

# HT48E30 8-Bit I/O Type MCU (With EEPROM)

## Features

- Operating voltage: f<sub>SYS</sub>=4MHz: 2.2V~5.5V f<sub>SYS</sub>=8MHz: 3.3V~5.5V
- Low voltage reset function
- 23 bidirectional I/O lines (max.)
- 1 interrupt input shared with an I/O line
- 8-bit programmable timer/event counter with overflow interrupt and 8-stage prescaler
- On-chip crystal and RC oscillator
- Watchdog Timer
- 2048×14 program memory ROM (MTP)
- 128×8 data memory EEPROM
- 96×8 data memory RAM
- Buzzer driving pair and PFD supported

## **General Description**

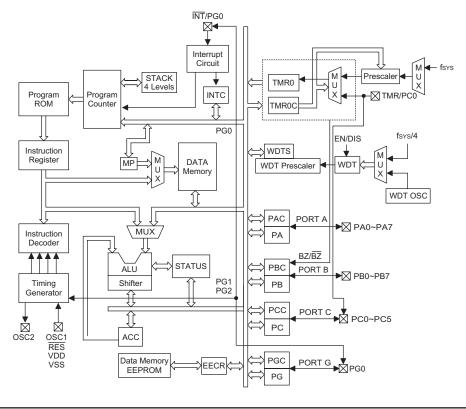

**Block Diagram** 

The HT48E30 is an 8-bit high performance, RISC architecture microcontroller device specifically designed for multiple I/O control product applications.

The advantages of low power consumption, I/O flexibility, timer functions, oscillator options, HALT and

- HALT function and wake-up feature reduce power consumption
- 4-level subroutine nesting
- + Up to 0.5 $\mu s$  instruction cycle with 8MHz system clock at V\_DD=5V
- Bit manipulation instruction
- 14-bit table read instruction
- 63 powerful instructions
- 10<sup>6</sup> erase/write cycles EEPROM data memory
- EEPROM data retention > 10 years
- · All instructions in one or two machine cycles
- In system programming (ISP)
- 24/28-pin SKDIP/SOP package

wake-up functions, watchdog timer, buzzer driver, as well as low cost, enhance the versatility of these devices to suit a wide range of application possibilities such as industrial control, consumer products, subsystem controllers, etc.

# **Pad Assignment**

\* The IC substrate should be connected to VSS in the PCB layout artwork.

# **Pad Description**

Pad Name	I/O	Options	Description
PA0~PA7	I/O	Pull-high* Wake-up CMOS/Schmitt trigger Input	Bidirectional 8-bit input/output port. Each bit can be configured as a wake-up input by options. Software instructions determine the CMOS output or Schmitt trigger or CMOS input (depends on options) with pull-high resistor (determined by 1-bit pull-high options).
PB0/BZ PB1/BZ PB2~PB7	I/O	Pull-high* PB0 or <u>BZ</u> PB1 or BZ	Bidirectional 8-bit input/output port. Software instructions determine the CMOS output or Schmitt trigger input with pull-high resistor (determined by pull-high options). The PB0 and PB1 are pin-shared with the BZ and $\overline{\text{BZ}}$ , respectively. Once the PB0 or PB1 is selected as buzzer driving outputs, the output signals come from an internal PFD generator (shared with timer/event counter).
VSS	_	_	Negative power supply, ground
PG0/INT	I/O	Pull-high*	Bidirectional I/O lines. Software instructions determine the CMOS out- put or Schmitt trigger input with pull-high resistor (determined by 1-bit pull-high options). This external interrupt input is pin-shared with PG0. The external interrupt input is activated on a high to low transition.
PC0/TMR PC1~PC5	I/O	Pull-high*	Bidirectional I/O lines. Software instructions determine the CMOS out- put or Schmitt trigger input with pull-high resistor (determined by 1-bit pull-high options). The timer input are pin-shared with PC0.
RES	Ι	_	Schmitt trigger reset input. Active low.
VDD	_		Positive power supply
OSC1 OSC2	і 0	Crystal or RC	OSC1and OSC2 are connected to an RC network or Crystal (deter- mined by options) for the internal system clock. In the case of RC oper- ation, OSC2 is the output terminal for 1/4 system clock.

Note: "\*" The pull-high resistors of each I/O port (PA, PB, PC, PG) are controlled by a 1-bit option. CMOS or Schmitt trigger option of port A is controlled by a 1-bit option.

## **Absolute Maximum Ratings**

Supply Voltage	V_{SS}=0.3V to V_{SS}+6.0V	Storage Temperature	–50°C to 125°C
Input Voltage	V <sub>SS</sub> –0.3V to V <sub>DD</sub> +0.3V	Operating Temperature	–40°C to 85°C

Note: These are stress ratings only. Stresses exceeding the range specified under "Absolute Maximum Ratings" may cause substantial damage to the device. Functional operation of this device at other conditions beyond those listed in the specification is not implied and prolonged exposure to extreme conditions may affect device reliability.

## **Functional Description**

## **Execution Flow**

The HT48E30 system clock is derived from either a crystal or an RC oscillator and is internally divided into four non-overlapping clocks. One instruction cycle consists of four system clock cycles.

Instruction fetching and execution are pipelined in such a way that a fetch takes an instruction cycle while decoding and execution takes the next instruction cycle. This pipelining scheme ensures that instructions are effectively executed in one cycle. If an instruction changes the contents of the program counter, two cycles are required to complete the instruction.

#### **Program Counter – PC**

The program counter (PC) controls the sequence in which the instructions stored in the program ROM are executed and its contents specify a full range of program memory.

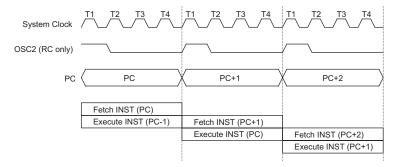

After accessing a program memory word to fetch an instruction code, the contents of the program counter are incremented by one. The program counter then points to the memory word containing the next instruction code.

When executing a jump instruction, conditional skip execution, loading into the PCL register, subroutine call or return from subroutine, initial reset, internal interrupt, external interrupt or return from interrupt, the PC manipulates the program transfer by loading the address corresponding to each instruction.

The conditional skip is activated by instructions. Once the condition is met, the next instruction, fetched during the current instruction execution, is discarded and a dummy cycle replaces it to get the proper instruction. Otherwise proceed with the next instruction.

The lower byte of the program counter (PCL) is a readable and writeable register (06H). Moving data into the PCL performs a short jump. The destination will be within the current program ROM page.

When a control transfer takes place, an additional dummy cycle is required.

Mode	Program Counter										
Mode	*10	*9	*8	*7	*6	*5	*4	*3	*2	*1	*0

#### In System Programming

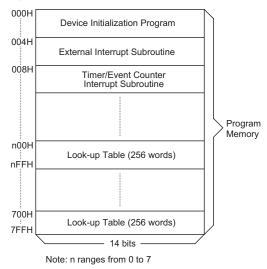

In system programming allows programming and reprogramming of HT48EXX microcontroller on application circuit board, this will save time and money, both during development in the lab. Using a simple 3-wire interface, the ISP communicates serially with the HT48EXX microcontroller, reprogramming program memory and EEPROM data memory on the chip.

Pin Name	Function	Description
PA0	SDATA	Serial data input/output
PA4	SCLK	Serial clock input
RES	RESET	Device reset
VDD	VDD	Power supply
VSS	VSS	Ground

ISP Pin Assignments

#### **Program Memory – ROM**

The program memory is used to store the program instructions which are to be executed. It also contains data, table, and interrupt entries, and is organized into 2048×14 bits, addressed by the program counter and table pointer.

#### Program Memory

Certain locations in the program memory are reserved for special usage:

Location 000H

This area is reserved for program initialization. After a chip reset, the program always begins execution at location 000H.

Location 004H

This area is reserved for the external interrupt service program. If the  $\overline{INT}$  input pin is activated, the interrupt is enabled and the stack is not full, the program begins execution at location 004H.

Location 008H

This area is reserved for the timer/event counter interrupt service program. If a timer interrupt results from a timer/event counter overflow, and if the interrupt is enabled and the stack is not full, the program begins execution at location 008H.

Table location

Any location in the program memory space can be used as look-up tables. The instructions "TABRDC [m]" (the current page, one page=256 words) and "TABRDL [m]" (the last page) transfer the contents of the lower-order byte to the specified data memory, and the higher-order byte to TBLH (08H). Only the destination of the lower-order byte in the table is well-defined, the other bits of the table word are transferred to the lower portion of TBLH, and the remaining 2-bits words are read as "0". The Table Higher-order byte register (TBLH) is read only. The table pointer (TBLP) is a read/write register (07H), which indicates the table location. Before accessing the table, the location must be placed in the TBLP. The TBLH is read only and cannot be restored. If the main routine and the ISR (Interrupt Service Routine) both employ the table read instruction, the contents of the TBLH in the main routine are likely to be changed by the table read instruction used in the ISR. Errors can occur. In other words, using the table read instruction in the main routine and the ISR simultaneously should be avoided. However, if the table read instruction has to be applied in both the main routine and the ISR, the interrupt is supposed to be disabled prior to the table read instruction. It will not be enabled until the TBLH has been backed up. All table related instructions require

Instruction		Table Location									
Instruction	*10	*9	*8	*7	*6	*5	*4	*3	*2	*1	*0
TABRDC [m]	P10	P9	P8	@7	@6	@5	@4	@3	@2	@1	@0
TABRDL [m]	1	1	1	@7	@6	@5	@4	@3	@2	@1	@0

#### **Table Location**

Note: \*10~\*0: Table location bits

@7~@0: Table pointer bits

P10~P8: Current program counter bits

HT48E30

two cycles to complete the operation. These areas may function as normal program memory depending upon the requirements.

#### Stack Register – STACK

This is a special part of the memory which is used to save the contents of the program counter (PC) only. The stack is organized into 4 levels and is neither part of the data nor part of the program space, and is neither readable nor writeable. The activated level is indexed by the stack pointer (SP) and is neither readable nor writeable. At a subroutine call or interrupt acknowledge signal, the contents of the program counter are pushed onto the stack. At the end of a subroutine or an interrupt routine, signaled by a return instruction (RET or RETI), the program counter is restored to its previous value from the stack. After a chip reset, the SP will point to the top of the stack.

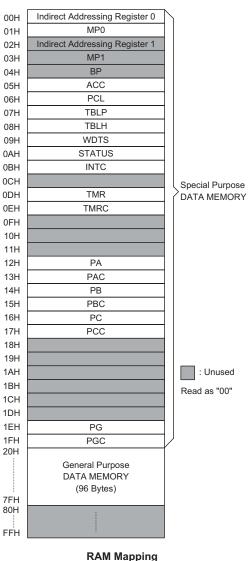

If the stack is full and a non-masked interrupt takes place, the interrupt request flag will be recorded but the acknowledge signal will be inhibited. When the stack pointer is decremented (by RET or RETI), the interrupt will be serviced. This feature prevents stack overflow allowing the programmer to use the structure more easily. In a similar case, if the stack is full and a "CALL" is subsequently executed, stack overflow occurs and the first entry will be lost (only the most recent 4 return addresses are stored).

#### Data Memory – RAM

The data memory has a capacity of  $115 \times 8$  bits and is divided into two functional groups: special function registers and general purpose data memory ( $96 \times 8$ ). Most are read/write, but some are read only.

The special function registers include the indirect addressing registers (R0;00H), timer/event counter (TMR;0DH), timer/event counter control register (TMRC;0EH), program counter lower-order byte register (PCL;06H), memory pointer registers (MP;01H), accumulator (ACC;05H), table pointer (TBLP;07H), table higher-order byte register (TBLH;08H), status register (STATUS;0AH), interrupt control register (INTC;0BH), Watchdog Timer option setting register (WDTS;09H), I/O registers (PA;12H, PB;14H, PC;16H, PG;1EH) and I/O control registers (PAC;13H, PBC;15H, PCC;17H, PGC;1FH). The remaining space before the 20H is reserved for future expanded usage and reading these locations will return the result "00H". The general purpose data memory, addressed from 20H to 7FH, is used for data and control information under instruction commands

All of the data memory areas can handle arithmetic, logic, increment, decrement and rotate operations directly. Except for some dedicated bits, each bit in the data memory can be set and reset by "SET [m].i" and "CLR [m].i". They are also indirectly accessible through

кам марріпу

memory pointer registers (MP). The control register of the EEPROM data memory is located at [40H] in Bank 1.

#### Indirect Addressing Register

Location 00H and 02H are indirect addressing registers that are not physically implemented. Any read/write operation on [00H] and [02H] access the RAM pointed to by MP0 (01H) and MP1 (03H) respectively. Reading location 00H or 02H indirectly returns the result 00H. While, writing it indirectly leads to no operation. The function of data movement between two indirect addressing registers is not supported. The memory pointer registers, MP0 and MP1, are both 7-bit registers used to access the RAM by combining corresponding indirect addressing registers. MP0 can only be applied to data memory in Bank 0, while MP1 can be applied to data memory in Bank 0 and Bank1.

#### Accumulator

The accumulator is closely related to ALU operations. It is also mapped to location 05H of the data memory and can carry out immediate data operations. The data movement between two data memory locations must pass through the accumulator.

#### Arithmetic and logic unit - ALU

This circuit performs 8-bit arithmetic and logic operations. The ALU provides the following functions:

- Arithmetic operations (ADD, ADC, SUB, SBC, DAA)
- Logic operations (AND, OR, XOR, CPL)
- Rotation (RL, RR, RLC, RRC)
- Increment and Decrement (INC, DEC)
- Branch decision (SZ, SNZ, SIZ, SDZ ....)

The ALU not only saves the results of a data operation but also changes the status register.

#### Status Register – STATUS

This 8-bit register (0AH) contains the zero flag (Z), carry flag (C), auxiliary carry flag (AC), overflow flag (OV), power down flag (PDF), and watchdog time-out flag (TO). It also records the status information and controls the operation sequence.

With the exception of the TO and PDF flags, bits in the status register can be altered by instructions like most other registers. Any data written into the status register will not change the TO or PDF flag. In addition operations related to the status register may give different results from those intended. The TO flag can be affected only by a system power-up, a WDT time-out or executing the "CLR WDT" or "HALT" instruction. The PDF flag can be affected only by executing the "HALT" or "CLR WDT" instruction or during a system power-up.

The Z, OV, AC and C flags generally reflect the status of the latest operations.

In addition, on entering the interrupt sequence or executing the subroutine call, the status register will not be pushed onto the stack automatically. If the contents of the status are important and if the subroutine may corrupt the status register, precautions must be taken to save it properly.

#### Interrupt

The device provides an external interrupt and internal timer/event counter interrupts. The Interrupt Control Register (INTC;0BH) contains the interrupt control bits to set the enable or disable and the interrupt request flags.

Once an interrupt subroutine is serviced, all the other interrupts will be blocked (by clearing the EMI bit). This scheme may prevent any further interrupt nesting. Other interrupt requests may occur during this interval but only the interrupt request flag is recorded. If a certain interrupt requires servicing within the service routine, the EMI bit and the corresponding bit of the INTC may be set to allow interrupt nesting. If the stack is full, the interrupt request will not be acknowledged, even if the related interrupt is enabled, until the SP is decremented. If immediate service is desired, the stack must be prevented from becoming full.

All these kinds of interrupts have a wake-up capability. As an interrupt is serviced, a control transfer occurs by pushing the program counter onto the stack, followed by a branch to a subroutine at specified location in the program memory. Only the program counter is pushed onto the stack. If the contents of the register or status register (STATUS) are altered by the interrupt service program which corrupts the desired control sequence, the contents should be saved in advance.

External interrupts are triggered by a high to low transition of the INT and the related interrupt request flag (EIF; bit 4 of INTC) will be set. When the interrupt is enabled, the stack is not full and the external interrupt is active, a

lt.		
Labels	Bits	Function
с	0	C is set if an operation results in a carry during an addition operation or if a borrow does not take place during a subtraction operation; otherwise C is cleared. C is also affected by a rotate through carry instruction.
AC	1	AC is set if an operation results in a carry out of the low nibbles in addition or no borrow from the high nibble into the low nibble in subtraction; otherwise AC is cleared.
Z	2	Z is set if the result of an arithmetic or logic operation is zero; otherwise Z is cleared.
ov	3	OV is set if an operation results in a carry into the highest-order bit but not a carry out of the high- est-order bit, or vice versa; otherwise OV is cleared.
PDF	4	PDF is cleared by a system power-up or executing the "CLR WDT" instruction. PDF is set by ex- ecuting the "HALT" instruction.
то	5	TO is cleared by a system power-up or executing the "CLR WDT" or "HALT" instruction. TO is set by a WDT time-out.
	6	Unused bit, read as "0"
_	7	Unused bit, read as "0"

#### **Status Register**

Register	Bit No.	Label	Function
	0	EMI	Controls the master (global) interrupt (1= enabled; 0= disabled)
	1	EEI	Controls the external interrupt (1= enabled; 0= disabled)
	2	ETI	Controls the Timer/Event Counter 0 interrupt (1= enabled; 0= disabled)
INTC	3		Unused bit, read as "0"
(0BH)	4	EIF	External interrupt request flag (1= active; 0= inactive)
	5	TF	Internal Timer/Event Counter 0 request flag (1= active; 0= inactive)
	6		Unused bit, read as "0"
	7		Unused bit, read as "0"

#### **INTC Register**

subroutine call to location 04H will occur. The interrupt request flag (EIF) and EMI bits will be cleared to disable other interrupts.

The internal timer/event counter interrupt is initialized by setting the timer/event counter interrupt request flag (TF; bit 5 of INTC), caused by a timer overflow. When the interrupt is enabled, the stack is not full and the TF bit is set, a subroutine call to location 08H will occur. The related interrupt request flag (TF) will be reset and the EMI bit cleared to disable further interrupts.

During the execution of an interrupt subroutine, other interrupt acknowledge signals are held until the "RETI" instruction is executed or the EMI bit and the related interrupt control bit are set to 1 (if the stack is not full). To return from the interrupt subroutine, "RET" or "RETI" may be invoked. RETI will set the EMI bit to enable an interrupt service, but RET will not.

Interrupts, occurring in the interval between the rising edges of two consecutive T2 pulses, will be serviced on the latter of the two T2 pulses, if the corresponding interrupts are enabled. In the case of simultaneous requests the following table shows the priority that is applied. These can be masked by resetting the EMI bit.

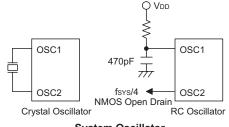

No.	Interrupt Source	Priority	Vector
а	External Interrupt	1	04H
b	Timer/Event Counter Overflow	2	08H

The timer/event counter interrupt request flag (TF), external interrupt request flag (EIF), enable timer/event counter interrupt bit (ETI), enable external interrupt bit (EEI) and enable master interrupt bit (EMI) constitute an interrupt control register (INTC) which is located at 0BH in the data memory. EMI, EEI, ETI are used to control the enabling/disabling of interrupts. These bits prevent the requested interrupt from being serviced. Once the interrupt request flags (TF, EIF) are set, they will remain in the INTC register until the interrupts are serviced or cleared by a software instruction.

It is recommended that a program does not use the "CALL subroutine" within the interrupt subroutine. Interrupts often occur in an unpredictable manner or need to be serviced immediately in some applications. If only one stack is left and enabling the interrupt is not well controlled, the original control sequence will be damaged once the "CALL" operates in the interrupt subroutine.

#### **Oscillator Configuration**

There are 2 oscillator circuits in the microcontroller.

## System Oscillator

All of them are designed for system clocks, namely, external RC oscillator and external Crystal oscillator, which are determined by options. No matter what oscillator type is selected, the signal provides the system clock. The HALT mode stops the system oscillator and ignores an external signal to conserve power.

If an RC oscillator is used, an external resistor between OSC1 and VDD is required and the resistance must range from  $24k\Omega$  to  $1M\Omega$ . The system clock, divided by 4, is available on OSC2, which can be used to synchronize external logic. The RC oscillator provides the most cost effective solution. However, the frequency of oscillation may vary with VDD, temperatures and the chip itself due to process variations. It is, therefore, not suitable for timing sensitive operations where an accurate oscillator frequency is desired.

If a Crystal oscillator is used, a crystal across OSC1 and OSC2 is needed to provide the feedback and phase shift required for the oscillator. No other external components are required. In stead of a crystal, a resonator can also be connected between OSC1 and OSC2 to obtain a frequency reference, but two external capacitors in OSC1 and OSC2 are required.

The WDT oscillator is a free running on-chip RC oscillator, and no external components are required. Even if the system enters the power down mode and the sys-

tem clock is stopped, the oscillator still works within a period of  $65\mu s$  at 5V. The WDT oscillator can be disabled by options to conserve power.

#### Watchdog Timer – WDT

The WDT clock source is implemented by a dedicated RC oscillator (WDT oscillator), instruction clock (system clock divided by 4), determines the options. This timer is designed to prevent a software malfunction or sequence from jumping to an unknown location with unpredictable results. The Watchdog Timer can be disabled by options. If the Watchdog Timer is disabled, all the executions related to the WDT result in no operation.

Once the internal WDT oscillator (RC oscillator with a period of 65µs at 5V normally) is selected, it is first divided by 256 (8-stage) to get the nominal time-out period of 18.6ms at 5V. This time-out period may vary with temperatures, VDD and process variations. By invoking the WDT prescaler, longer time-out periods can be realized. Writing data to WS2, WS1, WS0 (bit 2,1,0 of the WDTS) can give different time-out periods. If WS2, WS1, and WS0 are all equal to 1, the division ratio is up to 1:128, and the maximum time-out period is 2.4s at 5V seconds. If the WDT oscillator is disabled, the WDT clock may still come from the instruction clock and operates in the same manner except that in the HALT state the WDT may stop counting and lose its protecting purpose. In this situation the logic can only be restarted by an external logic. The high nibble and bit 3 of the WDTS are reserved for user's defined flags, which can be used to indicate some specified status.

If the device operates in a noisy environment, using the on-chip RC oscillator (WDT OSC) is strongly recommended, since the HALT will stop the system clock.

r									
WS2	WS1	WS0	Division Ratio						
0	0	0	1:1						
0	0	1	1:2						
0	1	0	1:4						
0	1	1	1:8						
1	0	0	1:16						
1	0	1	1:32						
1	1	0	1:64						
1	1	1	1:128						

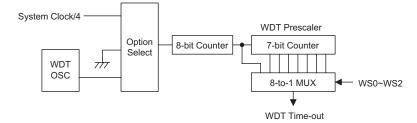

The WDT overflow under normal operation will initialize a "chip reset" and set the status bit "TO". But in the HALT mode, the overflow will initialize a "warm reset" and only the PC and SP are reset to zero. To clear the contents of WDT (including the WDT prescaler), three methods are adopted; external reset (a low level to RES), software instruction and a "HALT" instruction. The software instruction includes "CLR WDT" and the other set - "CLR WDT1" and "CLR WDT2". Of these two types of instruction, only one can be active depending on the option - "CLR WDT times selection option". If the "CLR WDT" is selected (i.e. CLRWDT times equal one), any execution of the "CLR WDT" instruction will clear the WDT. In the case that "CLR WDT1" and "CLR WDT2" are chosen (i.e. CLRWDT times equal two), these two instructions must be executed to clear the WDT; otherwise, the WDT may reset the chip as a result of time-out.

#### **Power Down Operation – HALT**

The HALT mode is initialized by the "HALT" instruction and results in the following...

- The system oscillator will be turned off but the WDT oscillator remains running (if the WDT oscillator is selected).
- The contents of the on chip RAM and registers remain unchanged.
- WDT and WDT prescaler will be cleared and recounted again (if the WDT clock is from the WDT oscillator).
- All of the I/O ports maintain their original status.
- The PDF flag is set and the TO flag is cleared.

The system can leave the HALT mode by means of an external reset, an interrupt, an external falling edge signal on port A or a WDT overflow. An external reset causes a device initialization and the WDT overflow performs a "warm reset". After the TO and PDF flags are examined, the reason for chip reset can be determined. The PDF flag is cleared by a system power-up or executing the "CLR WDT" instruction and is set when executing the "HALT" instruction. The TO flag is set if a WDT time-out occurs, and causes a wake-up that only resets the PC and SP; the others remain in their original status.

Watchdog Timer

The port A wake-up and interrupt methods can be considered as a continuation of normal execution. Each bit in port A can be independently selected to wake up the device by options. Awakening from an I/O port stimulus, the program will resume execution of the next instruction. If it awakens from an interrupt, two sequence may occur. If the related interrupt is disabled or the interrupt is enabled but the stack is full, the program will resume execution at the next instruction. If the interrupt is enabled and the stack is not full, a regular interrupt response takes place. If an interrupt request flag is set to "1" before entering the HALT mode, the wake-up function of the related interrupt will be disabled. Once a wake-up event occurs, it takes 1024 (system clock period) to resume to normal operation. In other words, a dummy period will be inserted after a wake-up. If the wake-up results from an interrupt acknowledge signal, the actual interrupt subroutine execution will be delayed by one or more cycles. If the wake-up results in the next instruction execution, this will be executed immediately after the dummy period is finished.

To minimize power consumption, all the I/O pins should be carefully managed before entering the HALT status.

## Reset

There are three ways in which a reset can occur:

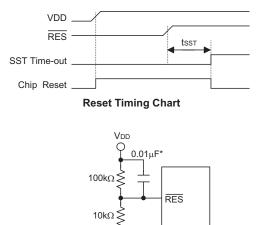

- RES reset during normal operation
- RES reset during HALT
- WDT time-out reset during normal operation

The time-out during HALT is different from other chip reset conditions, since it can perform a "warm reset" that resets only the PC and SP, leaving the other circuits in their original state. Some registers remain unchanged during other reset conditions. Most registers are reset to the "initial condition" when the reset conditions are met. By examining the PDF and TO flags, the program can distinguish between different "chip resets".

то	PDF	<b>RESET Conditions</b>			
0	0	RES reset during power-up			
u	u	RES reset during normal operation			
0	1	RES wake-up HALT			
1	u	WDT time-out during normal operation			
1	1	WDT wake-up HALT			

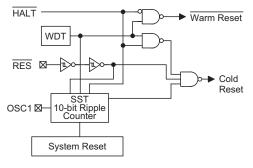

Note: "u" stands for unchanged

To guarantee that the system oscillator is started and stabilized, the SST (System Start-up Timer) provides an extra delay of 1024 system clock pulses when the system reset (power-up, WDT time-out or  $\overline{\text{RES}}$  reset) or the system awakes from the HALT state.

Reset Circuit

Note: "\*" Make the length of the wiring, which is connected to the RES pin as short as possible, to avoid noise interference.

**Reset Configuration** 

When a system reset occurs, the SST delay is added during the reset period. Any wake-up from HALT will enable an SST delay.

An extra option load time delay is added during system reset (power-up, WDT time-out at normal mode or  $\overline{\text{RES}}$  reset).

The functional unit chip reset status are shown below.

PC	000H
Interrupt	Disable
Prescaler	Clear
WDT	Clear. After master reset, WDT begins counting
Timer/Event Counter	Off
Input/Output Ports	Input mode
Stack Pointer, SP	Points to the top of the stack

Register	Reset (Power On)	WDT Time-out (Normal Operation)	RES Reset (Normal Operation)	RES Reset (HALT)	WDT Time-out (HALT)*
TMR	XXXX XXXX	XXXX XXXX	XXXX XXXX	XXXX XXXX	นนนน นนนน

EECR	1000	1000	1000	1000	uuuu

The registers status is summarized in the following table.

Note: "\*" stands for "warm reset" "u" stands for "unchanged"

"x" stands for "unknown"

#### **Timer/Event Counter**

Timer/event counters (TMR) is implemented in the microcontroller. The timer/event counter contains an 8-bit programmable count-up counter and the clock may come from an external source or from the system clock by 4.

Using the internal clock sources, there are 2 reference time-bases for the timer/event counter. The internal clock source can be selected as coming from  $f_{\rm SYS}$  or by options. Using an external clock input allows the user to count external events, measure time internals or pulse widths, or generate an accurate time base. While using the internal clock allows the user to generate an accurate time base.

The timer/event counter can generate PFD signals by using external or internal clock and the PFD frequency is determine by the equation  $f_{INT}/[2\times(256-N)]$ .

There are 2 registers related to the timer/event counter; TMR ([0DH]), TMRC ([0EH]). Two physical registers are mapped to TMR location; writing TMR makes the starting value be placed in the timer/event counter preload register and reading TMR retrieves the contents of the timer/event counter. The TMRC is a timer/event counter control register, which defines some options.

The TM0, TM1 bits define the operating mode. The event count mode is used to count external events, which means the clock source comes from an external (TMR) pin. The timer mode functions as a normal timer with the clock source coming from the  $f_{INT}$  clock. The pulse width measurement mode can be used to count the high or low level duration of the external signal (TMR). The counting is based on the  $f_{INT}$  clock.

In the event count or timer mode, once the timer/event counter starts counting, it will count from the current contents in the timer/event counter to FFH. Once over-flow occurs, the counter is reloaded from the timer/event counter preload register and generates the interrupt request flag (TF; bit 5 of INTC) at the same time.

In the pulse width measurement mode with the TON and TE bits equal to one, once the TMR has received a transient from low to high (or high to low if the TE bits is "0") it will start counting until the TMR returns to the original level and resets the TON. The measured result will remain in the timer/event counter even if the activated transient occurs again. In other words, only one cycle

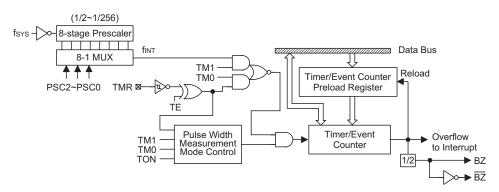

measurement can be done. Until setting the TON, the cycle measurement will function again as long as it receives further transient pulse. Note that, in this operating mode, the timer/event counter starts counting not according to the logic level but according to the transient edges. In the case of counter overflows, the counter is reloaded from the timer/event counter preload register and issues the interrupt request just like the other two modes. To enable the counting operation, the timer ON bit (TON; bit 4 of TMRC) should be set to 1. In the pulse width measurement mode, the TON will be cleared automatically after the measurement cycle is completed. But in the other two modes the TON can only be reset by instructions. The overflow of the timer/event counter is one of the wake-up sources. No matter what the operation mode is, writing a "0" to ETI can disable the corresponding interrupt services.

In the case of timer/event counter OFF condition, writing data to the timer/event counter preload register will also reload that data to the timer/event counter. But if the timer/event counter is turned on, data written to it will only be kept in the timer/event counter preload register. The timer/event counter will still operate until overflow occurs. When the timer/event counter (reading TMR) is read, the clock will be blocked to avoid errors. As clock blocking may results in a counting error, this must be taken into consideration by the programmer.

The bit0~bit2 of the TMRC can be used to define the pre-scaling stages of the internal clock sources of timer/event counter. The definitions are as shown. The overflow signal of the timer/event counter can be used to generate PFD signals for buzzer driving.

Label (TMRC)	Bits	Function
PSC0~PSC2	0~2	$ \begin{array}{l} \mbox{Defines the prescaler stages, PSC2, PSC1, PSC0=} \\ 000: \ f_{INT} = f_{SYS}/2 \\ 001: \ f_{INT} = f_{SYS}/4 \\ 010: \ f_{INT} = f_{SYS}/8 \\ 011: \ f_{INT} = f_{SYS}/16 \\ 100: \ f_{INT} = f_{SYS}/32 \\ 101: \ f_{INT} = f_{SYS}/64 \\ 110: \ f_{INT} = f_{SYS}/128 \\ 111: \ f_{INT} = f_{SYS}/256 \end{array} $
ТЕ	3	Defines the TMR active edge of the timer/event counter 0 (0=active on low to high; 1=active on high to low)
TON	4	Enable or disable timer 0 counting (0=disabled; 1=enabled)
	5	Unused bit, read as "0"
TM0 TM1	6 7	Defines the operating mode 01=Event count mode (external clock) 10=Timer mode (internal clock) 11=Pulse width measurement mode 00=Unused

#### **TMRC Register**

#### **Timer/Event Counter**

#### Input/Output Ports

There are 23 bidirectional input/output lines in the microcontroller, labeled from PA to PC and PG, which are mapped to the data memory of [12H], [14H], [16H] and [1EH] respectively. All of these I/O ports can be used for input and output operations. For input operation, these ports are non-latching, that is, the inputs must be ready at the T2 rising edge of instruction "MOV A,[m]" (m=12H, 14H, 16H or 1EH). For output operation, all the data is latched and remains unchanged until the output latch is rewritten.

Each I/O line has its own control register (PAC, PBC, PCC, PGC) to control the input/output configuration. With this control register, CMOS output or Schmitt trigger input with or without pull-high resistor structures can be reconfigured dynamically under software control. To function as an input, the corresponding latch of the control register must write a "1". The input source also depends on the control register. If the control register bit is "1", the input will read the pad state. If the control register bit is "0", the contents of the latches will move to the internal bus. The latter is possible in the "read-modify-write" instruction.

For output function, CMOS is the only configuration. These control registers are mapped to locations 13H, 15H, 17H and 1FH. After a chip reset, these input/output lines remain at high levels or floating state (depending on the pull-high options). Each bit of these input/output latches can be set or cleared by "SET [m].i" and "CLR [m].i" (m=12H, 14H, 16H or 1EH) instructions.

Some instructions first input data and then follow the output operations. For example, "SET [m].i", "CLR [m].i", "CPL [m]", "CPLA [m]" read the entire port states into the CPU, execute the defined operations (bit-operation), and then write the results back to the latches or the accumulator.

Each line of port A has the capability of waking-up the device. The highest 7-bit of port G are not physically implemented; on reading them a "0" is returned whereas writing then results in no operation. See Application note.

There is a pull-high option available for all I/O lines (bit option). Once the pull-high option of an I/O line is selected, the I/O line has a pull-high resistor. Otherwise, the pull-high resistor is absent. It should be noted that a non-pull-high I/O line operating in input mode will cause a floating state.

The PB0 and PB1 are pin-shared with BZ and  $\overline{\text{BZ}}$  signals, respectively. If the BZ/ $\overline{\text{BZ}}$  option is selected, the output signal in output mode of PB0/PB1 will be the PFD signal generated by timer/event counter 0 overflow signal. The input mode always remain in its original functions. Once the BZ/ $\overline{\text{BZ}}$  option is selected, the buzzer output signals are controlled by the PB0 data register only.

6									•	-
PB0 I/O	I	I	0	0	0	0	0	0	0	0
PB1 I/O	I	0	I	I	I	0	0	0	0	0
PB0 Mode	x	х	С	В	В	С	В	В	В	В
PB1 Mode	х	С	х	х	х	С	С	С	В	В
PB0 Data	x	х	D	0	1	D <sub>0</sub>	0	1	0	1
PB1 Data	х	D	х	х	х	D <sub>1</sub>	D	D	x	х
PB0 Pad Status	I	I	D	0	В	D <sub>0</sub>	0	В	0	В
PB1 Pad Status	I	D	I	I	I	D <sub>1</sub>	D	D	0	В

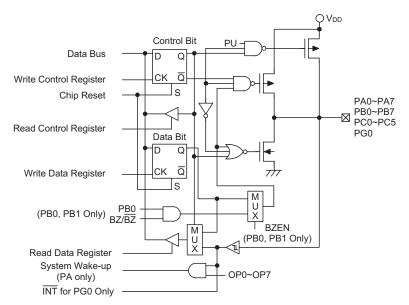

The I/O functions of PB0/PB1 are shown below.

Note: "I" input, "O" output, "D, D<sub>0</sub>, D<sub>1</sub>" data,

"B" buzzer option, BZ or  $\overline{BZ}$ , "x" don  $\Box$ t care

"C" CMOS output

Input/Output Ports

The PG0 is pin-shared with  $\overline{\text{INT}}$ .

It is recommended that unused or not bonded out I/O lines should be set as output pins by software instruction to avoid consuming power under input floating state.

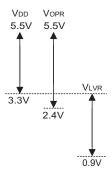

#### Low Voltage Reset – LVR

The HT48E30 provides a low voltage reset circuit in order to monitor the supply voltage of the device. If the supply voltage is within the range 0.9V-V<sub>LVR</sub>, such as while changing a battery, the LVR will automatically reset the device internally.

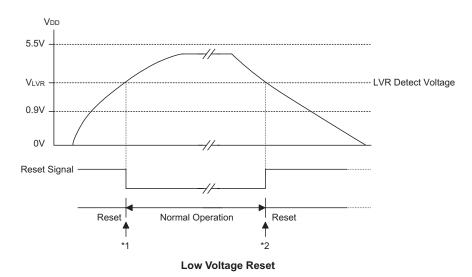

The LVR includes the following specifications:

- Within the low voltage range  $(0.9V \sim V_{LVR})$ , the device remains in their original state until exceeding 1ms. If the low voltage state does not exceed 1ms, the LVR will ignore it and does not perform a reset function.
- The LVR uses the "OR" function with the external  $\overline{\text{RES}}$  signal to perform chip reset.

The relationship between  $V_{\text{DD}}$  and  $V_{\text{LVR}}$  is shown below.

Note: V<sub>OPR</sub> is the voltage range for proper chip operation at 4MHz system clock.

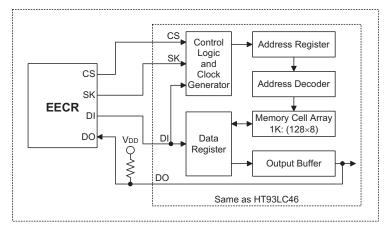

- Note: \*1: To make sure that the system oscillator has stabilized, the SST provides an extra delay of 1024 system clock pulses before entering the normal operation.
  - \*2: Since low voltage has to be maintained in its original state until exceeding 1ms, therefore after a 1ms delay, the device enters a reset mode.

## **EEPROM Data Memory**

The 128×8 bits EEPROM data memory is readable and writable during normal operation. It is indirectly addressed through the control register EECR ([40H] in Bank 1). The EECR can be read and written to only by indirect addressing mode using MP1.

Label (EECR)	Bits	Function
_	0~3	Unused bit, read as "0"
CS	4	EEPROM data memory select
SK	5	Serial clock input to EEPROM data memory
DI	6	Serial data input to EEPROM data memory
DO	7	Serial data output from EEPROM data memory

**EEPROM Data Memory Block Diagram** 

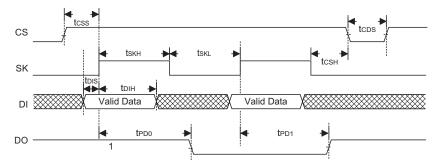

Ta=25°C

The EEPROM data memory is accessed via a three-wire serial communication interface by writing to EECR. It is arranged into 128 words by 8 bits. The EEPROM data memory contains seven instructions: READ, ERASE, WRITE, EWEN, EWDS, ERAL and WRAL. These instructions are all made up of 10 bits data: 1 start bit, 2 op-code bits and 7 address bits.

By writing CS, SK and DI, these instructions can be given to the EEPROM. These serial instruction data presented at the DI will be written into the EEPROM data memory at the rising edge of SK. During the READ cycle, DO acts as the data output and during the WRITE or ERASE cycle, DO indicates the BUSY/READY status. When the DO is active for read data or as a BUSY/ READY indicator the CS pin must be high; otherwise DO will be in a high state. For successful instructions, CS must be low once after the instruction is sent. After power on, the device is by default in the EWDS state. And, an EWEN instruction must be performed before any ERASE or WRITE instruction can be executed.

The following are the functional descriptions and timing diagrams of all seven instructions.

## EECR A.C. Characteristics

Symbol	Parameter	V <sub>CC</sub> =5	V±10%	V <sub>CC</sub> =2.2	Unit		
Symbol	Farameter	Min.	Max.	Min.	Max.	Unit	
f <sub>SK</sub>	Clock Frequency	0	2	0	1	MHz	
t <sub>SKH</sub>	SK High Time	250		500	_	ns	
t <sub>SKL</sub>	SK Low Time	250		500		ns	
t <sub>CSS</sub>	CS Setup Time	50		100		ns	
t <sub>CSH</sub>	CS Hold Time	0		0		ns	
t <sub>CDS</sub>	CS Deselect Time	250	_	250		ns	
t <sub>DIS</sub>	DI Setup Time	100		200		ns	
t <sub>DIH</sub>	DI Hold Time	100		200		ns	
t <sub>PD1</sub>	DO Delay to "1"	_	250	_	500	ns	
t <sub>PD0</sub>	DO Delay to "0"		250		500	ns	
t <sub>SV</sub>	Status Valid Time		250		250	ns	
t <sub>HZ</sub>	DO Disable Time	100		200		ns	
t <sub>PR</sub>	Write Cycle Time Per Word	_	2	_	5	ms	

## READ

The READ instruction will stream out data at a specified address on the DO. The data on DO changes during the low-to-high edge of SK. The 8 bits data stream is preceded by a logical "0" dummy bit. Irrespective of the condition of the EWEN or EWDS instruction, the READ command is always valid and independent of these two instructions. After the data word has been read the internal address will be automatically incremented by 1 allowing the next consecutive data word to be read out without entering further address data. The address will wrap around with CS High until CS returns to Low.

#### EWEN/EWDS

The EWEN/EWDS instruction will enable or disable the programming capabilities. At both the power on and power off state the device automatically entered the disable mode. Before a WRITE, ERASE, WRAL or ERAL instruction is given, the programming enable instruction EWEN must be issued, otherwise the ERASE/WRITE instruction is invalid. After the EWEN instruction is issued, the programming enable condition remains until power is turned off or an EWDS instruction is given. No data can be written into the EEPROM data memory in the programming disabled state. By so doing, the internal memory data can be protected.

#### ERASE

The ERASE instruction erases data at the specified addresses in the programming enable mode. After the ERASE op-code and the specified address have been issued, the data erase is activated by the falling edge of CS. Since the internal auto-timing generator provides all timing signals for the internal erase, so the SK clock is not required. During the internal erase, we can verify the busy/ready status if CS is high. The DO will remain low but when the operation is over, the DO will return to high and further instructions can be executed.

## WRITE

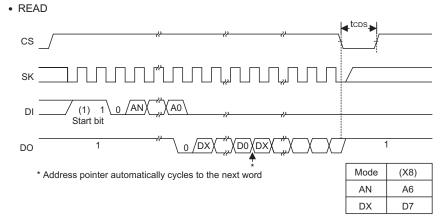

The WRITE instruction writes data into the EEPROM data memory at the specified addresses in the programming enable mode. After the WRITE op-code and the specified address and data have been issued, the data writing is activated by the falling edge of CS. Since the internal auto-timing generator provides all timing signal for the internal writing, so the SK clock is not required. The auto-timing write cycle includes an automatic erase-before-write capability. So, it is not necessary to erase data before the WRITE instruction. During the internal writing, we can verify the busy/ready status if CS is high. The DO will remain low but when the operation is over, the DO will return to high and further instructions can be executed.

#### ERAL

The ERAL instruction erases the entire 128×8 memory cells to a logical "1" state in the programming enable mode. After the erase-all instruction set has been issued, the data erase feature is activated by the falling edge of CS. Since the internal auto-timing generator provides all timing signal for the erase-all operation, so the SK clock is not required. During the internal erase-all operation, we can verify the busy/ready status if CS is high. The DO will remain low but when the operation is over, the DO will return to high and further instruction can be executed.

#### WRAL

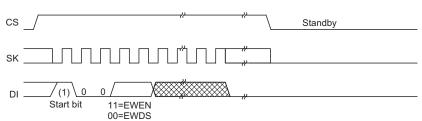

The WRAL instruction writes data into the entire 128×8 memory cells in the programming enable mode. After the write-all instruction set has been issued, the data writing is activated by the falling edge of CS. Since the internal auto-timing generator provides all timing signals for the write-all operation, so the SK clock is not required. During the internal write-all operation, we can verify the busy/ready status if CS is high. The DO will remain low but when the operation is over the DO will return to high and further instruction can be executed.

## EEPROM Data Memory Instruction Set Summary

Instruction	Comments	Start bit	Op Code	Address	Data
READ	Read data	1	10	A6~A0	D7~D0
ERASE	Erase data	1	11	A6~A0	_
WRITE	Write data	1	01	A6~A0	D7~D0
EWEN	Erase/Write Enable	1	00	11XXXXX	
EWDS	Erase/Write Disable	1	00	00XXXXX	
ERAL	Erase All	1	00	10XXXXX	
WRAL	Write All	1	00	01XXXXX	D7~D0

Note: "X" stands for "don't care"

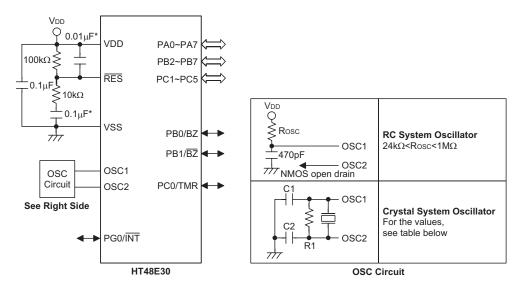

## Options

The following table shows all kinds of options in the microcontroller. All of the options must be defined to ensure proper system functioning.

Items	Options				
1	WDT clock source: WDT oscillator or f <sub>SYS</sub> /4 or disable				
2	CLRWDT instructions: 1 or 2 instructions				
3	Timer/event counter clock source: f <sub>SYS</sub>				
4	PA bit wake-up enable or disable				
5	PA CMOS or Schmitt input				
6	PA, PB, PC, PG pull-high enable or disable (by port)				
7	BZ/BZ enable or disable				
8	LVR enable or disable				
9	System oscillator: RC or crystal				

# **Application Circuits**

The following table shows the C1, C2 and R1 value according different crystal values.

Crystal or Resonator	C1, C2	R1
4MHz Crystal	0pF	10kΩ
4MHz Resonator (3 pin)	0pF	12kΩ
4MHz Resonator (2 pin)	10pF	12kΩ
3.58MHz Crystal	0pF	10kΩ
3.58MHz Resonator (2 pin)	25pF	10kΩ
2MHz Crystal & Resonator (2 pin)	25pF	10kΩ
1MHz Crystal	35pF	<b>27</b> kΩ
480kHz Resonator	300pF	9.1kΩ
455kHz Resonator	300pF	10kΩ
429kHz Resonator	300pF	10kΩ

Note: The resistance and capacitance for reset circuit should be designed in such a way as to ensure that the VDD is stable and remains within a valid operating voltage range before bringing RES to high.

"\*" Make the length of the wiring, which is connected to the  $\overline{\text{RES}}$  pin as short as possible, to avoid noise interference.

SNZ [m].i	Skip if bit i of data memory is not zero	1 <sup>(2)</sup>	None
SIZ [m]	Skip if increment data memory is zero	1 <sup>(3)</sup>	None
SDZ [m]	Skip if decrement data memory is zero	1 <sup>(3)</sup>	None
SIZA [m]	Skip if increment data memory is zero with result in ACC	1 <sup>(2)</sup>	None
SDZA [m]	Skip if decrement data memory is zero with result in ACC	1 <sup>(2)</sup>	None
CALL addr	Subroutine call	2	None
RET	Return from subroutine	2	None
RET A,x	Return from subroutine and load immediate data to ACC	2	None
RETI	Return from interrupt	2	None
Table Read			
TABRDC [m]	Read ROM code (current page) to data memory and TBLH	2 <sup>(1)</sup>	None
TABRDL [m]	Read ROM code (last page) to data memory and TBLH	2 <sup>(1)</sup>	None
Miscellaneou	S		
NOP	No operation	1	None
CLR [m]	Clear data memory	1 <sup>(1)</sup>	None
SET [m]	Set data memory	1 <sup>(1)</sup>	None
CLR WDT	Clear Watchdog Timer	1	TO,PDF
CLR WDT1	Pre-clear Watchdog Timer	1	TO <sup>(4)</sup> , PDF <sup>(4)</sup>
CLR WDT2	Pre-clear Watchdog Timer	1	TO <sup>(4)</sup> ,PDF <sup>(4)</sup>
SWAP [m]	Swap nibbles of data memory	1 <sup>(1)</sup>	None
SWAPA [m]	Swap nibbles of data memory with result in ACC	1	None
HALT	Enter power down mode	1	TO,PDF

- Note: x: Immediate data
  - m: Data memory address
  - A: Accumulator
  - i: 0~7 number of bits
  - addr: Program memory address
  - $\checkmark$ : Flag is affected
  - -: Flag is not affected
  - <sup>(1)</sup>: If a loading to the PCL register occurs, the execution cycle of instructions will be delayed for one more cycle (four system clocks).
  - <sup>(2)</sup>: If a skipping to the next instruction occurs, the execution cycle of instructions will be delayed for one more cycle (four system clocks). Otherwise the original instruction cycle is unchanged.
  - $^{(3)}$ :  $^{(1)}$  and  $^{(2)}$
  - <sup>(4)</sup>: The flags may be affected by the execution status. If the Watchdog Timer is cleared by executing the "CLR WDT1" or "CLR WDT2" instruction, the TO and PDF are cleared. Otherwise the TO and PDF flags remain unchanged.
