   | -      |
| Duty Cycle          | 45  | -       | 55  | %     | -      |
| High Time           | 7   | -       | -   | ns    | 49-19  |
| Low Time            | 7   | -       | -   | ns    | 49-19  |
| Rise Time           | -   | -       | 1.2 | ns    | 49-19  |
| Fall Time           | -   | -       | 1.2 | ns    | 49-19  |

Figure 49-19. Clock Timing

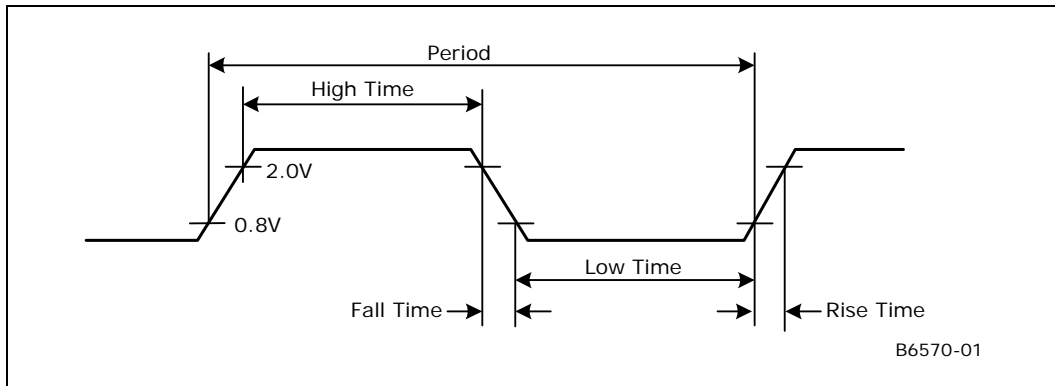

Table 49-35. USB Timing Specifications (Sheet 1 of 2)

| Parameter  | Min   | Max  | Units | Figure | Notes  |
|--|-------|------|-------|--------|--|
| <b>High-speed Source</b>                                       |       |      |       |        |  |

**Notes:**

1. Driver output resistance under steady state drive is specified at 28 ohms at minimum and 43 ohms at maximum.
2. Timing difference between the differential data signals.
3. Measured at crossover point of differential data signals.
4. Measured at 50% swing point of data signals.
5. Measured from last crossover point to 50% swing point of data line at leading edge of EOP.
6. Measured from 10% to 90% of the data signal.
7. High-speed Data Rate has minimum of 479.760 Mb/s and maximum of 480.240 Mb/s
8. Full-speed Data Rate has minimum of 11.97 Mb/s and maximum of 12.03 Mb/s.
9. Low-speed Data Rate has a minimum of 1.48 Mb/s and a maximum of 1.52 Mb/s.

Table 49-35. USB Timing Specifications (Sheet 2 of 2)

| Parameter   | Min  | Max  | Units | Figure | Notes                       |

## 49.5.6 System Management Bus (SMBus)

The SMBus is SMBus 2.0 compliant and is also compatible with most 2-wire components that are I<sup>2</sup>C compatible. The host interface allows the EP80579 to communicate via SMBus, the slave interface allows external microcontrollers to access system resource in the IICH. The SMB does not support access to internal configuration registers. Access to the external DIMMs is through the IICH, via I<sup>2</sup>C. This is used to determine the nature of the DIMMs present in order to configure the memory subsystem correctly, including the configuration of the D-unit.

This section describes the electrical characteristics of the System Management Bus (SMBus) interface.

### 49.5.6.1 SMBus Signal List

For SMBus pin description refer to Table 48-15, "SMBus Interface Signals" on page 1750.

### 49.5.6.2 SMBus DC Characteristics

**Table 49-36. SMBus DC Input Characteristics**

| Symbol            | Parameter             | Conditions                               | Min | Typical | Max | Units | Notes |
|-------------------|-----------------------|--|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high    | -  | 2.0 | -       | -   | V     | 2     |
| V <sub>IL</sub>   | Input voltage low     | -  | -   | -       | 0.8 | V     | 2     |
| I <sub>leak</sub> | Input Leakage Current | 0 < V <sub>IN</sub> < V <sub>cc3_3</sub> | -   | -       | ±5  | µA    | -     |
| C <sub>IN</sub>   | Input-pin capacitance | -  | -   | -       | 10  | pf    | 1     |

- 1.
2. V<sub>IH</sub> and V<sub>IL</sub> for Intruder# is guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-37. SMBus DC Output Characteristics**

| Symbol          | Parameter          | Conditions             | Min | Typical | Max | Units | Notes |
|-----------------|--------------------|------------------------|-----|---------|-----|-------|-------|
| V <sub>OL</sub> | Output voltage low | I <sub>out</sub> = 4mA |     |         | 0.4 | V     | 1,2   |

**Notes:**

1. V<sub>OH</sub> spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.
2. V<sub>OL</sub> for Intruder# is guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-38. SMBus DC Clock Specification (Sheet 1 of 2)**

| Symbol          | Parameter          | Conditions | Min | Typical | Max  | Units | Notes |
|-----------------|--------------------|------------|-----|---------|------|-------|-------|
| V <sub>IH</sub> | Input voltage high |            | 2.1 | -       | 3.63 | V     | -     |
| V <sub>IL</sub> | Input voltage low  |            |     | -       | 0.8  | V     | -     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Table 49-38. SMBus DC Clock Specification (Sheet 2 of 2)

| Symbol     | Parameter                          | Conditions                | Min | Typical | Max | Units | Notes |
|------------|------------------------------------|---------------------------|-----|---------|-----|-------|-------|
| $I_{OL}$   | Output sink current at low voltage | $V_{OL} < 0.8$            | -   | -       | 4   | mA    | -     |
| $I_{leak}$ | Input Leakage Current              | $0 < V_{IN} < V_{CC3\_3}$ | -   | -       | ±5  | µA    | -     |
| $C_{IN}$   | -                                  | -                         | -   | 5       | -   | pf    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

### 49.5.6.3 SMBus AC Characteristics

Table 49-39. SMBus Input AC Characteristics

| Sym                | Parameter  | Min | Typical | Max | Unit | Figure | Notes                   |
|--------------------|--|-----|---------|-----|------|--------|-------------------------|
| $f_{SMB}$          | Bus frequency  | 10  | -       | 100 | kHz  |        | per SMBus specification |
| $T_{SU}, t_{135}$  | SMB_DATA setup time  | 250 | -       |     | ns   | 49-23  |                         |
| $T_{hd}, t_{134}$  | SMB_DATA hold time   | 300 | -       |     | ns   | 49-23  | 6                       |
| $T_{DIO}, t_{136}$ | Device Timeout   | 25  | -       | 35  | ms   | 49-23  | 1                       |
| $t_{130}$          | Bus Tree Time Between Stop and Start Condition   | 4.7 | -       | -   | µs   | 49-23  |                         |
| $t_{131}$          | Hold Time after (repeated) Start Condition. After this period, the first clock is generated. | 4.0 | -       | -   | µs   | 49-23  |                         |
| $t_{132}$          | Repeated Start Condition Setup Time  | 4.7 | -       | -   | µs   | 49-23  |                         |
| $t_{133}$          | Stop Condition Setup Time  | 4.0 | -       | -   | µs   | 49-23  |                         |
| $t_{137}$          | Cumulative Clock Low Extend Time (slave device)  | -   | -       | 25  | ms   | 49-24  | 4                       |
| $t_{138}$          | Cumulative Clock Low Extend Time (master device)   | -   | -       | 10  | ms   | 49-24  | 5                       |

**Notes:**

1. A device time outs when any clock low exceeds this parameter.
2. Measured from ( $V_{IL} - 0.15$  V) to ( $V_{IH} + 0.15$  V).
3. Measured from ( $V_{IH} + 0.15$  V) to ( $V_{IL} - 0.15$  V), 1 kΩ pull-up, 400 pF load.
4.  $t_{137}$  is the cumulative time a slave device is allowed to extend the clock cycles in one message from the initial start to stop. If a slave device exceeds this time, it is expected to release both its clock and data lines and reset itself.
5.  $t_{138}$  is the cumulative time a master device is allowed to extend its clock cycles within each byte of a message as defined from start-to-ack, ack-to-ack or ack-to-stop.
6.  $t_{134}$  has a minimum timing for I<sup>2</sup>C of 0 ns, while the minimum timing for SMBus is 300 ns.

**Table 49-40. SMBus Clock Timings (SMBCLK)**

| Parameter           | Conditions | Min. | Typical | Max. | Units | Notes |
|---------------------|------------|------|---------|------|-------|-------|
| Operating Frequency |            | 10   |         | 100  | KHz   |       |
| SMB_CLK high time   |            | 4.0  |         | 50   | us    | 1     |
| SMB_CLK low time    |            | 4.7  |         |      | us    |       |
| SMB_CLK Rise time   |            |      |         | 1000 | ns    |       |
| SMB_CLK Fall time   |            |      |         | 300  | ns    |       |

**Note:**

1. The max high time provides a simple guaranteed method for devices to detect bus idle conditions

**Table 49-41. SMBus Output AC Characteristics**

| Sym | Parameter        | Min | Typical | Max  | Unit | Fig   | Notes                   |
|-----|------------------|-----|---------|------|------|-------|-------------------------|
| t19 | Bus frequency    | 10  |         | 100  | KHz  | 49-23 | per SMBus specification |
| t20 | Signal rise time |     |         | 1000 | ns   | 49-23 | 2                       |
| t21 | Signal fall time |     |         | 300  | ns   | 49-23 | 3                       |

**Notes:**

1. A device times out when any clock low exceeds this parameter.
2. Measured from ( $V_{IL} - 0.15 V$ ) to ( $V_{IH} + 0.15 V$ ).
3. Measured from ( $V_{IH} + 0.15 V$ ) to ( $V_{IL} - 0.15 V$ ), 1 kΩ pull-up, 400 pF load.

**Figure 49-23. SMBus Transaction**

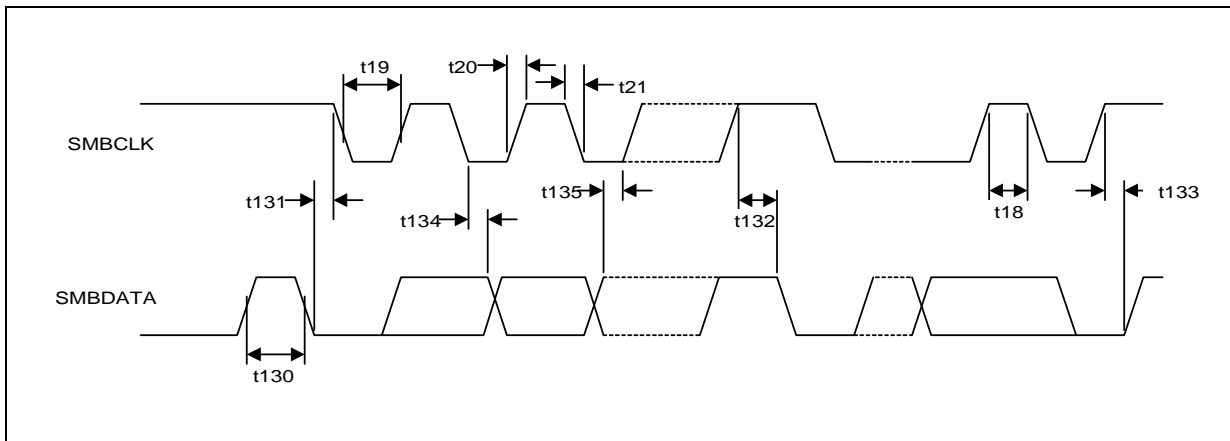

Figure 49-24.SMBus Timeout

## 49.5.7 UART

This section describes the Universal Asynchronous Receiver/Transmitter (UART) serial port used for the two UARTs that are integrated into the Serial I/O unit and Watchdog Timer (SIW). The UART can be controlled via programmed I/O. The basic programming model is the same for both UARTs, with the only difference being the Logical Device Number assigned to each. The serial port consists of a UART that supports all the functions of a standard 16550 UART, including hardware flow control interface.

This section describes the electrical characteristics of the UART interface.

### 49.5.7.1 UART Signal List

For UART pin description refer to Table 48-16, "UART Signals" on page 1751.

### 49.5.7.2 UART DC Characteristics

**Table 49-42. UART DC Input Characteristics**

| Symbol     | Parameter             | Conditions                | Min  | Typical | Max              | Units   | Notes |
|------------|-----------------------|---------------------------|------|---------|------------------|---------|-------|
| $V_{IH}$   | Input voltage high    | -                         | 2.0  | -       | $V_{CC33} + 0.5$ | V       | -     |
| $V_{IL}$   | Input voltage low     | -                         | -0.5 | -       | 0.8              | V       | -     |
| $I_{leak}$ | Input Leakage Current | $0 < V_{IN} < V_{CC3\_3}$ | -    | -       | 10               | $\mu$ A | -     |
| $C_{IN}$   | Input-pin capacitance | -                         | -    | -       | 10               | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing

**Table 49-43. UART DC Output Characteristics**

| Symbol   | Parameter                      | Conditions                | Min           | Typical | Max           | Units | Notes |
|----------|--------------------------------|---------------------------|---------------|---------|---------------|-------|-------|
| $V_{OH}$ | Output voltage high            | $I_{out} = -0.5\text{mA}$ | $0.9V_{CC33}$ | -       | -             | V     | 1     |
| $V_{OL}$ | Output voltage low             | $I_{out} = 1.5\text{mA}$  | -             | -       | $0.1V_{CC33}$ | V     |       |
| $I_{OH}$ | Output current at high voltage | $V_{OH} > 0.9V_{CC33}$    | -0.5          | -       | -             | mA    |       |
| $I_{OL}$ | Output current at low voltage  | $V_{OL} < 0.1V_{CC33}$    | -             | -       | 1.5           | mA    |       |

**Notes:**

1. VOH spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

Table 49-44. UART DC Clock Specification

| Symbol            | Parameter             | Conditions                               | Min                   | Typical | Max                      | Units | Notes |
|-------------------|-----------------------|--|-----------------------|---------|--------------------------|-------|-------|
| V <sub>IH</sub>   | Input voltage high    | -  | 0.5V <sub>VCC33</sub> | -       | V <sub>VCC33</sub> + 0.5 | V     | -     |
| V <sub>IL</sub>   | Input voltage low     | -  | -                     | -       | 0.8                      | V     | -     |
| I <sub>leak</sub> | Input Leakage Current | 0 < V <sub>IN</sub> < V <sub>VCC33</sub> | -10                   | -       | 10                       | μA    | -     |
| C <sub>IN</sub>   | Input-pin capacitance | -  | 5                     | -       | 12                       | pf    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

### 49.5.7.3 UART AC Characteristics

The AC electrical specifications of the UART interface are compliant with the *PCI Local Bus Specification*, Rev 3.0 (refer to AC specifications for 3.3V signaling for more information).

### 49.5.7.4 UART Receiver AC Specifications

Table 49-45. UART Timing

| Parameter  | Min. | Typical | Max. | Units | Notes |
|--|------|---------|------|-------|-------|
| SIU_RXD[2:1], SIU_CTS[2:1]#, SIU_DSR[2:1]#, SIU_DCD[2:1]#, and SIU_RI[2:1]# Set up time to UART_CLK rising | 7    |         |      | ns    |       |
| SIU_RXD[2:1], SIU_CTS[2:1]#, SIU_DSR[2:1]#, SIU_DCD[2:1]#, and SIU_RI[2:1]# hold time from UART_CLK rising | 0    |         |      | ns    |       |

#### 49.5.7.4.1 UART Transmitter AC Specifications

Table 49-46. UART Timing

| Parameter   | Min. | Typical | Max. | Units | Notes |
|---|------|---------|------|-------|-------|
| SIU_TXD[2:1] Valid Delay from UART_CLK rising                                   | 2    |         | 11   | ns    |       |
| SIU_TXD[2:1], SIU_DTR[2:1]# and SIU_RTS[2:1]#, Valid Delay from UART_CLK rising | 2    |         |      | ns    |       |

#### 49.5.7.4.2 UART Clock Timings

14.7456 MHz, and 48 MHz are supported for UART baud clock input.

## 49.5.8 Serial Peripheral Interface (SPI)<sup>1</sup>

This section describes the electrical characteristics of the Serial Peripheral Interface.

### 49.5.8.1 SPI Signal List

For SPI pin description refer to Table 48-13, “SPI Interface Signals” on page 1749.

### 49.5.8.2 SPI DC Characteristics

**Table 49-47. SPI DC Input Characteristics**

| Symbol            | Parameter                     | Conditions                            | Min | Typical | Max | Units | Notes |
|-------------------|-------------------------------|---------------------------------------|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high            | -                                     | 2.0 | -       |     | V     | -     |
| V <sub>IL</sub>   | Input voltage low             | -                                     | -   | -       | 0.8 | V     | -     |
| I <sub>OL</sub>   | Output current at low voltage | V <sub>OL</sub> <0.8                  | -   | -       | 4   | mA    | -     |
| I <sub>leak</sub> | Input Leakage Current         | 0<V <sub>IN</sub> <V <sub>cc3_3</sub> | -   | -       | 10  | μA    | -     |
| C <sub>in</sub>   | Input pin cap                 | -                                     | -   | -       | 5   | pf    | 1     |

**Notes:**

- Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-48. SPI DC Output Characteristics**

| Symbol          | Parameter                      | Conditions             | Min | Typical | Max | Units | Notes |
|-----------------|--------------------------------|------------------------|-----|---------|-----|-------|-------|
| V <sub>OH</sub> | Output voltage high            | I <sub>out</sub> =-6mA | 2.0 | -       | -   | V     | 1     |
| V <sub>OL</sub> | Output voltage low             | I <sub>out</sub> =6mA  | -   | -       | 0.4 | V     | -     |
| I <sub>OH</sub> | Output current at high voltage | V <sub>OH</sub> =2.4   | -12 | -27     | -48 | mA    | -     |
| I <sub>OL</sub> | Output current at low voltage  | V <sub>OL</sub> =0.8   | 12  | 18      | 26  | mA    | -     |

**Notes:**

- VOH spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

### 49.5.8.3 SPI AC Characteristics

**Table 49-49. SPI Timing Specifications (Sheet 1 of 2)**

| Symbol           | Parameter   | Min  | Max  | Units | Figures | Notes |
|------------------|---|------|------|-------|---------|-------|
|                  | Serial Clock Period - 20 MHz Operation  | 17.2 | 18.4 | MHz   | -       | 1     |
| t <sub>182</sub> | SPI Clock Duty cycle at the host  | -    | 50   | %     | 49-25   | -     |
| t <sub>183</sub> | T <sub>co</sub> of SPI_MOSI with respect to serial clock falling edge at the host | -5   | 13   | ns    | 49-25   | -     |

**Notes:**

- The typical clock frequency driven by the EP80579 is 17.86 MHz.

- Intel recommends using the SPI for Pre-boot firmware due to the reduced availability of LPC FWH.

Table 49-49. SPI Timing Specifications (Sheet 2 of 2)

| Symbol | Parameter   | Min | Max | Units | Figures | Notes |
|--------|---|-----|-----|-------|---------|-------|
| t184   | Setup of SPI_MISO with respect to serial clock falling edge at the host           | 16  | -   | ns    | 49-25   | -     |
| t185   | Hold of SPI_MISO with respect to serial clock falling edge at the host            | 0   | -   | ns    | 49-25   | -     |
| t186   | Setup of SPI_CS[1:0]# assertion with respect to serial clock rising at the host   | 30  | -   | ns    | 49-25   | -     |
| t187   | Hold of SPI_CS[1:0]# deassertion with respect to serial clock falling at the host | 30  | -   | ns    | 49-25   | -     |

**Notes:**

1. The typical clock frequency driven by the EP80579 is 17.86 MHz.

Figure 49-25. SPI Timing Diagram

### 49.5.9 Low Pin Count (LPC)

The LPC interface is used to control all the logical blocks on the Serial I/O unit and Watchdog Timer (SIW). LPC bus signals use PCI 33 MHz electrical signal characteristics. Refer to the *Low Pin Count (LPC) Interface Specification, Rev 1.1* for more information.

This section describes the electrical characteristics of the LPC interface.

#### 49.5.9.1 LPC Signal List

For LPC pin description refer to Table 48-14, "LPC and FWH Interface Signals" on page 1749.

### 49.5.9.2 LPC DC Characteristics

**Table 49-50. LPC DC Input Characteristics**

| Symbol     | Parameter             | Conditions                | Min  | Typical | Max           | Units   | Notes |
|------------|-----------------------|---------------------------|------|---------|---------------|---------|-------|
| $V_{IH}$   | Input voltage high    | -                         | 2.0  | -       | VCC33<br>+0.5 | V       | -     |
| $V_{IL}$   | Input voltage low     | -                         | -0.5 | -       | 0.8           | V       | -     |
| $I_{leak}$ | Input Leakage Current | $0 < V_{IN} < V_{CC3\_3}$ | -    | -       | 10            | $\mu$ A | -     |
| $C_{IN}$   | Input-pin capacitance | -                         | -    | -       | 10            | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing

**Table 49-51. LPC DC Output Characteristics**

| Symbol   | Parameter                      | Conditions                | Min      | Typical | Max      | Units | Notes |
|----------|--------------------------------|---------------------------|----------|---------|----------|-------|-------|
| $V_{OH}$ | Output voltage high            | $I_{out} = -0.5\text{mA}$ | 0.9VCC33 | -       | -        | V     | 1     |
| $V_{OL}$ | Output voltage low             | $I_{out} = 1.5\text{mA}$  | -        | -       | 0.1VCC33 | V     |       |
| $I_{OH}$ | Output current at high voltage | $V_{OH} > 0.9VCC33$       | -0.5     | -       | -        | mA    |       |
| $I_{OL}$ | Output current at low voltage  | $V_{OL} < 0.1VCC33$       | -        | -       | 1.5      | mA    |       |

**Notes:**

1. VOH spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

**Table 49-52. LPC DC Clock Specifications**

| Symbol     | Parameter             | Conditions           | Min      | Typical | Max            | Units   | Notes |
|------------|-----------------------|----------------------|----------|---------|----------------|---------|-------|
| $V_{IH}$   | Input voltage high    | -                    | 0.5VCC33 | -       | VCC33<br>+ 0.5 | V       | -     |
| $V_{IL}$   | Input voltage low     | -                    | -        | -       | 0.8            | V       | -     |
| $I_{leak}$ | Input Leakage Current | $0 < V_{IN} < VCC33$ | -10      | -       | 10             | $\mu$ A | -     |
| $C_{IN}$   | Input-pin capacitance | -                    | 5        | -       | 12             | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

### 49.5.9.3 LPC AC Characteristics

Table 49-53. LPC Clock AC Characteristics

| Parameter | Min | Max  | Units | Figure |
|-----------|-----|------|-------|--------|
| Period    | 30  | 33.3 | ns    | 49-26  |
| High Time | 11  | -    | ns    | 49-26  |
| Low Time  | 11  | -    | ns    | 49-26  |
| Rise Time | -   | 3    | ns    | 49-26  |
| Fall Time | -   | 3    | ns    | 49-26  |

#### 49.5.9.3.1 LPC Timing Specification

Table 49-54. LPC Input Timing Specification

| Parameter                                      | Min | Typical | Max | Units | Figure |
|--|-----|---------|-----|-------|--------|
| LAD[3:0]/FWH[3:0] Setup Time to PCICLK Rising  | 7   |         |     | ns    | 49-27  |
| LAD[3:0]/FWH[3:0] Hold Time from PCICLK Rising | 0   |         |     | ns    | 49-27  |
| LDRQ[1:0]# Setup Time to PCICLK Rising         | 12  |         |     | ns    | 49-27  |
| LDRQ[1:0]# Hold Time from PCICLK Rising        | 0   |         |     | ns    | 49-27  |

Table 49-55. LPC Output Timing Specification

| Parameter  | Min | Typical | Max | Units | Figure |
|--|-----|---------|-----|-------|--------|
| LAD[3:0]/FWH[3:0] Valid Delay from PCICLK Rising         | 2   |         | 11  | ns    | 49-28  |
| LAD[3:0]/FWH[3:0] Output Enable Delay from PCICLK Rising | 2   |         |     | ns    | 49-29  |
| LAD[3:0]/FWH[3:0] Float Delay from PCICLK Rising         |     |         | 28  | ns    | 49-30  |
| LFRAME#/FWH[4] Valid Delay from PCICLK Rising            | 2   |         | 11  | ns    | 49-28  |

#### 49.5.9.3.2 LPC Timing Diagrams

Figure 49-26. LPC Clock (PCICLK) Timing Diagram

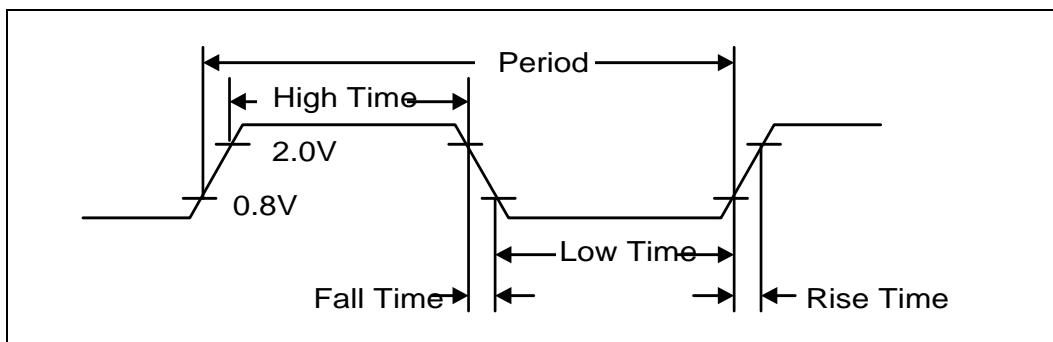

Figure 49-27.LPC Input Setup and Hold Timing Diagram

Figure 49-28.LPC Valid Delay from Rising Clock Edge Diagram

Figure 49-29.LPC Output Enable Delay Diagram

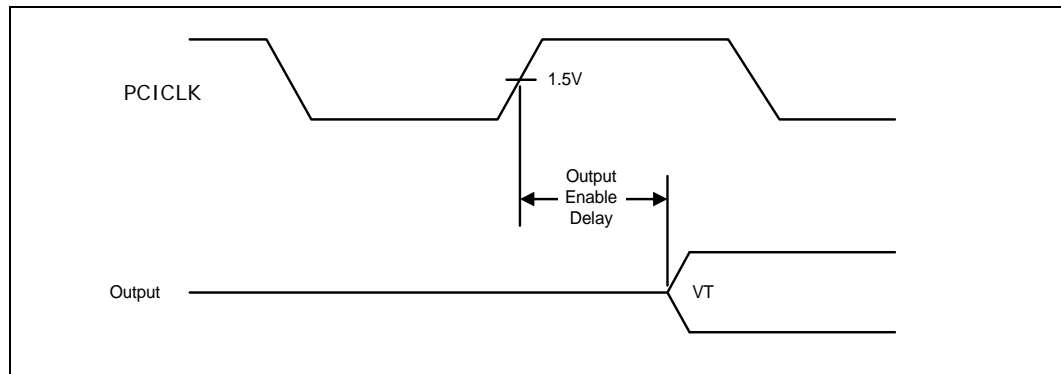

Figure 49-30.LPC Float Delay Diagram

49.5.9.3.3 LPC Reset

The LPC controller does not adhere to the section of the LPC specification that says "LRESET# is always asserted after LPCPD#". LRESET # is not always asserted after LPCPD#.

49.5.10 General Purpose I/O (GPIO)

GPIO are general-purpose I/O signals. These signals can be used for slow-speed, software-controlled I/O.

This section describes the electrical characteristics of the GPIO interface.

49.5.10.1 GPIO Signal List

For GPIO pin description refer to Table 48-11, "General-Purpose IO Signals" on page 1744.

49.5.10.2 GPIO DC Characteristics

Table 49-56. GPIO DC Input Characteristics

| Symbol     | Parameter             | Conditions                | Min  | Typical | Max        | Units   | Notes |
|------------|-----------------------|---------------------------|------|---------|------------|---------|-------|
| $V_{IH}$   | Input voltage high    | -                         | 2.0  | -       | VCC33 +0.5 | V       | -     |
| $V_{IL}$   | Input voltage low     | -                         | -0.5 | -       | 0.8        | V       | -     |
| $I_{leak}$ | Input Leakage Current | $0 < V_{IN} < V_{cc3\_3}$ | -    | -       | 10         | $\mu A$ | -     |
| $C_{IN}$   | Input-pin capacitance | -                         | -    | -       | 10         | pf      | 1     |

Notes:

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing

Table 49-57. GPIO DC Output Characteristics

| Symbol          | Parameter           | Conditions                | Min                      | Typical | Max                      | Units | Notes |
|-----------------|---------------------|---------------------------|--------------------------|---------|--------------------------|-------|-------|
| V <sub>OH</sub> | Output voltage high | I <sub>out</sub> = -0.5mA | 0.9V <sub>CC</sub><br>33 | -       | -                        | V     | 1     |
| V <sub>OL</sub> | Output voltage low  | I <sub>out</sub> = 1.5mA  | -                        | -       | 0.1V <sub>CC</sub><br>33 | V     | -     |

**Notes:**

1. V<sub>OH</sub> spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

### 49.5.10.3 GPIO AC Specifications

The AC electrical specifications of the GPIO interface are compliant with the *PCI Local Bus Specification, Rev. 3.0* (refer to the AC Specifications for 3.3V Signaling for more information).

### 49.5.11 IICH Interrupt Signal

This section describes the electrical characteristics of the IICH interrupt signal interface.

#### 49.5.11.1 IICH Interrupt Signal List

For IICH interrupt signal pin descriptions, refer to Table 48-12, "IICH Interrupt Signals" on page 1748.

#### 49.5.11.2 IICH Interrupt Signal DC Characteristics

Table 49-58. IICH Interrupt Signal DC Input Characteristics

| Symbol            | Parameter                     | Conditions                               | Min | Typical | Max | Units | Notes |
|-------------------|-------------------------------|--|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high            | -  | 2.0 | -       | -   | V     | -     |
| V <sub>IL</sub>   | Input voltage low             | -  | -   | -       | 0.8 | V     | -     |
| I <sub>OL</sub>   | Output current at low voltage | V <sub>OL</sub> < 0.8                    | -   | -       | 4   | mA    | -     |
| I <sub>leak</sub> | Input Leakage Current         | 0 < V <sub>IN</sub> < V <sub>cc3_3</sub> | -   | -       | 10  | μA    | -     |
| C <sub>in</sub>   | Input pin cap                 | -  | -   | -       | 5   | pf    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Table 49-59. IICH Interrupt Signal DC Output Characteristics (Sheet 1 of 2)

| Symbol          | Parameter           | Conditions              | Min | Typical | Max | Units | Notes |
|-----------------|---------------------|-------------------------|-----|---------|-----|-------|-------|
| V <sub>OH</sub> | Output voltage high | I <sub>out</sub> = -6mA | 2.4 | -       | -   | V     | 1     |

**Notes:**

1. V<sub>OH</sub> spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

**Table 49-59. IICH Interrupt Signal DC Output Characteristics (Sheet 2 of 2)**

| Symbol          | Parameter                      | Conditions            | Min | Typical | Max  | Units | Notes |
|-----------------|--------------------------------|-----------------------|-----|---------|------|-------|-------|
| V <sub>OL</sub> | Output voltage low             | I <sub>out</sub> =6mA |     | -       | 0.4  | V     | -     |
| I <sub>OH</sub> | Output current at high voltage | V <sub>OH</sub> =2.4  | -   | -       | 1.5  | mA    | -     |
| I <sub>OL</sub> | Output current at low voltage  | V <sub>OL</sub> =0.8  | -   | -       | -0.5 | mA    | -     |

**Notes:**

1. V<sub>OH</sub> spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

**49.5.11.3 IICH Interrupt Signal AC Input, Output Characteristics**

The AC electrical specifications of the IICH Interrupt Signal are compliant with the *PCI Local Bus Specification, rev. 3.0* (refer to AC Specifications for 3.3V Signaling for more information).

**49.5.11.4 IICH Interrupt Signal Timing Specification**

**Table 49-60. IICH Interrupt Signal Timing Specification**

| Parameter                           | Min | Typical | Max | Units | Note  |
|-------------------------------------|-----|---------|-----|-------|-------|
| SERIRQ Setup Time to PCICLK Rising  | 7   |         |     | ns    | 49-31 |
| SERIRQ Hold Time from PCICLK Rising | 0   |         |     | ns    | 49-31 |

**Figure 49-31. IICH Interrupt Signal Timing Diagram**

**49.5.11.5 IICH Clock AC Specifications**

**Table 49-61. IICH Clock (CLK14) AC Specifications (Sheet 1 of 2)**

| Parameters          | Min | Typical  | Max | Units | Figure | Note |
|---------------------|-----|----------|-----|-------|--------|------|
| Operating Frequency |     | 14.31818 |     | MHz   | -      |      |
| Period              | 67  | -        | 70  | ns    |        |      |
| High Time           | 20  | -        | -   | ns    | 49-32  |      |

**Notes:**

1. CLK14 edge rates in a system as measured from 0.8 V to 2.0 V.

Table 49-61. IICH Clock (CLK14) AC Specifications (Sheet 2 of 2)

| Parameters        | Min | Typical | Max | Units | Figure | Note |
|-------------------|-----|---------|-----|-------|--------|------|
| Low Time          | 20  | -       | -   | ns    | 49-32  |      |
| Rising Edge Rate  | 1.0 | -       | 4.0 | V/ns  | 49-32  | 1    |
| Falling Edge Rate | 1.0 | -       | 4.0 | V/ns  | 49-32  | 1    |

**Notes:**

1. CLK14 edge rates in a system as measured from 0.8 V to 2.0 V.

Figure 49-32. IICH Clock (CLK14) Timing Diagram

### 49.5.12 Real Time Clock (RTC)

This section describes the electrical characteristics of the Real Time Clock interface.

#### 49.5.12.1 RTC Signal List

For Real Time Clock pin description refer to Table 48-10, "Real Time Clock Interface Signals" on page 1744.

#### 49.5.12.2 RTC DC Characteristics

Table 49-62. RTC DC Input Characteristics (RTEST#)

| Symbol     | Parameter             | Conditions                | Min | Typical | Max | Units   | Notes |
|------------|-----------------------|---------------------------|-----|---------|-----|---------|-------|
| $V_{IH}$   | Input voltage high    | -                         | 2.0 | -       | -   | V       | -     |
| $V_{IL}$   | Input voltage low     | -                         | -   | -       | 0.8 | V       | -     |
| $I_{leak}$ | Input Leakage Current | $0 < V_{IN} < V_{CC3\_3}$ | -   | -       | 6   | $\mu A$ | -     |
| $C_{IN}$   | Input-pin capacitance | -                         | -   | -       | 10  | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-63. RTC DC Clock Input Characteristics (RTCX[2:1])**

| Symbol          | Parameter           | Min  | Typical | Max  | Units |
|-----------------|---------------------|------|---------|------|-------|
| V <sub>IL</sub> | Input voltage low   | -    | -       | 0.10 | V     |
| V <sub>IH</sub> | Input voltage high  | 0.40 | -       | 1.2  | V     |
| C <sub>L</sub>  | RTCX1 typical value | 6    |         |      | pf    |
| C <sub>L</sub>  | RTCX2 typical value | 6    |         |      | pf    |

**Notes:**

1. 3.3 V Clock Input
2. Guaranteed by design.

**49.5.12.3 RTC AC Characteristics**

**Table 49-64. RTC Clock Input (RTCX[2:1]) Timing Values**

| Symbol    | Parameter  | Min | Nominal | Max | Units | Notes |
|-----------|--|-----|---------|-----|-------|-------|
| RTCX[2:1] | RTC clock frequency  |     | 32.768  |     | KHz   | 1, 2  |
| Tolerance | This parameter specifies the crystal tolerance for RTCX[2:1] | -20 | -       | +20 | ppm   |       |

**Notes:**

1. RTCX[1] can be connected to a crystal along with RTCX[2] or to an oscillator
2. When using an oscillator only RTCX[1] is connected and RTCX[2] can remain unconnected.

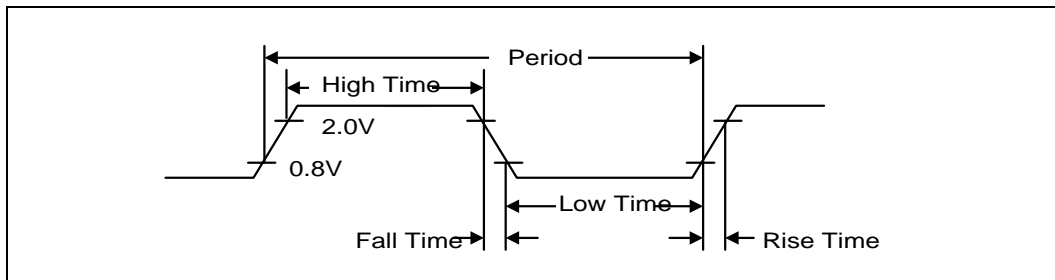

**Table 49-65. RTC Clock Output (SUSCLK) Timings**

| Parameters          | Min | Typical | Max | Units | Figure | Note |
|---------------------|-----|---------|-----|-------|--------|------|
| Operating Frequency | -   | 32.768  | -   | kHz   | -      | 1    |
| Duty Cycle          | 30  | -       | 70  | %     |        |      |
| High Time           | 10  | -       | -   | us    | 49-33  |      |
| Low Time            | 10  | -       | -   | us    | 49-33  |      |

**Notes:**

1. SUSCLK is the RTC generator output

**Figure 49-33. RTC Clock Output (SUSCLK) Timing Diagram**

### 49.5.13 Gigabit Ethernet (GbE: RMII, RGMII, MDIO, EEPROM)

The EP80579 contains three Gigabit Ethernet MACs. The GbE Ethernet MACs contained in the EP80579 resemble the Intel® 82545 Gigabit Ethernet Controller.

The EP80579 Gigabit Ethernet (GbE) MAC is based on a fourth generation Gigabit MAC to provide a standard IEEE 802.3 Ethernet interface for 1000BASE-T, 100BASE-Tx, and 10BASE-T applications. The MAC is capable of transmitting and receiving data rates of 10/100/1000 Mbps. Through the GbE interfaces, the EP80579 can be connected to Reduced Ethernet (RMII), or Reduced GMII (RGMII) external PHY devices.

The EP80579 can support both 3.3V and 2.5V PHY for the GbE interface. The media outputs use 2.5V drivers that are 3.3V tolerant. This is a violation of the RMII specification, which calls for TTL level outputs (not LVTTTL) and 5V input level tolerance. All major PHY devices that may be used in an EP80579 system are expected to drive a maximum voltage of 3.3V.

RGMII version 1.3 is specified as a 2.5V CMOS level I/O interface and as such, the EP80579 is fully compliant. RGMII version 2.0 is specified as a 1.5 V HSTL I/O interface and the EP80579 is NOT compliant with this standard. All PHY devices that are used with the EP80579 must support version 1.3. The MDIO, MDC, and serial EEPROM bus are implemented with 2.5V I/O drivers.

Management Data Input/Output (MDIO) interface provides a path to transfer control information and status between the PHY and the EP80579. The MDIO interface allows the software to continuously poll the PHY's configuration registers through and reprogram the GbE configuration. Management Data Clock (MDC) is sourced by the EP80579 to the PHY devices as a timing reference for the MDIO interface.

A single four-wire Microwire\* interface is provided for connection of an optional, externally connected serial EEPROM. The serial EEPROM may be used to provide configuration information to the GbE MACs upon power-up or reset. All three MACs share the same EEPROM.

This section describes the electrical characteristics of the GbE interface.

#### 49.5.13.1 Gigabit Ethernet Signal List

For Gigabit Ethernet MAC pin description refer to [Table 48-22, "Gigabit Ethernet Interface Signals"](#) on page 1760.

#### 49.5.13.2 Gigabit Ethernet DC Characteristics

##### 49.5.13.2.1 DC Characteristics: RMII and RGMII Mode of Operation

**Table 49-66. DC Input Characteristics: RMII Mode of Operation (Sheet 1 of 2)**

| Symbol   | Parameter          | Conditions                               | Min | Typical | Max | Units | Notes |
|----------|--------------------|--|-----|---------|-----|-------|-------|
| $V_{IH}$ | Input high voltage | $V_{IH} > V_{IH\_Min}$<br>$V_{CC} = Min$ | 2.0 | -       | 3.6 | V     | -     |
| $V_{IL}$ | Input low voltage  | $V_{IH} > V_{IL\_Max}$<br>$V_{CC} = Min$ | -   | -       | 0.8 | V     | -     |
| $I_{IH}$ | Input high current | $V_{CC} = Max$<br>$V_{IN} = 2.5 V$       | -   | -       | 15  | uA    | -     |

**Table 49-66. DC Input Characteristics: RMII Mode of Operation (Sheet 2 of 2)**

| Symbol          | Parameter         | Conditions                                       | Min | Typical | Max | Units | Notes |
|-----------------|-------------------|--|-----|---------|-----|-------|-------|
| I <sub>IL</sub> | Input low current | V <sub>CC</sub> = Max<br>V <sub>IN</sub> = 0.4 V | -15 | -       | -   | uA    | -     |
| C <sub>IN</sub> | Input pin cap     |  | -   | -       | 8   | pf    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-67. DC Output Characteristics: RMII Mode of Operation**

| Symbol          | Parameter           | Conditions   | Min | Typical | Max       | Units | Notes    |
|-----------------|---------------------|--|-----|---------|-----------|-------|----------|
| V <sub>OH</sub> | Output high voltage | V <sub>CC</sub> = 2.5V<br>I <sub>OH</sub> = -1mA   | 2.4 | -       | See Notes | V     | 1,Note 2 |
| V <sub>OH</sub> | Output high voltage | V <sub>CC</sub> = 2.375V<br>I <sub>OH</sub> = -1mA | 2.2 | -       | See Notes | V     | 1,Note 2 |
| V <sub>OL</sub> | Output low voltage  | V <sub>CC</sub> = Min<br>I <sub>OL</sub> = 1mA     | -   | -       | 0.4       | V     |          |

**Notes:**

1. The RMII buffer is powered from the 2.5v power rail - the output signal level is 100mV below the rail for RMII. In the ideal case, the Voh equals the 2.4v in accordance to the RMII specification. If the 2.5v power rail drops below the ideal value the buffer will violate the RMII specification and the 0.4v margin between Voh/Vih will be reduced under this condition.
2. V<sub>OH</sub> Max = VCC25 for GbE Ports 1 and 2 or VCCSUS25 for GbE Port 0

**Table 49-68. DC Input Characteristics: RGMII Mode of Operation**

| Symbol          | Parameter          | Conditions   | Min | Typical | Max | Units | Notes  |
|-----------------|--------------------|--|-----|---------|-----|-------|--------|
| V <sub>IH</sub> | Input high voltage | V <sub>IH</sub> > V <sub>IH_Min</sub><br>V <sub>CC</sub> = Min | 1.7 | -       | 3.6 | V     | -      |
| V <sub>IL</sub> | Input low voltage  | V <sub>IH</sub> > V <sub>IL_Max</sub><br>V <sub>CC</sub> = Min | -   | -       | 0.7 | V     | -      |
| I <sub>IH</sub> | Input high current | V <sub>CC</sub> = Max<br>V <sub>IN</sub> = 2.5 V               | -   | -       | 15  | uA    | -      |
| I <sub>IL</sub> | Input low current  | V <sub>CC</sub> = Max<br>V <sub>IN</sub> = 0.4 V               | -15 | -       | -   | uA    | -      |
| C <sub>IN</sub> | Input pin cap      |  | -   | -       | 8   | pF    | Note 1 |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-69. DC Output Characteristics: RGMII Mode of Operation**

| Symbol          | Parameter           | Conditions                                       | Min | Typical | Max       | Units | Notes |
|-----------------|---------------------|--|-----|---------|-----------|-------|-------|
| V <sub>OH</sub> | Output high voltage | V <sub>CC</sub> = 2.5V<br>I <sub>OH</sub> = -1mA | 2.4 | -       | See Notes | V     | 1     |
| V <sub>OL</sub> | Output low voltage  | V <sub>CC</sub> = Min<br>I <sub>OL</sub> = 1mA   | -   | -       | 0.4       | V     |       |

**Notes:**

1. V<sub>OH</sub> Max = VCC25 for GbE Ports 1 and 2 or VCCSUS25 for GbE Port 0

Table 49-70. DC Input Characteristics: MDIO Mode of Operation

| Symbol     | Parameter             | Conditions                               | Min | Typical | Max | Units | Notes |
|------------|-----------------------|--|-----|---------|-----|-------|-------|
| $V_{IH}$   | Input high voltage    | $V_{IH} > V_{IH\_Min}$<br>$V_{CC} = Min$ | 2.0 | -       | 3.6 | V     | -     |
| $V_{IL}$   | Input low voltage     | $V_{IH} > V_{IL\_Max}$<br>$V_{CC} = Min$ | -   | -       | 0.8 | V     | -     |
| $I_{IH}$   | Input high current    | $V_{CC} = Max$<br>$V_{IN} = 2.5 V$       | -   | -       | 15  | uA    | -     |
| $I_{IL}$   | Input low current     | $V_{CC} = Max$<br>$V_{IN} = 0.4 V$       | -15 | -       | -   | uA    | -     |
| $I_{leak}$ | Input Leakage Current | $0 < V_{IN} < V_{CC2\_5}$                | -10 | -       | 10  | μA    | -     |
| $C_{IN}$   | Input pin cap         |  | -   | -       | 8   | pF    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Table 49-71. DC Output Characteristics: MDIO Mode of Operation

| Symbol   | Parameter           | Conditions                           | Min  | Typical | Max       | Units | Notes |
|----------|---------------------|--------------------------------------|------|---------|-----------|-------|-------|
| $V_{OH}$ | Output high voltage | $V_{CC} = 2.5V$<br>$I_{OH} = -1mA$   | 2.4  | -       | =VCCSUS25 | V     | 1     |
| $V_{OH}$ | Output high voltage | $V_{CC} = 2.375V$<br>$I_{OH} = -4mA$ | 2.15 | -       | =VCCSUS25 | V     | 1     |
| $V_{OL}$ | Output low voltage  | $V_{CC} = Min$<br>$I_{OL} = 1mA$     | -    | -       | 0.4       | V     |       |

**Notes:**

1. The MDIO buffer is powered from the 2.5v power rail - the output signal level is 200mV below the rail for MDIO. In the ideal case, the Voh equals the 2.4v in accordance to the RMI1 specification. If the 2.5v power rail drops below the ideal value the buffer will violate the RMI1 specification and the 0.4v margin between Voh/Vih will be reduced under this condition.

## 49.5.13.2.2 DC Characteristics: EEPROM Interface

Table 49-72. DC Input Characteristics: EEPROM Interface

| Symbol   | Parameter          | Conditions                               | Min | Typical | Max | Units | Notes |
|----------|--------------------|--|-----|---------|-----|-------|-------|
| $V_{IH}$ | Input high voltage | $V_{IH} > V_{IH\_Min}$<br>$V_{CC} = Min$ | 1.7 | -       | 3.6 | V     | -     |
| $V_{IL}$ | Input low voltage  | $V_{IH} > V_{IL\_Max}$<br>$V_{CC} = Min$ | -   | -       | 0.7 | V     | -     |
| $C_{IN}$ | Input pin cap      |  | -   | -       | 8   | pF    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Table 49-73. DC Output Characteristics: EEPROM Interface

| Symbol          | Parameter           | Conditions                                       | Min | Typical | Max       | Units |
|-----------------|---------------------|--|-----|---------|-----------|-------|
| V <sub>OH</sub> | Output high voltage | V <sub>CC</sub> = 2.5V<br>I <sub>OH</sub> = -1mA | 2.4 | -       | =VCCSUS25 | V     |
| V <sub>OL</sub> | Output low voltage  | V <sub>CC</sub> = Min<br>I <sub>OL</sub> = 1mA   | -   | -       | 0.4       | V     |

### 49.5.13.2.3 GbE DC Clock Specifications

Table 49-74. Reference Clock DC Input Specification: (GBE\_REFCLK\_RMII, GBE\_REFCLK)

| Symbol          | Parameter          | Conditions   | Min | Typical | Max | Units | Notes  |
|-----------------|--------------------|--|-----|---------|-----|-------|--------|
| V <sub>IH</sub> | Input high voltage | V <sub>IH</sub> > V <sub>IH_Min</sub><br>V <sub>CC</sub> = Min | 1.7 | -       | 3.6 | V     | -      |
| V <sub>IL</sub> | Input low voltage  | V <sub>IH</sub> > V <sub>IL_Max</sub><br>V <sub>CC</sub> = Min | -   | -       | 0.7 | V     | -      |
| I <sub>IH</sub> | Input high current | V <sub>CC</sub> = Max<br>V <sub>IN</sub> = 2.5 V               | -   | -       | 15  | uA    | -      |
| I <sub>IL</sub> | Input low current  | V <sub>CC</sub> = Max<br>V <sub>IN</sub> = 0.4 V               | -15 | -       | -   | uA    | -      |
| C <sub>IN</sub> | Input pin cap      |  | -   | -       | 8   | pF    | Note 1 |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

### 49.5.13.3 Gigabit Ethernet AC Characteristics

#### 49.5.13.3.1 Frequency Requirements

Table 49-75 provides the frequency of all input clocks in a different mode of operation.

Table 49-75. Frequencies of All Input Clocks

| Model | Clock Name      | Frequency      |
|-------|-----------------|----------------|
| RMII  | GBE_REFCLK_RMII | 50 MHz         |
| RGMII | GBEn_RxCLK      | 2.5/25/125 MHz |
|       | GBEn_TxCLK      | 2.5/25/125 MHz |
|       | GBE_REFCLK      | 125 MHz        |

#### 49.5.13.3.2 GbE Ethernet Interface — RGMII Mode

This section describes the GbE Ethernet reference clock transmit and receive timings when operating in RGMII mode. RGMII works in source synchronous mode, where transmission and receive are done with respect to TXCLK and RXCLK. In RGMII mode, TXCLK and RXCLK run at 2.5/25/125MHz. In 2.5/25MHz mode, both transmit and receive occurs on rising edges of the clock. At 125MHz, data transfer (both Tx and Rx) occurs on both edges of the clock (same as DDR2).

The RGMII interface gets Rx clock from the PHY and Tx clock from the MAC. Both MAC and PHY receive a 125MHz reference clock from the board. The RGMII outputs uses 2.5V drivers that are 3.3V tolerant. Figure 49-34 shows the GbE block diagram with the signal connections in RGMII mode.

Figure 49-34. GbE RGMII Mode Signal Connection Block Diagram

49.5.13.3.3 GbE Ethernet Interface — RGMII Mode Reference Clock

Table 49-76 shows the RGMII 125 MHz reference clock AC specifications.

Table 49-76. GbE RGMII Reference Clock Timing Values

| Symbol              | Parameter  | Min | Nominal | Max  | Units | Notes |
|---------------------|--|-----|---------|------|-------|-------|
| T <sub>1</sub>      | RGMII reference clock period                     | -   | 8.0     | -    | ns    | 1     |
|                     | Frequency accuracy                               | -50 | -       | +50  | ppm   | 1     |
| T <sub>2</sub>      | Duty cycle with respect to T <sub>1</sub> (Nom.) | 45  | 50      | 55   | %     | 1, 5  |
| T <sub>3</sub>      | Low to high rise time (20% to 80%)               | -   | -       | 0.75 | ns    | 2, 5  |
| T <sub>4</sub>      | High to low fall time (80% to 20%)               | -   | -       | 0.75 | ns    | 3, 5  |
| T <sub>jitter</sub> | Cycle to Cycle Jitter                            | -   | -       | 80   | ps    | 4, 5  |
|                     | Peak to peak Jitter (aggregate)                  | -   | -       | 150  | ps    | 4, 5  |

Notes:

1. Applies to GBE<sub>en</sub>\_REFCLK signal operating in RGMII mode.
2. Measurement points for Rise time are 20% GBE V<sub>CC</sub> to 80% GBE V<sub>CC</sub>.
3. Measurement points for Fall time are 80% GBE V<sub>CC</sub> to 20% GBE V<sub>CC</sub>.
4. The maximum allowable jitter is 80 ps. This jitter can be less but never greater than 80 ps. This reference clock jitter directly translates into the jitter produced on the GBE<sub>en</sub>\_TxCLK signal. For example, a 40 ps jitter on the reference clock input would generate the same 40 ps jitter on the GBE<sub>en</sub>\_TxCLK signal.
5. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Figure 49-35 shows the RGMII 125 MHz reference clock timing diagram.

49.5.13.3.4 GbE Ethernet Interface — RGMII Mode Transmit Timings

Figure 49-35.RGMII 125 MHz Reference Clock Timing Diagram

Table 49-76 shows the AC specifications.

Table 49-77. GbE Transmit Timing Values — RGMII Mode

| Symbol         | Parameter  | Min  | Nominal | Max  | Units | Notes   |
|----------------|--|------|---------|------|-------|---------|
| T <sub>1</sub> | RGMII output clock period (1000 Base)                        | 7.2  | 8.0     | 8.8  | ns    | 1, 7    |
| T <sub>1</sub> | RGMII output clock period (100 Base)                         | 36   | 40      | 44   | ns    | 1, 7    |
| T <sub>1</sub> | RGMII output clock period (10 Base)                          | 360  | 400     | 440  | ns    | 1, 7    |
| T <sub>2</sub> | 1000 base duty cycle with respect to T <sub>1</sub> (Nom.)   | 45   | 50      | 55   | %     | 1, 3, 7 |
| T <sub>2</sub> | 100/10 base duty cycle with respect to T <sub>1</sub> (Nom.) | 40   | 50      | 60   | %     | 1, 3, 7 |
| T <sub>3</sub> | Low to high rise time (20% to 80%)                           | -    | -       | 0.75 | ns    | 1, 4, 7 |
| T <sub>4</sub> | High to low fall time (80% to 20%)                           | -    | -       | 0.75 | ns    | 1, 5, 7 |
| T <sub>5</sub> | Data to clock output SKEW (at transmitter)                   | -500 | 0       | 500  | ps    | 2, 7    |
| T <sub>6</sub> | Data to clock output SKEW (at receiver)                      | 1    | -       | 2.6  | ns    | 6, 7    |

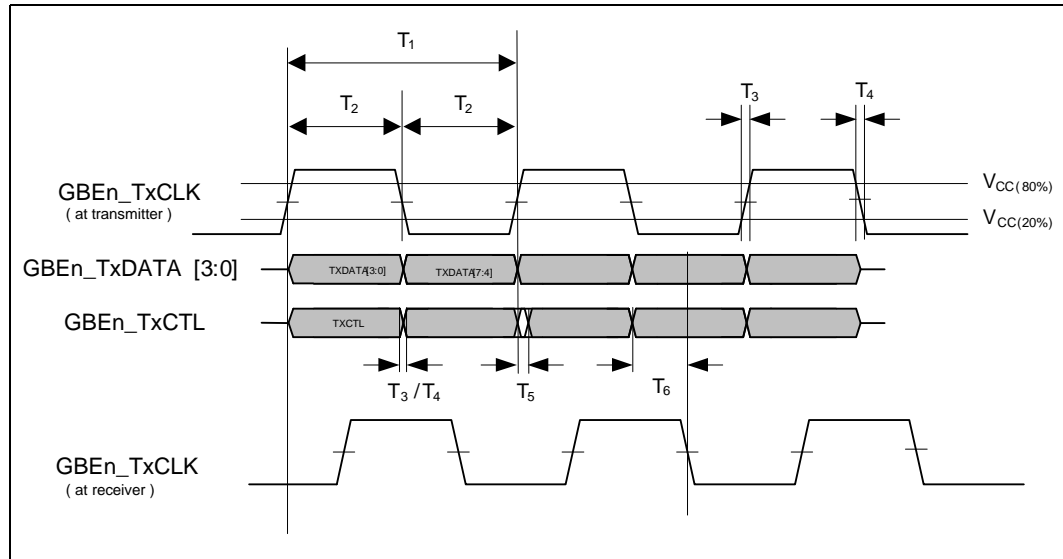

**Notes:**

1. This applies to the GBE<sub>n</sub>\_TxCLK signal operating in RGMII mode.
2. This applies to the GBE<sub>n</sub>\_TXDATA[3:0] signals for RGMII mode.
3. Duty cycle may be stretched/shrunk during speed changes or while transitioning to a received packet's clock domain as long as minimum duty cycle is not violated and stretching occurs for no more than three T<sub>cy</sub> of the lowest speed transitioned between.
4. Measurement points for Rise time are 20% GBE V<sub>CC</sub> to 80% GBE V<sub>CC</sub>.
5. Measurement points for Fall time are 80% GBE V<sub>CC</sub> to 20% GBE V<sub>CC</sub>.
6. The RGMII specification v1.3 requires the board design to induce trace delay such that an additional trace delay of greater than 1.5 ns and less than 2.0 ns is added to the GBE<sub>n</sub>\_TxCLK signal between the MAC output and the PHY input. This method would require "x-inches" of trace to routed for the GBE<sub>n</sub>\_TxCLK signal. Some PHYs solve this by supporting an internal delay within the PHY. Refer to your chosen PHY data sheet for additional information on these clock delay modes.
7. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Figure 49-36 shows the RGMII transmit timing diagram.

Figure 49-36. GbE Transmit Waveform — RGMII Mode

### 49.5.13.3.5 GbE Ethernet Interface — RGMII Mode Receive Timings

Table 49-78 shows the AC specification.

Table 49-78. GbE Receive Timing Values — RGMII Mode

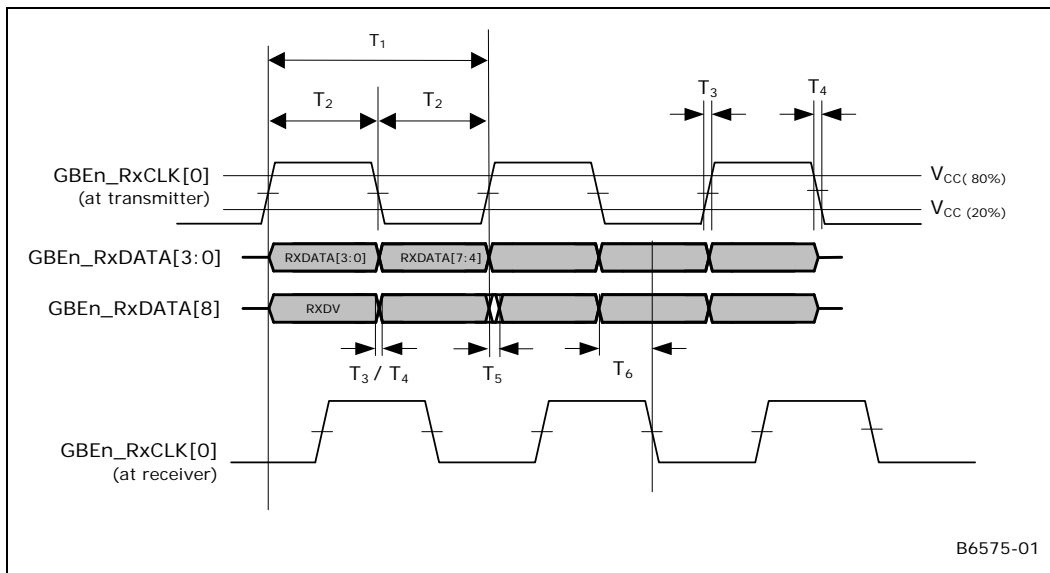

| Symbol         | Parameter  | Min  | Nominal | Max | Units | Notes      |
|----------------|--|------|---------|-----|-------|------------|
| T <sub>1</sub> | RGMII input clock period (1000 Base)                         | 7.2  | 8.0     | 8.8 | ns    | 1, 6       |
| T <sub>1</sub> | RGMII input clock period (100 Base)                          | 36   | 40      | 44  | ns    | 1, 6       |
| T <sub>1</sub> | RGMII input clock period (10 Base)                           | 360  | 400     | 440 | ns    | 1, 6       |
| T <sub>2</sub> | 1000 base duty cycle with respect to T <sub>1</sub> (Nom.)   | 45   | 50      | 55  | %     | 1, 3, 6    |
| T <sub>2</sub> | 100/10 base duty cycle with respect to T <sub>1</sub> (Nom.) | 40   | 50      | 60  | %     | 1, 3, 4, 6 |
| T <sub>3</sub> | Low to high rise time (20% to 80%)                           | -    | -       | 1.0 | ns    | 1, 5, 6    |
| T <sub>4</sub> | High to low fall time (80% to 20%)                           | -    | -       | 1.0 | ns    | 1, 5, 6    |
| T <sub>5</sub> | Data to clock output SKEW (at transmitter)                   | -500 | 0       | 500 | ps    | 1, 3, 6    |
| T <sub>6</sub> | Data to clock output SKEW (at receiver)                      | 1    | -       | 2.6 | ns    | 6          |

**Notes:**

1. This applies to the GBEn\_RxCLK signal operating in RGMII mode.
2. This applies to the GBEn\_RXDATA[3:0] signals for RGMII mode.
3. Duty cycle may be stretched/shrunk during speed changes or while transitioning to a received packet's clock domain as long as minimum duty cycle is not violated and stretching occurs for no more than three T<sub>cy</sub> of the lowest speed transitioned between.
4. Measurement points for Rise time are 20% GBE V<sub>CC</sub> to 80% GBE V<sub>CC</sub>.
5. Measurement points for Fall time are 80% GBE V<sub>CC</sub> to 20% GBE V<sub>CC</sub>.
6. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Figure 49-37 shows the RGMII receive timing diagram.

Figure 49-37. GbE Receive Waveform — RGMII Mode

### 49.5.13.3.6 Design to Test Loads

The I/Os are implemented to support a 5pF load to ground for AC timing.

**49.5.13.3.7 GbE Ethernet Interface — RMI Mode**

This section describes the AC timings for GbE interface when the interconnect is designed for a RMI interface.

In RMI mode of operation, both transmit and receive (TX\_DATA and RX\_DATA) are with respect to external clock, which in 10/100 Base T is 50 MHz.

Figure 49-38 shows the GbE signal connections used in RMI mode for 10/100 Base connections. An external clock is sourcing the reference clock.

**Figure 49-38. GbE RMI Mode Signal Connection Block Diagram — External Clock Source**

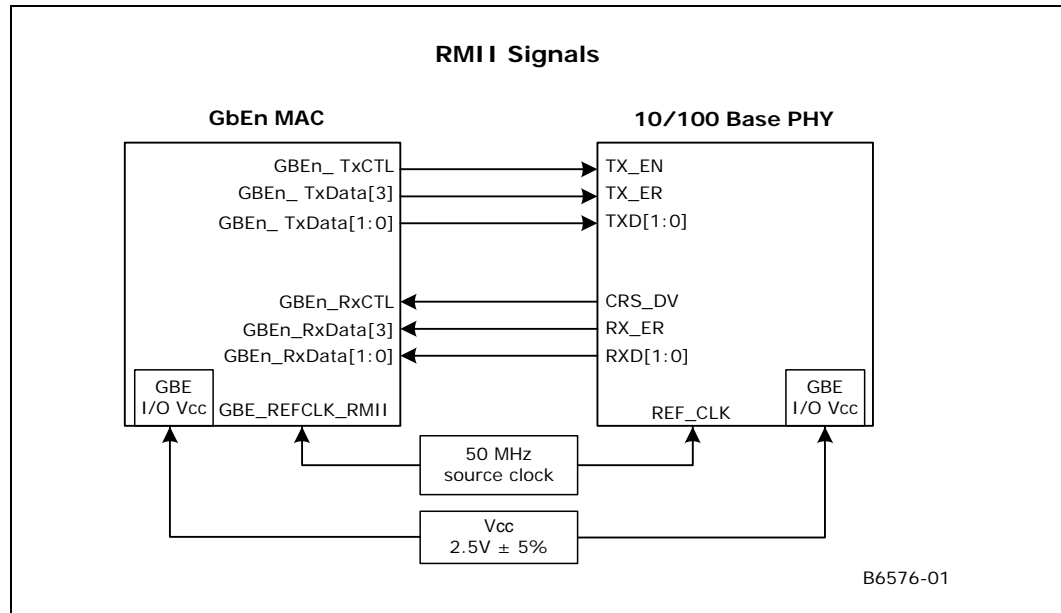

Figure 49-39 shows the timing diagram for RMI mode of operation.

**Figure 49-39. GbE RMI Transmit and Receive Waveforms — RMI Mode**

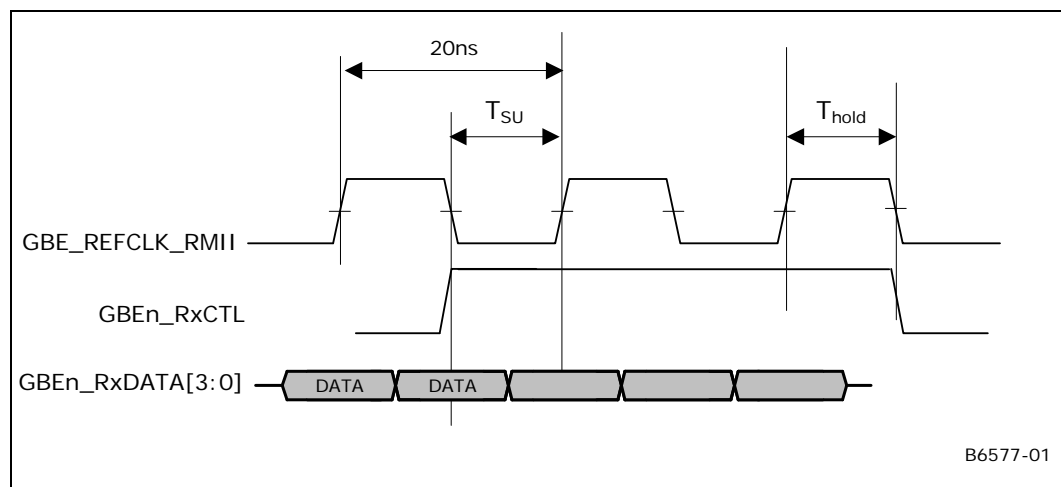

Table 49-79 shows the transmit and receive timing values for RMI 100/10 base mode of operation.

**Table 49-79. GbE Transmit and Receive Timing Values — RMI I 100/10 Base Mode**

| Symbol | Parameter  | Min | Typical | Max | Units | Notes |
|--------|--|-----|---------|-----|-------|-------|
|        | REF_CLK frequency  | -   | 50      | -   | MHz   |       |
|        | REF_CLK duty cycle   | 35  |         | 65  | %     | 1     |
|        | REF_CLK jitter   | -   | -       | 80  | ps    |       |
| Tsu    | TXD[1:0], TX_EN,RXD[1:0], CRS_DV, RX_ER Data Setup to REF_CLK rising edge  | 4   |         |     | ns    |       |
| Thold  | TXD[1:0], TX_EN,RXD[1:0], CRS_DV, RX_ER Data hold from REF_CLK rising edge | 2   |         |     | ns    |       |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**49.5.13.3.8 MDIO Timing Specification**

This section describes the AC timing for the MDIO interface.

**Figure 49-40. MDIO Output Timing Diagram (EP80579 is Sourcing MDIO)**

**Figure 49-41. MDIO Input Timing Diagram (PHY is Sourcing MDIO)**

**Table 49-80. MDIO Timings Values**

| Symbol         | Parameter   | Min | Max           | Units | Figure | Notes |
|----------------|---|-----|---------------|-------|--------|-------|
| t <sub>1</sub> | MDIO, clock to output timing with respect to rising edge of MDC clock |     | MDC/2 + 10 ns | ns    | 49-40  | -     |
| t <sub>2</sub> | MDIO output hold timing after the rising edge of MDC clock            | 10  |               | ns    | 49-40  | -     |
| t <sub>3</sub> | MDIO input setup prior to rising edge of MDC clock                    | 10  |               | ns    | 49-41  | -     |
| t <sub>4</sub> | MDIO input hold time after the rising edge of MDC clock               | 0   | -             | ns    | 49-41  | -     |
| t <sub>5</sub> | MDC clock period  | -   | 500           | ns    | 49-41  | 1     |

**Notes:**

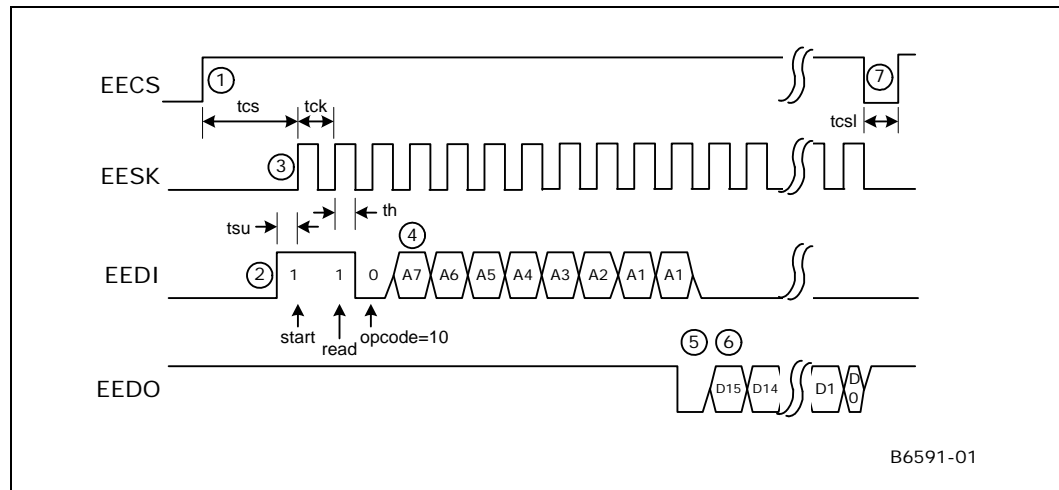

1. The MDC clock period is 641 ns in SKU 2 and 8

**49.5.13.3.9 EEPROM Timing Specification**

This section describes the AC timing for the EEPROM interface.

Figure 49-42 shows a typical EEPROM read operation generated by the EP80579.

**Figure 49-42. EEPROM Interface Timing Diagram**

**Table 49-81. EEPROM Read Operation (Sheet 1 of 2)**

| Step | Parameter   |
|------|---|
| 1    | The EP80579 activates the EEPROM by asserting EECS.   |
| 2    | After the chip select, The EP80579 starts driving data. It drives a 1 for the start bit, then a 10 (binary) for the read opcode.  |
| 3    | The EP80579 starts driving the clock after driving the initial start bit. The EEPROM device latches a bit on every rising edge of the clock. The output data is driven near the falling edge of the clock to maximize setup and hold times. Likewise the read data is sampled near the falling edge of the clock. |
| 4    | After driving the start bit and read opcode EP80579 drives the address, starting at the most significant bit. A 256-word EEPROM requires 8 address bits (as shown in the diagram), while a 64-word EEPROM requires only 6 address bits.   |

Table 49-81. EEPROM Read Operation (Sheet 2 of 2)

| Step | Parameter   |
|------|---|
| 5    | An internal pullup is implemented on the EEDO pin so the pin initially floats high. When the EEPROM latches its last address bit it drives EEDO low. This can be used during the initial read to determine the size of the EEPROM. A 64-word EEPROM drives "data out" low after 6 address bits, while a 256-word EEPROM drives "data out" low after 8 address bits. |
| 6    | After driving its "data out" low, the EEPROM device drives 16 data bits, starting at the most significant bit. Each bit is driven after the rising edge of the clock.   |
| 7    | After the read cycle, the EP80579 stops driving the clock and deasserts the chip select. When the chip select is deasserted the EEPROM stops driving the data.  |

Table 49-82. EEPROM Timing Values

| Symbol | Parameter                            | Min  | Max  | Units | Figure | Notes |
|--------|--------------------------------------|------|------|-------|--------|-------|
| tcs    | Chip select to first clock edge.     | 1024 | 3048 | ns    | 49-42  | 1     |
| tck    | EEPROM clock cycle                   | 1024 | 4160 | ns    | 49-42  | 1     |
| tsu    | Setup time before rising clock edge. | 480  | -    | ns    | 49-42  | 1     |
| th     | Hold time after rising clock edge.   | 480  | -    | ns    | 49-42  | 1     |
| tcsi   | Chip select deassertion time         | 992  | -    | ns    | 49-42  | 1     |

**Notes:**  
1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

#### 49.5.13.4 GbE Reset Conditions

There is no special reset sequence required for GbE I/O buffers. GbE receives a power-on reset signal from the CRU, but drives input data present on the input pins into the core during reset. Core logic forces all outputs to High-Z during reset.

#### 49.5.13.5 RComp

The GbE RCOMP (resistive compensation) circuitry dynamically compensates the GbE I/O output drivers for variations in operating conditions due to process, temperature, voltage and PCB layout. These variations are measured through a resistive mechanism in two special I/O pads. The resistive mechanism on those I/O pads reference external resistors that the user provides to match output driver strength. Thus the output driver impedance can be tuned specifically to the application PCB characteristics for nominal signal transfer into the transmission lines formed by the PCB traces. The RCOMP design is nominally set to operate at 50 ohm, but the user is free to set the impedance in the range 45 ohm to 55 ohm.

Two RCOMP pins are provided to establish the GbE output driver impedance, one to control the drive high strength, and one to control the drive low strength. These RCOMP outputs drive into external resistors. The drivers form a resistor divider and the voltages developed in these dividers are compared to a reference voltage. The RCOMP state machine independently adjusts the strength of the drivers making them stronger or weaker until the comparator signals that the voltage is greater than or less than the reference. The state machine continues making adjustments causing the comparators to oscillate between two strength settings just above and just below the comparator trip point. Logic in the RCOMP state machine recognizes when this "dithering" between the two values has begun, and holds the strength output for the GbE outputs fixed at one of the two settings. Note this algorithm is independently and concurrently applied to the drive high strength and to the drive low strength.

The GbE RCOMP controller starts operation when the GBE\_AUX\_PWR\_GOOD input is asserted. This condition indicates the power supplies are stable; the condition also indicates that the GBE\_REFCLK input is being driven with a 125Mhz clock. The GBE\_REFCLK input is divided by either 4 or 16 and then used to drive the RCOMP state machine. Software accessible registers that provide options to monitor/overwrite internal bias and comparator output are also present.

#### 49.5.13.6 Voltage Domains

The GbE ports and associated miscellaneous I/Os (MDIO, EE, REFCLK, PME\_WAKE, and RCOMP) are powered with 2.5V power supply. A secondary low current 3.3V power supply is also required to allow 3.3V input level tolerance. The GbE IO interface supports “wake-on-LAN” operation and therefore some of the I/O signals are powered with sustain power supplies that are always powered on while other I/O signals are powered with “core” power supplies that are only active when the remainder of the chip is powered on. GbE port 0 and the miscellaneous MDIO, EE, REFCLK, PME\_WAKE, and RCOMP IOs are powered through the sustain power supply VCCSUS25, and the 3.3V VCCGBEPSUS for 3.3V input tolerance. GbE ports 1 and 2 are powered with the VCC25 power supply and the VCCGBE33 is connected for 3.3V input level tolerance. The user may consider connecting VCCGBEPSUS power supply pins to the VCCPSUS power supply and connecting VCCGBE33 to the VCC33 power supply on the PCB in order to reduce the number of regulators used in the system. VCC25 and VCCSUS25 are only used in the GbE IO interface section of the chip.

#### 49.5.14 Time Division Multiplex (TDM)

This section describes the electrical characteristics of the TDM interface.

##### 49.5.14.1 TDM Signal List

For TDM pin descriptions, refer to [Table 48-23, “TDM Interface Signals,”](#) on page 1764.

##### 49.5.14.2 TDM DC Characteristics

**Table 49-83. TDM DC Input Characteristics**

| Symbol            | Parameter                     | Conditions                            | Min | Typical | Max | Units | Notes |
|-------------------|-------------------------------|---------------------------------------|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high            | -                                     | 2.0 | -       |     | V     | -     |
| V <sub>IL</sub>   | Input voltage low             | -                                     | -   | -       | 0.8 | V     | -     |
| I <sub>OL</sub>   | Output current at low voltage | V <sub>OL</sub> <0.8                  | -   | -       | 4   | mA    | -     |
| I <sub>leak</sub> | Input Leakage Current         | 0<V <sub>IN</sub> <V <sub>cc3_3</sub> | -   | -       | 10  | μA    | -     |
| C <sub>in</sub>   | Input pin cap                 | -                                     | -   | -       | 5   | pf    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Table 49-84. TDM DC Output Characteristics

| Symbol          | Parameter                      | Conditions             | Min | Typical | Max | Units | Notes |
|-----------------|--------------------------------|------------------------|-----|---------|-----|-------|-------|
| V <sub>OH</sub> | Output voltage high            | I <sub>out</sub> =-6mA | 2.0 | -       | -   | V     | 1     |
| V <sub>OL</sub> | Output voltage low             | I <sub>out</sub> =6mA  | -   | -       | 0.4 | V     | -     |
| I <sub>OH</sub> | Output current at high voltage | V <sub>OH</sub> =2.4   | -12 | -27     | -48 | mA    | -     |
| I <sub>OL</sub> | Output current at low voltage  | V <sub>OL</sub> =0.8   | 12  | 18      | 26  | mA    | -     |

**Notes:**

1. V<sub>OH</sub> spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

### 49.5.14.3 TDM DC Clock Specification

Table 49-85. TDM DC Clock Input Specifications (RX\_CLKn)

| Symbol            | Parameter                     | Conditions                            | Min | Typical | Max | Units | Notes |
|-------------------|-------------------------------|---------------------------------------|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high            | -                                     | 2.0 | -       | -   | V     | -     |
| V <sub>IL</sub>   | Input voltage low             | -                                     | -   | -       | 0.8 | V     | -     |
| I <sub>OL</sub>   | Output current at low voltage | V <sub>OL</sub> <0.8                  | -   | -       | 4   | mA    | -     |
| I <sub>leak</sub> | Input Leakage Current         | 0<V <sub>IN</sub> <V <sub>cc3_3</sub> | -   | -       | 10  | μA    | -     |
| C <sub>in</sub>   | Input pin cap                 | -                                     | -   | -       | 5   | pf    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Table 49-86. TDM DC Clock Output Specifications (TX\_CLKn)

| Symbol          | Parameter                      | Conditions             | Min | Typical | Max | Units | Notes |
|-----------------|--------------------------------|------------------------|-----|---------|-----|-------|-------|
| V <sub>OH</sub> | Output voltage high            | I <sub>out</sub> =-6mA | 2.4 | -       | -   | V     | 1     |
| V <sub>OL</sub> | Output voltage low             | I <sub>out</sub> =6mA  | -   | -       | 0.4 | V     | -     |
| I <sub>OH</sub> | Output current at high voltage | V <sub>OH</sub> =2.4   | 12  | -27     | -48 | mA    | -     |
| I <sub>OL</sub> | Output current at low voltage  | V <sub>OL</sub> =0.8   | 12  | 18      | 26  | mA    | -     |

**Notes:**

1. V<sub>OH</sub> spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

#### 49.5.14.4 TDM AC Characteristics

##### 49.5.14.4.1 Transmit and Receive Timings

**Table 49-87. TDM, Serial Timings Values**

| Symbol         | Parameter   | Min             | Max           | Units | Notes   |
|----------------|---|-----------------|---------------|-------|---------|
| T <sub>1</sub> | Setup time of TX_FRAME, RX_FRAME, and RX_DATA_IN prior to the rising edge of clock          | 5               |               | ns    | 1, 2, 3 |
| T <sub>2</sub> | Hold time of TX_FRAME, RX_FRAME, and RX_DATA_IN after the rising edge of clock              | 0               |               | ns    | 1, 2, 3 |
| T <sub>3</sub> | Setup time of TX_FRAME, RX_FRAME, and RX_DATA_IN prior to the falling edge of clock         | 5               |               | ns    | 1, 2, 3 |
| T <sub>4</sub> | Hold time of TX_FRAME, RX_FRAME, and RX_DATA_IN after the falling edge of clock             | 0               |               | ns    | 1, 2, 3 |
| T <sub>5</sub> | Rising edge of clock to output delay for TX_FRAME, RX_FRAME, and TX_DATA_OUT                |                 | 15            | ns    | 1, 4    |
| T <sub>6</sub> | Falling edge of clock to output delay for TX_FRAME, RX_FRAME, and TX_DATA_OUT               |                 | 15            | ns    | 1, 3, 4 |
| T <sub>7</sub> | Output Hold Delay after rising edge of final clock for TX_FRAME, RX_FRAME, and TX_DATA_OUT  | 0               |               | ns    | 1, 3, 4 |
| T <sub>8</sub> | Output Hold Delay after falling edge of final clock for TX_FRAME, RX_FRAME, and TX_DATA_OUT | 0               |               | ns    | 1, 3, 4 |
| T <sub>9</sub> | TX_CLK period and RX_CLK period   | 1/<br>8.192 MHz | 1/<br>512 kHz | ns    | 5, 6    |

**Notes:**

1. TX\_CLK and RX\_CLK may be coming from external independent sources or being driven by the EP80579. The signals are shown to be synchronous for illustrative purposes and are not required to be synchronous.
2. Applicable to when the RX\_FRAME and TX\_FRAME signals are being driven by an external source as inputs into the EP80579. Always applicable to RX\_DATA\_IN.
3. The RX\_FRAME and TX\_FRAME can be configured to accept data on the rising or falling edge of the given reference clock. RX\_FRAME and RX\_DATA\_IN signals are synchronous to RX\_CLK and TX\_FRAME and TX\_DATA\_OUT signals are synchronous to the TX\_CLK.
4. Applicable to when the RX\_FRAME and TX\_FRAME signals are being driven by the EP80579 to an external source. Always applicable to TX\_DATA\_OUT.
5. The TX\_CLK can be configured to be driven by an external source or be driven by the EP80579. The slowest clock speed that can be accepted or driven is 512 kHz. The maximum clock speed that can be accepted or driven is 8.192 MHz. The clock duty cycle accepted is 50/50 + 20%.
6. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

### 49.5.14.4.2 TDM Transmit and Receive Timing Diagrams

Figure 49-43. TDM, Serial Timings

## 49.5.15 Local Expansion Bus (LEB)

The Local Expansion bus is a 16-bit 33-80MHz bus with 8 programmable chip selects. This section describes the electrical characteristics of the LEB interface.

### 49.5.15.1 LEB Signal List

For Local Expansion Bus pin descriptions, refer to [Table 48-24, "Expansion Bus Signals"](#) on page 1765.

### 49.5.15.2 LEB DC Characteristics

Table 49-88. LEB DC Input Characteristics

| Symbol     | Parameter                     | Conditions                | Min | Typical | Max | Units   | Notes |
|------------|-------------------------------|---------------------------|-----|---------|-----|---------|-------|
| $V_{IH}$   | Input voltage high            | -                         | 2.0 | -       |     | V       | -     |
| $V_{IL}$   | Input voltage low             | -                         | -   | -       | 0.8 | V       | -     |
| $I_{OL}$   | Output current at low voltage | $V_{OL} < 0.8$            | -   | -       | 4   | mA      | -     |
| $I_{leak}$ | Input Leakage Current         | $0 < V_{IN} < V_{CC3\_3}$ | -   | -       | 10  | $\mu$ A | -     |
| Cin        | Input pin cap                 | -                         | -   | -       | 5   | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Table 49-89. LEB DC Output Characteristics

| Symbol   | Parameter                      | Conditions              | Min | Typical | Max | Units |
|----------|--------------------------------|-------------------------|-----|---------|-----|-------|
| $V_{OH}$ | Output voltage high            | $I_{out} = -6\text{mA}$ | 2.0 |         |     | V     |
| $V_{OL}$ | Output voltage low             | $I_{out} = 6\text{mA}$  |     |         | 0.4 | V     |
| $I_{OH}$ | Output current at high voltage | $V_{OH} = 2.4$          | -20 | -29     | -35 | mA    |
| $I_{OL}$ | Output current at low voltage  | $V_{OL} = 0.8$          | 20  | 21      | 24  | mA    |

### 49.5.15.2.1 LEB DC Clock Specification

Table 49-90. LEB DC Clock Input Specifications (External Clock)

| Symbol     | Parameter                     | Conditions                | Min | Typical | Max | Units   | Notes |
|------------|-------------------------------|---------------------------|-----|---------|-----|---------|-------|
| $V_{IH}$   | Input voltage high            | -                         | 2.0 | -       |     | V       | -     |
| $V_{IL}$   | Input voltage low             | -                         | -   | -       | 0.8 | V       | -     |
| $I_{OL}$   | Output current at low voltage | $V_{OL} < 0.8$            | -   | -       | 4   | mA      | -     |
| $I_{leak}$ | Input Leakage Current         | $0 < V_{IN} < V_{CC3\_3}$ | -   | -       | 10  | $\mu$ A | -     |
| Cin        | Input pin cap                 | -                         | -   | -       | 5   | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

### 49.5.15.3 LEB AC Characteristics

#### 49.5.15.3.1 Local Expansion Bus Synchronous Operation

Figure 49-44. Local Expansion Bus Synchronous Timing

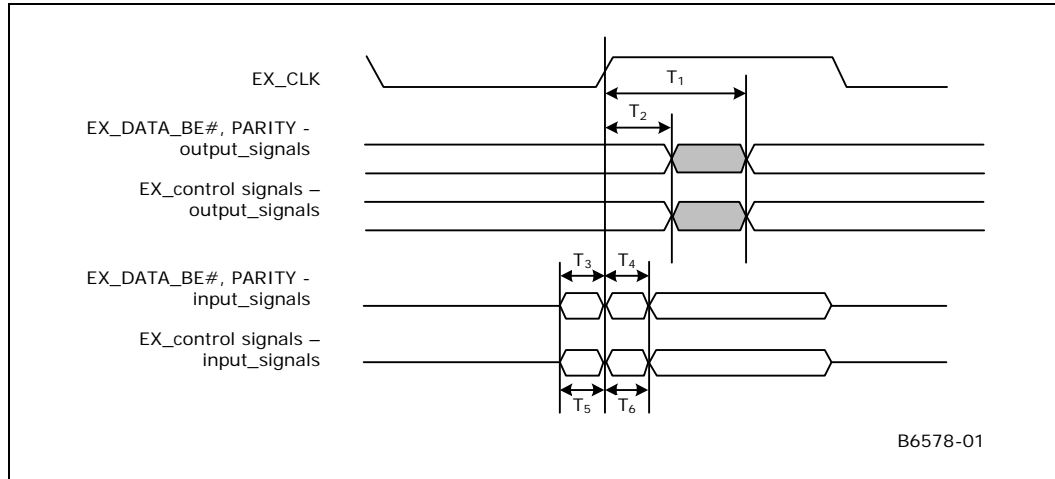

Table 49-91. Local Expansion Bus Synchronous Operation Timing Values

| Symbol | Parameter   | 33 MHz |     | 66 MHz |     | 80 MHz |     | Units | Notes |
|--------|---|--------|-----|--------|-----|--------|-----|-------|-------|
|        |   | Min    | Max | Min    | Max | Min    | Max |       |       |
| $T_1$  | Valid rising edge of EX_CLK to valid signal on the output.            |        | 8.5 |        | 8.0 |        | 7.5 | ns    | 1     |
| $T_2$  | Valid signal hold time after the rising edge of EX_CLK                | 1      |     | 1      |     | 1      |     | ns    | 1, 4  |
| $T_3$  | Valid data signal on an input prior to the rising edge of EX_CLK      | 2.5    |     | 2.5    |     | 2.5    |     | ns    | 1     |
| $T_4$  | Required hold time of a data input after the rising edge of EX_CLK    | 0.5    |     | 0.5    |     | 0.5    |     | ns    | 1, 4  |
| $T_5$  | Valid control signal on an input prior to the rising edge of EX_CLK   | 3.5    |     | 3.5    |     | 3.5    |     | ns    | 1     |
| $T_6$  | Required hold time of a control input after the rising edge of EX_CLK | 0.5    |     | 0.5    |     | 0.5    |     | ns    | 1, 4  |
| CLoad  | Load Capacitance  | 5      | 60  | 5      | 50  | 5      | 40  | pF    | 4     |

**Notes:**

1. Drive settings do not apply to EX\_CS# signals and are expected to be point to point.
2. EX\_control\_signals output signals consist of EX\_ALE, EX\_ADDR, EX\_CS#, EX\_RD#, EX\_WR#, EX\_WAIT#
3. EX\_control\_signals input signals consist of EX\_ADDR, EX\_CS#, EX\_BURST, EX\_RD#, EX\_WR#
4. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

## 49.5.16 Controller Area Network (CAN)

The EP80579 provides a CAN interface that includes support for CAN 2.0B protocol, 11-bit and 29-bit identifiers, and supports bit rates up to 1 Mbps. The EP80579 provides support for various external PHY chips, such as the TI-SN65HVD230D transceiver.

This section describes the electrical characteristics of the CAN interface.

### 49.5.16.1 CAN Signal List

For a pin description for the CAN Interface, refer to [Table 48-21, “Controller Area Network Bus Signals”](#) on page 1759.

### 49.5.16.2 CAN DC Characteristics

**Table 49-92. CAN DC Input Characteristics**

| Symbol     | Parameter                     | Conditions                | Min | Typical | Max | Units   | Notes |
|------------|-------------------------------|---------------------------|-----|---------|-----|---------|-------|
| $V_{IH}$   | Input voltage high            | -                         | 2.0 | -       |     | V       | -     |
| $V_{IL}$   | Input voltage low             | -                         | -   | -       | 0.8 | V       | -     |
| $I_{OL}$   | Output current at low voltage | $V_{OL} < 0.8$            | -   | -       | 4   | mA      | -     |
| $I_{leak}$ | Input Leakage Current         | $0 < V_{IN} < V_{CC3\_3}$ | -   | -       | 10  | $\mu$ A | -     |
| Cin        | Input pin cap                 | -                         | -   | -       | 5   | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-93. CAN DC Output Characteristics**

| Symbol   | Parameter                      | Conditions              | Min | Typical | Max | Units |
|----------|--------------------------------|-------------------------|-----|---------|-----|-------|
| $V_{OH}$ | Output voltage high            | $I_{out} = -6\text{mA}$ | 2.0 | -       | -   | V     |
| $V_{OL}$ | Output voltage low             | $I_{out} = 6\text{mA}$  | -   | -       | 0.4 | V     |
| $I_{OH}$ | Output current at high voltage | $V_{out} = 2.4$         | -12 | -27     | -48 | mA    |
| $I_{OL}$ | Output current at low voltage  | $V_{out} = 0.8$         | 12  | 18      | 26  | mA    |

## 49.5.17 Synchronous Serial Port (SSP)

This section describes the electrical characteristics of the SSP interface.

### 49.5.17.1 SSP Signal List

For a pin description for the SSP Interface, refer to [Table 48-25, “SSP Interface Signals”](#) on page 1768.

### 49.5.17.2 SSP DC Characteristics

This section describes the DC characteristics of the SSP interface.

**Table 49-94. SSP DC Input Characteristics**

| Symbol            | Parameter                     | Conditions                            | Min | Typical | Max | Units | Notes |
|-------------------|-------------------------------|---------------------------------------|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high            | -                                     | 2.0 | -       |     | V     | -     |
| V <sub>IL</sub>   | Input voltage low             | -                                     | -   | -       | 0.8 | V     | -     |
| I <sub>OL</sub>   | Output current at low voltage | V <sub>OL</sub> <0.8                  | -   | -       | 4   | mA    | -     |
| I <sub>leak</sub> | Input Leakage Current         | 0<V <sub>IN</sub> <V <sub>cc3_3</sub> | -   | -       | 10  | μA    | -     |
| C <sub>in</sub>   | Input pin cap                 | -                                     | -   | -       | 5   | pf    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

### 49.5.17.2.1 SSP DC Output Characteristics

**Table 49-95. SSP DC Output Characteristics**

| Symbol          | Parameter                      | Conditions             | Min | Typical | Max | Units | Notes |
|-----------------|--------------------------------|------------------------|-----|---------|-----|-------|-------|
| V <sub>OH</sub> | Output voltage high            | I <sub>out</sub> =-6mA | 2.0 | -       | -   | V     | 1     |
| V <sub>OL</sub> | Output voltage low             | I <sub>out</sub> =6mA  | -   | -       | 0.4 | V     | -     |
| I <sub>OH</sub> | Output current at high voltage | V <sub>OH</sub> =2.4   | -12 | -27     | -48 | mA    | -     |
| I <sub>OL</sub> | Output current at low voltage  | V <sub>OL</sub> =0.8   | 12  | 18      | 26  | mA    | -     |

**Notes:**

1. VOH spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

**Table 49-96. SSP DC Clock Specification**

| Symbol            | Parameter                     | Conditions                            | Min | Typical | Max | Units | Notes |
|-------------------|-------------------------------|---------------------------------------|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high            | -                                     | 2.0 | -       |     | V     | -     |
| V <sub>IL</sub>   | Input voltage low             | -                                     | -   | -       | 0.8 | V     | -     |
| I <sub>OL</sub>   | Output current at low voltage | V <sub>OL</sub> <0.8                  | -   | -       | 4   | mA    | -     |
| I <sub>leak</sub> | Input Leakage Current         | 0<V <sub>IN</sub> <V <sub>cc3_3</sub> | -   | -       | 10  | μA    | -     |
| C <sub>in</sub>   | Input pin cap                 | -                                     | -   | -       | 5   | pf    | 1     |

**Notes:**

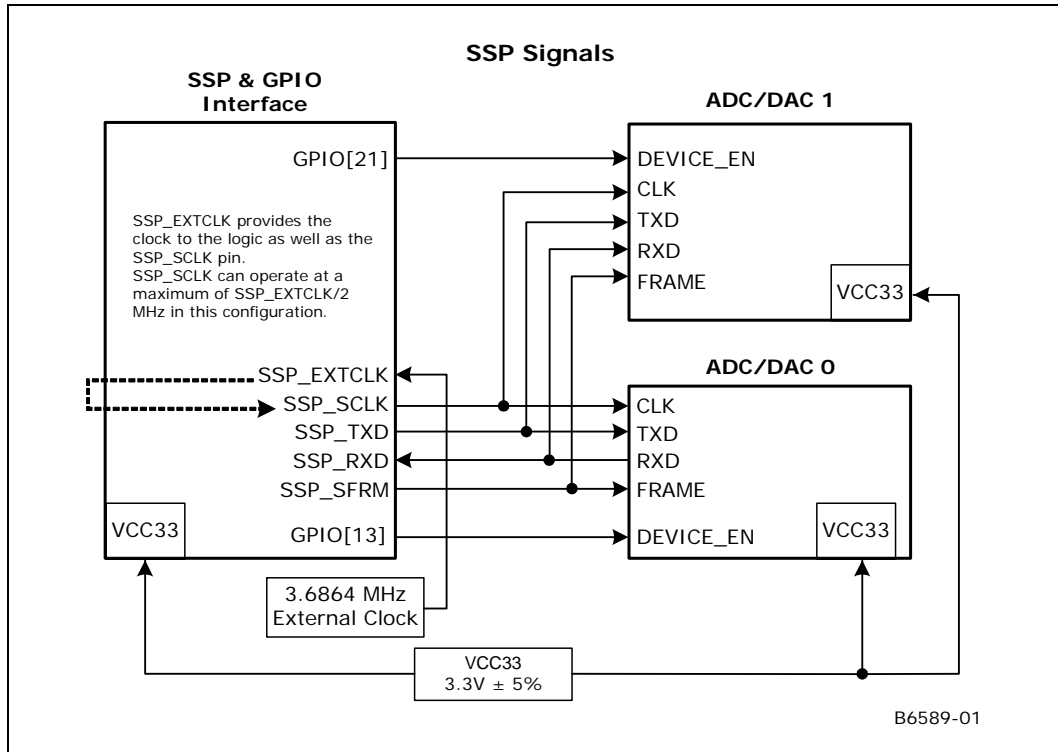

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

49.5.17.2.2 SSP Block Diagram

Figure 49-45 shows the SSP signal connections used when connecting to multiple analog-to-digital converters, with a multi-bus connection, and using an external clock generation mode.

Figure 49-45.SSP Signal Connection Block Diagram - Multi-Drop Connections

### 49.5.17.3 SSP AC Characteristics

Table 49-97. SSP Timing Values and Test Conditions

| Symbol         | Parameter  | Min | Nominal | Max | Units | Notes      |
|----------------|--|-----|---------|-----|-------|------------|
| SSP_SCLK       | Clock period of SSP_SCLK when the clock is being generated from the internally generated 3.6864 MHz clock                      | -   | 271     | -   | ns    | 1, 3, 4    |
| -              | SSP_SCLK clock period that can be produced when the clock is being generated from the external 3.6864 MHz clock via SSP_EXTCLK | 542 | -       | -   | ns    | 1, 3       |
| SSP_EXTCLK     | Clock period when the clock is being generated from the externally supplied maximum clock rate of 3.6864 MHz clock             | 271 | -       | -   | ns    | 1, 3       |
| T <sub>1</sub> | Output Valid Delay from SSP_EXTCLK to SSP_SCLK in external clock mode  | 2   | -       | 15  | ns    | 1, 3       |
| T <sub>2</sub> | Input Setup time for data prior to the valid edge of SSP_SCLK. These signals include SSP_RXD.                                  | 15  | -       | -   | ns    | 1, 5       |
| T <sub>3</sub> | Input hold time for data after the valid edge of SSP_SCLK. These signals include SSP_SRXD.                                     | 0   | -       | -   | ns    | 1, 3, 5    |
| T <sub>4</sub> | SSP_SCLK clock to output valid delay from output signals. These signals include SSP_TXD and SSP_SFRM.                          | -   | -       | 6   | ns    | 1, 2, 3, 5 |
| T <sub>5</sub> | Output data hold valid from valid edge of SSP_SCLK. These signals include SSP_TXD and SSP_SFRM.                                | 1   | -       | -   | ns    | 1, 2, 3, 5 |

**Notes:**

1. Timing was designed for a system load between 5pF and 40pF
2. Clock jitter on the SSP\_SCLK is designed to be an average of the specified clock frequency. The SSP\_SCLK jitter specification is unspecified.
3. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.
4. For low-power SKU configured for internal mode the SSP\_SCLK is 360 ns from an internal generated 2.777 MHz clock.
5. For reference purposes, the timing diagram shows a positive clock edge launch and a positive clock edge capture, however, depending on the frame format selected, each transmitted bit is driven on either the rising or falling edge of SSP\_SCLK, and is sampled on the opposite clock edge.

Figure 49-46. SSP Interface Timing Diagram

B6590-02

### 49.5.18 IEEE 1588-2008 Hardware Assist Interface

This section describes the electrical characteristics of the IEEE 1588-2008 Hardware Assist Interface.

#### 49.5.18.1 IEEE 1588-2008 Hardware Assist Signal List

For a pin description for the IEEE 1588-2008 Hardware Assist Interface, refer to Table 48-26, "IEEE 1588-2008 Hardware Assist Interface Signals" on page 1768.

#### 49.5.18.2 IEEE 1588-2008 Hardware Assist DC Characteristics

Table 49-98. IEEE 1588-2008 Hardware Assist DC Input Characteristics

| Symbol     | Parameter             | Conditions                | Min | Typical | Max | Units   | Notes |
|------------|-----------------------|---------------------------|-----|---------|-----|---------|-------|
| $V_{IH}$   | Input voltage high    | -                         | 2.0 | -       | -   | V       | -     |
| $V_{IL}$   | Input voltage low     | -                         | -   | -       | 0.8 | V       | -     |
| $I_{leak}$ | Input Leakage Current | $0 < V_{IN} < V_{cc3\_3}$ | -   | -       | 10  | $\mu$ A | -     |
| $C_{IN}$   | Input-pin capacitance | -                         | -   | -       | 10  | pf      | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Table 49-99. IEEE 1588-2008 Hardware Assist DC Output Characteristics

| Symbol   | Parameter                      | Conditions              | Min | Typical | Max | Units | Notes |
|----------|--------------------------------|-------------------------|-----|---------|-----|-------|-------|
| $V_{OH}$ | Output voltage high            | $I_{out} = -6\text{mA}$ | 2.0 | -       | -   | V     | 1     |
| $V_{OL}$ | Output voltage low             | $I_{out} = 6\text{mA}$  | -   | -       | 0.4 | V     | -     |
| $I_{OH}$ | Output current at high voltage | $V_{OH} = 2.4$          | -12 | -27     | -48 | mA    | -     |
| $I_{OL}$ | Output current at low voltage  | $V_{OL} = 0.8$          | 12  | 18      | 26  | mA    | -     |

**Notes:**

1. VOH spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

#### 49.5.18.3 IEEE 1588-2008 Hardware Assist AC Characteristics

The IEEE 1588-2008 Hardware Assist Interface is an edge-dependent interface and has no critical AC timing requirements.

### 49.5.19 IICH Miscellaneous Signals (PME#, PCIRST#, SPKR)

This section describes the electrical characteristics of the IICH Miscellaneous signals.

#### 49.5.19.1 IICH Miscellaneous Signal List

For a pin description for the IICH Miscellaneous signals, refer to Table 48-28, "Miscellaneous Signals" on page 1770.

### 49.5.19.2 IICH Miscellaneous Signals DC Characteristics

**Table 49-100. IICH Miscellaneous Signals DC Input Characteristics**

| Symbol            | Parameter             | Conditions                               | Min | Typical | Max | Units | Notes |
|-------------------|-----------------------|--|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high    | -  | 2.0 | -       | -   | V     | -     |
| V <sub>IL</sub>   | Input voltage low     | -  | -   | -       | 0.8 | V     | -     |
| I <sub>leak</sub> | Input Leakage Current | 0 < V <sub>IN</sub> < V <sub>CC3_3</sub> | -   | -       | 10  | μA    | -     |
| C <sub>IN</sub>   | Input-pin capacitance | -  | -   | -       | 10  | pf    | 1     |

**Notes:**

1. Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-101. IICH Miscellaneous Signals DC Output Characteristics**

| Symbol          | Parameter                      | Conditions              | Min | Typical | Max | Units | Notes |
|-----------------|--------------------------------|-------------------------|-----|---------|-----|-------|-------|
| V <sub>OH</sub> | Output voltage high            | I <sub>out</sub> = -6mA | 2.0 | -       | -   | V     | 1     |
| V <sub>OL</sub> | Output voltage low             | I <sub>out</sub> = 6mA  | -   | -       | 0.4 | V     | -     |
| I <sub>OH</sub> | Output current at high voltage | V <sub>OH</sub> = 2.4   | -12 | -27     | -48 | mA    | -     |
| I <sub>OL</sub> | Output current at low voltage  | V <sub>OL</sub> = 0.8   | 12  | 18      | 26  | mA    | -     |

**Notes:**

1. V<sub>OH</sub> spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

### 49.5.19.3 IICH Miscellaneous Signals AC Characteristics

The AC electrical specifications of the EP80579 IICH Miscellaneous signals are compliant with the *PCI Local Bus Specification*, Rev. 3.0 (refer to AC Specifications for 3.3V Signaling for more information).

## 49.5.20 Clock Resource Unit (CRU)

The CRU unit is responsible for generating and distributing the clocks to the various functional units within the SOC.

This section describes the electrical characteristics of the Global Clock signals.

### 49.5.20.1 CRU Signal List

For a pin description for the CRU Signals, refer to [Table 48-5, "Global Clock and Reset \(CRU\) Signals"](#) on page 1736.

49.5.20.2 CRU DC Characteristics

Table 49-102.CRU Differential Clock DC Specifications

| Symbol                  | Parameter               | Min                                | Typical | Max                                | Units | Figure       | Notes            |
|-------------------------|-------------------------|------------------------------------|---------|------------------------------------|-------|--------------|------------------|
| V <sub>IL</sub>         | Input Low Voltage       | -0.150                             | 0.00    | 0.150                              | V     | 49-47        | 1                |
| V <sub>IH</sub>         | Input High Voltage      | 0.660                              | 0.710   | 0.850                              | V     | 49-47        | 1                |
| V <sub>CROSS(abs)</sub> | Absolute Crossing Point | 0.250                              | N/A     | 0.550                              | V     | 49-47, 49-48 | 1, 2, 3, 6, 9    |
| V <sub>CROSS(rel)</sub> | Relative Crossing Point | 0.250+0.5(V <sub>HAVg</sub> -0.71) | N/A     | 0.550+0.5(V <sub>HAVg</sub> -0.71) | V     | 49-47, 49-48 | 1, 2, 3, 6, 7, 9 |
| ΔV <sub>CROSS</sub>     | Range of Crossing Point | N/A                                | N/A     | 0.140                              | V     | 49-47, 49-48 | 1, 2, 8, 9       |
| V <sub>RBM</sub>        | Ringback Margin         | 0.200                              | N/A     | N/A                                | V     | 49-47        | 1, 4, 9          |
| V <sub>TM</sub>         | Threshold Margin        | V <sub>CROSS</sub> -0.10           | N/A     | V <sub>CROSS</sub> +0.10           | V     | 49-47        | 1, 5, 9          |

Notes:

- Unless otherwise noted, all specifications in this table apply to all processor frequencies.
- Crossing voltage is defined as the instantaneous voltage value when the rising edge of CLKP100 equals the falling edge of CLKN100.
- V<sub>Havg</sub> is the statistical average of the V<sub>H</sub> measured by the oscilloscope.
- Ringback Margin is defined as the absolute voltage difference between the maximum Rising Edge Ringback and the maximum Falling Edge Ringback.
- Threshold Region is defined as a region entered around the crossing point voltage in which the differential receiver switches. It includes input threshold hysteresis.
- The crossing point must meet the absolute and relative crossing point specifications simultaneously.
- V<sub>Havg</sub> can be measured directly using "Vtop" on Agilent\* scopes and "High" on Tektronix\* scopes.
- ΔV<sub>CROSS</sub> is defined as the total variation of all crossing voltages as defined in note 2.
- Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Figure 49-48. CRU Differential Clock Cross-Point Specification

49.5.20.3 CRU AC Specifications

Table 49-103. CRU Differential Input Clock Timing Specifications (Sheet 1 of 2)

| Symbol                                    | Parameter                              | Min   | Nom  | Max    | Unit | Figures | Notes   |
|---|--|-------|------|--------|------|---------|---------|
| <b>CLKN100/CLKP100 (100MHz FSB clock)</b> |  |       |      |        |      |         |         |
| -   | CLK100 Frequency                       |       | -    | 100    | MHz  | -       | -       |
| -   | Duty Cycle                             | 45    | -    | 55     | %    | -       | -       |
| T1  | CLK100 Period                          | 9.997 | -    | 10.20  | ns   | 49-47   | 1, 6    |
| T2  | CLK100 Period Stability                | N/A   | -    | 200.00 | ps   | -       | 2, 6    |
| -   | Frequency Tolerance                    | -     | -    | 350    | ppm  | -       | -       |
| -   | Clock Jitter                           | -     | 50   | 150    | ps   | -       | -       |
| T3  | T <sub>PH</sub> CLK100 Pulse High Time | 3.94  | 5.00 | 6.12   | ns   | 49-47   | 4, 6    |
| T4  | T <sub>PL</sub> CLK100 Pulse Low Time  | 3.94  | 5.00 | 6.12   | ns   | 49-47   | 4, 6    |
| T5  | CLK100 Rise Time                       | 175   | -    | 700    | ps   | 49-47   | 3, 5, 6 |
| T6  | CLK100 Fall Time                       | 175   | -    | 700    | ps   | 49-47   | 3, 5, 6 |

Notes:

- The period specified here is the average period. A given period may vary from this specification as governed by the period Stability specification (T2).
- In this context, period stability is defined as the worst case timing difference between successive crossover voltages. In other words, the largest absolute difference between adjacent clock periods must be less than the period stability. Slew rate is measured between the 35% and 65% points of the clock swing (VL to VH).
- Combining the longest clock-high and clock-low times would violate the max clock period, and that combining the shortest clock-high and clock-low times would violate the minimum clock period. The clock-high and clock-low times specify the most extreme allowable combination of clock period and duty cycle.
- Slew rate specifications apply to both rising and falling edges.
- Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

Table 49-103. CRU Differential Input Clock Timing Specifications (Sheet 2 of 2)

| Symbol                                    | Parameter                              | Min   | Nom  | Max    | Unit | Figures | Notes   |
|---|--|-------|------|--------|------|---------|---------|
| <b>CLKN100/CLKP100 (133MHz FSB clock)</b> |  |       |      |        |      |         |         |
| -   | CLK100 Frequency                       |       | -    | 133    | MHz  | -       | -       |
| -   | Duty Cycle                             | 45    | -    | 55     | %    | -       | 6       |
| T1  | CLK100 Period                          | 7.497 | -    | 7.65   | ns   | 49-47   | 1, 6    |
| T2  | CLK100 Period Stability                | N/A   | -    | 200    | ps   |         | 2, 6    |
| -   | Frequency Tolerance                    | -     | -    | 350    | ppm  | -       | -       |
| -   | Clock Jitter                           | -     | 50   | 150    | ps   | -       | -       |
| T3  | T <sub>PH</sub> CLK100 Pulse High Time | 3.375 | 3.75 | 4.2075 | ns   | 49-47   | 4, 6    |
| T4  | T <sub>PL</sub> CLK100 Pulse Low Time  | 3.375 | 3.75 | 4.2075 | ns   | 49-47   | 4, 6    |
| T5  | CLK100 Rise Time                       | 175   |      | 700    | ps   | 49-47   | 3, 5, 6 |
| T6  | CLK100 Fall Time                       | 175   |      | 700    | ps   | 49-47   | 3, 5, 6 |

**Notes:**

- The period specified here is the average period. A given period may vary from this specification as governed by the period Stability specification (T2).
- In this context, period stability is defined as the worst case timing difference between successive crossover voltages. In other words, the largest absolute difference between adjacent clock periods must be less than the period stability. Slew rate is measured between the 35% and 65% points of the clock swing (VL to VH).
- Slew rate is measured between the 35% and 65% points of the clock swing (VL to VH).
- Combining the longest clock-high and clock-low times would violate the max clock period, and that combining the shortest clock-high and clock-low times would violate the minimum clock period. The clock-high and clock-low times specify the most extreme allowable combination of clock period and duty cycle.
- Slew rate specifications apply to both rising and falling edges.
- Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

### 49.5.21 Sideband Miscellaneous Signals

This section describes the electrical characteristics of the Sideband Miscellaneous signals.

#### 49.5.21.1 Sideband Miscellaneous Signals Signal List

For a pin description for these sideband signals, refer to Table 48-6, "Sideband Miscellaneous Signals" on page 1737.

#### 49.5.21.2 Sideband Miscellaneous Signals DC Characteristics

Table 49-104. Sideband Miscellaneous Signals DC Input Characteristics

| Symbol            | Parameter             | Conditions                               | Min | Typical | Max | Units | Notes |
|-------------------|-----------------------|--|-----|---------|-----|-------|-------|
| V <sub>IH</sub>   | Input voltage high    | -  | 2.0 | -       | -   | V     | -     |
| V <sub>IL</sub>   | Input voltage low     | -  | -   | -       | 0.8 | V     | -     |
| I <sub>leak</sub> | Input Leakage Current | 0 < V <sub>IN</sub> < V <sub>CC3_3</sub> | -   | -       | 10  | μA    | -     |
| C <sub>IN</sub>   | Input-pin capacitance | -  | -   | -       | 10  | pf    | 1     |

**Notes:**

- Guaranteed by design. These values are typical values seen for this process, but not measured during production testing.

**Table 49-105. Sideband Miscellaneous Signals DC Output Characteristics**

| Symbol          | Parameter                      | Conditions                | Min      | Typical | Max      | Units | Notes |
|-----------------|--------------------------------|---------------------------|----------|---------|----------|-------|-------|
| V <sub>OH</sub> | Output voltage high            | I <sub>out</sub> =-0.5mA  | 0.9VCC33 | -       | -        | V     | 1     |
| V <sub>OL</sub> | Output voltage low             | I <sub>out</sub> =1.5mA   | -        | -       | 0.1VCC33 | V     |       |
| I <sub>OH</sub> | Output current at high voltage | V <sub>OH</sub> >0.9VCC33 | -0.5     | -       | -        | mA    |       |
| I <sub>OL</sub> | Output current at low voltage  | V <sub>OL</sub> <0.1VCC33 | -        | -       | 1.5      | mA    |       |

**Notes:**

1. V<sub>OH</sub> spec does not apply to signals that are open drain driver. Open drain signals must have an external pull up resistor.

**49.5.21.3 Sideband Miscellaneous Signals AC Characteristics**

## 50.0 Thermal Specifications and Design Considerations

---

The EP80579 requires a thermal solution that maintains the maximum case temperature defined in [Table 50-1, "EP80579 Thermal Design Power \(TDP\) and Maximum Case Temperature Specifications \(TC-MAX\)"](#). Any attempt to operate outside these operating limits may result in permanent damage to the processor and potentially other components in the system. As processor technology changes, thermal management becomes increasingly crucial when building computer systems. Maintaining the proper thermal environment is key to reliable long-term system operation. A complete thermal solution includes both component-level and system-level thermal management features. Refer to the *Intel® EP80579 Integrated Processor product line Thermal Design Guide* for a thorough treatment of thermal design considerations.

To allow for the optimal operation and long-term reliability of Intel® architecture-based systems, the system/processor thermal solution must be designed such that the processor remains within the minimum and maximum case temperature ( $T_{C-MAX}$ ) specifications at the corresponding Thermal Design Power (TDP) value listed in [Table 50-1](#). Thermal solutions that are not designed to provide this level of thermal capability may affect the long-term reliability of the processor and the system. The case temperature is defined at the geometric top center of the Integrated Heat Spreader (IHS).

The EP80579 monitors die temperature using a thermal sensor. The thermal sensor (described in [Section 50.2, "Thermal Sensor"](#)) must be used to determine when the maximum specified component temperature has been reached. The on-die thermal sensor is designed to help protect the processor in the unlikely event that an application exceeds the TDP recommendation for a sustained period of time. For more details on the usage of this feature, refer to [Section 50.2, "Thermal Sensor"](#). In all cases, the thermal sensor feature must be enabled for the processor to remain within the operating limits.

### 50.1 Thermal Characteristics

Consult the *Intel® EP80579 Integrated Processor product line Thermal Design Guide* for complete information about thermal characteristics. Contact your local Intel sales office or your distributor to obtain the latest version.

### 50.1.1 Specifications

### 50.1.2 Thermal Design Power (TDP) Dissipation

The Thermal Design Power (TDP) values in Table 50-1 assume full-speed operation by all peripherals and internal components in a realistic application. This TDP value provides a high-level estimate for target applications.

The processor’s power is specified as Thermal Design Power (TDP) for thermal solution design. TDP is defined as a system design target associated with the maximum component operating temperature specifications. TDP values are determined based on typical DC electrical specification and maximum component temperature for a realistic-case application running at maximum utilization. The Intel TDP specification is a recommended design point and is not representative of the absolute maximum power the processor may dissipate under worst-case conditions. For any excursions beyond TDP, the processor passive cooling feature is available to maintain the processor thermal specifications. Refer to Section 50.2, “Thermal Sensor”

Table 50-1. EP80579 Thermal Design Power (TDP) and Maximum Case Temperature Specifications (T<sub>C-MAX</sub>)

|                           | Intel® EP80579 Integrated Processor |       |      |      | Intel® EP80579 Integrated Processor with Intel® QuickAssist Technology |      |      |      |
|---------------------------|-------------------------------------|-------|------|------|--|------|------|------|
| SKU                       | 2                                   | 8     | 4    | 6    | 1  | 3    | 7    | 5    |
| Processor Frequency (MHz) | 600                                 | 600   | 1066 | 1200 | 600  | 1066 | 1066 | 1200 |
| TDP <sup>1</sup> (Watts)  | 11                                  | 11    | 18   | 19   | 13   | 20   | 20   | 21   |
| T <sub>CASE-MAX</sub>     | 100°C                               | 100°C | 97°C | 95°C | 100°C  | 97°C | 97°C | 95°C |

**Notes:**

1. Thermal Design Power (TDP) is a system design target associated with the maximum component operating temperature specifications. TDP values are determined based on typical DC electrical specification and maximum component temperature for a realistic-case application running at maximum utilization.

Refer to Section 50.0, “Thermal Specifications and Design Considerations” for further thermal specifications.

## 50.2 Thermal Sensor

An independent thermal sensor helps control the silicon temperature by activating the thermal control sequence when the EP80579 reaches its maximum operating temperature. The temperature at which the EP80579 activates this thermal control sequence is not user configurable and is not visible to the software.

The thermal sensor is an independent sensor that provides two outputs, THRMTRIP# and PROCHOT#. Refer to Section 50.2.1, “Catastrophic Thermal Protection” for details about THRMTRIP# and to Section 50.2.2, “Thermal Sensor Features” for details about PROCHOT#.

The EP80579 provides the IA-32 core thermal monitor. The IA-32 core thermal monitor has a throttling capability that can be activated via software or pre-boot firmware. Refer to Section 50.2.2.2, “Processor Passive Cooling” and Section 50.2.2.3, “On-Demand Passive Cooling” for details.

## 50.2.1 Catastrophic Thermal Protection

The EP80579 provides catastrophic thermal protection via an on-die thermal sensor that detects when the silicon has reached approximately 20°C above  $T_{CASE-MAX}$ . This catastrophic trip point is programmed at the factory. The catastrophic trip point will initiate the Processor Thermal Trip control sequence, which is described in [Section 50.2.1.1, "THRMTRIP# Control Sequence"](#). Once the thermal sensor has detected this over heat condition, THRMTRIP# is asserted.

THRMTRIP# is also available as an input pin to support platform thermal management requirements. An external thermal sensor could be implemented to monitor the platform thermal condition, asserting THRMTRIP# when catastrophic thermal conditions exist on the platform. The EP80579 receives this signal and initiates the THRMTRIP# Control Sequence described in [Section 50.2.1.1, "THRMTRIP# Control Sequence"](#).

*Note:* Intel recommends that an external thermal sensor be used to protect the EP80579 and the system against excessive temperature. Even with the activation of THRMTRIP#, which halts all internal clocks and activity, leakage current can be high enough such that the EP80579 cannot be protected in all conditions without completely removing the supplied power source. If the external thermal sensor detects the silicon has reached a catastrophic temperature approximately 20°C above  $T_{CASE-MAX}$ , or if the THRMTRIP# signal is asserted, the VCC supply to the processor must be turned off within 500 ms to prevent silicon damage due to thermal runaway.

### 50.2.1.1 THRMTRIP# Control Sequence

A catastrophic thermal trip event will assert THRMTRIP#, which indicates that the on-die thermal sensor has detected an overheat condition. Intel recommends that immediate action be taken to prevent silicon damage.

The temperature which the EP80579 activates this thermal control sequence is not user configurable and is not software visible. The following list provides additional information:

- If THRMTRIP# goes active, the processor is indicating an overheat condition, and will immediately transition to an S5 state. However, since the processor has overheated, it will not respond to the STPCLK# pin with a stop grant special cycle. Therefore, the EP80579 will not wait for one.
- Immediately upon seeing THRMTRIP# low, EP80579 will initiate a transition to the S5 state, drive signals SLP\_S3#, SLP\_S4#, SLP\_S5# low, and set the CTS bit. The transition will generally look like a power button override.
- When a THRMTRIP# event occurs, the EP80579 must power down immediately without following the normal S0 -> S5 path. This can happen in parallel, but the EP80579 must immediately enter a power down state. The EP80579 will do this by driving signals SLP\_S3#, SLP\_S4#, and SLP\_S5# within 3 PCICLKs after sampling THRMTRIP# active.
- If the processor is running extremely hot and is heating up, it is possible (although very unlikely) that components around it are no longer executing cycles properly. Therefore, if THRMTRIP# goes active, any other components that are relying on state machine logic to perform the power down, may not power down correctly. Because the state machine may not be working, the system may not power down completely.

The EP80579 will follow the flow in the steps that follow for THRMTRIP#:

1. At boot (PLTRST# low), THRMTRIP# ignored.
2. After power-up (PLTRST# high), if THRMTRIP# sampled active, SLP\_S3#, SLP\_S4#, and SLP\_S5# fire, and normal sequence of sleep machine starts.

3. Until sleep machine enters the S5 state, SLP\_S3#, SLP\_S4#, and SLP\_S5# stay active, even if THRMTRIP# is now inactive. This is the equivalent of “latching” the thermal trip event.
4. When the S5 state reached, return to step 1 above, otherwise stay here. If the EP80579 never gets to S5, the EP80579 does not reboot until power is cycled.

During boot, THRMTRIP# is ignored until SLP\_S3#, PWROK, VRMPWRGD, and PLTRST# are all '1'. During entry into a powered-down state (due to S3,S4, S5 entry, power cycle reset, etc.) THRMTRIP# is ignored until any of the following occurs:

- SLP\_S3# = 0
- PWROK = 0
- VRMPWRGD = 0

1. Set the AFTERG3\_EN bit
2. Clear the PWRBTN\_STS bit
3. Clear all the GPE0\_EN register bits
4. Clear the SMB\_WAK\_STS bit only if SMB\_WAK\_STS was set due to SMBus slave receiving message and not set due to SMBAlert.

*Note:* The THRMTRIP# pin must be glitch free.

## 50.2.2 Thermal Sensor Features

PROCHOT# is asserted when the silicon temperature has reached the maximum operating limit. If the EP80579 reaches the trip temperature indicated in [Table 50-1, “EP80579 Thermal Design Power \(TDP\) and Maximum Case Temperature Specifications \(TC-MAX\)”](#), then PROCHOT# is asserted and the EP80579 initiates a SMI# or SCI.

PROCHOT# provides platform visibility of a thermal condition determined by the thermal sensor. PROCHOT# should be implemented in the platform design as a thermal warning, by initiating passive cooling, turning on fans or power management.

When PROCHOT# is asserted, Intel recommends that power management software begins a processor-initiated passive cooling routine, which is described in [Section 50.2.2.2, “Processor Passive Cooling”](#).

For platform thermal sensor designs, on-demand throttling is provided. [Section 50.2.2.3, “On-Demand Passive Cooling”](#) provides more information.

### 50.2.2.1 PROCHOT# Control Sequence

The PROCHOT# signal is a status output pin from the thermal sensor. The signal indicates that the EP80579 has reached the maximum operating limit. When this maximum operating temperature is reached, power management software or pre-boot firmware should take action to reduce the temperature. The EP80579 follows these behaviors with regard to the PROCHOT# signal:

- Based on the PROCHOT# signal activation, the EP80579 generates an SMI# or SCI (depending on SCI\_EN).
- If the PROCHOT\_POL bit is set low, when PROCHOT# goes low, the PROCHOT\_STS bit will be set. This indicates that the thermal threshold has been exceeded. If the PROCHOT\_EN bit is set, then when PROCHOT\_STS goes active, either an SMI# or SCI# will be generated (depending on the SCI\_EN bit being set). The power management software (pre-boot firmware or ACPI) can then take measures to start reducing the temperature. Examples include shutting unneeded subsystems or halting the processor. Another method to reduce the temperature is processor-

initiated passive cooling. Refer to [Section 50.2.2.2, “Processor Passive Cooling”](#) for more information.

- By setting the PROCHOT\_POL bit to high, another SMI# or SCI# can optionally be generated when the PROCHOT# signal goes back high. This allows the software (pre-boot firmware or ACPI) to turn off the cooling methods.
- PROCHOT# assertion does not cause a TCO event message in S3 or S4. The level of the signal is not reported in the heartbeat message.

### 50.2.2.2 Processor Passive Cooling

The EP80579 provides a processor-initiated passive cooling feature that activates a clock throttling mechanism, which can be used by power management software or pre-boot firmware to reduce the temperature.

The FORCE\_THTL bit allows the pre-boot firmware to force passive cooling independent of the ACPI software (which uses the THTL\_EN and THTL\_DTY bits). The FORCE\_THTL bit has the following behavior:

- If the FORCE\_THTL bit is set, the EP80579 will start throttling using the ratio in the PROCHOT\_DTY field. The duty cycle indicates the approximate percentage of time the STPCLK# signal is asserted while in thermal throttle mode. The STPCLK# throttle period is 1024 PCICLKs (PCICLK = 33 MHz). Throttling only occurs if the system is in the C0 state. If in the C2, C3, or C4 state, no throttling occurs.  
*Note:* Refer to [Table 50-2](#) for duty cycle ratio settings.
- If the FORCE\_THTL bit is turned off (cleared), the EP80579 will stop throttling, unless the THTL\_EN bit is set (indicating that ACPI software is attempting throttling).
- If both the THTL\_EN and FORCE\_THTL bits are set, then the IICH uses the duty cycle defined by the PROCHOT\_DTY field, not the THTL\_DTY field. (PROCHOT\_DTY has higher priority).
- Once the PROCHOT\_DTY field is written, subsequent writes have no effect until PLTRST# goes active.

### 50.2.2.3 On-Demand Passive Cooling

The EP80579 provides an on-demand passive cooling feature, which may be used in customer designs that require power management capabilities that take advantage of clock throttling. The on-demand feature is similar to the processor passive cooling in that it supports clock throttling, but the on-demand feature is initiated by software setting the THTL\_EN and THTL\_DTY bits.

The on-demand passive cooling feature behaves as follows:

- Software sets the THTL\_DTY bits to select throttle ratio and the THTL\_EN bit to enable the throttling.
- Throttling results in STOPCLK# active for a minimum time of 12.5% and a maximum of 87.5%. The period is 1024 PCI clocks (PCICLK = 33 MHz). Thus, the STOPCLK# signal can be active for as little as 128 PCI clocks or as much as 896 PCI clocks. The actual slowdown (and cooling) of the processor will depend on the instruction stream, because the processor is allowed to finish the current instruction. Furthermore, the EP80579 waits for the STOP-GRANT cycle before starting the count for the time the STOPCLK# signal is active.  
*Note:* Refer to [Table 50-2](#) for duty cycle ratio settings.

Table 50-2. PROCHOT\_DTY/THTL\_DTY Throttle Ratios

| Throttle Mode            | PCI Clocks |
|--------------------------|------------|
| Default<br>(will be 50%) | 512        |
| 87.5%                    | 896        |
| 75.0%                    | 768        |
| 62.5%                    | 640        |
| 50%                      | 512        |
| 37.5%                    | 384        |
| 25%                      | 256        |
| 12.5%                    | 128        |

Intel® EP80579 Integrated Processor with Intel® QuickAssist Technology, 80579EB600c, 600mhz

| Socket    | Step | Step TDP | Ordering Code | Spec Code | Low Halogen | VT-x |
|-----------|------|----------|---------------|-----------|-------------|------|
| FCBGA1088 |      | 13 W     | NU80579EB600C |           | No          | No   |

### Block Diagrams

### Disclaimers

"Announced" SKUs are not yet available. Please refer to the Launch Date for market availability.

Enabling Execute Disable Bit functionality requires a PC with a processor with Execute Disable Bit capability and a supporting operating system. Check with your PC manufacturer on whether your system delivers Execute Disable Bit functionality.

64-bit computing on Intel® architecture requires a computer system with a processor, chipset, BIOS, operating system, device drivers and applications enabled for Intel® 64 architecture. Processors will not operate (including 32-bit operation) without an Intel 64 architecture-enabled BIOS. Performance will vary depending on your hardware and software configurations. Consult with your system vendor for more information.

Hyper-Threading Technology (HT Technology) requires a computer system with an Intel® processor supporting HT Technology and an HT Technology enabled chipset, BIOS and operating system. Performance will vary depending on the specific hardware and software you use. See [www.intel.com/products/ht/hyperthreading\\_more.htm](http://www.intel.com/products/ht/hyperthreading_more.htm) for more information including details on which processors support HT Technology.

Intel® Virtualization Technology requires a computer system with a processor, chipset, BIOS, virtual machine monitor (VMM) and for some uses, certain platform software, enabled for it. Functionality, performance or other benefit will vary depending on hardware and software configurations. Intel Virtualization Technology-enabled VMM applications are currently in development.

Note: Prices subject to change without notice. Prices are for direct Intel customers in 1000-unit bulk quantities and, unless specified, represent the latest technology versions of the products. Taxes and shipping, etc. not included. Prices may vary for other package types and shipment quantities, and special promotional arrangements may apply.

Intel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. See [http://www.intel.com/products/processor\\_number](http://www.intel.com/products/processor_number) for details.

System and Maximum TDP is based on worst case scenarios. Actual TDP may be lower if not all I/Os for chipsets are used.

All information provided is subject to change at any time, without notice. Intel may make changes to manufacturing life cycle, specifications, and product descriptions at any time, without notice. The information herein is provided "as-is" and Intel does not make any representations or warranties whatsoever regarding accuracy of the information, nor on the product features, availability, functionality, or compatibility of the products listed. Please contact system vendor for more information on specific products or systems.

Low Halogen implies the following:

Bromine and/or chlorine in materials that may be used during processing, but do not remain within the final product are not included in this definition. The halogens fluorine (F), iodine (I), and astatine (At) are not restricted by this standard.

"BFR/CFR and PVC-Free" Definition :

All PCB laminates must meet Br and Cl requirements for low halogen as defined in IPC-4101B

For components other than PCB laminates, all homogeneous materials must contain < 900 ppm (0.09%) of Bromine [if the Bromine (Br) source is from BFRs] and < 900 ppm (0.09%) of Chlorine [if the Chlorine (Cl) source is from CFRs or PVC. Higher concentrations of Br and Cl are allowed in homogenous materials of components other than PCB laminates as long as their sources are not BFRs, CFRs, PVC.

Although the elemental analysis for Br and Cl in homogeneous materials can be performed by any analytical method with sufficient sensitivity and selectivity, the presence or absence of BFRs, CFRs or PVC must be verified by any acceptable analytical techniques that allow for the unequivocal identification of the specific Br or Cl compounds, or by appropriate material declarations agreed to between customer and supplier.

Max Turbo Frequency refers to the maximum single-core frequency that can be achieved with Intel® Turbo Boost Technology, which requires a PC with a processor with Intel Turbo Boost Technology capability. Intel Turbo Boost Technology performance varies depending on hardware, software, and overall system configuration. Check with your PC manufacturer on whether your system delivers Intel Turbo Boost Technology. See [www.intel.com/technology/turboboost/](http://www.intel.com/technology/turboboost/) for more information.

Some products can support AES New Instructions with a Processor Configuration update, in particular, i7-2630QM/i7-2635QM, i7-2670QM/i7-2675QM, i5-2430M/i5-2435M, i5-2410M/i5-2415M. Please contact OEM for the BIOS that includes the latest Processor configuration update.

See [www.intel.com/products/ht/hyperthreading\\_more.htm](http://www.intel.com/products/ht/hyperthreading_more.htm) for more information including details on which processors support HT Technology.

Intel® Virtualization Technology requires a computer system with a processor, chipset, BIOS, virtual machine monitor (VMM) and for some uses, certain platform software, enabled for it. Functionality, performance or other benefit will vary depending on hardware and software configurations. Intel Virtualization Technology-enabled VMM applications are currently in development.

Note: Prices subject to change without notice. Prices are for direct Intel customers in 1000-unit bulk quantities and, unless specified, represent the latest technology versions of the products. Taxes and shipping, etc. not included. Prices may vary for other package types and shipment quantities, and special promotional arrangements may apply.

Intel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. See [http://www.intel.com/products/processor\\_number](http://www.intel.com/products/processor_number) for details.

System and Maximum TDP is based on worst case scenarios. Actual TDP may be lower if not all I/Os for chipsets are used.

All information provided is subject to change at any time, without notice. Intel may make changes to manufacturing life cycle, specifications, and product descriptions at any time, without notice. The information herein is provided "as-is" and Intel does not make any representations or warranties whatsoever regarding accuracy of the information, nor on the product features, availability, functionality, or compatibility of the products listed. Please contact system vendor for more information on specific products or systems.

Low Halogen implies the following:

Bromine and/or chlorine in materials that may be used during processing, but do not remain within the final product are not included in this definition. The halogens fluorine (F), iodine (I), and astatine (At) are not restricted by this standard.

"BFR/CFR and PVC-Free" Definition::

All PCB laminates must meet Brand Cl requirements for low halogen as defined in PC-4101B

For components other than PCB laminates, all homogeneous materials must contain < 900 ppm (0.09%) of Bromine [if the Bromine (Br) source is from BFRs] and < 900 ppm (0.09%) of Chlorine [if the Chlorine (Cl) source is from CFRs or PVC]. Higher concentrations of Brand Cl are allowed in homogeneous materials of components other than PCB laminates as long as their sources are not BFRs, CFRs, PVC.

Although the elemental analysis for Brand Cl in homogeneous materials can be performed by any analytical method with sufficient sensitivity and selectivity, the presence or absence of BFRs, CFRs or PVC must be verified by any acceptable analytical techniques that allow for the unequivocal identification of the specific Br or Cl compounds, or by appropriate material declarations agreed to between customer and supplier.

Max Turbo Frequency refers to the maximum single-core frequency that can be achieved with Intel® Turbo Boost Technology, which requires a PC with a processor with Intel Turbo Boost Technology capability. Intel Turbo Boost Technology performance varies depending on hardware, software, and overall system configuration. Check with your PC manufacturer on whether your system delivers Intel Turbo Boost Technology. See [www.intel.com/technology/turboboost/](http://www.intel.com/technology/turboboost/) for more information.

Some products can support AES New Instructions with a Processor Configuration update, in particular, *I*-2630QM/*I*-2635QM, *I*-2670QM/*I*-2675QM, *E*-2430M/*E*-2435M, *E*-2410M/*E*-2415M. Please contact OEM for the BIOS that includes the latest Processor configuration update.

#### Specifications

##### Essentials

|                            |          |
|----------------------------|----------|
| Status                     | Launched |
| Launch Date                | Q3'08    |
| # of Cores                 | 1        |
| # of Threads               | 1        |
| Clock Speed                | 1.2 GHz  |
| L2 Cache                   | 256 KB   |
| FSB Parity                 | No       |
| Instruction Set            | 32-bit   |
| Embedded Options Available | Yes      |
| Supplemental SKU           | No       |
| Lithography                | 90 nm    |
| Max TDP                    | 21 W     |
| VID Voltage Range          | 1.3      |

##### Memory Specifications

|  |   |
|--|---|
| Max Memory Size (dependent on memory type) | 4 GB                                      |
| Memory Types                               | DDR2-400 / DDR2-533 / DDR2-667 / DDR2-800 |
| # of Memory Channels                       | 1   |
| Physical Address Extensions                | 32-bit                                    |
| ECC Memory Supported                       | Yes                                       |

##### Graphics Specifications

|                               |    |
|-------------------------------|----|
| Integrated Graphics           | No |
| Dual Display Capable          | No |
| Macrovision* License Required | No |

##### Expansion Options

|                      |     |
|----------------------|-----|
| PCI Express Revision | 1.1 |
|----------------------|-----|

|  |                  |
|--|------------------|
| PCI Express Configurations                               | 1x8, 2x4, or 2x1 |
| <b>I/O Specifications</b>                                |                  |
| USB Revision   | USB 2.0          |
| # of USB Ports   | 2                |
| # of SATA Ports  | 2                |
| Integrated LAN   | 10/100/1000      |
| General Purpose IO                                       | 36 GPIO          |
| UART   | 2                |
| <b>Package Specifications</b>                            |                  |
| TCASE  | 95°C             |
| Package Size   | 37.5mm x 37.5mm  |
| Low Halogen Options Available                            | No               |
| <b>Advanced Technologies</b>                             |                  |
| Intel® Turbo Boost Technology                            | No               |

## Disclaimers

“Announced” SKUs are not yet available. Please refer to the Launch Date for market availability.

Enabling Execute Disable Bit functionality requires a PC with a processor with Execute Disable Bit capability and a supporting operating system. Check with your PC manufacturer on whether your system delivers Execute Disable Bit functionality.

64-bit computing on Intel® architecture requires a computer system with a processor, chipset, BIOS, operating system, device drivers and applications enabled for Intel® 64 architecture. Processors will not operate (including 32-bit operation) without an Intel 64 architecture-enabled BIOS. Performance will vary depending on your hardware and software configurations. Consult with your system vendor for more information.

Hyper-Threading Technology (HT Technology) requires a computer system with an Intel® processor supporting HT Technology and an HT Technology enabled chipset, BIOS and operating system. Performance will vary depending on the specific hardware and software you use. See [www.intel.com/products/ht/hyperthreading\\_more.htm](http://www.intel.com/products/ht/hyperthreading_more.htm) for more information including details on which processors support HT Technology.

Intel® Virtualization Technology requires a computer system with a processor, chipset, BIOS, virtual machine monitor (VMM) and for some uses, certain platform software, enabled for it. Functionality, performance or other benefit will vary depending on hardware and software configurations. Intel Virtualization Technology-enabled VMM applications are currently in development.

Note: Prices subject to change without notice. Prices are for direct Intel customers in 1000-unit bulk quantities and, unless specified, represent the latest technology versions of the products. Taxes and shipping, etc. not included. Prices may vary for other package types and shipment quantities, and special promotional arrangements may apply.

Intel processor numbers are not a measure of performance. Processor numbers differentiate features within each processor family, not across different processor families. See [http://www.intel.com/products/processor\\_number](http://www.intel.com/products/processor_number) for details.

System and Maximum TDP is based on worst case scenarios. Actual TDP may be lower if not all I/Os for chipsets are used.
