

**FEATURES**

JESD204B (Subclass 1) coded serial digital outputs

Lane rates up to 15 Gbps

1.66 W total power at 500 MSPS

415 mW per analog-to-digital converter (ADC) channel

SFDR = 82 dBFS at 305 MHz (1.80 V p-p input range)

SNR = 66.8 dBFS at 305 MHz (1.80 V p-p input range)

Noise density = -151.5 dBFS/Hz (1.80 V p-p input range)

0.975 V, 1.8 V, and 2.5 V dc supply operation

No missing codes

Internal ADC voltage reference

Analog input buffer

On-chip dithering to improve small signal linearity

Flexible differential input range

1.44 V p-p to 2.16 V p-p (1.80 V p-p nominal)

1.4 GHz analog input full power bandwidth

Amplitude detect bits for efficient AGC implementation

4 integrated wideband digital processors

48-bit NCO, up to 4 cascaded half-band filters

Differential clock input

Integer clock divide by 1, 2, 4, or 8

On-chip temperature diode

Flexible JESD204B lane configurations

**APPLICATIONS**

Communications

Diversity multiband, multimode digital receivers

3G/4G, W-CDMA, GSM, LTE, LTE-A

General-purpose software radios

Ultrawideband satellite receivers

Instrumentation

Radars

Signals intelligence (SIGINT)

## REVISION HISTORY

10/2016—Revision 0: Initial Version

## GENERAL DESCRIPTION

The [AD9694](#) is a quad, 14-bit, 500 MSPS analog-to-digital converter (ADC). The device has an on-chip buffer and a sample-and-hold circuit designed for low power, small size, and ease of use. This device is designed for sampling wide bandwidth analog signals of up to 1.4 GHz. The [AD9694](#) is optimized for wide input bandwidth, high sampling rate, excellent linearity, and low power in a small package.

The quad ADC cores feature a multistage, differential pipelined architecture with integrated output error correction logic. Each ADC features wide bandwidth inputs supporting a variety of user-selectable input ranges. An integrated voltage reference eases design considerations.

The analog inputs and clock signals are differential inputs. Each pair of ADC data outputs is internally connected to two DDCs through a crossbar mux. Each DDC consists of up to five cascaded signal processing stages: a 48-bit frequency translator, NCO, and up to four half-band decimation filters.

In addition to the DDC blocks, the [AD9694](#) has several functions that simplify the automatic gain control (AGC) function in the communications receiver. The programmable threshold detector allows monitoring of the incoming signal power using the fast detect output bits of the ADC. If the input signal level exceeds the programmable threshold, the fast detect indicator goes high. Because this threshold indicator has low latency, the user can quickly turn down the system gain to avoid an overrange condition at the ADC input.

Users can configure each pair of intermediate frequency (IF) receiver outputs onto either one or two lanes of Subclass 1 JESD204B-based high speed serialized outputs, depending on the decimation ratio and the acceptable lane rate of the receiving logic device. Multiple device synchronization is supported through the SYSREF±, SYNCINB±AB, and SYNCINB±CD input pins.

The [AD9694](#) has flexible power-down options that allow significant power savings when desired. All of these features can be programmed using the 1.8 V capable, 3-wire SPI.

The [AD9694](#) is available in a Pb-free, 72-lead LFCSP and is specified over the  $-40^{\circ}\text{C}$  to  $+105^{\circ}\text{C}$  junction temperature range. This product may be protected by one or more U.S. or international patents.

## PRODUCT HIGHLIGHTS

1. Low power consumption per channel.
2. JESD204B lane rate support up to 15 Gbps.
3. Wide full power bandwidth supports IF sampling of signals up to 1.4 GHz.
4. Buffered inputs ease filter design and implementation.
5. Four integrated wideband decimation filters and numerically controlled oscillator (NCO) blocks supporting multiband receivers.
6. Programmable fast overrange detection.
7. On-chip temperature diode for system thermal management.

## SPECIFICATIONS

### DC SPECIFICATIONS

AVDD1 = 0.975 V, AVDD1\_SR = 0.975 V, AVDD2 = 1.8 V, AVDD3 = 2.5 V, DVDD = 0.975 V, DRVDD1 = 0.975 V, DRVDD2 = 1.8 V, SPIVDD = 1.8 V, 500 MSPS, clock divider = 4, 1.8 V p-p full-scale differential input, 0.5 V internal reference,  $A_{IN} = -1.0$  dBFS, default SPI settings, unless otherwise noted. Minimum and maximum specifications are guaranteed for the full operating junction temperature ( $T_j$ ) range of  $-40^{\circ}\text{C}$  to  $+105^{\circ}\text{C}$ . Typical specifications represent performance at  $T_j = 50^{\circ}\text{C}$  ( $T_A = 25^{\circ}\text{C}$ ).

Table 1.

Parameter	Min	Typ	Max	Unit
RESOLUTION	14			Bits
ACCURACY				
No Missing Codes		Guaranteed		
Offset Error		0		% FSR
Offset Matching		0		% FSR
Gain Error	-5.0		+5.0	% FSR
Gain Matching		1.0		% FSR
Differential Nonlinearity (DNL)	-0.7	$\pm 0.4$	+0.7	LSB
Integral Nonlinearity (INL)	-5.1	$\pm 1.0$	+5.1	LSB

Rise Time ( $t_R$ ) (20% to 80% into 100 $\Omega$ Load)		31.25		ps
Fall Time ( $t_F$ ) (20% to 80% into 100 $\Omega$ Load)		31.37		ps
PLL Lock Time		5		ms
Data Rate per Channel (Nonreturn-to-Zero (NRZ)) <sup>4</sup>	1.5625	10	15	Gbps

Parameter	Min	Typ	Max	Unit
LATENCY <sup>5</sup>				
Pipeline Latency		54		Sample clock cycles
Fast Detect Latency			30	Sample clock cycles
APERTURE				
Aperture Delay ( $t_A$ )		160		ps
Aperture Uncertainty (Jitter, $t_j$ )		44		fs rms
Out of Range Recovery Time		1		Sample clock cycles

<sup>1</sup> The maximum sample rate is the clock rate after the divider.  
<sup>2</sup> The minimum sample rate operates at 240 MSPS with  $L = 2$  or  $L = 1$ . See SPI Register 0x011A to reduce the threshold of the clock detect circuit.  
<sup>3</sup> Baud rate =  $1/UL$ . A subset of this range can be supported.  
<sup>4</sup> Default  $L = 2$  for each link. This number can be changed based on the sample rate and decimation ratio.  
<sup>5</sup> No DDCs used.  $L = 2$ ,  $M = 2$ ,  $F = 2$  for each link.

**TIMING SPECIFICATIONS**

Table 7.

Parameter	Test Conditions/Comments	Min	Typ	Max	Unit
CLK+ to SYSREF+ TIMING REQUIREMENTS	See Figure 3				
$t_{SU\_SR}$	Device clock to SYSREF+ setup time		-44.8		ps
$t_{H\_SR}$	Device clock to SYSREF+ hold time		64.4		ps
SPI TIMING REQUIREMENTS	See Figure 4				
$t_{DS}$	Setup time between the data and the rising edge of SCLK	4			ns
$t_{DH}$	Hold time between the data and the rising edge of SCLK	2			ns
$t_{CLK}$	Period of the SCLK	40			ns
$t_S$	Setup time between CSB and SCLK	2			ns
$t_H$	Hold time between CSB and SCLK	2			ns
$t_{HIGH}$	Minimum period that SCLK must be in a logic high state	10			ns
$t_{LOW}$	Minimum period that SCLK must be in a logic low state	10			ns
$t_{ACCESS}$	Maximum time delay between falling edge of SCLK and output data valid for a read operation		6	10	ns
$t_{DIS\_SDIO}$	Time required for the SDIO pin to switch from an output to an input relative to the CSB rising edge (not shown in Figure 4)	10			ns

Environmental	
Operating Junction Temperature Range	−40°C to +105°C
Maximum Junction Temperature	125°C
Storage Temperature Range (Ambient)	−65°C to +150°C

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Careful attention to PCB thermal design is required.

$\theta_{JA}$  is the natural convection junction to ambient thermal resistance measured in a one cubic foot sealed enclosure.

$\theta_{JC\_BOT}$  is the bottom junction to case thermal resistance.

Table 9. Thermal Resistance

PCB Type	Airflow Velocity (m/sec)	$\theta_{JA}$	$\theta_{JC\_BOT}$	Unit
JEDEC 2s2p Board	0.0	21.58 <sup>1,2</sup>	1.95 <sup>1,5</sup>	°C/W
	1.0	17.94 <sup>1,2</sup>	N/A <sup>4</sup>	°C/W
	2.5	16.58 <sup>1,2</sup>	N/A <sup>4</sup>	°C/W
10-Layer Board	0.0	9.74	1.00	°C/W

<sup>1</sup> Per JEDEC 51-7, plus JEDEC 51-5 2s2p test board.

<sup>2</sup> Per JEDEC JESD51-2 (still air) or JEDEC JESD51-6 (moving air).

<sup>3</sup> Per JEDEC JESD51-8 (still air).

<sup>4</sup> N/A means not applicable.

<sup>5</sup> Per MIL-STD 883, Method 1012.1.

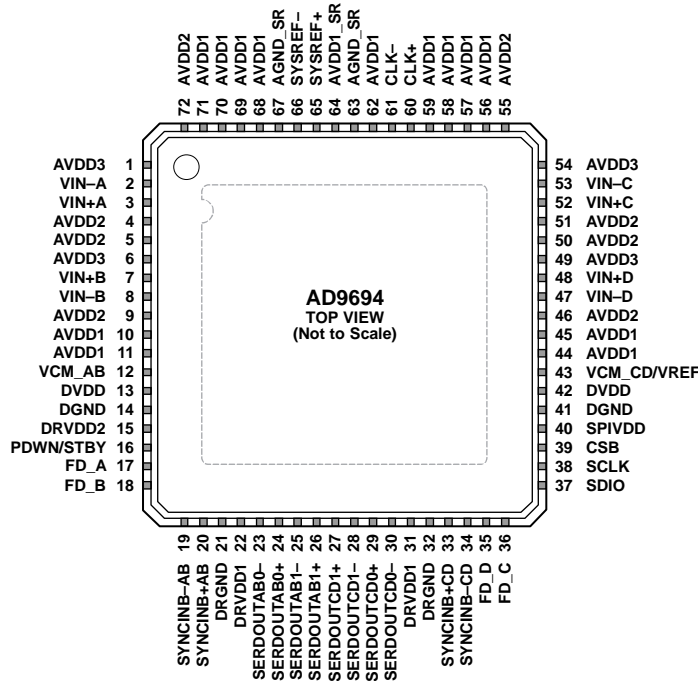

## ESD CAUTION

### ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

# PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

- NOTES**
1. EXPOSED PAD. ANALOG GROUND. THE EXPOSED THERMAL PAD ON THE BOTTOM OF THE PACKAGE PROVIDES THE GROUND REFERENCE FOR AVDDx, SPIVDD, DVDD, DRVDD1, AND DRVDD2. THIS EXPOSED PAD MUST BE CONNECTED TO GROUND FOR PROPER OPERATION.

Figure 5. Pin Configuration (Top View)

Table 10. Pin Function Descriptions

Pin No.	Mnemonic	Type	Description
0	AGND/EPAD	Ground	Exposed Pad. Analog Ground. The exposed thermal pad on the bottom of the package provides the ground reference for AVDDx, SPIVDD, DVDD, DRVDD1, and DRVDD2. This exposed pad must be connected to ground for proper operation.
1, 6, 49, 54	AVDD3	Supply	Analog Power Supply (2.5 V Nominal).
2, 3	VIN-A, VIN+A	Input	ADC A Analog Input Complement/True.
4, 5, 9, 46, 50, 51, 55, 72	AVDD2	Supply	Analog Power Supply (1.8 V Nominal).
7, 8	VIN+B, VIN-B	Input	ADC B Analog Input True/Complement.
10, 11, 44, 45, 56, 57, 58, 59, 62, 68, 69, 70, 71	AVDD1	Supply	Analog Power Supply (0.975 V Nominal).
12	VCM_AB	Output	Common-Mode Level Bias Output for Analog Input Channel A and Channel B.
13, 42	DVDD	Supply	Digital Power Supply (0.975 V Nominal).
14, 41	DGND	Ground	Ground Reference for DVDD and SPIVDD.
15	DRVDD2	Supply	Digital Power Supply for JESD204B PLL (1.8 V Nominal).
16	PDWN/STBY	Input	Power-Down Input (Active High). The operation of this pin depends on the SPI mode and can be configured as power-down or standby. Requires external 10 kΩ pull-down resistor.
17, 18, 35, 36	FD_A, FD_B, FD_D, FD_C	Output	Fast Detect Outputs for Channel A, Channel B, Channel C, and Channel D.
19	SYNCINB-AB	Input	Active Low JESD204B LVDS Sync Input Complement for Channel A and Channel B.
20	SYNCINB+AB	Input	Active Low JESD204B LVDS/CMOS Sync Input True for Channel A and Channel B.

Pin No.	Mnemonic	Type	Description
21, 32	DRGND	Ground	Ground Reference for DRVDD1 and DRVDD2.
22, 31	DRVDD1	Supply	Digital Power Supply for SERDOUT Pins (0.975 V Nominal).
23, 24	SERDOUTAB0-, SERDOUTAB0+	Output	Lane 0 Output Data Complement/True for Channel A and Channel B.
25, 26	SERDOUTAB1-, SERDOUTAB1+	Output	Lane 1 Output Data Complement/True for Channel A and Channel B.
27, 28	SERDOUTCD1+, SERDOUTCD1-	Output	Lane 1 Output Data True/Complement for Channel C and Channel D.
29, 30	SERDOUTCD0+, SERDOUTCD0-	Output	Lane 0 Output Data True/Complement for Channel C and Channel D.
33	SYNCINB+CD	Input	Active Low JESD204B LVDS/CMOS Sync Input True for Channel C and Channel D.
34	SYNCINB-CD	Input	Active Low JESD204B LVDS Sync Input Complement for Channel C and Channel D.
37	SDIO	Input/output	SPI Serial Data Input/Output.
38	SCLK	Input	SPI Serial Clock.
39	CSB	Input	SPI Chip Select (Active Low).
40	SPIVDD	Supply	Digital Power Supply for SPI (1.8 V Nominal).
43	VCM_CD/VREF	Output/input	Common-Mode Level Bias Output for Analog Input Channel C and Channel D/0.5 V Reference Voltage Input. This pin is configurable through the SPI as an output or an input. Use this pin as the common-mode level bias output if using the internal reference. This pin requires a 0.5 V reference voltage input if using an external voltage reference source.
47, 48	VIN-D, VIN+D	Input	ADC D Analog Input Complement/True.
52, 53	VIN+C, VIN-C	Input	ADC C Analog Input True/Complement.
60, 61	CLK+, CLK-	Input	Clock Input True/Complement.
63, 67	AGND_SR	Ground	Ground Reference for SYSREF±.
64	AVDD1_SR	Supply	Analog Power Supply for SYSREF± (0.975 V Nominal).
65, 66	SYSREF+, SYSREF-	Input	Active Low JESD204B LVDS System Reference Input True/Complement. DC-coupled input only.

### TYPICAL PERFORMANCE CHARACTERISTICS

AVDD1 = 0.975 V, AVDD1\_SR = 0.975 V, AVDD2 = 1.80 V, AVDD3 = 2.5 V, DVDD = 0.975 V, DRVDD1 = 0.975 V, DRVDD2 = 1.8 V, SPIVDD = 1.8 V, specified maximum sampling rate, clock divider = 4, 1.8 V p-p full-scale differential input, 0.5 V internal reference,  $A_{IN} = -1.0$  dBFS, default SPI settings, unless otherwise noted. Minimum and maximum specifications are guaranteed for the full operating junction temperature ( $T_J$ ) range of  $-40^{\circ}\text{C}$  to  $+105^{\circ}\text{C}$ . Typical specifications represent performance at  $T_J = 50^{\circ}\text{C}$  ( $T_A = 25^{\circ}\text{C}$ ).

## THEORY OF OPERATION

### ADC ARCHITECTURE

The architecture of the AD9694 consists of an input buffered pipelined ADC. The input buffer is designed to provide a 200  $\Omega$  termination impedance to the analog input signal. The equivalent circuit diagram of the analog input termination is shown in Figure 44.

The input buffer provides a linear high input impedance (for ease of drive) and reduces kickback from the ADC. The buffer is optimized for high linearity, low noise, and low power. The quantized outputs from each stage are combined into a final 14-bit result in the digital correction logic. The pipelined architecture permits the first stage to operate with a new input sample while at the same time, the remaining stages operate with the preceding samples. Sampling occurs on the rising edge of the clock.

### ANALOG INPUT CONSIDERATIONS

The analog input to the AD9694 is a differential buffer with an internal common-mode voltage of 1.35 V. The clock signal alternately switches the input circuit between sample mode and hold mode. Either a differential capacitor or two single-ended capacitors can be placed on the inputs to provide a matching passive network. This configuration ultimately creates a low-pass filter at the input, which limits unwanted broadband noise. See Figure 74 and Figure 75 for details on input network recommendations.

For best dynamic performance, the source impedances driving VIN+x and VIN-x must be matched such that common-mode settling errors are symmetrical. These errors are reduced by the common-mode rejection of the ADC. An internal reference buffer creates a differential reference that defines the span of the ADC core.

Maximum SNR performance is achieved by setting the ADC to the largest span in a differential configuration. In the case of the AD9694, the available span is programmable through the SPI port from 1.44 V p-p to 2.16 V p-p differential, with 1.80 V p-p differential being the default.

### Dither

The AD9694 has internal on-chip dither circuitry that improves the ADC linearity and SFDR particularly at smaller signal levels. A known but random amount of white noise is injected into the input of the AD9694. This dither improves the small signal linearity within the ADC transfer function and is precisely subtracted out digitally. The dither is turned on by default and does not reduce the ADC input dynamic range. The data sheet specifications and limits are obtained with the dither turned on. The dither can be disabled using SPI writes to Register 0x0922. Disabling the dither can slightly improve the SNR (by about 0.2 dB) at the expense of the small signal SFDR.

### Differential Input Configurations

There are several ways to drive the AD9694, either actively or passively. However, optimum performance is achieved by driving the analog input differentially.

For applications where SNR and SFDR are key parameters, differential transformer coupling is the recommended input configuration (see Figure 55 and Figure 56) because the noise performance of most amplifiers is not adequate to achieve the true performance of the AD9694.

For low to midrange frequencies, a double balun or double transformer network (see Figure 55) is recommended for optimum performance of the AD9694. For higher frequencies in the second or third Nyquist zones, it is better to remove some of the front-end passive components to ensure wideband operation (see Figure 56).

Figure 55. Differential Transformer Coupled Configuration for First and Second Nyquist Frequencies

Figure 56. Differential Transformer Coupled Configuration for Third and Fourth Nyquist Zones

**Input Common Mode**

The analog inputs of the AD9694 are internally biased to the common mode as shown in Figure 57.

For dc-coupled applications, the recommended operation procedure is to export the common-mode voltage to the VCM\_CD/VREF pin using the SPI writes listed in this section. The common-mode voltage must be set by the exported value to ensure proper ADC operation. Disconnect the internal common-mode buffer from the analog input using Register 0x1908.

When performing SPI writes for dc coupling operation, use the following register settings in order:

1. Set Register 0x1908, Bit 2 to 1 to disconnect the internal common-mode buffer from the analog input.
2. Set Register 0x18A6 to 0x00 to turn off the voltage reference.
3. Set Register 0x18E6 to 0x00 to turn off the temperature diode export.
4. Set Register 0x18E0 to 0x04.
5. Set Register 0x18E1 to 0x1C.
6. Set Register 0x18E2 to 0x14.
7. Set Register 0x18E3, Bit 6 to 0x01 to turn on the VCM export.
8. Set Register 0x18E3, Bits[5:0] to the buffer current setting (copy the buffer current setting from Register 0x1A4C and Register 0x1A4D to improve the accuracy of the common-mode export).

**Analog Input Controls and SFDR Optimization**

The AD9694 offers flexible controls for the analog inputs, such as buffer current and input full-scale adjustment. All of the available controls are shown in Figure 57.

Figure 57. Analog Input Controls

Using Register 0x1A4C and Register 0x1A4D, the buffer currents on each channel can be scaled to optimize the SFDR over various input frequencies and bandwidths of interest. As the input buffer currents are set, the amount of current required by the AVDD3 supply changes. This relationship is shown in Figure 58. For a complete list of buffer current settings, see Table 38.

Figure 58. AVDD3 Power vs. Buffer Current Setting

In certain high frequency applications, the SFDR can be improved by reducing the full-scale setting.

Table 11 shows the recommended buffer current settings for the different analog input frequency ranges.

**Table 11. SFDR Optimization for Input Frequencies**

Nyquist Zone	Input Buffer Current Control Setting, Register 0x1A4C and Register 0x1A4D
First, Second, and Third Nyquist	240 (Register 0x1A4C, Bits[5:0] = Register 0x1A4D, Bits[5:0] = 01100)
Fourth Nyquist	400 (Register 0x1A4C, Bits[5:0] = Register 0x1A4D, Bits[5:0] = 10100)

**Absolute Maximum Input Swing**

The absolute maximum input swing allowed at the inputs of the AD9694 is 4.3 V p-p differential. Signals operating near or at this level can cause permanent damage to the ADC.

**VOLTAGE REFERENCE**

A stable and accurate 0.5 V voltage reference is built into the AD9694. This internal 0.5 V reference is used to set the full-scale input range of the ADC. The full-scale input range can be adjusted via the ADC function register (Register 0x1910). For more information on adjusting the input swing, see Table 38. Figure 59 shows the block diagram of the internal 0.5 V reference controls.

Figure 59. Internal Reference Configuration and Controls

Figure 60. External Reference Using the ADR130

Register 0x18A6 enables the user to either use this internal 0.5 V reference, or to provide an external 0.5 V reference. When using an external voltage reference, provide a 0.5 V reference. The full-scale adjustment is made using the SPI, irrespective of the reference voltage. For more information on adjusting the full-scale level of the AD9694, refer to the Memory Map section.

The SPI writes required to use the external voltage reference, in order, are as follows:

1. Set Register 0x18E3 to 0x00 to turn off VCM export.
2. Set Register 0x18E6 to 0x00 to turn off temperature diode export.
3. Set Register 0x18A6 to 0x01 to turn on the external voltage reference.

The use of an external reference may be necessary, in some applications, to enhance the gain accuracy of the ADC or to improve thermal drift characteristics.

The external reference has to be a stable 0.5 V reference. The ADR130 is a good option for providing the 0.5 V reference. Figure 60 shows how the ADR130 can be used to provide the external 0.5 V reference to the AD9694. The grayed out areas show unused blocks within the AD9694 while using the ADR130 to provide the external reference.

### DC OFFSET CALIBRATION

The AD9694 contains a digital filter to remove the average dc offset from the output of the ADC. For ac-coupled applications, this filter can be enabled by writing 0x86 to Register 0x0701. The filter computes the average dc signal and it is digitally subtracted from the ADC output. As a result, the dc offset is improved to better than 70 dBFS at the output. Because the filter does not distinguish between the source of dc signals, this feature can be used when the signal content at dc is not of interest. The filter corrects dc up to 512 codes and saturates beyond that.

### CLOCK INPUT CONSIDERATIONS

For optimum performance, drive the AD9694 sample clock inputs (CLK+ and CLK-) with a differential signal. This signal is typically ac-coupled to the CLK+ and CLK- pins via a transformer or clock drivers. These pins are biased internally and require no additional biasing.

Figure 61 shows a preferred method for clocking the AD9694. The low jitter clock source is converted from a single-ended signal to a differential signal using an RF transformer.

Figure 61. Transformer-Coupled Differential Clock

Another option is to ac couple a differential CML or LVDS signal to the sample clock input pins, as shown in Figure 62 and Figure 63.

Figure 62. Differential CML Sample Clock

150Ω RESISTORS ARE OPTIONAL.

Figure 63. Differential LVDS Sample Clock

### Clock Duty Cycle Considerations

Typical high speed ADCs use both clock edges to generate a variety of internal timing signals. The AD9694 contains an internal clock divider and a duty cycle stabilizer (DCS). In applications where the clock duty cycle cannot be guaranteed to be 50%, a higher multiple frequency clock along with the usage of the clock divider is recommended. When it is not possible to provide a higher frequency clock, it is recommended to turn on the DCS using Register 0x011C. The output of the divider offers a 50% duty cycle, high slew rate (fast edge) clock signal to the internal ADC. See the Memory Map section for more details on using this feature.

### Input Clock Divider

The AD9694 contains an input clock divider with the ability to divide the input clock by 1, 2, 4, and 8. The divider ratios can be selected using Register 0x0108 (see Figure 64).

In applications where the clock input is a multiple of the sample clock, care must be taken to program the appropriate divider ratio into the clock divider before applying the clock signal, which ensures that the current transients during device startup are controlled.

Figure 64. Clock Divider Circuit

The AD9694 clock divider can be synchronized using the external SYSREF± input. A valid SYSREF± causes the clock divider to reset to a programmable state. This synchronization feature allows multiple devices to have their clock dividers aligned to guarantee simultaneous input sampling.

### Clock Jitter Considerations

High speed, high resolution ADCs are sensitive to the quality of the clock input. The degradation in SNR at a given input frequency ( $f_A$ ) due only to aperture jitter ( $t_j$ ) can be calculated by

$$SNR = -20 \times \log(2 \times \pi \times f_A \times t_j)$$

In this equation, the rms aperture jitter represents the root mean square of all jitter sources, including the clock input, analog input signal, and ADC aperture jitter specifications. IF undersampling applications are particularly sensitive to jitter (see Figure 65).

Figure 65. Ideal SNR vs. Analog Input Frequency over Jitter

Treat the clock input as an analog signal in cases where aperture jitter may affect the dynamic range of the AD9694. Separate the power supplies for clock drivers from the ADC output driver supplies to avoid modulating the clock signal with digital noise. If the clock is generated from another type of source (by gating, dividing, or other methods), retime the clock by the original clock at the last step. Refer to the AN-501 Application Note and the AN-756 Application Note for more in depth information about jitter performance as it relates to ADCs.

Figure 65 shows the estimated SNR of the AD9694 across input frequency for different clock induced jitter values. The SNR can be estimated by using the following equation:

$$SNR(\text{dBFS}) = -10 \log \left( 10^{\left( \frac{-SNR_{ADC}}{10} \right)} + 10^{\left( \frac{-SNR_{JITTER}}{10} \right)} \right)$$

### Power-Down/Standby Mode

The AD9694 has a PDWN/STBY pin that configures the device in power-down or standby mode. The default operation is power-down. The PDWN/STBY pin is a logic high pin. When in power-down mode, the JESD204B link is disrupted. The power-down option can also be set via Register 0x003F and Register 0x0040.

In standby mode, the JESD204B link is not disrupted and transmits zeros for all converter samples. This state can be changed using Register 0x0571, Bit 7 to select /K/ characters.

### Temperature Diode

The AD9694 contains a diode-based temperature sensor for measuring the temperature of the die. This diode can output a voltage and serve as a coarse temperature sensor to monitor the internal die temperature.

The temperature diode voltage can be output to the VCM\_CD/VREF pin using the SPI. Use Register 0x18E6 to enable or disable the diode. Register 0x18E6 is a local register. Both cores must be selected in the core index register (Register 0x0009 = 0x03) to enable the temperature diode readout. It is important to note that other voltages may be exported to the same pin at the same time, which can result in undefined behavior. Thus, to ensure a proper readout, switch off all other voltage exporting circuits as detailed as follows.

The SPI writes required to export the temperature diode are as follows (see Table 38 for more information):

1. Set Register 0x0009 to 0x03 to select both cores.
2. Set Register 0x18E3 to 0x00 to turn off the VCM export.
3. Set Register 0x18A6 to 0x00 to turn off the voltage reference. Set Register 0x18E6 to 0x01 to turn on temperature diode export. The typical voltage response of the temperature diode is shown in Figure 66. However, it is recommended to take measurements from a pair of diodes into account introducing another step.
4. Set Register 0x18E6 to 0x02 to turn on the second temperature diode (that is 20× the size) of the pair.

For the method utilizing two diodes simultaneously to provide a more accurate result, see the [AN-1432 Application Note](#), *Practical Thermal Modeling and Measurements in High Power ICs*.

Figure 66. Temperature Diode Voltage vs. Junction Temperature

## ADC OVERRANGE AND FAST DETECT

In receiver applications, it is desirable to have a mechanism to reliably determine when the converter is about to be clipped. The standard overrange bit in the JESD204B outputs provides information on the state of the analog input that is of limited usefulness. Therefore, it is helpful to have a programmable threshold below full scale that allows time to reduce the gain before the clip actually occurs. In addition, because input signals can have significant slew rates, the latency of this function is of major concern. Highly pipelined converters can have significant latency. The AD9694 contains fast detect circuitry for individual channels to monitor the threshold and to assert the FD\_A, FD\_B, FD\_C, and FD\_D pins.

### ADC OVERRANGE

The ADC overrange indicator is asserted when an overrange is detected on the input of the ADC. The overrange indicator can be embedded within the JESD204B link as a control bit (when CSB > 0). The latency of this overrange indicator matches the sample latency.

### FAST THRESHOLD DETECTION (FD\_A, FD\_B, FD\_C, AND FD\_D)

The fast detect (FD) bits in Register 0x0040 are immediately set whenever the absolute value of the input signal exceeds the programmable upper threshold level. The FD bits are cleared only when the absolute value of the input signal drops below the lower threshold level for greater than the programmable dwell time. This feature provides hysteresis and prevents the FD bits from excessively toggling.

The operation of the upper threshold and lower threshold registers, along with the dwell time registers, is shown in Figure 67.

The FD indicator is asserted if the input magnitude exceeds the value programmed in the fast detect upper threshold registers, located at Register 0x0247 and Register 0x0248. The selected threshold register is compared with the signal magnitude at the output of the ADC. The fast upper threshold detection has a latency of 30 clock cycles (maximum). The approximate upper threshold magnitude is defined by

$$\text{Upper Threshold Magnitude (dBFS)} = 20 \log (\text{Threshold Magnitude} / 2^{13})$$

The FD indicators are not cleared until the signal drops below the lower threshold for the programmed dwell time. The lower threshold is programmed in the fast detect lower threshold registers, located at Register 0x0249 and Register 0x024A. The fast detect lower threshold register is a 13-bit register that is compared with the signal magnitude at the output of the ADC. This comparison is subject to the ADC pipeline latency, but is accurate in terms of converter resolution. The lower threshold magnitude is defined by

$$\text{Lower Threshold Magnitude (dBFS)} = 20 \log (\text{Threshold Magnitude} / 2^{13})$$

For example, to set an upper threshold of -6 dBFS, write 0xFFFF to Register 0x0247 and Register 0x0248. To set a lower threshold of -10 dBFS, write 0xA1D to Register 0x0249 and Register 0x024A.

The dwell time can be programmed from 1 to 65,535 sample clock cycles by placing the desired value in the fast detect dwell time registers, located at Register 0x024B and Register 0x024C. See the Memory Map section (Register 0x0040, and Register 0x0245 to Register 0x024C in Table 38) for more details.

Figure 67. Threshold Settings for the FD\_A and FD\_B Signals

## SIGNAL MONITOR

The signal monitor block provides additional information about the signal being digitized by the ADC. The signal monitor computes the peak magnitude of the digitized signal. This information can be used to drive an AGC loop to optimize the range of the ADC in the presence of real-world signals.

The results of the signal monitor block can be obtained either by reading back the internal values from the SPI port or by embedding the signal monitoring information into the JESD204B interface as special control bits. A global, 24-bit programmable period controls the duration of the measurement. Figure 68 shows the simplified block diagram of the signal monitor block.

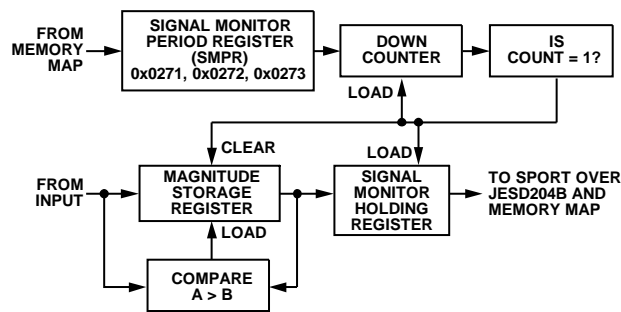

Figure 68. Signal Monitor Block

The peak detector captures the largest signal within the observation period. The detector only observes the magnitude of the signal. The resolution of the peak detector is a 13-bit value, and the observation period is 24 bits and represents converter output samples. The peak magnitude can be derived by using the following equation:

$$\text{Peak Magnitude (dBFS)} = 20\log(\text{Peak Detector Value}/2^{13})$$

The magnitude of the input port signal is monitored over a programmable time period, which is determined by the signal monitor period register (SMPR). The peak detector function is enabled by setting Bit 1 of Register 0x0270 in the signal monitor control register. The 24-bit SMPR must be programmed before activating this mode.

After enabling peak detection mode, the value in the SMPR is loaded into a monitor period timer, which decrements at the decimated clock rate. The magnitude of the input signal is

compared with the value in the internal magnitude storage register (not accessible to the user), and the greater of the two is updated as the current peak level. The initial value of the magnitude storage register is set to the current ADC input signal magnitude. This comparison continues until the monitor period timer reaches a count of 1.

When the monitor period timer reaches a count of 1, the 13-bit peak level value is transferred to the signal monitor holding register, which can be read through the memory map or output through the SPORT over the JESD204B interface. The monitor period timer is reloaded with the value in the SMPR, and the countdown restarts. In addition, the magnitude of the first input sample is updated in the magnitude storage register, and the comparison and update procedure, as explained in the Fast Threshold Detection (FD\_A, FD\_B, FD\_C, and FD\_D) section, continues.

### SPORT OVER JESD204B

The signal monitor data can also be serialized and sent over the JESD204B interface as control bits. These control bits must be deserialized from the samples to reconstruct the statistical data. The signal control monitor function is enabled by setting Bits[1:0] of Register 0x0279 and Bit 1 of Register 0x027A. Figure 69 shows two different example configurations for the signal monitor control bit locations inside the JESD204B samples. A maximum of three control bits can be inserted into the JESD204B samples; however, only one control bit is required for the signal monitor. Control bits are inserted from MSB to LSB. If only one control bit is to be inserted (CS = 1), only the most significant control bit is used (see Example Configuration 1 and Example Configuration 2 in Figure 69). To select the SPORT over JESD204B option, program Register 0x0559, Register 0x055A, and Register 0x058F. See Table 39 for more information on setting these bits.

Figure 70 shows the 25-bit frame data that encapsulates the peak detector value. The frame data is transmitted MSB first with five 5-bit subframes. Each subframe contains a start bit that can be used by a receiver to validate the deserialized data. Figure 71 shows the SPORT over JESD204B signal monitor data with a monitor period timer set to 80 samples.

## DIGITAL DOWNCONVERTER (DDC)

The AD9694 includes four digital downconverters (DDCs) that provide filtering and reduce the output data rate. This digital processing section includes an NCO, a half-band decimating filter, a finite impulse response (FIR\_ filter, a gain stage, and a complex to real conversion stage. Each of these processing blocks has control lines that allow it to be independently enabled and disabled to provide the desired processing function. Each pair of ADC channels has two DDCs (DDC0 and DDC1) for a total of four DDCs. The digital downconverter can be configured to output either real data or complex output data.

The DDCs output a 16-bit stream. To enable this operation, the converter number of bits, N, is set to a default value of 16, even though the analog core only outputs 14 bits. In full bandwidth operation, the ADC outputs are the 14-bit word followed by two zeros, unless the tail bits are enabled.

### DDC I/Q INPUT SELECTION

The AD9694 has four ADC channels and four DDC channels. Each DDC channel has two input ports that can be paired to support both real and complex inputs through the I/Q crossbar mux. For real signals, both DDC input ports must select the same ADC channel (that is, DDC Input Port I = ADC Channel A and DDC Input Port Q = ADC Channel A). For complex signals, each DDC input port must select different ADC channels (that is, DDC Input Port I = ADC Channel A and DDC Input Port Q = ADC Channel B or DDC Input Port I = ADC Channel C and DDC Input Port Q = ADC Channel D).

The inputs to each DDC are controlled by the DDC input selection registers (Register 0x0311 and Register 0x0331) in conjunction with the pair index register (Register 0x0009). See Table 38 for information on how to configure the DDCs.

### DDC I/Q OUTPUT SELECTION

Each DDC channel has two output ports that can be paired to support both real and complex outputs. For real output signals, only the DDC Output Port I is used (the DDC Output Port Q is invalid). For complex I/Q output signals, both DDC Output Port I and DDC Output Port Q are used.

The I/Q outputs to each DDC channel are controlled by the DDCx complex to real enable bit, Bit 3, in the DDC control registers (Register 0x0310 and Register 0x0330) in conjunction with the pair index register (Register 0x0009).

The Chip Q ignore bit in the chip mode register (Register 0x0200, Bit 5) controls the chip output muxing of all the DDC channels.

When all DDC channels use real outputs, set this bit high to ignore all DDC Q output ports. When any of the DDC channels are set to use complex I/Q outputs, the user must clear this bit to use both DDC Output Port I and DDC Output Port Q. For more information, see Figure 80.

### DDC GENERAL DESCRIPTION

The four DDC blocks are used to extract a portion of the full digital spectrum captured by the ADC(s). The DDC blocks are intended for IF sampling or oversampled baseband radios requiring wide bandwidth input signals.

Each DDC block contains the following signal processing stages:

- Frequency translation stage (optional)
- Filtering stage
- Gain stage (optional)
- Complex to real conversion stage (optional)

#### **Frequency Translation Stage (Optional)**

This stage consists of a 48-bit complex NCO and quadrature mixers that can be used for frequency translation of both real and complex input signals. This stage shifts a portion of the available digital spectrum down to baseband.

#### **Filtering Stage**

After shifting down to baseband, this stage decimates the frequency spectrum using a chain of up to four half-band low-pass filters for rate conversion. The decimation process lowers the output data rate, which in turn reduces the output interface rate.

#### **Gain Stage (Optional)**

To compensate for losses associated with mixing a real input signal down to baseband, this stage adds an additional 0 dB or 6 dB of gain.

#### **Complex to Real Conversion Stage (Optional)**

When real outputs are necessary, this stage converts the complex outputs back to real by performing an  $f_s/4$  mixing operation plus a filter to remove the complex component of the signal.

Figure 72 shows the detailed block diagram of the DDCs implemented in the AD9694.

Figure 72. DDC Detailed Block Diagram

Figure 73 shows an example usage of one of the four DDC blocks with a real input signal and four half-band filters (HB4 + HB3 + HB2 + HB1). It shows both complex (decimate by 16) and real (decimate by 8) output options.

When DDCs have different decimation ratios, the chip decimation ratio register (Register 0x0201) must be set to the lowest decimation ratio of all the DDC blocks on a per pair basis in conjunction with the pair index register (Register 0x0009). In this scenario, samples of higher decimation ratio DDCs are repeated to match the chip decimation ratio sample rate. Whenever the NCO

frequency is set or changed, the DDC soft reset must be issued. If the DDC soft reset is not issued, the output may potentially show amplitude variations.

Table 12 through Table 16 show the DDC samples when the chip decimation ratio is set to 1, 2, 4, 8, or 16, respectively. When DDCs have different decimation ratios, the chip decimation ratio must be set to the lowest decimation ratio of all the DDC channels. In this scenario, samples of higher decimation ratio DDCs are repeated to match the chip decimation ratio sample rate.

# FREQUENCY TRANSLATION

## GENERAL DESCRIPTION

Frequency translation is accomplished by using a 48-bit complex NCO with a digital quadrature mixer. This stage translates either a real or complex input signal from an IF to a baseband complex digital output (carrier frequency = 0 Hz).

The frequency translation stage of each DDC can be controlled individually and supports four different IF modes using Bits[5:4] of the DDC control registers (Register 0x0310 and Register 0x0330) in conjunction with the pair index register (Register 0x0009). These IF modes are

- Variable IF mode
- 0 Hz IF or zero IF (ZIF) mode
- $f_s/4$  Hz IF mode
- Test mode

### Variable IF Mode

NCO and mixers are enabled. NCO output frequency can be used to digitally tune the IF frequency.

### 0 Hz IF (ZIF) Mode

The mixers are bypassed, and the NCO is disabled.

### $f_s/4$ Hz IF Mode

The mixers and the NCO are enabled in special downmixing by  $f_s/4$  mode to save power.

### Test Mode

Input samples are forced to 0.9599 to positive full scale. The NCO is enabled. This test mode allows the NCOs to directly drive the decimation filters.

Figure 74 and Figure 75 show examples of the frequency translation stage for both real and complex inputs.

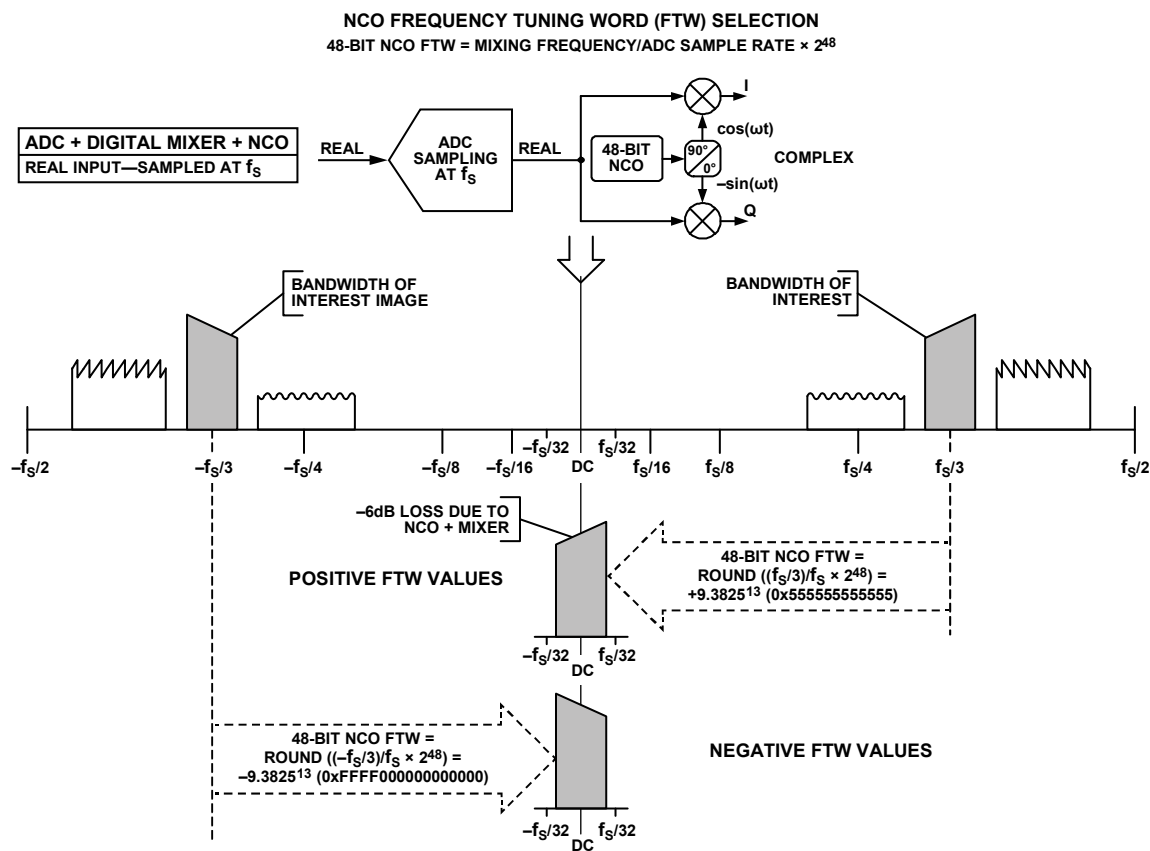

Figure 74. DDC NCO Frequency Tuning Word Selection—Real Inputs

Figure 75. DDC NCO Frequency Tuning Word Selection—Complex Inputs

14409P-058

### DDC NCO AND MIXER LOSS AND SFDR

When mixing a real input signal down to baseband, 6 dB of loss is introduced in the signal due to filtering of the negative image. An additional 0.05 dB of loss is introduced by the NCO. The total loss of a real input signal mixed down to baseband is 6.05 dB. For this reason, it is recommended that the user compensate for this loss by enabling the 6 dB of gain in the gain stage of the DDC to recenter the dynamic range of the signal within the full scale of the output bits.

When mixing a complex input signal down to baseband, the maximum value that each I/Q sample can reach is 1.414 × full scale after it passes through the complex mixer. To avoid overrange of the I/Q samples and to keep the data bit widths aligned with real mixing, 3.06 dB of loss is introduced in the mixer for complex signals. An additional 0.05 dB of loss is introduced by the NCO. The total loss of a complex input signal mixed down to baseband is -3.11 dB.

The worst case spurious signal from the NCO is greater than 102 dBc SFDR for all output frequencies.

### NUMERICALLY CONTROLLED OSCILLATOR

The AD9694 has a 48-bit NCO for each DDC that enables the frequency translation process. The NCO allows the input spectrum to be tuned to dc, where it can be effectively filtered by the subsequent filter blocks to prevent aliasing. The NCO can be set up by providing a frequency tuning word (FTW) and a phase offset word (POW).

### Setting Up the NCO FTW and POW

The NCO frequency value is given by the 32-bit two's complement number entered in the NCO FTW. Frequencies between -fs/2 and +fs/2 (fs/2 excluded) are represented using the following frequency words:

- 0x800 represents a frequency of -fs/2.
- 0x000 represents dc (frequency is 0 Hz).
- 0x7FF represents a frequency of +fs/2 - fs/2<sup>12</sup>.

The NCO frequency tuning word can be calculated using the following equation:

$$NCO\_FTW = \text{round} \left( 2^{48} \frac{\text{mod}(f_c, f_s)}{f_s} \right)$$

where:

NCO\_FTW is a 48-bit two's complement number representing the NCO FTW.

fc is the desired carrier frequency in Hz.

fs is the AD9694 sampling frequency (clock rate) in Hz.

round( ) is a rounding function. For example, round(3.6) = 4 and for negative numbers, round(-3.4) = -3.

mod( ) is a remainder function. For example, mod(110,100) = 10 and for negative numbers, mod(-32,10) = -2.

Note that this equation applies to the aliasing of signals in the digital domain (that is, aliasing introduced when digitizing analog signals).

For example, if the ADC sampling frequency ( $f_s$ ) is 500 MSPS and the carrier frequency ( $f_c$ ) is 140.312 MHz, then

$$NCO\_FTW = \text{round}\left(2^{48} \frac{\text{mod}(140.312, 500)}{500}\right) = 7.89886 \times 10^{13} \text{ Hz}$$

This, in turn, converts to 0x47D in the 12-bit twos complement representation for NCO\_FTW. The actual carrier frequency,  $f_{C\_ACTUAL}$ , is calculated based on the following equation:

$$f_{C\_ACTUAL} = \frac{NCO\_FTW \times f_s}{2^{48}} = 140.312 \text{ MHz}$$

A 48-bit POW is available for each NCO to create a known phase relationship between multiple AD9694 chips or individual DDC channels inside one AD9694 chip.

Use the following procedure to update the FTW and/or POW registers to ensure proper operation of the NCO:

1. Write to the FTW registers for all the DDCs.
2. Write to the POW registers for all the DDCs.
3. Synchronize the NCOs either through the DDC NCO soft reset bit (Register 0x0300, Bit 4), which is accessible through the SPI or through the assertion of the SYSREF± pin.

It is important to note that the NCOs must be synchronized either through the SPI or through the SYSREF± pin after all writes to the FTW or POW registers are complete. This step is necessary to ensure the proper operation of the NCO.

### NCO Synchronization

Each NCO contains a separate phase accumulator word (PAW). The initial reset value of each PAW is set to zero and the phase increment value of each PAW is determined by the FTW. The POW is added to the PAW to produce the instantaneous phase of the NCO. See the Setting Up the NCO FTW and POW section for more information.

Use the following two methods to synchronize multiple PAWs within the chip:

- Using the SPI. Use the DDC NCO soft reset bit in the DDC synchronization control register (Register 0x0300, Bit 4) to reset all the PAWs in the chip. This is accomplished by setting the DDC NCO soft reset bit high and then setting this bit low. Note that this method can only be used to synchronize DDC channels within the same pair (A/B or C/D) of a AD9694 chip.
- Using the SYSREF± pin. When the SYSREF± pin is enabled in the SYSREF± control registers (Register 0x0120 and Register 0x0121) and the DDC synchronization is enabled in the DDC synchronization control register (Register 0x0300, Bits[1:0]), any subsequent SYSREF± event resets all the PAWs in the chip. Note that this method can be used to synchronize DDC channels within the same AD9694 chip or DDC channels within separate AD9694 chips.

### Mixer

The NCO is accompanied by a mixer. Its operation is similar to an analog quadrature mixer. It performs the downconversion of input signals (real or complex) by using the NCO frequency as a local oscillator. For real input signals, this mixer performs a real mixer operation (with two multipliers). For complex input signals, the mixer performs a complex mixer operation (with four multipliers and two adders). The mixer adjusts its operation based on the input signal (real or complex) provided to each individual channel. The selection of real or complex inputs can be controlled individually for each DDC block using Bit 7 of the DDC control registers (Register 0x0310 and Register 0x0330) in conjunction with the pair index register (Register 0x0009).

## FIR FILTERS

### OVERVIEW

Four sets of decimate by 2, low-pass, half-band, finite impulse response (FIR) filters (labeled HB1 FIR, HB2 FIR, HB3 FIR, and HB4 FIR in Figure 72) follow the frequency translation stage. After the carrier of interest is tuned down to dc (carrier frequency = 0 Hz), these filters efficiently lower the sample rate, while providing sufficient alias rejection from unwanted adjacent carriers around the bandwidth of interest.

HB1 FIR is always enabled and cannot be bypassed. The HB2, HB3, and HB4 FIR filters are optional and can be bypassed for higher output sample rates.

Table 18 shows the different bandwidths selectable by including different half-band filters. In all cases, the DDC filtering stage on the AD9694 provides  $<-0.001$  dB of pass-band ripple and  $>100$  dB of stop band alias rejection.

Table 19 shows the amount of stop band alias rejection for multiple pass-band ripple/cutoff points. The decimation ratio of the filtering stage of each DDC can be controlled individually through Bits[1:0] of the DDC control registers (Register 0x0310 and Register 0x0330) in conjunction with the pair index register (Register 0x0009).

**Table 18. DDC Filter Characteristics**

Half-Band Filter Selection	Real Output		Complex (I/Q) Output		Alias Protected Bandwidth (MHz)	Ideal SNR Improvement <sup>1</sup> (dB)	Pass-Band Ripple (dB)	Alias Rejection (dB)
	Decimation Ratio	Output Sample Rate (MSPS)	Decimation Ratio	Output Sample Rate (MSPS)				
HB1	1	500	2	250 (I) + 250 (Q)	200	1	$<-0.0001$	$>100$
HB1 + HB2	2	250	4	125 (I) + 125 (Q)	100	4		
HB1 + HB2 + HB3	4	125	8	62.5 (I) + 62.5 (Q)	50	7		
HB1 + HB2 + HB3 + HB4	8	62.5	16	31.25 (I) + 31.25 (Q)	25	10		

<sup>1</sup> Ideal SNR improvement due to oversampling and filtering =  $10\log(\text{bandwidth}/(f_s/2))$ .

**Table 19. DDC Filter Alias Rejection**

Alias Rejection (dB)	Pass-Band Ripple/Cutoff Point (dB)	Alias Protected Bandwidth for Real (I) Outputs <sup>1</sup>	Alias Protected Bandwidth for Complex (I/Q) Outputs
$>100$	$<-0.0001$	$<40\% \times f_{\text{OUT}}$	$<80\% \times f_{\text{OUT}}$
95	$<-0.0002$	$<40.12\% \times f_{\text{OUT}}$	$<80.12\% \times f_{\text{OUT}}$
90	$<-0.0003$	$<40.23\% \times f_{\text{OUT}}$	$<80.46\% \times f_{\text{OUT}}$
85	$<-0.0005$	$<40.36\% \times f_{\text{OUT}}$	$<80.72\% \times f_{\text{OUT}}$
80	$<-0.0009$	$<40.53\% \times f_{\text{OUT}}$	$<81.06\% \times f_{\text{OUT}}$
25.07	-0.5	$45.17\% \times f_{\text{OUT}}$	$90.34\% \times f_{\text{OUT}}$
19.3	-1.0	$46.2\% \times f_{\text{OUT}}$	$92.4\% \times f_{\text{OUT}}$
10.7	-3.0	$48.29\% \times f_{\text{OUT}}$	$96.58\% \times f_{\text{OUT}}$

<sup>1</sup>  $f_{\text{OUT}} = \text{ADC input sample rate} \div \text{DDC decimation}$ .

**HALF-BAND FILTERS**

The AD9694 offers four half-band filters to enable digital signal processing of the ADC converted data. These half-band filters are bypassable and can be individually selected.

**HB4 Filter**

The first decimate by 2, half-band, low-pass, FIR filter (HB4) uses an 11-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption. The HB4 filter is only used when complex outputs (decimate by 16) or real outputs (decimate by 8) are enabled; otherwise, it is bypassed. Table 20 and Figure 76 show the coefficients and response of the HB4 filter.

**Table 20. HB4 Filter Coefficients**

HB4 Coefficient Number	Normalized Coefficient	Decimal Coefficient (15-Bit)
C1, C11	0.006042	99
C2, C10	0	0
C3, C9	-0.049377	-809
C4, C8	0	0
C5, C7	0.293334	4806
C6	0.500000	8192

Figure 76. HB4 Filter Response

**HB3 Filter**

The second decimate by 2, half-band, low-pass, FIR filter (HB3) uses an 11-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption. The HB3 filter is only used when complex outputs (decimate by 8 or 16) or real outputs (decimate by 4 or 8) are enabled; otherwise, it is bypassed. Table 21 and Figure 77 show the coefficients and response of the HB3 filter.

**Table 21. HB3 Filter Coefficients**

HB3 Coefficient Number	Normalized Coefficient	Decimal Coefficient (17-Bit)
C1, C11	0.006638	435
C2, C10	0	0
C3, C9	-0.051055	-3346
C4, C8	0	0
C5, C7	0.294418	19,295
C6	0.500000	32,768

Figure 77. HB3 Filter Response

**HB2 Filter**

The third decimate by 2, half-band, low-pass, FIR filter (HB2) uses a 19-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption.

The HB2 filter is only used when complex or real outputs (decimate by 4, 8, or 16) is enabled; otherwise, it is bypassed.

Table 22 and Figure 78 show the coefficients and response of the HB2 filter.

**Table 22. HB2 Filter Coefficients**

HB2 Coefficient Number	Normalized Coefficient	Decimal Coefficient (18-Bit)
C1, C19	0.000671	88
C2, C18	0	0
C3, C17	-0.005325	-698
C4, C16	0	0

C9, C11	0.306091	40,120
C10	0.500000	65,536

Figure 78. HB2 Filter Response

**HB1 Filter**

The fourth and final decimate by 2, half-band, low-pass, FIR filter (HB1) uses a 63-tap, symmetrical, fixed coefficient filter implementation that is optimized for low power consumption. The HB1 filter is always enabled and cannot be bypassed.

Table 23 and Figure 79 show the coefficients and response of the HB1 filter.

**Table 23. HB1 Filter Coefficients**

Figure 79. HB1 Filter Response

**DDC GAIN STAGE**

Each DDC contains an independently controlled gain stage. The gain is selectable as either 0 dB or 6 dB. When mixing a real input signal down to baseband, it is recommended that the user enable the 6 dB of gain to recenter the dynamic range of the signal within the full scale of the output bits.

When mixing a complex input signal down to baseband, the mixer has already recentered the dynamic range of the signal within the full scale of the output bits, and no additional gain is necessary. However, the optional 6 dB gain compensates for low signal strengths. The downsample by 2 portion of the HB1 FIR filter is bypassed when using the complex to real conversion stage.

**DDC COMPLEX TO REAL CONVERSION**

Each DDC contains an independently controlled complex to real conversion block. The complex to real conversion block reuses the last filter (HB1 FIR) in the filtering stage along with an  $f_s/4$  complex mixer to upconvert the signal. After upconverting the signal, the Q portion of the complex mixer is no longer needed and is dropped.

Figure 80 shows a simplified block diagram of the complex to real conversion.

Figure 80. Complex to Real Conversion Block

<sup>1</sup>  $f_s$  is the ADC sample rate. Bandwidths listed are  $<-0.001$  dB of pass-band ripple and  $>100$  dB of stop band alias rejection.

<sup>2</sup> The NCOs must be synchronized either through the SPI or through the SYSREF $\pm$  pin after all writes to the FTW or POW registers have completed. This synchronization is necessary to ensure the proper operation of the NCO. See the NCO Synchronization section for more information.

## DIGITAL OUTPUTS

### INTRODUCTION TO THE JESD204B INTERFACE

The AD9694 digital outputs are designed to the JEDEC standard, JESD204B, serial interface for data converters. JESD204B is a protocol to link the AD9694 to a digital processing device over a serial interface with lane rates of up to 15 Gbps. The benefits of the JESD204B interface over LVDS include a reduction in required board area for data interface routing, and an ability to enable smaller packages for converter and logic devices.

### SETTING UP THE AD9694 DIGITAL INTERFACE

The following SPI writes are required for the AD9694 at startup and each time the ADC is reset (datapath reset, soft reset, link power-down/power-up, or hard reset):

1. Write 0x4F to Register 0x1228.
2. Write 0x0F to Register 0x1228.
3. Write 0x04 to Register 0x1222.
4. Write 0x00 to Register 0x1222.
5. Write 0x08 to Register 0x1262.
6. Write 0x00 to Register 0x1262.

The JESD204B data transmit blocks assemble the parallel data from the ADC into frames and uses 8B/10B encoding as well as optional scrambling to form serial output data. Lane synchronization is supported through the use of special control characters during the initial establishment of the link. Additional control characters are embedded in the data stream to maintain synchronization thereafter. A JESD204B receiver is required to complete the serial link. For additional details on the JESD204B interface, refer to the JESD204B standard.

The JESD204B data transmit blocks in the AD9694 map up to two physical ADCs or up to four virtual converters (when the DDCs are enabled) over each of the two JESD204B links. Each link can be configured to use one or two JESD204B lanes for up to a total of four lanes for the AD9694 chip. The JESD204B specification refers to a number of parameters to define the link, and these parameters must match between the JESD204B transmitter (the AD9694 output) and the JESD204B receiver (the logic device input). The JESD204B outputs of the AD9694 function effectively as two individual JESD204B links. The two JESD204B links can be synchronized if desired using the SYSREF± input.

Each JESD204B link is described according to the following parameters:

- L = number of lanes per converter device (lanes per link) (AD9694 value = 1 or 2)
- M = number of converters per converter device (virtual converters per link) (AD9694 value = 1, 2, or 4)
- F = octets per frame (AD9694 value = 1, 2, 4, or 8)
- N' = number of bits per sample (JESD204B word size) (AD9694 value = 8 or 16)
- N = converter resolution (AD9694 value = 7 to 16)
- CS = number of control bits per sample (AD9694 value = 0, 1, 2, or 3)
- K = number of frames per multiframe (AD9694 value = 4, 8, 12, 16, 20, 24, 28, or 32)
- S = samples transmitted per single converter per frame cycle (AD9694 value = set automatically based on L, M, F, and N')
- HD = high density mode (AD9694 = set automatically based on L, M, F, and N')
- CF = number of control words per frame clock cycle per converter device (AD9694 value = 0)

Figure 81 shows a simplified block diagram of the AD9694 JESD204B link. By default, the AD9694 is configured to use four converters and four lanes. The Converter A and Converter B data is output to SERDOUTAB0± and SERDOUTAB1±, and the Converter C and Converter D data is output to SERDOUTCD0± and SERDOUTCD1±. The AD9694 allows other configurations, such as combining the outputs of each pair of converters into a single lane, or changing the mapping of the digital output paths. These modes are set up via a quick configuration register in the SPI register map, along with additional customizable options.

By default in the AD9694, the 14-bit converter word from each converter is broken into two octets (eight bits of data). Bit 13 (MSB) through Bit 6 are in the first octet. The second octet contains Bit 5 through Bit 0 (LSB) and two tail bits. The tail bits can be configured as zeros or a pseudorandom number sequence. The tail bits can also be replaced with control bits indicating overrange, SYSREF±, or fast detect output. Control bits are filled and inserted MSB first such that enabling CS = 1 activates Control Bit 2, enabling CS = 2 activates Control Bit 2 and Control Bit 1, and enabling CS = 3 activates Control Bit 2, Control Bit 1, and Control Bit 0.

The two resulting octets can be scrambled. Scrambling is optional; however, it is recommended to avoid spectral peaks when transmitting similar digital data patterns. The scrambler uses a self synchronizing, polynomial-based algorithm defined by the equation  $1 + x^{14} + x^{15}$ . The descrambler in the receiver is a self-synchronizing version of the scrambler polynomial.

The two octets are then encoded with an 8B/10B encoder. The 8B/10B encoder works by taking eight bits of data (an octet) and encoding them into a 10-bit symbol. Figure 82 shows how the 14-bit data is taken from the ADC, the tail bits are added, the two octets are scrambled, and how the octets are encoded into two 10-bit symbols. Figure 82 shows the default data format.

Figure 82. ADC Output Data Path Showing Data Framing

1480B-065

Figure 83. Data Flow

1480B-066

**FUNCTIONAL OVERVIEW**

The block diagram in Figure 83 shows the flow of data through each of the two JESD204B links from the sample input to the physical output. The processing can be divided into layers that are derived from the open source initiative (OSI) model widely used to describe the abstraction layers of communications systems. These layers are the transport layer, data link layer, and physical layer (serializer and output driver).

**Transport Layer**

The transport layer handles packing the data (consisting of samples and optional control bits) into JESD204B frames that are mapped to 8-bit octets. These octets are sent to the data link layer. The transport layer mapping is controlled by rules derived from the link parameters. Tail bits are added to fill gaps where required. Use the following equation to determine the number of tail bits within a sample (JESD204B word):

$$T = N' - N - CS$$

**Data Link Layer**

The data link layer is responsible for the low level functions of passing data across the link. These functions include optionally scrambling the data, inserting control characters for multichip synchronization, lane alignment, or monitoring, and encoding 8-bit octets into 10-bit symbols. The data link layer is also responsible for sending the initial lane alignment sequence (ILAS), which contains the link configuration data used by the receiver to verify the settings in the transport layer.

**Physical Layer**

The physical layer consists of the high speed circuitry clocked at the serial clock rate. In this layer, parallel data is converted into one, two, or four lanes of high speed differential serial data.

**JESD204B LINK ESTABLISHMENT**

The AD9694 JESD204B transmitter (Tx) interface operates in Subclass 1 as defined in the JEDEC Standard 204B (July 2011 specification). The link establishment process is divided into the following steps: code group synchronization and SYNCINB±AB/ SYNCINB±CD, initial lane alignment sequence, and user data and error correction.

**Code Group Synchronization (CGS) and SYNCINB±**

The CGS is the process by which the JESD204B receiver finds the boundaries between the 10-bit symbols in the stream of data. During the CGS phase, the JESD204B transmit block transmits /K28.5/ characters. The receiver must locate /K28.5/

characters in its input data stream using clock and data recovery (CDR) techniques.

The receiver issues a synchronization request by asserting the SYNCINB±AB and SYNCINB±CD pins of the AD9694 low. The JESD204B Tx then begins sending /K/ characters. After the receiver synchronizes, it waits for the correct reception of at least four consecutive /K/ symbols. It then deasserts SYNCINB±AB and SYNCINB±CD. The AD9694 then transmits an ILAS on the following local multiframe clock (LMFC) boundary.

For more information on the code group synchronization phase, refer to the JEDEC Standard JESD204B, July 2011, Section 5.3.3.1.

The SYNCINB±AB and SYNCINB±CD pin operation can also be controlled by the SPI. The SYNCINB±AB and SYNCINB±CD signals are differential LVDS mode signals by default, but can also be driven single-ended. For more information on configuring the SYNCINB±AB and SYNCINB±CD pin operation, refer to Register 0x0572.

**Initial Lane Alignment Sequence (ILAS)**

The ILAS phase follows the CGS phase and begins on the next LMFC boundary. The ILAS consists of four multiframe, with an /R/ character marking the beginning and an /A/ character marking the end. The ILAS begins by sending an /R/ character followed by 0 to 255 ramp data for one multiframe. On the second multiframe, the link configuration data is sent, starting with the third character. The second character is a /Q/ character to confirm that the link configuration data follows. All undefined data slots are filled with ramp data. The ILAS sequence is never scrambled.

The ILAS sequence construction is shown in Figure 84. The four multiframe include the following:

- Multiframe 1. Begins with an /R/ character (/K28.0/) and ends with an /A/ character (/K28.3/).
- Multiframe 2. Begins with an /R/ character followed by a /Q/ (/K28.4/) character, followed by link configuration parameters over 14 configuration octets (see Table 25) and ends with an /A/ character. Many of the parameter values are of the value - 1 notation.
- Multiframe 3. Begins with an /R/ character (/K28.0/) and ends with an /A/ character (/K28.3/).
- Multiframe 4. Begins with an /R/ character (/K28.0/) and ends with an /A/ character (/K28.3/).

Figure 84. Initial Lane Alignment Sequence

14808-087

### User Data and Error Detection

After the initial lane alignment sequence is complete, the user data is sent. Normally, within a frame, all characters are considered user data. However, to monitor the frame clock and multiframe clock synchronization, there is a mechanism for replacing characters with /F/ or /A/ alignment characters when the data meets certain conditions. These conditions are different for unscrambled and scrambled data. The scrambling operation is enabled by default, but it may be disabled using the SPI.

For scrambled data, any 0xFC character at the end of a frame is replaced by an /F/, and any 0xFD character at the end of a multiframe is replaced with an /A/. The JESD204B receiver (Rx) checks for /F/ and /A/ characters in the received data stream and verifies that they only occur in the expected locations. If an unexpected /F/ or /A/ character is found, the receiver handles the situation by using dynamic realignment or asserting the SYNCINB±x signal for more than four frames to initiate a resynchronization. For unscrambled data, if the final character of two subsequent frames are equal, the second character is replaced with an /F/ if it is at the end of a frame, and an /A/ if it is at the end of a multiframe.

Insertion of alignment characters can be modified using the SPI. The frame alignment character insertion (FACI) is enabled by default. More information on the link controls is available in the Memory Map section, Register 0x0571.

### 8B/10B Encoder

The 8B/10B encoder converts 8-bit octets into 10-bit symbols and inserts control characters into the stream when needed. The control characters used in JESD204B are shown in Table 25. The 8B/10B encoding ensures that the signal is dc balanced by using the same number of ones and zeros across multiple symbols.

The 8B/10B interface has options that can be controlled via the SPI. These operations include bypass and invert. These options are intended to be troubleshooting tools for the verification of the digital front end (DFE). Refer to the Memory Map section, Register 0x0572, Bits[2:1] for information on configuring the 8B/10B encoder.

Table 25. AD9694 Control Characters used in JESD204B

Abbreviation	Control Symbol	8-Bit Value	10-Bit Value, RD <sup>1</sup> = -1	10-Bit Value, RD <sup>1</sup> = +1	Description
/R/	/K28.0/	000 11100	001111 0100	110000 1011	Start of multiframe
/A/	/K28.3/	011 11100	001111 0011	110000 1100	Lane alignment
/Q/	/K28.4/	100 11100	001111 0100	110000 1101	Start of link configuration data
/K/	/K28.5/	101 11100	001111 1010	110000 0101	Group synchronization
/F/	/K28.7/	111 11100	001111 1000	110000 0111	Frame alignment

<sup>1</sup> RD means running disparity.

## PHYSICAL LAYER (DRIVER) OUTPUTS

### Digital Outputs, Timing, and Controls

The AD9694 physical layer consists of drivers that are defined in the JEDEC Standard JESD204B, July 2011. The differential digital outputs are powered up by default. The drivers use a dynamic 100 Ω internal termination to reduce unwanted reflections.

Place a 100 Ω differential termination resistor at each receiver input to result in a nominal 300 mV p-p swing at the receiver (see Figure 85). Alternatively, single-ended 50 Ω termination can be used. When single-ended termination is used, the termination voltage is DRVDD1/2. Otherwise, 0.1 μF ac coupling capacitors can be used to terminate to any single-ended voltage.

Figure 85. AC-Coupled Digital Output Termination Example

The AD9694 digital outputs can interface with custom ASICs and FPGA receivers, providing superior switching performance in noisy environments. Single point to point network topologies are recommended with a single differential 100 Ω termination resistor placed as close to the receiver inputs as possible. The common mode of the digital output automatically biases itself to half the DRVDD1 supply of 1.25 V ( $V_{CM} = 0.6$  V). See Figure 86 for dc coupling the outputs to the receiver logic.

Figure 86. DC-Coupled Digital Output Termination Example

If there is no far end receiver termination, or if there is poor differential trace routing, timing errors may result. To avoid such timing errors, it is recommended that the trace length be less than six inches, and that the differential output traces be close together and at equal lengths.

Figure 87 through Figure 89 show examples of the digital output data eye, time interval error (TIE) jitter histogram, and bathtub curve for one AD9694 lane running at 15 Gbps. The format of the output data is twos complement by default. To change the output data format, see the Memory Map section (Register 0x0561 in Table 38).

Figure 87. Digital Outputs Data Eye Diagram; External 100 Ω Terminations at 15 Gbps

Figure 88. Digital Outputs Histogram; External 100 Ω Terminations at 15 Gbps

Figure 89. Digital Outputs Bathtub Curve; External 100 Ω Terminations at 15 Gbps

**De-Emphasis**

De-emphasis enables the receiver eye diagram mask to be met in conditions where the interconnect insertion loss does not meet the JESD204B specification. Use the de-emphasis feature only when the receiver is unable to recover the clock due to excessive insertion loss. Under normal conditions, it is disabled to conserve power. Additionally, enabling and setting too high a de-emphasis value on a short link can cause the receiver eye diagram to fail. Use the de-emphasis setting with caution because it may increase electromagnetic interference (EMI). See the Memory Map section (Register 0x05C4 to Register 0x05C6 in Table 38) for more details.

**Phase-Locked Loop (PLL)**

The PLL generates the serializer clock, which operates at the JESD204B lane rate. The status of the PLL lock can be checked in the PLL lock status bit (Register 0x056F, Bit 7). This read only bit alerts the user if the PLL has achieved a lock for the specific setup. The JESD204B lane rate control bit, Bit 4 of Register 0x056E, must be set to correspond with the lane rate.

**JESD204B Tx CONVERTER MAPPING**

To support the different chip operating modes, the AD9694 design treats each sample stream (real or I/Q) as originating from separate virtual converters. The I/Q samples are always mapped in pairs with the I samples mapped to the first virtual converter and the Q samples mapped to the second virtual converter. With this transport layer mapping, the number of virtual converters are the same whether a single real converter is used along with a digital downconverter block producing I/Q outputs, or an analog downconversion is used with two real converters producing I/Q outputs.

Figure 90 shows a block diagram of the two scenarios described for I/Q transport layer mapping.

The JESD204B Tx block for AD9694 supports up to four DDC blocks. Each DDC block outputs either two sample streams (I/Q) for the complex data components (real + imaginary), or one sample stream for real (I) data. The JESD204B interface can

be configured to use up to eight virtual converters depending on the DDC configuration. Figure 91 shows the virtual converters and their relationship to the DDC outputs when complex outputs are used. Table 26 shows the virtual converter mapping for each chip operating mode when channel swapping is disabled.

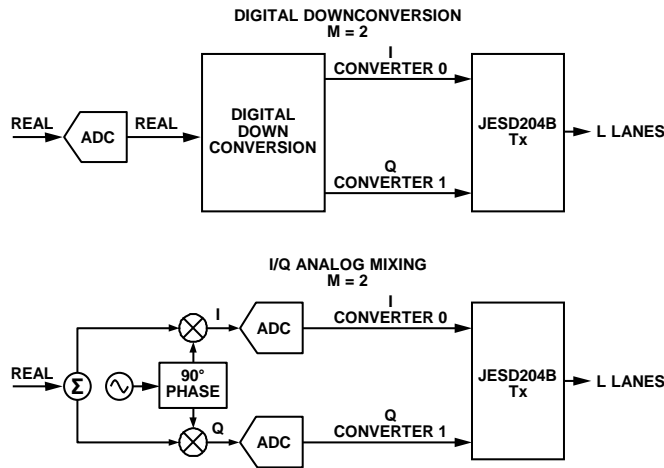

Figure 90. I/Q Transport Layer Mapping

Figure 91. DDCs and Virtual Converter Mapping

## CONFIGURING THE JESD204B LINK

The AD9694 has two JESD204B links. The device offers an easy way to set up the JESD204B link through the JESD04B quick configuration register (Register 0x570). One link consists of serial outputs SERDOUTAB0± and SERDOUTAB1± and the second link consists of serial outputs SERDOUTCD0± and SERDOUTCD1±. The basic parameters that determine the link setup are

- Number of lanes per link (L)
- Number of converters per link (M)
- Number of octets per frame (F)

If the internal DDCs are used for on-chip digital processing, M represents the number of virtual converters. The virtual converter mapping setup is shown in Figure 91.

The maximum lane rate allowed by the JESD204B specification is 15 Gbps. The lane line rate is related to the JESD204B parameters using the following equation:

$$\text{Lane Line Rate} = \frac{M \times N' \times \left(\frac{10}{8}\right) \times f_{OUT}}{L}$$

where:

$$f_{OUT} = \frac{f_{ADC\_CLOCK}}{\text{Decimation Ratio}}$$

The decimation ratio (DCM) is the parameter programmed in Register 0x0201.

**Table 26. Virtual Converter Mapping (Per Link)**

Number of Virtual Converters Supported	Chip Operating Mode (Register 0x0200, Bits[1:0])	Chip Q Ignore (Register 0x0200, Bit 5)	Virtual Converter Mapping			
			0	1	2	3
1 to 2	Full bandwidth mode (0x0)	Real or complex (0x0)	ADC A/ADC C samples	ADC B/ADC D samples	Unused	Unused
1	One DDC mode (0x1)	Real (I only) (0x1)	DDC 0 I samples	Unused	Unused	Unused
2	One DDC mode (0x1)	Complex (I/Q) (0x0)	DDC 0 I samples	DDC 0 Q samples	Unused	Unused
2	Two DDC mode (0x2)	Real (I only) (0x1)	DDC 0 I samples	DDC 1 I samples	Unused	Unused
4	Two DDC mode (0x2)	Complex (I/Q) (0x0)	DDC 0 I samples	DDC 0 Q samples	DDC 1 I samples	DDC 1 Q samples

Use the following steps to configure the output:

1. Power down the link.
2. Select the quick configuration options.
3. Configure any detailed options.
4. Set the output lane mapping (optional).
5. Set additional driver configuration options (optional).
6. Power up the link.

If the lane line rate calculated is less than 6.25 Gbps, select the low line rate option. This is done by programming a value of 0x10 to Register 0x056E.

Table 27 and Table 28 show the JESD204B output configurations supported for both  $N' = 16$  and  $N' = 8$  for a given number of virtual converters. Take care to ensure that the serial line rate for a given configuration is within the supported range of 1.5625 Gbps to 15 Gbps.

See the Example 1: Full Bandwidth Mode section and the Example 2: ADC with DDC Option (Two ADCs Plus Two DDCs in Each Pair) section for two examples describing which JESD204B transport layer settings are valid for a given chip mode.

Table 27. JESD204B Output Configurations for N'=16 (Per Link)

Number of Virtual Converters Supported (Same Value as M)	JESD204B Quick Configuration (Register 0x0570)	JESD204B Serial Line Rate <sup>1</sup>	JESD204B Transport Layer Settings <sup>2</sup>								
			L	M	F	S	HD	N	N'	CS	K <sup>3</sup>
1	0x01	20 × f <sub>OUT</sub>	1	1	2	1	0	8 to 16	16	0 to 3	Only valid K values that are divisible by 4 are supported
	0x40	10 × f <sub>OUT</sub>	2	1	1	1	1	8 to 16	16	0 to 3	
	0x41	10 × f <sub>OUT</sub>	2	1	2	2	0	8 to 16	16	0 to 3	
2	0x0A	40 × f <sub>OUT</sub>	1	2	4	1	0	8 to 16	16	0 to 3	
	0x49	20 × f <sub>OUT</sub>	2	2	2	1	0	8 to 16	16	0 to 3	
4	0x13	80 × f <sub>OUT</sub>	1	4	8	1	0	8 to 16	16	0 to 3	
	0x52	40 × f <sub>OUT</sub>	2	4	4	1	0	8 to 16	16	0 to 3	

<sup>1</sup> f<sub>OUT</sub> = output sample rate = ADC sample rate/chip decimation ratio. The JESD204B serial line rate must be ≥1687.5 Mbps and ≤15,000 Mbps. When the serial line rate is ≤15 Gbps and ≥13.5 Gbps, set Bits[7:4] to 0x3 in Register 0x056E. When the serial line rate is ≤13.5 Gbps and ≥6.75 Gbps, set Bits[7:4] to 0x0 in Register 0x056E. When the serial line rate is <6.75 Gbps and ≥3.375 Gbps, set Bits[7:4] to 0x1 in Register 0x056E. When the serial line rate is ≤3.375 Gbps and ≥1687.5 Mbps, set Bits[7:4] to 0x5 in Register 0x056E.

<sup>2</sup> JESD204B transport layer descriptions are as described in the Setting Up the AD9694 Digital Interface section.

<sup>3</sup> For F = 1, K = 20, 24, 28, and 32. For F = 2, K = 12, 16, 20, 24, 28, and 32. For F = 4, K = 8, 12, 16, 20, 24, 28, and 32. For F = 8 and F = 16, K = 4, 8, 12, 16, 20, 24, 28, and 32.

Table 28. JESD204B Output Configurations for N'=8 (Per Link)

	0x48	10 × f <sub>OUT</sub>	2	2	1	1	0	7 to 8	8	0 to 1	
	0x49	10 × f <sub>OUT</sub>	2	2	2	2	0	7 to 8	8	0 to 1	

<sup>1</sup> f<sub>OUT</sub> = output sample rate = ADC sample rate/chip decimation ratio. The JESD204B serial line rate must be ≥1687.5 Mbps and ≤15,000 Mbps. When the serial line rate is ≤15 Gbps and ≥13.5 Gbps, set Bits[7:4] to 0x3 in Register 0x056E. When the serial line rate is ≤13.5 Gbps and ≥6.75 Gbps, set Bits[7:4] to 0x0 in Register 0x056E. When the serial line rate is <6.75 Gbps and ≥3.375 Gbps, set Bits[7:4] to 0x1 in Register 0x056E. When the serial line rate is ≤3.375 Gbps and ≥1687.5 Mbps, set Bits[7:4] to 0x5 in Register 0x056E.

<sup>2</sup> JESD204B transport layer descriptions are as described in the Setting Up the AD9694 Digital Interface section.

<sup>3</sup> For F = 1, K = 20, 24, 28, and 32. For F = 2, K = 12, 16, 20, 24, 28, and 32. For F = 4, K = 8, 12, 16, 20, 24, 28, and 32. For F = 8 and F = 16, K = 4, 8, 12, 16, 20, 24, 28, and 32.

**Example 1: Full Bandwidth Mode**

In this example, the chip application mode is full bandwidth mode (see Figure 92), as follows:

- Two 14-bit converters at 500 MSPS
- Full bandwidth application layer mode
- No decimation

The JESD204B output configuration is as follows:

- Two virtual converters required (see Table 27)
- Output sample rate ( $f_{OUT}$ ) = 500/1 = 500 MSPS

The JESD204B supported output configurations (see Table 27) include the following:

- $N' = 16$  bits
- $N = 16$  bits
- $L = 2, M = 2,$  and  $F = 2$  (quick configuration = 0x48)
- $CS = 0$  to 2
- $K = 32$
- Output serial line rate = 10 Gbps per lane

**Example 2: ADC with DDC Option (Two ADCs Plus Two DDCs in Each Pair)**

In this example, the chip application mode is two-DDC mode. (see Figure 93), as follows:

- Two 14-bit converters at 500 MSPS
- Two DDC application layer mode with complex outputs (I/Q)
- Chip decimation ratio = 4
- DDC decimation ratio = 4 (see Table 27)

The JESD204B output configuration is as follows:

- Virtual converters required = 4 (see Table 27)
- Output sample rate ( $f_{OUT}$ ) = 500/4 = 125 MSPS
- $N' = 16$  bits
- $N = 14$  bits
- $L = 1, M = 4,$  and  $F = 8$  (quick configuration = 0x13)
- $CS = 0$  to 1
- $K = 32$
- Output serial line rate = 5 Gbps per lane ( $L = 1$ ) or 2.5 Gbps per lane ( $L = 2$ )

For  $L = 1$ , set Register 0x056E, Bits[7:4] to 0x1. For  $L = 2$ , set Register 0x056E, Bits[7:4] to 0x5.

Example 2 shows the flexibility in the digital and lane configurations for the AD9694. The sample rate is 500 MSPS, but the outputs are all combined in either one or two lanes, depending on the input/output speed capability of the receiving device.

## LATENCY

### END-TO-END TOTAL LATENCY

Total latency in the [AD9694](#) is dependent on the various digital signal processing (DSP) and JESD204B configuration modes. Latency is fixed at 28 encode clocks through the ADC itself, but the latency through the DSP and JESD204B blocks can vary greatly, depending on the configuration. Therefore, the total latency must be calculated based on the DSP options selected and the JESD204B configuration.

Table 29 shows the combined latency through the ADC, DSP, and JESD204B blocks for some of the different application modes supported by the [AD9694](#). Latency is in units of the encode clock.

**Table 29. Latency Through the [AD9694](#)**

ADC Application Mode	JESD204B Transport Layer Settings			Latency (Number of Encode Clocks)		
	L	M	F	ADC + DSP	JESD204B	Total
Full Bandwidth (9-Bit)	2	2	2	30	14	44
DDC (HB1) <sup>1</sup>	2	4	4	92	17	109
DDC (HB2 + HB1) <sup>1</sup>	1	4	8	162	13	175
DDC (HB3 + HB2 + HB1) <sup>1</sup>	1	4	8	292	28	320
DDC (HB4 + HB3 + HB2 + HB1) <sup>1</sup>	1	4	8	548	39	587

<sup>1</sup> No mixer, complex outputs.

## MULTICHIP SYNCHRONIZATION

The [AD9694](#) has a SYSREF $\pm$  input that provides flexible options for synchronizing the internal blocks. The SYSREF $\pm$  input is a source synchronous system reference signal that enables multichip synchronization. The input clock divider, DDCs, signal monitor block, and JESD204B link can be synchronized using the SYSREF $\pm$  input. For the highest level of timing accuracy, SYSREF $\pm$  must meet setup and hold requirements relative to the CLK $\pm$  input.

The flowchart in Figure 94 describes the internal mechanism for multichip synchronization in the [AD9694](#). The [AD9694](#) supports several features that aid users in meeting the

requirements set out for capturing a SYSREF $\pm$  signal. The SYSREF sample event can be defined as either a synchronous low to high transition, or a synchronous high to low transition. Additionally, the [AD9694](#) allows the SYSREF $\pm$  signal to be sampled using either the rising edge or falling edge of the CLK $\pm$  input. The [AD9694](#) also has the ability to ignore a programmable number (up to 16) of SYSREF $\pm$  events. Select the SYSREF $\pm$  control options using Register 0x0120 and Register 0x0121.

Figure 94. Multichip Synchronization

14809-076

**SYSREF± SET UP AND HOLD WINDOW MONITOR**

To ensure a valid SYSREF± signal capture, the AD9694 has a SYSREF± setup and hold window monitor. This feature allows the system designer to determine the location of the SYSREF± signals relative to the CLK± signals by reading back the amount of setup/hold margin on the interface through the memory

map. Figure 95 and Figure 96 show the setup and hold status values for different phases of SYSREF±. The setup detector returns the status of the SYSREF± signal before the CLK± edge, and the hold detector returns the status of the SYSREF± signal after the CLK± edge. Register 0x0128 stores the status of SYSREF± and alerts the user if the SYSREF± signal is captured by the ADC.

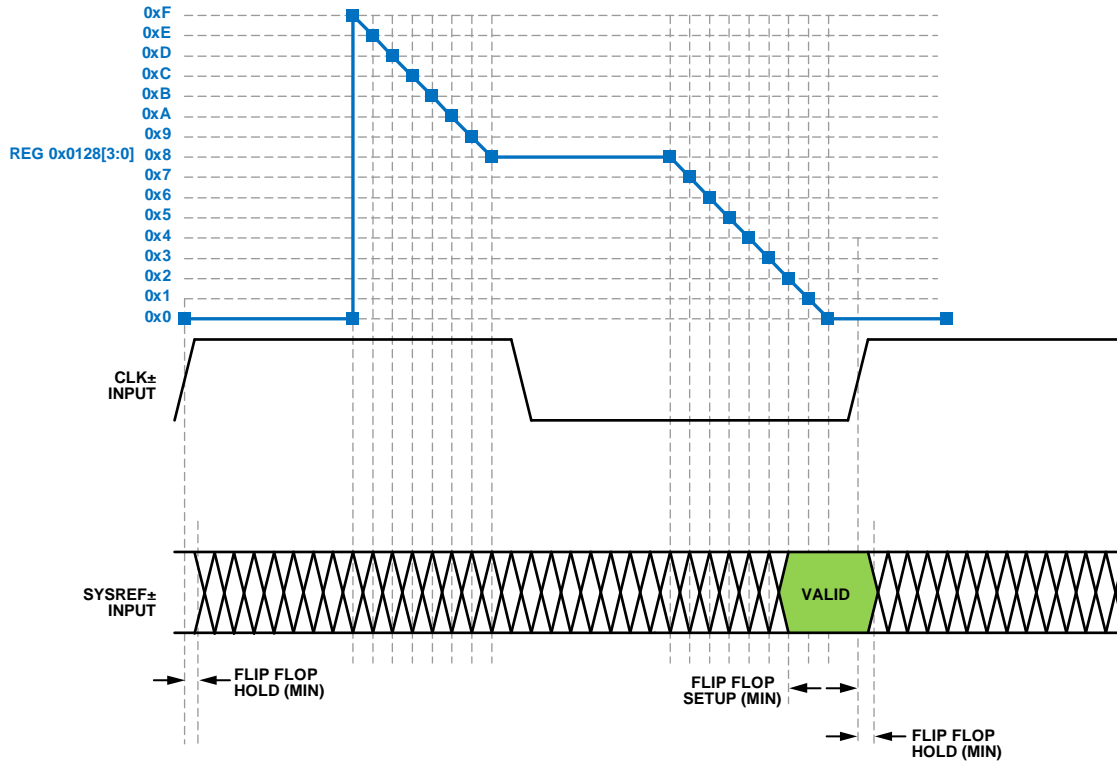

Figure 95. SYSREF± Setup Detector

14808-077

Figure 96. SYSREF± Hold Detector

Table 30 shows the description of the contents of Register 0x0128 and how to interpret them.

Table 30. SYSREF± Setup and Hold Monitor, Register 0x0128

Register 0x0128, Bits[7:4], Hold Status	Register 0x0128, Bits[3:0], Setup Status	Description
0x0	0x0 to 0x7	Possible setup error. The smaller this number, the smaller the setup margin.
0x0 to 0x8	0x8	No setup or hold error (best hold margin).
0x8	0x9 to 0xF	No setup or hold error (best setup and hold margin).
0x8	0x0	No setup or hold error (best setup margin).
0x9 to 0xF	0x0	Possible hold error. The larger this number, the smaller the hold margin.
0x0	0x0	Possible setup or hold error.

## TEST MODES

### ADC TEST MODES

The AD9694 has various test options that aid in the system level implementation. The AD9694 has ADC test modes that are available in Register 0x0550. These test modes are described in Table 31. When an output test mode is enabled, the analog section of the ADC is disconnected from the digital back-end blocks, and the test pattern is run through the output formatting block. Some of the test patterns are subject to output formatting, and some are not. The PN generators from the PN sequence tests can be reset by setting Bit 4 or Bit 5 of Register 0x0550. These tests can be performed with or without an analog signal (if present, the analog signal is ignored); however, they do require an encode clock.

If the application mode is set to select a DDC mode of operation, the test modes must be enabled for each DDC enabled. The test patterns can be enabled via Bit 2 and Bit 0 of Register 0x0327, Register 0x0347, and Register 0x0367, depending on which DDC(s) are selected. The (I) data uses the test patterns selected for Channel A, and the (Q) data uses the test patterns selected for Channel B. For DDC3 only, the (I) data uses the test patterns from Channel A, and the (Q) data does not output test patterns. Bit 0 of Register 0x0387 selects the Channel A test patterns to be used for the (I) data. For more information, see the [AN-877 Application Note, Interfacing to High Speed ADCs via SPI](#).

Table 31. ADC Test Modes

Output Test Mode Bit Sequence	Pattern Name	Expression	Default/Seed Value	Sample (N, N + 1, N + 2, ...)
0000	Off (default)	Not applicable	Not applicable	Not applicable
0001	Midscale short	00 0000 0000 0000	Not applicable	Not applicable
0010	Positive full-scale short	01 1111 1111 1111	Not applicable	Not applicable
0011	Negative full-scale short	10 0000 0000 0000	Not applicable	Not applicable
0100	Checkerboard	10 1010 1010 1010	Not applicable	0x1555, 0x2AAA, 0x1555, 0x2AAA, 0x1555
0101	PN sequence long	$x^{23} + x^{18} + 1$	0x3AFF	0x3FD7, 0x0002, 0x26E0, 0x0A3D, 0x1CA6
0110	PN sequence short	$x^9 + x^5 + 1$	0x0092	0x125B, 0x3C9A, 0x2660, 0x0c65, 0x0697
0111	One-word/zero-word toggle	11 1111 1111 1111	Not applicable	0x0000, 0x3FFF, 0x0000, 0x3FFF, 0x0000
1000	User input	Register 0x0551 to Register 0x0558	Not applicable	User Pattern 1, Bits[15:2], User Pattern 2, Bits[15:2], User Pattern 3, Bits[15:2], User Pattern 4, Bits[15:2], User Pattern 1, Bits[15:2] ... for repeat mode User Pattern 1, Bits[15:2], User Pattern 2, Bits[15:2], User Pattern 3, Bits[15:2], User Pattern 4, Bits[15:2], 0x0000 ... for single mode
1111	Ramp output	$(x) \% 2^{14}$	Not applicable	$(x) \% 2^{14}, (x + 1) \% 2^{14}, (x + 2) \% 2^{14}, (x + 3) \% 2^{14}$

## JESD204B BLOCK TEST MODES

In addition to the ADC pipeline test modes, the AD9694 also has flexible test modes in the JESD204B block. These test modes are listed in Register 0x0573 and Register 0x0574. These test patterns can be injected at various points along the output data path. These test injection points are shown in Figure 82. Table 32 describes the various test modes available in the JESD204B block. For the AD9694, a transition from test modes (Register 0x0573  $\neq$  0x00) to normal mode (Register 0x0573 = 0x00) requires an SPI soft reset. This is done by writing 0x81 to Register 0x0000 (self cleared).

### Transport Layer Sample Test Mode

The transport layer samples are implemented in the AD9694 as defined by Section 5.1.6.3 in the JEDEC JESD204B specification. These tests are shown in Register 0x0571, Bit 5. The test pattern is equivalent to the raw samples from the ADC.

### Interface Test Modes

The interface test modes are described in Register 0x0573, Bits[3:0]. These test modes are also explained in Table 32. The interface tests can be injected at various points along the data. See Figure 82

for more information on the test injection points. Register 0x0573, Bits[5:4] show where these tests are injected.

Table 33, Table 34, and Table 35 show examples of some of the test modes when injected at the JESD204B sample input, physical layer (PHY) 10-bit input, and scrambler 8-bit input. In Table 32 through Table 35, UPx represents the user pattern control bits from the customer register map.

### Data Link Layer Test Modes

The data link layer test modes are implemented in the AD9694 as defined by Section 5.3.3.8.2 in the JEDEC JESD204B specification. These tests are shown in Register 0x0574, Bits[2:0]. Test patterns inserted at the data link layer are useful for verifying the functionality of the data link layer. When the data link layer test modes are enabled, disable SYNCINB $\pm$ x by writing 0xC0 to Register 0x0572.

Table 32. JESD204B Interface Test Modes

Output Test Mode Bit Sequence	Pattern Name	Expression	Default
0000	Off (default)	Not applicable	Not applicable
0001	Alternating checker board	0x5555, 0xAAAA, 0x5555, ...	Not applicable
0010	1/0 word toggle	0x0000, 0xFFFF, 0x0000, ...	Not applicable
0011	31-bit PN sequence	$x^{31} + x^{28} + 1$	0x0003AFFF
0100	23-bit PN sequence	$x^{23} + x^{18} + 1$	0x003AFF
0101	15-bit PN sequence	$x^{15} + x^{14} + 1$	0x03AF
0110	9-bit PN sequence	$x^9 + x^5 + 1$	0x092

## SERIAL PORT INTERFACE

The AD9694 SPI allows the user to configure the converter for specific functions or operations through a structured register space provided inside the ADC. The SPI gives the user added flexibility and customization, depending on the application.

Addresses are accessed via the serial port and can be written to or read from the port. Memory is organized into bytes that can be further divided into fields. These fields are documented in the Memory Map section. For detailed operational information, see the [Serial Control Interface Standard \(Rev. 1.0\)](#).

### CONFIGURATION USING THE SPI

Three pins define the SPI of this ADC: the SCLK pin, the SDIO pin, and the CSB pin (see Table 36). The SCLK (serial clock) pin is used to synchronize the read and write data presented from nd to the ADC. The SDIO (serial data input/output) pin is a dual-purpose pin that allows data to be sent and read from the internal ADC memory map registers. The CSB (chip select bar) pin is an active low control that enables or disables the read and write cycles.

**Table 36. Serial Port Interface Pins**

Pin	Function
SCLK	Serial clock. The serial shift clock input, which is used to synchronize serial interface, reads, and writes.
SDIO	Serial data input/output. A dual-purpose pin that typically serves as an input or an output, depending on the instruction being sent and the relative position in the timing frame.
CSB	Chip select bar. An active low control that gates the read and write cycles.

The falling edge of CSB, in conjunction with the rising edge of SCLK, determines the start of the framing. An example of the serial timing and its definitions can be found in Figure 4 and Table 7.

Other modes involving the CSB pin are available. The CSB pin can be held low indefinitely, which permanently enables the device; this is called streaming. The CSB can stall high between bytes to allow for additional external timing. When CSB is tied high, SPI functions are placed in a high impedance mode. This mode turns on any SPI pin secondary functions.

All data is composed of 8-bit words. The first bit of each individual byte of serial data indicates whether a read or write command is issued. This allows the SDIO pin to change direction from an input to an output.

**Table 37. Features Accessible Using the SPI**

Feature Name	Description
Mode	Allows the user to set either power-down mode or standby mode.
Clock	Allows the user to access the clock divider via the SPI.
DDC	Allows the user to set up decimation filters for different applications.
Test Input/Output	Allows the user to set test modes to have known data on output bits.
Output Mode	Allows the user to set up outputs.
Serializer/Deserializer (SERDES) Output Setup	Allows the user to vary SERDES settings such as swing and emphasis.

In addition to word length, the instruction phase determines whether the serial frame is a read or write operation, allowing the serial port to be used both to program the chip and to read the contents of the on-chip memory. If the instruction is a readback operation, performing a readback causes the SDIO pin to change direction from an input to an output at the appropriate point in the serial frame.

Data can be sent in MSB first mode or in LSB first mode. MSB first mode is the default on power-up and can be changed via the SPI port configuration register. For more information about this and other features, see the [Serial Control Interface Standard \(Rev. 1.0\)](#).

### HARDWARE INTERFACE

The pins described in Table 36 comprise the physical interface between the user programming device and the serial port of the AD9694. The SCLK pin and the CSB pin function as inputs when using the SPI interface. The SDIO pin is bidirectional, functioning as an input during write phases and as an output during readback.

The SPI interface is flexible enough to be controlled by either FPGAs or microcontrollers. One method for SPI configuration is described in detail in the [AN-812 Application Note, Microcontroller-Based Serial Port Interface \(SPI\) Boot Circuit](#).

Do not activate the SPI port during periods when the full dynamic performance of the converter is required. Because the SCLK signal, the CSB signal, and the SDIO signal are typically asynchronous to the ADC clock, noise from these signals can degrade converter performance. If the on-board SPI bus is used for other devices, it may be necessary to provide buffers between this bus and the AD9694 to prevent these signals from transitioning at the converter inputs during critical sampling periods.

### SPI ACCESSIBLE FEATURES

Table 37 provides a brief description of the general features that are accessible via the SPI. These features are described in detail in the [Serial Control Interface Standard \(Rev. 1.0\)](#). The AD9694 device specific features are described in the Memory Map section.

## MEMORY MAP

### READING THE MEMORY MAP REGISTER TABLE

Each row in the memory map register table has eight bit locations. The memory map is divided into four sections: the Analog Devices SPI registers (Register 0x0000 to Register 0x000D and Register 0x18A6 to Register 0x1A4C), the ADC function registers (Register 0x003F to Register 0x027A), the DDC function registers (Register 0x0300 to Register 0x0347), and the digital outputs and test modes registers (Register 0x0550 to Register 0x05C0).

Table 38 (see the Memory Map section) documents the default hexadecimal value for each hexadecimal address shown. The column with the heading Bit 7 (MSB) is the start of the default hexadecimal value given. For example, Address 0x0561, the output mode register, has a hexadecimal default value of 0x01. This default value means that Bit 0 = 1, and the remaining bits are 0s. This setting is the default output format value, which is twos complement. For more information on this function and others, see the Table 38.

### Unassigned and Reserved Locations

All address and bit locations that are not included in Table 38 are not currently supported for this device. Write unused bits of a valid address location with 0s unless the default value is set otherwise. Writing to these locations is required only when part of an address location is unassigned (for example, Address 0x0561). If the entire address location is open (for example, Address 0x0013), do not write to this address location.

### Default Values

After the AD9694 is reset, critical registers are loaded with default values. The default values for the registers are given in the memory map register table, Table 38.

### Logic Levels

An explanation of logic level terminology follows:

- “Bit is set” is synonymous with “bit is set to Logic 1” or “writing Logic 1 for the bit.”
- “Clear a bit” is synonymous with “bit is set to Logic 0” or “writing Logic 0 for the bit.”
- X denotes a don't care bit.

### ADC Pair Addressing

The AD9694 functionally operates as two pairs of dual IF receiver channels. There are two ADCs and two DDCs in each pair making for a total of four of each for the AD9694 device. To access the SPI registers for each pair, the pair index must be written in Register 0x0009. The pair index register must be written prior to any other SPI write to the AD9694.

### Channel Specific Registers

Some channel setup functions, such as the fast detect control (Register 0x0247), can be programmed to a different value for each channel. In these cases, channel address locations are internally duplicated for each channel. These registers and bits are designated in Table 38 as local. These local registers and bits can be accessed by setting the appropriate Channel A/Channel C or Channel B/Channel D bits in Register 0x0008. The particular channel that is addressed is dependent upon the pair selection written to Register 0x0009. If both bits are set, the subsequent write affects the registers of both channels. In a read cycle, set only Channel A/Channel C or Channel B/Channel D to read one of the two registers. If both bits are set during an SPI read cycle, the device returns the value for Channel A. If both pairs and both channels are selected via Register 0x0009 and Register 0x0008, the device returns the value for Channel A.

The names of the registers listed in Table 38 and Table 39 are prefixed with either global map, channel map, JESD204B map, or pair map. Registers in the pair map and JESD204B map apply to a pair of channels, either Pair A/B or Pair C/D. To write registers in the pair map and JESD204B map, the pair index register (Register 0x0009) must be written to address the appropriate pair. The SPI Configuration A (Register 0x0000), SPI Configuration B (Register 0x0001), and pair index (Register 0x0009) registers are the only registers that reside in the global map. Registers in the channel map are local to each channel, either Channel A, Channel B, Channel C, or Channel D. To write registers in the channel map, the pair index register (Register 0x0009) must be written first to address the desired pair (Pair A/B or Pair C/D) followed by writing the channel index register (Register 0x0008) to select the desired channel (Channel A/Channel C or Channel B/Channel D).

For example, to write Channel A to test mode (set by Register 0x0550), first write 0x01 to Register 0x0009 to select Pair A/B, followed by writing 0x01 to Register 0x0008 to select Channel A. Then, write Register 0x0550 to the value for the desired test mode. To write all channels to a test mode (set by Register 0x0550), first write Register 0x0009 to a value of 0x03 to select both Pair A/B and Pair C/D, followed by writing Register 0x0008 to a value of 0x03 to select Channel A, Channel B, Channel C, and Channel D. Next, write Register 0x0550 to the value for the desired test mode.

### SPI Soft Reset

After issuing a soft reset by programming 0x81 to Register 0x0000, the AD9694 requires 5 ms to recover. When programming the AD9694 for application setup, ensure that an adequate delay is programmed into the firmware after asserting the soft reset and before starting the device setup.

# MEMORY MAP

## REGISTER TABLE SUMMARY

All address locations that are not included in Table 38 are not currently supported for this device and must not be written.

**Table 38. Memory Map Summary**

Reg.	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Reset	RW	
0x0000	Global Map SPI Configuration A	Soft reset (self clearing)	LSB first mirror	Address ascension mirror	Reserved	Reserved	Address ascension	LSB first	Soft reset (self clearing)	0x00	R/W

## APPLICATIONS INFORMATION

### POWER SUPPLY RECOMMENDATIONS

The [AD9694](#) must be powered by the following seven supplies: AVDD1 = AVDD1\_SR = 0.975 V, AVDD2 = 1.8 V, AVDD3 = 2.5 V, DVDD = 0.975 V, DRVDD1 = 0.975 V, and SPIVDD = 1.8 V. For applications requiring an optimal high power efficiency and low noise performance, it is recommended that the [ADP5054](#) quad switching regulator be used to convert the 6.0 V or 12 V input rails to intermediate rails (1.3 V, 2.4 V and 3.0 V). These intermediate rails are then postregulated by very low noise, low dropout (LDO) regulators (such as the [ADP1762](#), [ADP7159](#), [ADP151](#), and [ADP7118](#)). Figure 97 shows the recommended power supply scheme for [AD9694](#).

Figure 97. High Efficiency, Low Noise Power Solution for the [AD9694](#)

It is not necessary to split all of these power domains in all cases. The recommended solution shown in Figure 97 provides the lowest noise, highest efficiency power delivery system for the [AD9694](#). If only one 0.975 V supply is available, route to AVDD1 first and then tap it off and isolate it with a ferrite bead or a filter choke, preceded by decoupling capacitors for AVDD1\_SR, DVDD, and DRVDD1, in that order. The user can employ several different decoupling capacitors to cover both high and low frequencies. These must be located close to the point of entry at the PCB level and close to the devices, with minimal trace lengths.

### EXPOSED PAD THERMAL HEAT SLUG RECOMMENDATIONS

It is required that the exposed pad on the underside of the ADC be connected to AGND to achieve the best electrical and thermal performance of the [AD9694](#). Connect an exposed continuous copper plane on the PCB to the [AD9694](#) exposed pad, Pin 0. The copper plane must have several vias to achieve the lowest possible resistive thermal path for heat dissipation to flow through the bottom of the PCB. These vias must be solder filled or plugged. The number of vias and the fill determine the resultant  $\theta_{JA}$  measured on the board, which is shown in Table 9.

See Figure 98 for a PCB layout example. For detailed information on packaging and the PCB layout of chip scale packages, see the [AN-772 Application Note, A Design and Manufacturing Guide for the Lead Frame Chip Scale Package \(LFCSP\)](#).

Figure 98. Recommended PCB Layout of Exposed Pad for the [AD9694](#)

### AVDD1\_SR (PIN 64) AND AGND\_SR (PIN 63 AND PIN 67)

AVDD1\_SR (Pin 64) and AGND\_SR (Pin 63 and Pin 67) can provide a separate power supply node to the SYSREF± circuits of [AD9694](#). If running in Subclass 1, the [AD9694](#) can support periodic one-shot or gapped signals. To minimize the coupling of this supply into the AVDD1 supply node, adequate supply bypassing is needed.
