X5001

CPU Supervisor

Features

- **200ms Power On Reset Delay**
- **Low Vcc Detection and Reset Assertion**
  - **—Five Standard Reset Threshold Voltages**
  - **—Adjust Low Vcc Reset Threshold Voltage using special programming sequence**
  - **—Reset Signal Valid to Vcc=1V**
- **Selectable Nonvolatile Watchdog Timer**
  - **—0.2, 0.6, 1.4 seconds**
  - **—Off selection**
  - **—Select settings through software**
- **Long Battery Life With Low Power Consumption**
  - **—<50μA Max Standby Current, Watchdog On**
  - **—<1μA Max Standby Current, Watchdog Off**
- **2.7V to 5.5V Operation**
- **SPI Mode 0 interface**
- **Built-in Inadvertent Write Protection**
  - **—Power-Up/Power-Down Protection Circuitry**
  - **—Watchdog Change Latch**
- **High Reliability**
- **Available Packages**
  - **—8-Lead TSSOP**
  - **—8-Lead SOIC**
  - **—8 Pin PDIP**

DESCRIPTION

This device combines three popular functions, Power on Reset, Watchdog Timer, and Supply Voltage Supervision in one package. This combination lowers system cost, reduces board space requirements, and increases reliability.

The Watchdog Timer provides an independent protection mechanism for microcontrollers. During a system failure, the device will respond with a $\overline{RESET}$ signal after a selectable time-out interval. The user selects the interval from three preset values. Once selected, the interval does not change, even after cycling the power.

The user's system is protected from low voltage conditions by the device's low Vcc detection circuitry. When Vcc falls below the minimum Vcc trip point, the system is reset. $\overline{RESET}$ is asserted until Vcc returns to proper operating levels and stabilizes. Five industry standard V_{TRIP} thresholds are available, however, Xicor's unique circuits allow the thresold to be reprogrammed to meet custom requirements or to fine-tune the threshold for applications requiring higher precision.

The device utilizes Xicor's proprietary Direct Write™ cell for the Watchdog TImer control bits and the V_{TRIP} storage element, providing a minimum endurance of 100,000 write cycles and a minimum data retention of 100 years.

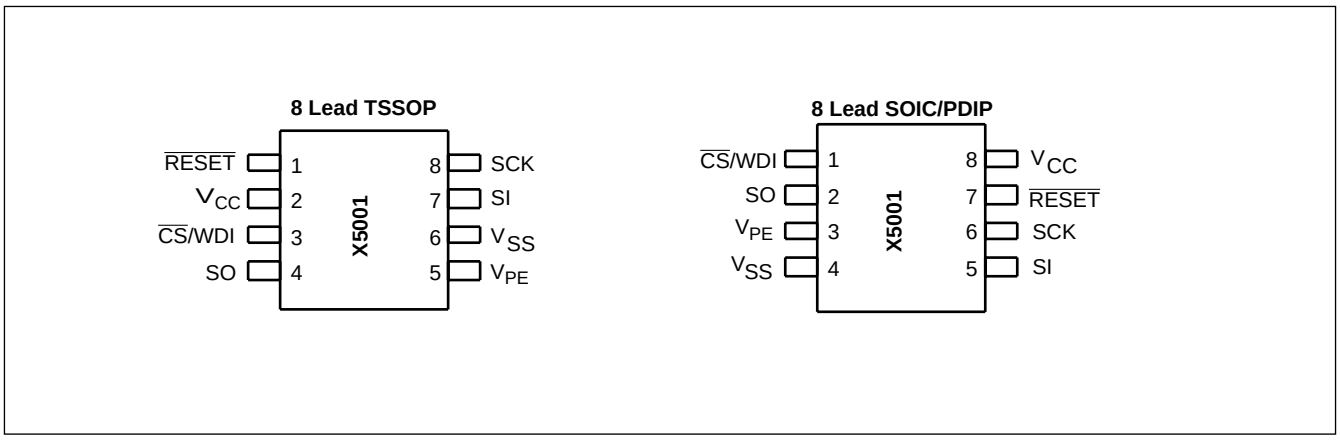
PIN DESCRIPTION

PIN (SOIC/PDIP)	PIN TSSOP	Name	Function
1	1	$\overline{CS}$/WDI	**Chip Select Input.** $\overline{CS}$ HIGH, deselects the device and the SO output pin is at a high impedance state. Unless a nonvolatile write cycle is underway, the device will be in the standby power mode. $\overline{CS}$ LOW enables the device, placing it in the active power mode. Prior to the start of any operation after power up, a HIGH to LOW transition on $\overline{CS}$ is required **Watchdog Input.** A HIGH to LOW transition on the WDI pin restarts the Watchdog timer. The absence of a HIGH to LOW transition within the watchdog time-out period results in $\overline{RESET}$/RESET going active.
2	2	SO	**Serial Output.** SO is a push/pull serial data output pin. A read cycle shifts data out on this pin. The falling edge of the serial clock (SCK) clocks the data out.
5	8	SI	**Serial Input.** SI is a serial data input pin. Input all opcodes, byte addresses, and memory data on this pin. The rising edge of the serial clock (SCK) latches the input data. Send all opcodes (Table 1), addresses and data MSB first.
6	9	SCK	**Serial Clock.** The Serial Clock controls the serial bus timing for data input and output. The rising edge of SCK latches in the opcode, address, or watchdog bits present on the SI pin. The falling edge of SCK changes the data output on the SO pin.
3	6	V_{PE}	**V_{TRIP} Program Enable.** When V_{PE} is LOW, the V_{TRIP} point is fixed at the last valid programmed level. To readjust the V_{TRIP} level, requires that the VPE pin be pulled to a high voltage (15-18V).
4	7	V_{SS}	**Ground**
8	14	V_{CC}	**Supply Voltage**
7	13	$\overline{RESET}$	**Reset Output**. $\overline{RESET}$ is an active LOW, open drain output which goes active whenever Vcc falls below the minimum Vcc sense level. It will remain active until Vcc rises above the minimum Vcc sense level for 200ms. $\overline{RESET}$ goes active if the Watchdog Timer is enabled and $\overline{CS}$/WDI remains either HIGH or LOW longer than the selectable Watchdog time-out period. A falling edge of $\overline{CS}$/WDI will reset the Watchdog Timer. $\overline{RESET}$ goes active on power up at 1V and remains active for 200ms after the power supply stabilizes.
	3-5,10-12	NC	No internal connections

Figure 1. PIN CONFIGURATION



PRINCIPLES OF OPERATION

Power On Reset

Application of power to the X5001 activates a Power On Reset Circuit. This circuit goes active at 1V and pulls the $\overline{RESET}$/RESET pin active. This signal prevents the system microprocessor from starting to operate with insufficient voltage or prior to stabilization of the oscillator. When Vcc exceeds the device V_{TRIP} value for 200ms (nominal) the circuit releases $\overline{RESET}$, allowing the processor to begin executing code.

Low voltage monitoring

During operation, the X5001 monitors the V_{CC} level and asserts $\overline{RESET}$ if supply voltage falls below a preset minimum V_{TRIP} The $\overline{RESET}$ signal prevents the microprocessor from operating in a power fail or brownout condition. The $\overline{RESET}$ signal remains active until the voltage drops below 1V. It also remains active until Vcc returns and exceeds V_{TRIP} for 200ms.

watchdog timer

The Watchdog Timer circuit monitors the microprocessor activity by monitoring the WDI input. The microprocessor must toggle the $\overline{CS}$/WDI pin periodically to prevent a $\overline{RESET}$ signal. The $\overline{CS}$/WDI pin must be toggled from HIGH to LOW prior to the expiration of the watchdog timeout period. The state of two nonvolatile control bits in the Watchdog Register determine the watchdog timer period.

Vcc Threshold Reset Procedure

The X5001 is shipped with a standard Vcc threshold (V_{TRIP}) voltage. This value will not change over normal operating and storage conditions. However, in applications where the standard V_{TRIP} is not exactly right, or if higher precision is needed in the V_{TRIP} value, the X5001 threshold may be adjusted. The procedure is described below, and requires the application of a high voltage control signal.

Setting the V_{TRIP} Voltage

This procedure is used to set the V_{TRIP} to a higher voltage value. For example, if the current V_{TRIP} is 4.4V and the new V_{TRIP} is 4.6V, this procedure will directly make the change. If the new setting is to be lower than the current setting, then it is necessary to reset the trip point before setting the new value.

To set the new V_{TRIP} voltage, apply the desired V_{TRIP} threshold voltage to the Vcc pin and tie the W_{PE} pin to the programming voltage V_P. Then a V_{TRIP} programming command sequence is sent to the device over the SPI interface. This V_{TRIP} programming sequence consists of pulling $\overline{CS}$ LOW, then clocking in data 03h, 00h and 01h. This is followed by bringing $\overline{CS}$ HIGH then LOW and clocking in data 02h, 00h, and 01h (in order) and bringing $\overline{CS}$ HIGH. This initiates the V_{TRIP} programming sequence. V_P is brought LOW to end the operation.

Resetting the V_{TRIP} Voltage

This procedure is used to set the V_{TRIP} to a “native” voltage level. For example, if the current V_{TRIP} is 4.4V and the new V_{TRIP} must be 4.0V, then the V_{TRIP} must be reset. When V_{TRIP} is reset, the new V_{TRIP} is something less than 1.7V. This procedure must be used to set the voltage to a lower value.

To reset the V_{TRIP} voltage, apply greater than 3V to the Vcc pin and tie the W_{PE} pin to the programming voltage Vp. Then a V_{TRIP} command sequence is sent to the device over the SPI interface. This V_{TRIP} programming sequence consists of pulling $\overline{CS}$ LOW, then clocking in data 03h, 00h and 01h. This is followed by bringing $\overline{CS}$ HIGH then LOW and clocking in data 02h, 00h, and 03h (in order) and bringing $\overline{CS}$ HIGH. This initiates the V_{TRIP} programming sequence. V_P is brought LOW to end the operation.

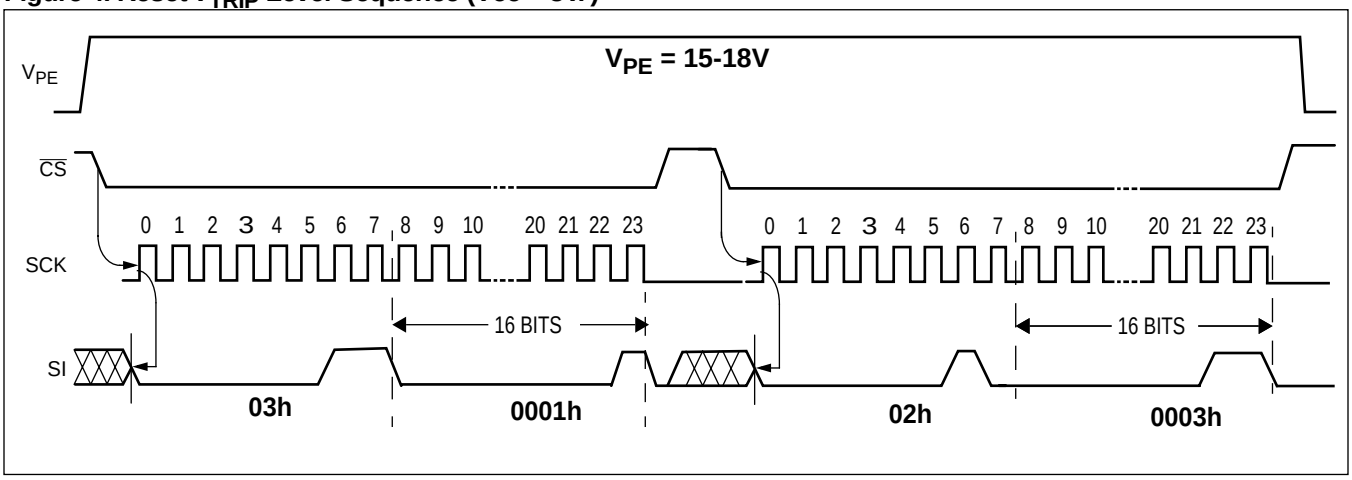

Figure 5. Vtrip Programming Sequence

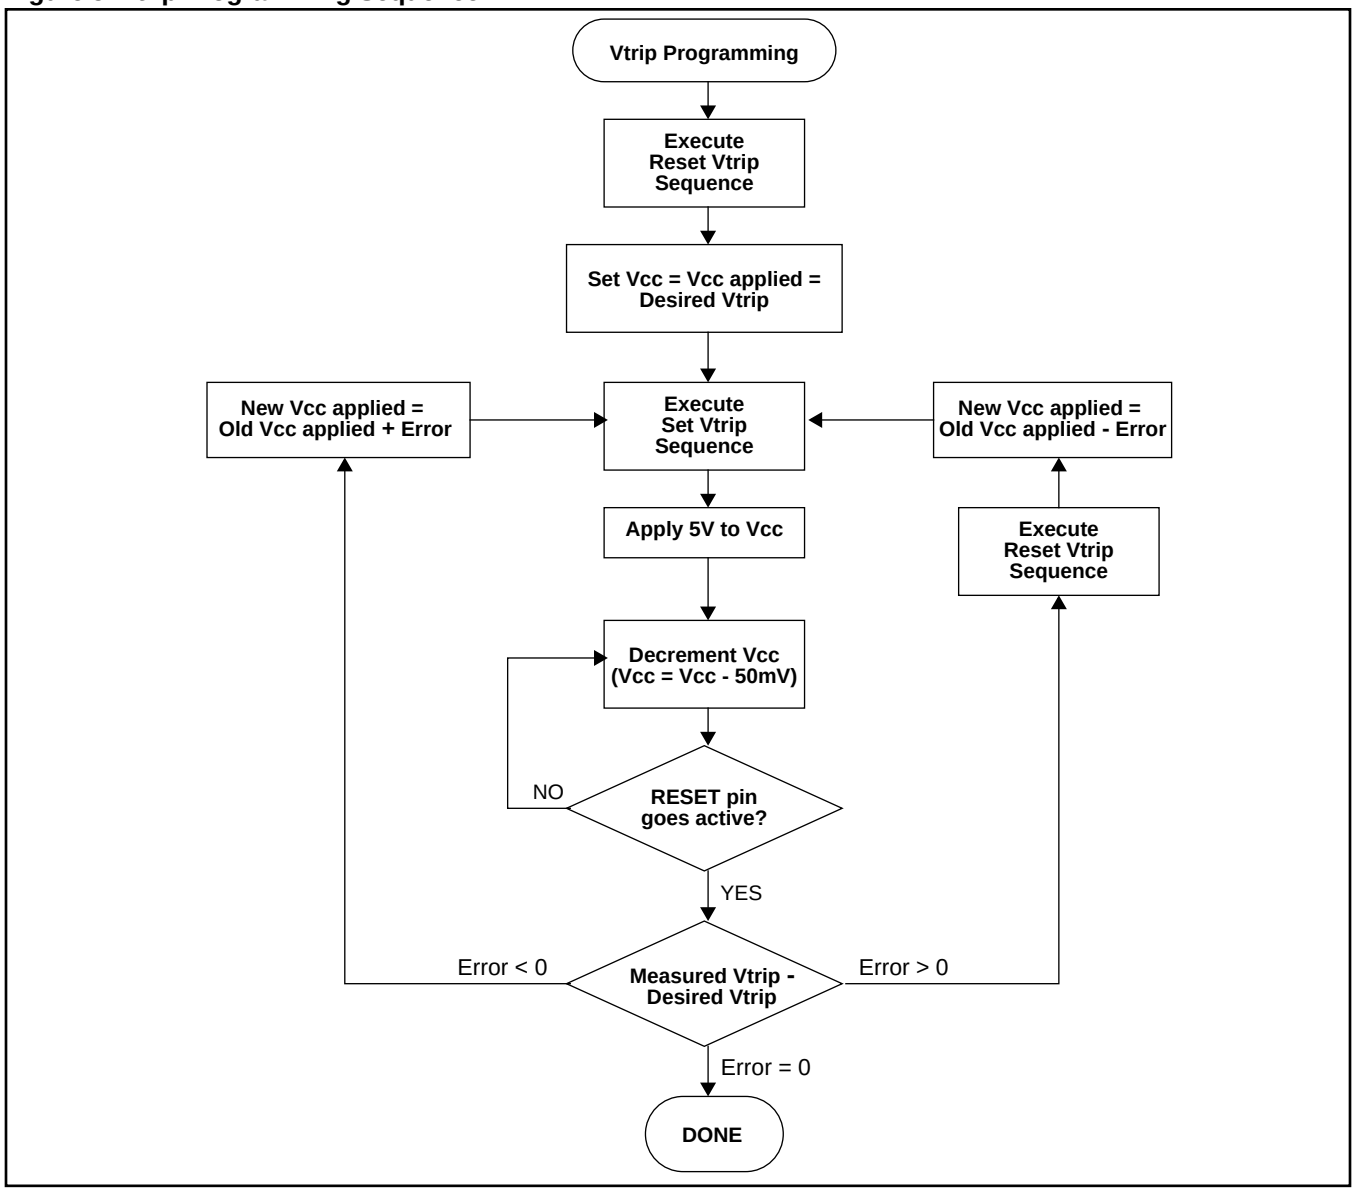

spi Interface

The device is designed to interface directly with the synchronous Serial Peripheral Interface (SPI) of many popular microcontroller families.

The device monitors the $\overline{CS}$/WDI line and asserts $\overline{RESET}$ output if there is no activity within user selctable time-out period. The device also monitors the Vcc supply and asserts the $\overline{RESET}$ if Vcc falls below a preset minimum (V_{TRIP}). The device contains an 8-bit Watchdog Timer Register to control the watchdog time-out period. The current settings are accessed via the SI and SO pins.

All instructions (Table 1) and data are transferred MSB first. Data input on the SI line is latched on the first rising edge of SCK after $\overline{CS}$ goes LOW. Data is output on the SO line by the falling edge of SCK. SCK is static, allowing the user to stop the clock and then start it again to resume operations where left off.

Watchdog Timer Register

7	6	5	4	3	2	1	0
0	0	0	WD_1	WD_0	0	0	0

Watchdog Timer Control Bits

The Watchdog Timer Control bits, WD_0 and WD_1, select the Watchdog Time-out Period. These nonvolatile bits are programmed with the Set Watchdog Timer (SWDT) instruction.

Watchdog Control Bits		Watchdog Time-out (Typical)
WD1	WD0	
0	0	1.4 Seconds
0	1	600 Milliseconds
1	0	200 Milliseconds
1	1	Disabled

Write Watchdog Register Operation

Changing the Watchdog Timer Register is a two step process. First, the change must be enabled with by setting the Watchdog Change Latch (see below). This instruction is followed by the Set Watchdog Timer (SWDT) instruction, which includes the data to be written (Figure 5). Data bits 3 and 4 contain the Watchdog settings and data bits 0, 1, 2, 5, 6 and 7 must be “0” .

Watchdog Change Latch

The Watchdog Change Latch must be SET before a Write Watchdog Timer Operation is initiated. The Enable Watchdog Change (EWDC) instruction will set the latch and the Disable Watchdog Change (DWDC) instruction will reset the latch (See Figure 2.) This latch is automatically reset upon a power-up condition and after the completion of a valid nonvolatile write cycle.

Read Watchdog Timer Register Operation

If there is not a nonvolatile write in progress, the Read Watchdog Timer instruction returns the setting of the watchdog timer control bits. The other bits are reserved and will return ’0’ when read. See Figure 3.

If a nonvolatile write is in progress, the Read Watchdog Timer Register Instruction returns a HIGH on SO. When the nonvolatile write cycle is completed, a seperate Read Watchdog Timer instruction should be used to determine the current status of the Watchdog control bits.

$\overline{RESET}$ Operation

The $\overline{RESET}$ (X5001) output is designed to go LOW whenever V_{CC} has dropped below the minimum trip point and/or the Watchdog timer has reached its programmable time-out limit.

The $\overline{RESET}$ output is an open drain output and requires a pull up resistor.

Operational Notes

The device powers-up in the following state:

- The device is in the low power standby state.
- A HIGH to LOW transition on $\overline{CS}$ is required to enter an active state and receive an instruction.
- SO pin is high impedance.
- The Watchdog Change Latch is reset.
- The $\overline{RESET}$ Signal is active for t_{PURST}.

Data Protection

The following circuitry has been included to prevent inadvertent writes:

- A EWDC instruction must be issued to enable a change to the watchdog timeout setting.
- $\overline{CS}$ must come HIGH at the proper clock count in order to implement the requested changes to the watchdog timeout setting.

Table 1. Instruction Set Definition

Instruction Format	Instruction Name and Operation
0000 0110	**EWDC: Enable Watchdog Change Operation**
0000 0100	**DWDC: Disable Watchdog Change Operation**
0000 0001	**SWDT: Set Watchdog Timer control bits:** Instruction followed by contents of register: 000(WD_1) (WD_0)000 See Watchdog Timer Settings and Figure 3.
0000 0101	**RWDT: Read Watchdog Timer control bits**

Notes: Instructions are shown with MSB in leftmost position. Instructions are transferred MSB first.
