## ASCOT™ INTEGRATED ADSL CMOS ANALOG FRONT-END CIRCUIT

- FULLY INTEGRATED AFE FOR CPE ADSL
- OVERALL 12 BIT RESOLUTION, 1.1MHz SIGNAL BANDWIDTH IN Rx
- 8.8MS/s ADC
- 8.8MS/s DAC
- THD: -60dB @FULL SCALE
- 4-BIT DIGITAL INTERFACE TO/FROM THE DMT MODEM
- 1V FULL SCALE INPUT
- DIFFERENTIAL ANALOG I/O
- ACCURATE CONTINUOUS-TIME CHANNEL FILTERING
- 3rd \& 4th ORDER TUNABLE CONTINUOUS TIME LP FILTERS
- 0.5 WATT AT 3.3V
- 0.5mm HCMOS5 LA TECHNOLOGY
- 64 PIN TQFP PACKAGE

## DESCRIPTION

ST70134 is the Analog Front End of the STMicroelectronics ASCOT ${ }^{\text {TM }}$ ADSL chipset and when coupled with ST70135A or ST70235 (DMT modem) allows to get a T1.413 Issue 2 or G.dmt compliant solution.

The ST70134 analog front end handles 2 transmission channels on a balanced 2 wire interconnection; a 16 to 640Kbit/s upstream transmit channel and a 1.536Mbit/s to 8.192Mbit/s downstream receive channel.

This asymmetrical data transmission system uses high resolution, high speed analog to digital and digital to analog conversion and high order analog filtering to reduce the echo and noise in both receivers and transmitters.

External low noise driver and input stage used with ST70134 guarantee low noise performances. The filters, with a programmable cutoff frequency, use automatic Continuous Time Tuning to avoid time varying phase characteristic which can be of dramatic consequence for DMT modem.
It requires few external components, uses a 3.3V supply. It is packaged in a 64-pin TQFP in order to reduce PCB area.

Figure 1 : Block Diagram

## The Receiver (RX) Part

The DMT signal coming from the line to the ST70134 is first filtered by two external filters, Pots HP and channel filters.
An analog multiplexer allows the selection between two input ports which can be used to select an attenuated ( $0,10 \mathrm{~dB}$ for ex.) version of the signal in case of short loop or large echo.
The signal is amplified by a low noise gain stage ( $0-31 \mathrm{~dB}$ ) then low-pass filtered to avoid aliasing and to ease further digital processing by removing unwanted high frequency out-of-band noise.A 13-bit A/D converter samples the data at 8.832MS/s (or 4.416MS/s in alternative mode), transforms the signal into a digital representation and sends it to the DMT signal processor via the digital interface.

## The Transmitter (TX) part

The 12-bit data words at $8.832 \mathrm{MS} / \mathrm{s}$ (or $4.416 \mathrm{MS} /$ s) coming from the DMT signal processor through the digital interface are transformed by D/A converter into a analog signal.
This signal is then filtered to decrease DMT sidelobes level and meet the ANSI transmitter spectral response but also to reduce the out-of-band noise (which can be echoed to the RX path) to an acceptable level. The pre-driver buffers the signal
for the external line driver and in case of short loop provide attenuation (-15...0dB).

## The VCXO Part

The VCXO is divided in a XTAL driver and a auxiliary 8 bits DAC for timing recovery.The XTAL driver is able to operate at 35.328 MHz .
The DAC which is driven by the CTRLIN pin provides a current output with 8 -bit resolution and can be used to tune the XTAL frequency with the help of external components.

A time constant between DAC input and VCXO output can be introduced (via the CTLIN interface) and programmed with the help of an external capacitor (on VCOC pin). See chapter 'VCXO' for the external circuit related to the VCXO.

## The Digital Interface Part

The digital part of the ST70134 can be divided in 2 sections:

- The data interface converts the multiplexed data from/to the DMT signal processor into valid representation for the TX DAC and RX ADC.
- The control interface allows the board processor to configure the STL70134 paths (RX/TX gains, filter band, ...) or settings (OSR, vcodac enable, digital / analog loopback,...).

## DMT Signal (Done by the DMT companion chip)

A DMT signal is basically the sum of $N$ independently QAM modulated signals, each carried over a distinct carrier. The frequency separation of each carrier is 4.3125 kHz with a total number of 256 carriers (ANSI). For N large, the signal can be modelled by a gaussian process with a certain amplitude probability density function. Since the maximum amplitude is expected to arise very rarely, we decide to clip the signal and to trade-off the resulting SNR loss against AD/DA dynamic. A clipping factor (Vpeak/Vrms = "crest factor") of 5.3 will be used resulting in a maximum SNR of 75 dB .

ADSL DMT signals are nominally sent at an average of $-38 \mathrm{dBmHz}(-1.65 \mathrm{dBm} /$ carrier $)$ with a maximal power of 15.7 mW for the transmitter (upstream for ADSL over Pots, DMT carriers are
from 7 to 31, for ADSL over ISDN DMT carriers are from 31 to 64).

## Maximum / Minimum Signal Levels

The following table gives the transmitted and received signal levels for CPE (ATU-R) and, for reference, at ATU-C. All the levels are referred to the line voltages (i.e. after hybrid and transformers in TX direction, before hybrid and transformer in RX direction).
Note that signal amplitudes shown below are for illustration purpose and depending on the transmit power and line impedance signal amplitudes can differ from these values.
The reference line impedance for all power calculations is $100 \Omega$.

## Package

The ST70134 is packaged in a 64-pin TQFP package (body size $10 \times 10 \mathrm{~mm}$, pitch 0.5 mm ).

Table 1 : Target Signal Levels (on the line)

| Parameter | ATU - R |  | ATU - C (for reference) |  |
| :--- | :---: | :---: | :---: | :---: |
|  | RX | TX | RX | TX |
| Max level | 3.95 Vpdif * | 6.8 Vpdif | 1.66 mV pdif | 15.8 Vpdif ${ }^{*}$ |
| Max RMS level | 791 mVrms | 671 mVrms | 168 mVrms | 3.16 Vrms |
| Min level | 42 mVpdif | 839 mVpdif | 54 mVpdif | 3.95 Vpdif |
| Min RMS level | 8 mVrms | 168 mVrms | 11 mVrms | 791 mVrms |

* Power cut back software co facility.

Table 2 : Pin Functions

| Numbers | Name | Function | PCB connection | Supply |
| :---: | :---: | :---: | :---: | :---: |

Figure 3 : Grounding and Decoupling Networks

## BLOCK DIAGRAM

Application principle is described in Figure 4.
A LP filter may be used on the TX path to reduce DMT sidelobes and out of band noise influence on the receiver. On the RX path, a HP filter must be used in order to reduce the echo signal level and to avoid saturation of the input stage of the receiver. The POTS filter is used in both directions to reduce crosstalk between ADSL signals and POTS speech and signalling. Low pass POTS filter can be very simple for Lite - ADSL application (see Figure 4).

## RX Path

## Speech Filter

An external bi-directional LC filter for up and downstream POTS service splits the speech signal from the ADSL signal to the POTS circuits. The ADSL analog front end integrated circuit does not contain any circuitry for the POTS service but it guarantees that bandwidth is not disturbed by spurious signals from the ADSL-spectrum.

## Channel Filters

The external analog circuits provide partial echo cancellation by an analog filtering of the transmit upstream signal. This is feasible because the upstream and the downstream data are modulated on separate carriers (FDM) (see Figure 4).

## Signal to Noise Performance

## RX- PATH SENSITIVITY AT MAXIMUM GAIN

The RX path sensitivity at the maximal RX-AGC of the receiver is defined at $-140 \mathrm{dBm} / \mathrm{Hz}$ (for $100 \Omega$ ref) on the line. This figure corresponds to the equivalent input noise of $31 \mathrm{nVHz}^{-1 / 2}$ seen on the line.
The maximum noise density within the pass band can exceed the average value as follows:
RX path (max AGC setting):

$$
\begin{aligned}
& <100 \mathrm{nVHz}^{-1 / 2} @ 138 \mathrm{kHz} \\
& <31 \mathrm{nVHz}
\end{aligned}
$$

Figure 4 : Block Diagram

[^0]
## RX-PATH NOISE AT MINIMUM GAIN

At the minimum AGC the total average thermal noise of the analog RX-path at the ADC input should be lower than the ADC quantisation noise. The maximum noise density within the pass band can exceed the average value as follows:

RX path (min AGC setting) $<500 \mathrm{nVHz}^{-1 / 2}$ 138 kHz < f

These noise specifications correspond to 10bit resolution of the complete RX-path.
Table 3 : RX Common-mode Voltage

| Description | Value/Unit |
| :--- | :---: |
| Common mode signal VCM <br> at RXIN1 and RXIN2: | $1.6 \mathrm{~V}<\mathrm{VCM}<1.7 \mathrm{~V}$ |

## AGC of RX Path

The AGC gain in the RX-path is controlled through a 5-bits digital code.

Four inputs are provided for RX input and the selection is made with the RXMUX bits of the CTRLIN interface.

This can be used to make lower gain paths in case of high input signal.
Table 4 : AGC Characteristics

| Description | Value/Unit |
| :--- | :--- |
| Input referred noise(max. gain) | $31 \mathrm{nVHz}^{-1 / 2}$ |
| Max. input level | 1 Vpd |
| Max. output level | 1 Vpd |
| Gain range | 0 to 31 dB with <br> step $=1 \mathrm{~dB}$ |
| Gain and step accuracy | $\pm 0.3 \mathrm{~dB}$ |

## RX Filters

The combination of the external filter (an LC ladder filter typically) with the integrated lowpass filter must provide:

- Echo reduction to improve dynamic range.
- DMT sidelobe and out of band (anti-aliasing) attenuation.
- Anti alias filter (60dB rejection @ image frequency).

## RX Filters

The integrated filter have the following characteristics:

Table 5 : Integrated HC Filter Characteristics

| Description | Value / Unit |
| :--- | :--- |
| Maximum input level | 1 Vpd |
| Maximum output level | 1 Vpd |
| Type | 3rd order butterworth |
| Frequency band | $1.104 \mathrm{MHz}(0 \%$ setting, see below) |
| Frequency tuning | $-43.75 \%->+0 \%$ |
| Max. in-band ripple | 1 dB |
| Matlab Model | $[\mathrm{B}, \mathrm{A}]=$ butter (3, w0, 's') |
| Default cut off frequency @ -3dB | $\mathrm{FO}=1560 \mathrm{KHz}$ |
| Actual cut off @ -3dB | $\mathrm{w} 0=2^{*}$ pi $\mathrm{FO} /((20+\mathrm{n}) / 16)$ |
| HC Freq. selection register | $\mathrm{n}=-4, . ., 3$ see (AFE settings,Table 19) |

Table 6 : Phase Characteristic

| Description | Value $/$ Unit |
| :--- | :--- |
| Total $R X$ filter group delay | $<50 \mu \mathrm{~s} @ 138 \mathrm{kHz}<\mathrm{f}<1.104 \mathrm{MHz}$ |
| Total RX filter group delay distortion | $<15 \mu \mathrm{~s} @ 138 \mathrm{kHz}<\mathrm{f}<1.104 \mathrm{MHz}$ |

Figure 5 : HC Filter Mask for RX

Note: The total RX path (including ADC) group delay distortion is $16 \mu \mathrm{~s}$ (i.e. $=15 \mu \mathrm{~s}+1 \mu \mathrm{~s}$ of ADC )

## Linearity of RX

Linearity of the RX analog path is defined by the IM3 product of two sinusoidal signals with frequencies f1 and f2 and each with 0.5 Vpd amplitude (total $\leq 1 \mathrm{Vpd}$ ) at the output of the RX - AGC amplifier (i.e: before the ADC) for the case of minimal AGC setting.
Table 7 lists the RX path intermodulation distortion (as S/IM3 ratio) in downstream and upstream bandwidth.
Table 7 : Linearity of RX

| $\begin{aligned} & \hline \mathrm{f} 1(0.5 \mathrm{Vpd}) \\ & \mathrm{f} 2(0.5 \mathrm{Vpd}) \end{aligned}$ | $\begin{aligned} & 300 \mathrm{kHz} \\ & 200 \mathrm{kHz} \end{aligned}$ | $\begin{aligned} & 500 \mathrm{kHz} \\ & 400 \mathrm{kHz} \end{aligned}$ | $\begin{aligned} & 700 \mathrm{kHz} \\ & 600 \mathrm{kHz} \end{aligned}$ |
| :---: | :---: | :---: | :---: |
| $\begin{aligned} & \mathrm{S} / \mathrm{IM} 3 \\ & (\mathrm{AGC}=0 \mathrm{~dB}) \end{aligned}$ | $\begin{array}{\|l} 59.5 \mathrm{~dB} @ 100 \mathrm{kHz} \\ 53.5 \mathrm{~dB} @ 400 \mathrm{kHz} \\ 43.5 \mathrm{~dB} @ 700 \mathrm{kHz} \\ 42.5 \mathrm{~dB} @ 800 \mathrm{kHz} \end{array}$ | $\begin{aligned} & 59.5 \mathrm{~dB} @ 300 \mathrm{kHz} \\ & 48.0 \mathrm{~dB} @ 600 \mathrm{kHz} \end{aligned}$ | $\begin{aligned} & 48.0 \mathrm{~dB} @ 500 \mathrm{kHz} \\ & 42.5 \mathrm{~dB} @ 800 \mathrm{kHz} \end{aligned}$ |

Table 8 : RX Filter to A/D Interface

| RX filter to $A / D$ maximal level: | $1 \mathrm{Vpd}=$ full scale of $A / D$ |
| :--- | :--- |

Table 9 : A/D Converters

| Numbers of bits: | 12bits |
| :--- | :--- |
| Minimum resolution of the A/D converter | 11 bits |
| Linearity error of the A/D converter | $<1 \mathrm{LSB}$ (out of 12bits) |
| Full scale input range: | $1 \mathrm{Vpdif} \pm 5 \%$ |
| Sampling rate: | 8.832 MHz (or 4.416 MHz in OSR $=2$ mode) |
| Maximum attenuation at $1.1 \mathrm{MHz}:$ | $<0.5 \mathrm{~dB}$ without in-band ripple |
| Maximum group delay: | $<3 \mu \mathrm{~s}$ |
| Maximum group delay distortion: | $<1 \mu \mathrm{~s}$ |

## Power Supply Rejection

The noise on the power supplies for the RX path must be lower than the following: <50mVrms in band white noise for any AVDD.
In this case, PSR (power supply rejection) of ST70134 RX path is lower than -43 dB .

## ST70134A

## TX Pre-driver Capability

The pre-driver drives an external line power amplifier which transmits the required power to the line.
Table 10 : TX Pre-driver

| TX drive level to the external line driver for max. AGC setting |  | 1.5 Vpdif |
| :---: | :---: | :---: |
| External line driver input impedance: | resistive capacitive | $\begin{aligned} & >500 \Omega \\ & <30 \mathrm{pF} \end{aligned}$ |
| Pre-driver characteristics: |  |  |
| Closed loop gain: | -15 dB ...0dB with step $=1 \mathrm{~dB}$ |  |
| Output characteristics |  |  |
| Output offset voltage (0dB) | < 10 mV |  |
| Output noise voltage (0dB) | $\begin{aligned} & <150 \mathrm{nVHz}^{-1 / 2} @ \mathrm{f}>250 \mathrm{kHz} \\ & <500 \mathrm{nVHz}^{-1 / 2} @ 34.5 \mathrm{kHz}<\mathrm{f}<138 \mathrm{kHz} \end{aligned}$ | OdB |
| Output common mode voltage: | 1.6 V < Vcm < 1.7V |  |

## TX Filter

The TX filter acts not only to suppress the DMT sidebands but also as smoothing filter on the D/A convertor's output to suppress the image spectrum. For this reason it must be realized in a continuous time approach.

## ATU-R TX Filter

The purpose of this filter is to remove out-of-band noise of the TX path echoed to the RX path. In order to meet the transmitter spectral response, an additional filtering must be (digitally) performed. The integrated filter has the following characteristics:
Table 11 : Integrated SC Filter Characteristics

| Description | Value/Unit |
| :---: | :---: |
| Maximum input level | 1 Vpd |
| Maximum output level | 1 Vpd |
| Type | 4th order chebytchef |
| Frequency band | 138 kHz (0\% setting see below) |
| Frequency tuning | -25\% -> +25\% |
| Max. in-band ripple | 1dB |
| Matlab Model <br> Default cut-off frequency @ -3dB <br> Actual cut-off @ -3dB <br> SC Frequency selection register | $\begin{aligned} & {[\text { [B,A] }=\text { cheby } 1(4,0.5, \text { W0,'s') }\{\text { ripple }=0.5\}} \\ & F 0=151.8 \mathrm{kHz} \\ & \text { W0 } \left.=2^{*} \mathrm{pi*} \mathrm{FO} /(17+\mathrm{n}) / 16\right) \\ & \mathrm{n}=-4, . ., 3 \text { see (AFE settings, Table 19) } \end{aligned}$ |
| Total TX filter group delay | $<50 \mu \mathrm{~s}$ @ $34.5 \mathrm{kHz}<\mathrm{f}<138 \mathrm{kHz}$ |
| Total TX filter group delay distortion | $<20 \mu \mathrm{~s}$ @ $34.5 \mathrm{kHz}<\mathrm{f}<138 \mathrm{kHz}$ |

Note: The total TX path (including DAC) group delay distortion is $16 \mu \mathrm{~s}$ (i.e. $=15 \mu \mathrm{~s}+1 \mu \mathrm{~s}$ of DAC).

Figure 6 : SC Filter Mask for TX

Table 12 : D/A Converter (A current steering architecture is used)

| Description | Value / Unit |
| :--- | :--- |
| Numbers of bits: | 12 bits |
| Minimum resolution of the D/A converters | 11 bits |
| Linearity error of the A/D converter | $<1 \mathrm{LSB}$ (out of 12bits) |
| Full scale input range: | $1 \mathrm{Vpdif} \pm 5 \%$ |
| Sampling rate: | 8.832 MHz (or 4.416 MHz in compatible mode) |
| Maximum group delay: | $<3 \mu \mathrm{~s}$ |
| Maximum group delay distortion: | $<1 \mu \mathrm{~s}$ |

## Linearity in TX

Linearity of the TX is defined by the IM3 product of two sinusoidal signals with frequencies f 1 and f 2 and each with 0.5 Vpd amplitude (total $\leq 1 \mathrm{Vpd}$ ) at the output of the pre-driver for the case of a total $A G C=0 d B$.
Table 13 : Linearity in TX

| $\mathrm{f} 1(0.5 \mathrm{Vpd})$ | 80 kHz |
| :--- | :--- |
| $\mathrm{f} 2(0.5 \mathrm{Vpd})$ | 70 kHz |
| $\mathrm{S} / \mathrm{IM} 3(\mathrm{AGC}=0 \mathrm{~dB})$ | $59.5 \mathrm{~dB}(@ 60 \mathrm{KHz}, 90 \mathrm{KHz})$ |

## TX Idle Channel Noise

The idle channel noise specifications correspond with 11bit resolution of the complete TX-path. TX idle channel output noise on TXP, TXN.
Table 14 : TX idle channel noise

| For max AGC setting (0dB) |  |  |
| :--- | :--- | :--- |
| In-band noise <br> Out-of-band noise | $1.6 \mu \mathrm{VHz}^{-1 / 2}$ <br> $150 \mathrm{nVHz}^{-1 / 2}$ | $@ 34.5 \mathrm{kHz}-138 \mathrm{kHz}$ <br> $@ 250 \mathrm{kHz}-1.104 \mathrm{MHz}$ |
| For min AGC setting (=-15dB) | $500 \mathrm{nVHz}^{-1 / 2}$ | $@ 34 \mathrm{kHz}-138 \mathrm{kHz}$ |
| In-band noise |  |  |

## Power Supply Rejection

The noise on the power supplies for the TX-path must be lower than the following:
$<50 \mathrm{mVrms}$ in-band white noise for AVDD.
$<15 \mathrm{mVrms}$ in-band white noise for Pre-driver AVDD.

## VCXO

A voltage controlled crystal oscillator driver is integrated in ST70134. The nominal frequency is 35.328 MHz . The quartz crystal is connected between the pins XTALI and XTALO. The principle of the VCXO control is shown in Figure 7.

The information coming from the digital processor via the CTRLIN path is used to drive an 8-bit DAC which generates a control current. This current is externally converted and filtered to generate the required control voltage (range:- 15 V to 0.5 V ) for the varicap. The VCXO circuit characteristics are given in Table 15.

Table 15 : VCXO circuit Characteristics

| Symbol | Parameter | Minimum | Nominal | Maximum | Note |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{f}_{\text {abs }}$ | Absolute frequency accuracy | -15 ppm | 35.328 MHz | +15 ppm |  |
| $\mathrm{f}_{\text {range }}$ | Frequency Tuning Range |  | $\pm 50 \mathrm{ppm}$ |  |  |
| IO | VCXO Output Current |  | $100 \mu \mathrm{~A}$ |  | Rref $=16.5 \mathrm{k} \Omega$ <br> AVDD $=3.3 \mathrm{~V}$ |
| li | Reference Input Current | $100 \mu \mathrm{~A}$ |  | 1 mA | AVDD $=3.3 \mathrm{~V}$ |

N.B: frequency tuning range is proportional to the crystal dynamic capacitance Cm .

Figure 7 : Principle of VCXO control

The tuning must be monotonic with 8 -bit resolution with the worst-case tuning step of <2ppm/LSB (8-bit). The time constant of the tuning must be variable from 5 s to 10 s through an external capacitor $\mathrm{Cs}(\mathrm{R}=$ $1 \mathrm{M} \Omega \pm 30 \%$ ). This determines the speed of the VCXO in normal operation (slow speed in "show time") with filtered VCXO. For faster tracking, the previous filter is not used and the speed depends on CtRt.

## DIGITAL INTERFACE

## Control Interface

The digital setting codes for the ST70134 configuration are sent over a serial line (CTRLIN) using the word clock (CLWD).
The data burst is composed of 16 bits from which the first bit is used as start bit ('0'), the three LSBs being used to identify the data contained in the 12 remaining bits.

Table 16 ：Control Interface Bit Mapping

＊For each filter， 8 possible frequency values（see Table 5 and Table 11）．Notation is 2＇s complement range from $-4=100 b+3=011 b$ ．Fc is the frequency band（ -1 dB ）

## Control Interface Timing

The word clock (CLWD) is used to sample at negative going edge the control information. The start bit b15 is transmitted first followed by bits $\mathrm{b}[14: 0]$ and at least 16 stop bits need to be provided to validate the data.
Figure 8 : Control Interface

Data set-up and hold time versus falling edge CLWD must be greater than 10 nsec.

## Receive / Transmit Interface

## RECEIVE / TRANSMIT PROTOCOL

The digital interface is based on $4 \times 8.832 \mathrm{MHz}(35.328 \mathrm{MHz})$ data lines in the following manner:
If OSR $=2$ (OSR bit set to 1 ) is selected, CLKNIB is used as nibble clock ( 17.664 MHz , disabled in normal mode), and all the RXi, TXi, CLKWD periods are twice as long as in normal mode. This ensures a compatibility with lower speed products.

## TX Signal Dynamic

The dynamic of data signal for both TX DACs is 12 bits extracted from the available signed 16 bit representation coming from the digital processor.
The maximal positive number is $2^{14}-1$, the most negative number is $-2^{14}$, the 3 LSBs are filled with ' 0 '. Any signal exceeding these limits is clamped to the maximum value.
Table 18 : TX Data Bit Map

| BIT MAP/NIBBLE | N0 | N1 | N2 | N3 |
| :---: | :---: | :---: | :---: | :---: |
| TXD0 | not used | data bit 1 | data bit 5 | data bit 9 |
| TXD1 | not used | data bit 2 | data bit 6 | data bit 10 |
| TXD2 | not used | data bit 3 | data bit 7 | data SIGN |
| TXD3 | d0 $=$ data bit 0 (LSB) | data bit 4 | data bit 8 | data SIGN |

Table 19 : TX Nibble Bit Map

| N3 |  |  |  | N2 |  |  |  | N1 |  |  |  | N0 |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

The two sign bits must be identical.

## ST70134A

## RX Signal Dynamic

The dynamic of the signal from the ADC is limited to 13bits. Those bits are converted to a signed (2's complement) representation with a maximal positive number of $2^{14}-1$ and a most negative number $-2^{14}$. The 2 LSBs are filled with ' 0 '.
Table 20 : RX Data Bit Map

| BIT MAP/NIBBLE | N0 | N1 | N2 | N3 |
| :---: | :---: | :---: | :---: | :---: |
| RXD0 | 0 | data bit 2 | data bit 6 | data bit 10 |
| RXD1 | 0 | data bit 3 | data bit 7 | data bit 11 |
| RXD2 | d0 = data bit 0 (LSB) | data bit 4 | data bit 8 | data SIGN |
| RXD3 | data bit 1 | data bit 5 | data bit 9 | data SIGN |

Table 21 : RX Nibble Bit Map

| N3 |  |  | N2 |  |  |  | N1 |  |  |  | N0 |  |  |  |  |

| sign | sign | $d 11$ | $d 10$ | $d 9$ | $d 8$ | $d 7$ | $d 6$ | $d 5$ | $d 4$ | $d 3$ | $d 2$ | $d 1$ | $d 0$ | 0 | 0 |

The two sign bits must be identical.
Figure 9 :TX/ RX Digital Interface Timing

## Receive / Transmit Interface Timing

The interface is a quadruple ( $R X, T X$ ) nibble serial interface running at 8.8 MHz sampling (normal mode). The data are represented in 16bits format, and transferred in groups of 4 bits (nibbles). The LSBs are transferred first. The ST70134 generates a nibble clock (CLKM master clock in normal mode, CLKNIB in OSR = 2 mode) and word signals shared by the three interfaces.
Data is transmitted on the rising edge of the master clock (CLKM/CLKNIB) and sampled on the falling edge of CLKM/CLKNIB. This holds for the data stream from ST70134 and from the digital processor.
Data, CLWD setup and hold times are 5 ns with reference to the falling edge of CLKM/CLKNIB. (not floating).
Data is transmitted on the rising edge of the master clock (CLKM/CLKNIB) and sampled on the low going edge of CLKM/CLKNIB. This holds for the data stream from ST70134 and from the digital processor.Data, CLWD setup and hold times are 5 ns with reference to the falling edge of CLKM/ CLKNIB. (not floating).

## Power Down

When pin Pdown = "1", the chip is set in power down mode. As the Pdown signal is synchronously sampled, minimum duration is 2 periods of the 35 MHz clock. In this mode all analog functional blocks are deactivated except: preamplifiers (TX), clock circuits for output clock CLKM. Pdown will not affect the digital part of the chip. Anyway, after a Pdown transition, the digital part status, is updated after 3 clock periods (worst case).
The chip is activated when Pdown $=$ " 0 ".
In power down mode the following conditions hold:

- Output voltages at TXP/TXN = AGND
- Preamplifier is on with maximum gain setting (0dB), (digital gain setting coefficients are overruled)
- The XTAL output clock on pin CLKM keeps running.
- All digital setting are retained.
- Digital output on pins RXDx don't care(not floating).

In power-down mode the power consumption is 100 mW .
Following external conditions are added:

- Clock pin CLW is running.
- CTRLIN signals can still be allowed.
- AGND remains at AVDD/2 (circuit is powered up)
- Input signal at TXDx inputs are not strobed.

The Pdown signal controls asynchronously the power-down of each analog module:

- After a few $\mu \mathrm{s}$ the analog channel is functional
- After about 100 ms the analog channel delivers full performance

## Reset Function

The reset function is implied when the RESETN pin is at a low voltage input level. In this condition, the reset function can be easily used for power up reset conditions.

## Detailed Description

During reset: (reset is asynchronous, tenths of ns are enough to put the IC in reset).
All clock outputs are deactivated and put to logical "1" (except for the XTAL and master clock CLKM).
After reset: ( 4 clock periods after reset transition, as worst case).

- OSR = 4
- All analog gains ( $\mathrm{RX}, \mathrm{TX}$ ) are set to minimum value
- Nominal filter frequency bands $(138 \mathrm{kHz}$, 1.104 MHz )
- LNA input = "11" (max. attenuation)
- VCO dac disabled

Digital outputs are placed in don't care condition (non-floating).
N.B. If a Xtal oscillator is used, the RESET must be released at last $10 \mu \mathrm{~s}$ after power-on, to ensure a correct duty cycle for the clk 35 clock signal.

## ELECTRICAL RATINGS AND CHARACTERISTICS

## Absolute Maximum Ratings

| Symbol | Parameter | Minimum | Maximum | Unit |
