8M-BIT [x 1 / x 2] CMOS SERIAL FLASH**FEATURES****GENERAL**

- Single Power Supply Operation
 - 2.7 to 3.6 volt for read, erase, and program operations
- Serial Peripheral Interface compatible -- Mode 0 and Mode 3
- 8,388,608 x 1 bit structure or 4,194,304 x 2 bits (Dual Output mode) structure
- 256 Equal Sectors with 4K byte each
 - Any Sector can be erased individually
- 16 Equal Blocks with 64K byte each
 - Any Block can be erased individually
- Program Capability
 - Byte base
 - Page base (256 bytes)
- Latch-up protected to 100mA from -1V to Vcc +1V

PERFORMANCE

- High Performance
 - Fast access time: 86MHz serial clock
 - Serial clock of Dual Output mode : 80MHz
 - Fast program time: 0.6ms(typ.) and 3ms(max.)/page
 - Byte program time: 9us (typical)
 - Fast erase time: 40ms(typ.) /sector ; 0.4s(typ.) /block
- Low Power Consumption
 - Low active read current: 12mA(max.) at 86MHz
 - Low active programming current: 15mA (typ.)
 - Low active Sector/Block erase current: 9mA (typ.)
 - Low standby current: 15uA (typ.)
 - Deep power-down mode 2uA (typ.)
- Typical 100,000 erase/program cycles
- 20 years of data retention

SOFTWARE FEATURES

- Input Data Format
 - 1-byte Command code
- Advanced Security Features
 - Block lock protection
 - The BP2-BP0 status bit defines the size of the area to be software protection against program and erase instructions
 - Additional 512 bit secured area for unique ID
- Auto Erase and Auto Program Algorithm
 - Automatically erases and verifies data at selected sector
 - Automatically programs and verifies data at selected page by an internal algorithm that automatically times the program pulse widths (Any page to be programmed should have page in the erased state first)

- Status Register Feature
- Electronic Identification
 - JEDEC 1-byte manufacturer ID and 2-byte device ID
 - RES command for 1-byte Device ID
 - REMS command for 1-byte manufacturer ID and 1-byte device ID
- Support Serial Flash Discoverable Parameters (SFDP) mode

HARDWARE FEATURES

- PACKAGE
 - 8-pin SOP (200mil)
 - **All devices are RoHS Compliant & Halogen-free.**

GENERAL DESCRIPTION

The device features a serial peripheral interface and software protocol allowing operation on a simple 3-wire bus. The three bus signals are a clock input (SCLK), a serial data input (SI), and a serial data output (SO). Serial access to the device is enabled by CS# input.

When it is in Dual Output read mode, the SI and SO pins become SIO0 and SIO1 pins for data output.

The device provides sequential read operation on the whole chip.

After program/erase command is issued, auto program/erase algorithms which program/erase and verify the specified page or sector/block locations will be executed. Program command is executed on byte basis, or page basis, or word basis. Erase command is executed on sector, or block, or whole chip basis.

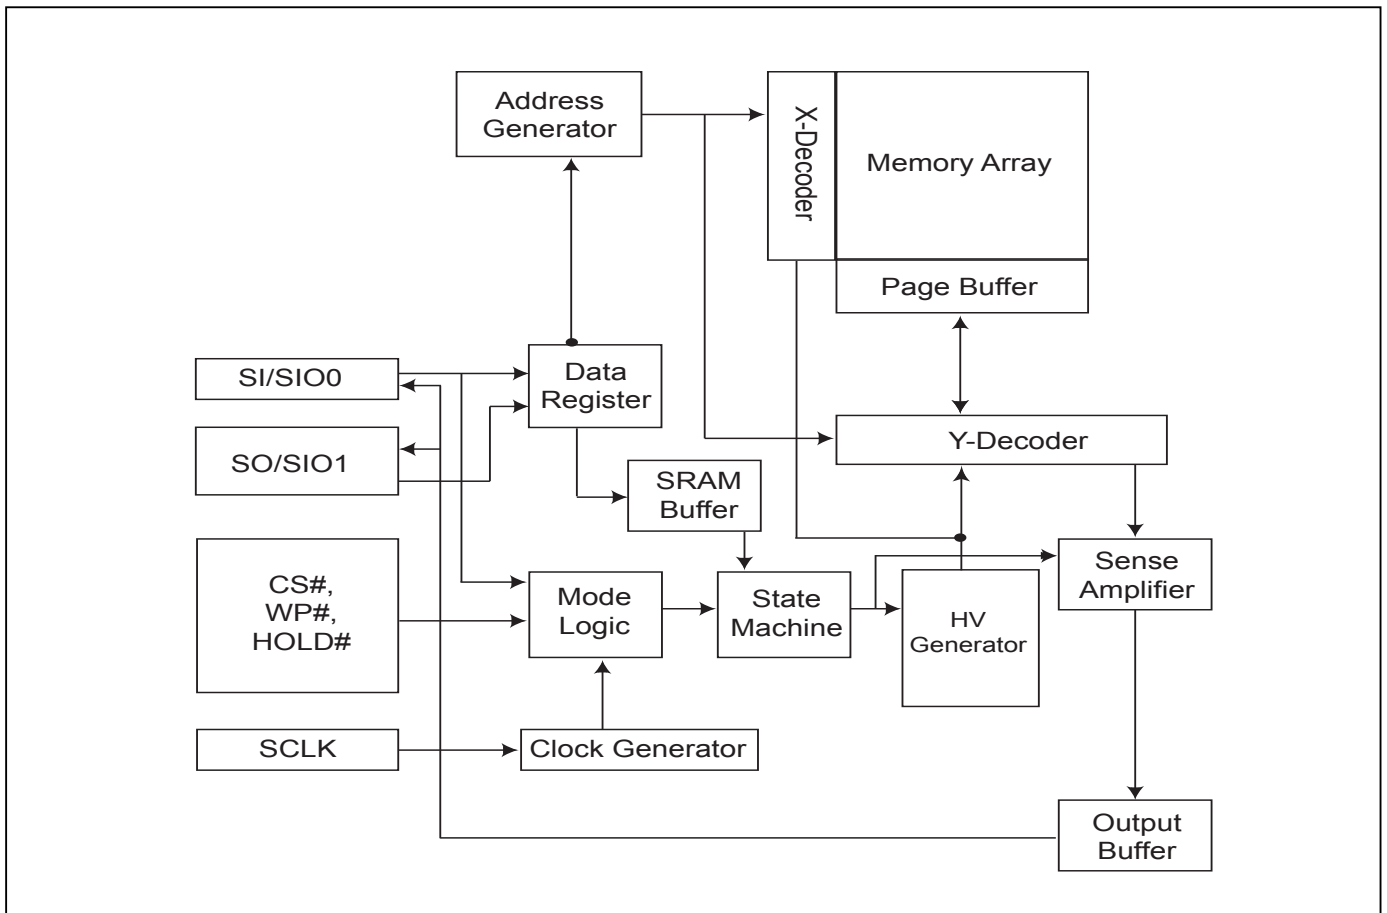

To provide user with ease of interface, a status register is included to indicate the status of the chip. The status read command can be issued to detect completion status of a program or erase operation via WIP bit.

Advanced security features enhance the protection and security functions, please see security features section for more details.

When the device is not in operation and CS# is high, it is put in standby mode.

The device utilizes Macronix's proprietary memory cell, which reliably stores memory contents even after typical 100,000 program and erase cycles.

BLOCK DIAGRAM

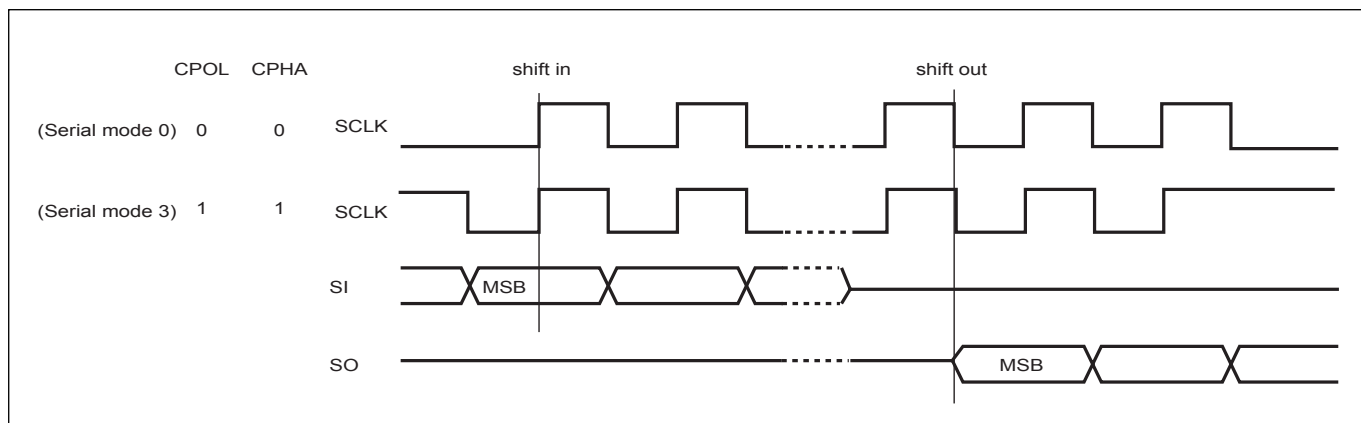

MEMORY ORGANIZATION**Table 1. Memory Organization**

Block	Sector	Address Range	
15	255	0FF000h	0FFFFFFh
	:	:	:
	240	0F0000h	0F0FFFh
14	239	0EF000h	0EFFFFFFh
	:	:	:
	224	0E0000h	0E0FFFh
:	:	:	:
:	:	:	:
0	15	00F000h	00FFFFFFh
	:	:	:
	3	003000h	003FFFh
	2	002000h	002FFFh
	1	001000h	001FFFh
	0	000000h	000FFFh

DEVICE OPERATION

1. Before a command is issued, status register should be checked to ensure device is ready for the intended operation.
2. When incorrect command is inputted to this device, it enters standby mode and remains in standby mode until next CS# falling edge. In standby mode, SO pin of the device is High-Z. The CS# falling time needs to follow tCHCL spec.
3. When correct command is inputted to this device, it enters active mode and remains in active mode until next CS# rising edge. The CS# rising time needs to follow tCLCH spec.
4. Input data is latched on the rising edge of Serial Clock(SCLK) and data is shifted out on the falling edge of SCLK. The difference of Serial mode 0 and mode 3 is shown in Figure 1.
5. For the following instructions: RDID, RDSR, RDSCUR, READ, FAST_READ, RDSFDP, DREAD, RES, and REMS the shifted-in instruction sequence is followed by a data-out sequence. After any bit of data being shifted out, the CS# can be high. For the following instructions: WREN, WRDI, WRSR, SE, BE, CE, PP, RDP, DP, ENSA, EXSO, and WRSCUR, the CS# must go high exactly at the byte boundary; otherwise, the instruction will be rejected and not executed.
6. While a Write Status Register, Program, or Erase operation is in progress, access to the memory array is neglected and will not affect the current operation of Write Status Register, Program, Erase.

Figure 1. Serial Modes Supported

Note:

CPOL indicates clock polarity of Serial master, CPOL=1 for SCLK high while idle, CPOL=0 for SCLK low while not transmitting. CPHA indicates clock phase. The combination of CPOL bit and CPHA bit decides which Serial mode is supported.

DATA PROTECTION

During power transition, there may be some false system level signals which result in inadvertent erasure or programming. The device is designed to protect itself from these accidental write cycles.

The state machine will be reset as standby mode automatically during power up. In addition, the control register architecture of the device constrains that the memory contents can only be changed after specific command sequences have completed successfully.

In the following, there are several features to protect the system from the accidental write cycles during VCC power-up and power-down or from system noise.

- Valid command length checking: The command length will be checked whether it is at byte base and completed on byte boundary.
- Write Enable (WREN) command: WREN command is required to set the Write Enable Latch bit (WEL) before other command to change data. The WEL bit will return to reset stage under following situation:
 - Power-up
 - Write Disable (WRDI) command completion
 - Write Status Register (WRSR) command completion
 - Page Program (PP) command completion
 - Sector Erase (SE) command completion
 - Block Erase (BE) command completion
 - Chip Erase (CE) command completion
- Deep Power Down Mode: By entering deep power down mode, the flash device also is under protected from writing all commands except Release from deep power down mode command (RDP) and Read Electronic Signature command (RES).
- Advanced Security Features: there are some protection and security features which protect content from inadvertent write and hostile access.

I. Block lock protection

- The Software Protected Mode (SPM):

MX25L8008E: use (BP2, BP1, BP0) bits to allow part of memory to be protected as read only. The protected area definition is shown as "[Table 2. Protected Area Sizes](#)", the protected areas are more flexible which may protect various area by setting value of BP0-BP2 bits.

Please refer to "[Table 2. Protected Area Sizes](#)".

- The Hardware Protected Mode (HPM) uses WP# to protect the MX25L8008E:BP2-BP0 bits and SRWD bit.

Table 2. Protected Area Sizes

Status bit			Protect Level
BP2	BP1	BP0	MX25L8008E
0	0	0	0 (none)
0	0	1	1 (1block, block 15th)
0	1	0	2 (2blocks, block 14th-15th)
0	1	1	3 (4blocks, block 12th-15th)
1	0	0	4 (8blocks, block 8th-15th)
1	0	1	5 (All)
1	1	0	6 (All)
1	1	1	7 (All)

II. Additional 512-bit Secured Area for unique ID: to provide 512-bit read-only unique ID data. Please refer to "[Table 3. 512-bit Secured Area Definition](#)".

- Security register bit 0 indicates whether the chip is locked by factory or not.
- To read the 512-bit secured area by entering 512-bit secured area mode (with ENSA command), and going through normal read procedure, and then exiting 512-bit secured area mode by writing EXSA command.

Table 3. 512-bit Secured Area Definition

Address range	Size	Standard Factory Lock
xxxx00~xxxx3F	512-bit	unique ID

HOLD FEATURES

HOLD# pin signal goes low to hold any serial communications with the device. The HOLD feature will not stop the operation of write status register, programming, or erasing in progress.

The operation of HOLD requires Chip Select (CS#) keeping low and starts on falling edge of HOLD# pin signal while Serial Clock (SCLK) signal is being low (if Serial Clock signal is not being low, HOLD operation will not start until Serial Clock signal being low). The HOLD condition ends on the rising edge of HOLD# pin signal while Serial Clock (SCLK) signal is being low (if Serial Clock signal is not being low, HOLD operation will not end until Serial Clock being low), see "[Figure 2. Hold Condition Operation](#)".

Figure 2. Hold Condition Operation

The Serial Data Output (SO) is high impedance, both Serial Data Input (SI) and Serial Clock (SCLK) are don't care during the HOLD operation. If Chip Select (CS#) drives high during HOLD operation, it will reset the internal logic of the device. To re-start communication with chip, the HOLD# must be at high and CS# must be at low.

COMMAND DESCRIPTION

Table 4. COMMAND DEFINITION

Command (byte)	WREN (write enable)	WRDI (write disable)	WRSR (write status register)	RDID (read identification)	RDSR (read status register)	READ (read data)	FAST READ (fast read data)
1st byte	06 (hex)	04 (hex)	01 (hex)	9F (hex)	05 (hex)	03 (hex)	0B (hex)
2nd byte						AD1	AD1
3rd byte						AD2	AD2
4th byte						AD3	AD3
5th byte							Dummy
Action	sets the (WEL) write enable latch bit	resets the (WEL) write enable latch bit	to write new values to the status register	outputs JEDEC ID: 1-byte Manufacturer ID & 2-byte Device ID	to read out the values of the status register	n bytes read out until CS# goes high	n bytes read out until CS# goes high

Command (byte)	RDSFDP (Read SFDP)	RES (read electronic ID)	REMS (read electronic manufacturer & device ID)	DREAD (Dual Output Mode command)	SE (sector erase)	BE (block erase)	CE (chip erase)
1st byte	5A (hex)	AB (hex)	90 (hex)	3B (hex)	20 (hex)	52 or D8 (hex)	60 or C7 (hex)
2nd byte	AD1	x	x	AD1	AD1	AD1	
3rd byte	AD2	x	x	AD2	AD2	AD2	
4th byte	AD3	x	ADD (<i>Note 1</i>)	AD3	AD3	AD3	
5th byte	Dummy			Dummy			
Action	Read SFDP mode	to read out 1-byte Device ID	output the Manufacturer ID & Device ID	n bytes read out by Dual Output until CS# goes high	to erase the selected sector	to erase the selected block	to erase whole chip

Command (byte)	PP (page program)	RDSCUR (read security register)	WRSCUR (write security register)	ENSA (enter secured area)	EXSA (exit secured area)	DP (Deep power down)	RDP (Release from deep power down)
1st byte	02 (hex)	2B (hex)	2F (hex)	B1 (hex)	C1 (hex)	B9 (hex)	AB (hex)
2nd byte	AD1						
3rd byte	AD2						
4th byte	AD3						
5th byte							
Action	to program the selected page	to read value of security register	to set the lock-down bit as "1" (once lock-down, cannot be updated)	to enter the 512 bit secured area mode	to exit the 512 bit secured area mode	enters deep power down mode	release from deep power down mode

Note 1: ADD=00H will output the manufacturer ID first and ADD=01H will output device ID first.

Note 2: It is not recommended to adopt any other code not in the command definition table, which will potentially enter the hidden mode.

(1) Write Enable (WREN)

The Write Enable (WREN) instruction is for setting Write Enable Latch (WEL) bit. For those instructions like PP, SE, BE, CE, and WRSR, which are intended to change the device content, should be set every time after the WREN instruction setting the WEL bit.

The sequence is shown as [Figure 11](#).

(2) Write Disable (WRDI)

The Write Disable (WRDI) instruction is for resetting Write Enable Latch (WEL) bit.

The sequence is shown as [Figure 12](#).

The WEL bit is reset by following situations:

- Power-up
- Write Disable (WRDI) instruction completion
- Write Status Register (WRSR) instruction completion
- Page Program (PP) instruction completion
- Sector Erase (SE) instruction completion
- Block Erase (BE) instruction completion
- Chip Erase (CE) instruction completion

(3) Read Status Register (RDSR)

The RDSR instruction is for reading Status Register Bits. The Read Status Register can be read at any time (even in program/erase/write status register condition) and continuously. It is recommended to check the Write in Progress (WIP) bit before sending a new instruction when a program, erase, or write status register operation is in progress.

The sequence is shown as [Figure 13](#).

The definition of the status register bits is as below:

WIP bit. The Write in Progress (WIP) bit, a volatile bit, indicates whether the device is busy in program/erase/write status register progress. When WIP bit sets to 1, which means the device is busy in program/erase/write status register progress. When WIP bit sets to 0, which means the device is not in progress of program/erase/write status register cycle.

WEL bit. The Write Enable Latch (WEL) bit, a volatile bit, indicates whether the device is set to internal write enable latch. When WEL bit sets to 1, which means the internal write enable latch is set, the device can accept program/erase/write status register instruction. When WEL bit sets to 0, which means no internal write enable latch; the device will not accept program/erase/write status register instruction. The program/erase command will be ignored and not affect value of WEL bit if it is applied to a protected memory area.

BP2, BP1, BP0 bits. The Block Protect (BP2-BP0) bits, non-volatile bits, indicate the protected area (as defined in "[Table 2. Protected Area Sizes](#)") of the device to against the program/erase instruction without hardware protection mode being set. To write the Block Protect (BP2-BP0) bits requires the Write Status Register (WRSR) instruction to be executed. Those bits define the protected area of the memory to against Page Program (PP), Sector Erase (SE), Block Erase (BE) and Chip Erase(CE) instructions (only if all Block Protect bits set to 0, the CE instruction can be executed).

SRWD bit. The Status Register Write Disable (SRWD) bit, non-volatile bit, is operated together with Write Protection (WP#) pin for providing hardware protection mode. The hardware protection mode requires SRWD sets to 1 and WP# pin signal is low stage. In the hardware protection mode, the Write Status Register (WRSR) instruction is no longer accepted for execution and the SRWD bit and Block Protect bits (BP2-BP0) are read only.

Status Register

bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
SRWD (status register write protect)	0	0	BP2 (level of protected block)	BP1 (level of protected block)	BP0 (level of protected block)	WEL (write enable latch)	WIP (write in progress bit)
1=status register write disable	0	0	<i>(note 1)</i>	<i>(note 1)</i>	<i>(note 1)</i>	1=write enable 0=not write enable	1=write operation 0=not in write operation
Non-volatile bit	0	0	Non-volatile bit	Non-volatile bit	Non-volatile bit	volatile bit	volatile bit

note 1: see the ["Table 2. Protected Area Sizes"](#).

(4) Write Status Register (WRSR)

The WRSR instruction is for changing the values of Status Register Bits. Before sending WRSR instruction, the Write Enable (WREN) instruction must be decoded and executed to set the Write Enable Latch (WEL) bit in advance. The WRSR instruction can change the value of Block Protect (BP2-BP0) bits to define the protected area of memory (as shown in ["Table 2. Protected Area Sizes"](#)). The WRSR also can set or reset the Status Register Write Disable (SRWD) bit in accordance with Write Protection (WP#) pin signal. The WRSR instruction cannot be executed once the Hardware Protected Mode (HPM) is entered.

The sequence is shown as [Figure 14](#).

The WRSR instruction has no effect on b6, b1, b0 of the status register.

The CS# must go high exactly at the byte boundary; otherwise, the instruction will be rejected and not executed. The self-timed Write Status Register cycle time (tW) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be check out during the Write Status Register cycle is in progress. The WIP sets 1 during the tW timing, and sets 0 when Write Status Register Cycle is completed, and the Write Enable Latch (WEL) bit is reset.

Table 5. Protection Modes

Mode	Status register condition	WP# and SRWD bit status	Memory
Software protection mode (SPM)	Status register can be written in (WEL bit is set to "1") and the SRWD, BP2-BP0 bits can be changed	WP#=1 and SRWD bit=0, or WP#=0 and SRWD bit=0, or WP#=1 and SRWD=1	The protected area cannot be program or erase.
Hardware protection mode (HPM)	The SRWD, BP2-BP0 of status register bits cannot be changed	WP#=0, SRWD bit=1	The protected area cannot be program or erase.

Note:

1. As defined by the values in the Block Protect (BP2-BP0) bits of the Status Register, as shown in "[Table 2. Protected Area Sizes](#)".

As the above table showing, the summary of the Software Protected Mode (SPM) and Hardware Protected Mode (HPM).

Software Protected Mode (SPM):

- When SRWD bit=0, no matter WP# is low or high, the WREN instruction may set the WEL bit and can change the values of SRWD, BP2-BP0. The protected area, which is defined by BP2-BP0 is at software protected mode (SPM).
- When SRWD bit=1 and WP# is high, the WREN instruction may set the WEL bit can change the values of SRWD, BP2-BP0. The protected area, which is defined by BP2-BP0, is at software protected mode (SPM).

Note: If SRWD bit=1 but WP# is low, it is impossible to write the Status Register even if the WEL bit has previously been set. It is rejected to write the Status Register and not be executed.

Hardware Protected Mode (HPM):

- When SRWD bit=1, and then WP# is low (or WP# is low before SRWD bit=1), it enters the hardware protected mode (HPM). The data of the protected area is protected by software protected mode by BP2-BP0 and hardware protected mode by the WP# to against data modification.

Note: to exit the hardware protected mode requires WP# driving high once the hardware protected mode is entered. If the WP# pin is permanently connected to high, the hardware protected mode can never be entered; only can use software protected mode via BP2-BP0.

(5) Read Data Bytes (READ)

The read instruction is for reading data out. The address is latched on rising edge of SCLK, and data shifts out on the falling edge of SCLK at a maximum frequency f_R . The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out at a single READ instruction. The address counter rolls over to 0 when the highest address has been reached.

The sequence is shown as [Figure 15](#).

(6) Read Data Bytes at Higher Speed (FAST_READ)

The FAST_READ instruction is for quickly reading data out. The address is latched on rising edge of SCLK, and data of each bit shifts out on the falling edge of SCLK at a maximum frequency f_C . The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out at a single FAST_READ instruction. The address counter rolls over to 0 when the highest address has been reached.

The sequence is shown as [Figure 16](#).

While Program/Erase/Write Status Register cycle is in progress, FAST_READ instruction is rejected without any impact on the Program/Erase/Write Status Register current cycle.

(7) Dual Output Mode (DREAD)

The DREAD instruction enable double throughput of Serial Flash in read mode. The address is latched on rising edge of SCLK, and data of every two bits(interleave on 1I/2O pins) shift out on the falling edge of SCLK at a maximum frequency f_T . The first address byte can be at any location. The address is automatically increased to the next higher address after each byte data is shifted out, so the whole memory can be read out at a single DREAD instruction. The address counter rolls over to 0 when the highest address has been reached. Once writing DREAD instruction, the data out will perform as 2-bit instead of previous 1-bit.

The sequence is shown as [Figure 17](#).

While Program/Erase/Write Status Register cycle is in progress, DREAD instruction is rejected without any impact on the Program/Erase/Write Status Register current cycle.

The DREAD only perform read operation. Program/Erase /Read ID/Read status....operation do not support DREAD throughputs.

(8) Sector Erase (SE)

The Sector Erase (SE) instruction is for erasing the data of the chosen sector to be "1". The instruction is used for any 4K-byte sector. A Write Enable (WREN) instruction must execute to set the Write Enable Latch (WEL) bit before sending the Sector Erase (SE). Any address of the sector (see "[Table 1. Memory Organization](#)") is a valid address for Sector Erase (SE) instruction. The CS# must go high exactly at the byte boundary (the least significant bit of the address been latched-in); otherwise, the instruction will be rejected and not executed.

Address bits [Am-A12] (Am is the most significant address) select the sector address.

The sequence is shown as [Figure 18](#).

The self-timed Sector Erase Cycle time (tSE) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be checked while the Sector Erase cycle is in progress. The WIP sets during the tSE timing, and clears when Sector Erase Cycle is completed, and the Write Enable Latch (WEL) bit is cleared. If the page is protected by BP2-BP0 bits, the Sector Erase (SE) instruction will not be executed on the page.

(9) Block Erase (BE)

The Block Erase (BE) instruction is for erasing the data of the chosen block to be "1". The instruction is used for 64K-byte sector erase operation. A Write Enable (WREN) instruction must be executed to set the Write Enable Latch (WEL) bit before sending the Block Erase (BE). Any address of the block (see "[Table 1. Memory Organization](#)") is a valid address for Block Erase (BE) instruction. The CS# must go high exactly at the byte boundary (the least significant of address byte been latched-in); otherwise, the instruction will be rejected and not executed.

The sequence is shown as [Figure 19](#).

The self-timed Block Erase Cycle time (tBE) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be checked while the Block Erase cycle is in progress. The WIP sets during the tBE timing, and clears when Sector Erase Cycle is completed, and the Write Enable Latch (WEL) bit is cleared. If the page is protected by BP2-BP0 bits, the Block Erase (BE) instruction will not be executed on the page.

(10) Chip Erase (CE)

The Chip Erase (CE) instruction is for erasing the data of the whole chip to be "1". A Write Enable (WREN) instruction must be executed to set the Write Enable Latch (WEL) bit before sending the Chip Erase (CE). Any address of the sector (see "[Table 1. Memory Organization](#)") is a valid address for Chip Erase (CE) instruction. The CS# must go high exactly at the byte boundary (the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed.

The sequence is shown as [Figure 20](#).

The self-timed Chip Erase Cycle time (tCE) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be checked while the Chip Erase cycle is in progress. The WIP sets during the tCE timing, and clears when Chip Erase Cycle is completed, and the Write Enable Latch (WEL) bit is cleared. If the chip is protected by BP2-BP0 bits, the Chip Erase (CE) instruction will not be executed. It will be only executed when BP2-BP0 all set to "0".

(11) Page Program (PP)

The Page Program (PP) instruction is for programming the memory to be "0". A Write Enable (WREN) instruction must be executed to set the Write Enable Latch (WEL) bit before sending the Page Program (PP). The last address byte (the 8 least significant address bits, A7-A0) should be set to 0 for 256 bytes page program. If A7-A0 are not all zero, transmitted data that exceed page length are programmed from the starting address (24-bit address that last 8 bit are all 0) of currently selected page. The CS# must keep during the whole Page Program cycle. The CS# must go high exactly at the byte boundary (the latest eighth of address byte been latched-in); otherwise, the instruction will be rejected and not executed. If the data bytes sent to the device exceeds 256, the last 256 data byte is programmed at the request page and previous data will be disregarded. If the data bytes sent to the device has not exceeded 256, the data will be programmed at the request address of the page. There will be no effort on the other data bytes of the same page.

The sequence is shown as [Figure 21](#).

The self-timed Page Program Cycle time (tPP) is initiated as soon as Chip Select (CS#) goes high. The Write in Progress (WIP) bit still can be checked while the Page Program cycle is in progress. The WIP sets during the tPP timing, and clears when Page Program Cycle is completed, and the Write Enable Latch (WEL) bit is cleared. If the page is protected by BP2-BP0 bits, the Page Program (PP) instruction will not be executed.

(12) Deep Power-down (DP)

The Deep Power-down (DP) instruction is for setting the device to minimum power consumption (the standby current is reduced from standby to Deep Power-down). The Deep Power-down mode requires the Deep Power-down (DP) instruction to enter, during the Deep Power-down mode, the device is not active and all Write/Program/Erase instruction are ignored.

The sequence is shown as [Figure 22](#).

Once the DP instruction is set, all instruction will be ignored except the Release from Deep Power-down mode (RDP) and Read Electronic Signature (RES) instruction. (those instructions allow the ID being reading out). When Power-down, the deep power-down mode automatically stops, and when power-up, the device automatically is in standby mode. For RDP instruction the CS# must go high exactly at the byte boundary (the latest eighth bit of instruction code been latched-in); otherwise, the instruction will not executed. As soon as Chip Select (CS#) goes high, a delay of tDP is required before entering the Deep Power-down mode and reducing the current to ISB2.

(13) Release from Deep Power-down (RDP), Read Electronic Signature (RES)

The Release from Deep Power-down (RDP) instruction is completed by driving Chip Select (CS#) High. When Chip Select (CS#) is driven High, the device is put in the Stand-by Power mode. If the device was not previously in the Deep Power-down mode, the transition to the Stand-by Power mode is immediate. If the device was previously in the Deep Power-down mode, though, the transition to the Stand-by Power mode is delayed by tRES2, and Chip Select (CS#) must remain High for at least tRES2 (max), as specified in [Table 9](#). Once in the Stand-by Power mode, the device waits to be selected, so that it can receive, decode and execute instructions.

RES instruction is for reading out the old style of 8-bit Electronic Signature, whose values are shown as "[Table 6. ID DEFINITIONS](#)". This is not the same as RDID instruction. It is not recommended to use for new design. For new design, please use RDID instruction. Even in Deep power-down mode, the RDP and RES are also allowed to be executed, only except the device is in progress of program/erase/write cycle; there's no effect on the current program/erase/write cycle in progress.

The sequence is shown in [Figure 23](#) and [Figure 24](#).

The RES instruction is ended by CS# goes high after the ID been read out at least once. The ID outputs repeatedly if continuously send the additional clock cycles on SCLK while CS# is at low. If the device was not previously in Deep Power-down mode, the device transition to standby mode is immediate. If the device was previously in Deep Power-down mode, there's a delay of tRES2 to transit to standby mode, and CS# must remain to high at least tRES2(max). Once in the standby mode, the device waits to be selected, so it can be receive, decode, and execute instruction.

The RDP instruction is for releasing from Deep Power Down Mode.

(14) Read Identification (RDID)

The RDID instruction is for reading the manufacturer ID of 1-byte and followed by Device ID of 2-byte. The MXIC Manufacturer ID and Device ID are listed as "[Table 6. ID DEFINITIONS](#)".

The sequence is shown as [Figure 25](#).

While Program/Erase operation is in progress, it will not decode the RDID instruction, so there's no effect on the cycle of program/erase operation which is currently in progress. When CS# goes high, the device is at standby stage.

(15) Read Electronic Manufacturer ID & Device ID (REMS)

The REMS instruction is an alternative to the Release from Power-down/Device ID instruction that provides both the JEDEC assigned manufacturer ID and the specific device ID.

The REMS instruction is very similar to the Release from Power-down/Device ID instruction. The instruction is initiated by driving the CS# pin low and shift the instruction code "90h" followed by two dummy bytes and one bytes address (A7~A0). After which, the Manufacturer ID for MXIC and the Device ID are shifted out on the falling edge of SCLK with most significant bit (MSB) first as shown in [Figure 26](#). The Device ID values are listed in "[Table 6. ID DEFINITIONS](#)". If the one-byte address is initially set to 01h, then the device ID will be read first and then followed by the Manufacturer ID. The Manufacturer and Device IDs can be read continuously, alternating from one to the other. The instruction is completed by driving CS# high.

Table 6. ID DEFINITIONS

Command Type	MX25L8008E		
RDID Command	manufacturer ID	memory type	memory density
	C2	20	14
RES Command	electronic ID		
	13		
REMS	manufacturer ID	device ID	
	C2	13	

(16) Enter Secured Area (ENSA)

The ENSA instruction is for entering the additional 512-bit secured area mode. The additional 512-bit secured area is independent from main array, which is used to store unique ID for system identifier. After entering the Secured Area mode, follow standard read procedure to read out the data.

The sequence of issuing ENSA instruction is: CS# goes low→ sending ENSA instruction to enter Secured Area mode→ CS# goes high.

Please note that WRSR/WRSCUR commands are not acceptable during the access of secure area region.

(17) Exit Secured Area (EXSA)

The EXSA instruction is for exiting the additional 512-bit secured area mode.

The sequence of issuing EXSA instruction is: CS# goes low→ sending EXSA instruction to exit Secured Area mode→ CS# goes high.

(18) Read Security Register (RDSCUR)

The RDSCUR instruction is for reading the value of Security Register bits. The Read Security Register can be read at any time (even in program/erase/write status register/write security register condition) and continuously.

The sequence of issuing RDSCUR instruction is: CS# goes low → sending RDSCUR instruction → Security Register data out on SO → CS# goes high.

The sequence is shown as [Figure 27](#).

The definition of the Security Register bits is as below:

Secured Area Indicator bit. The Secured Area indicator bit shows the chip is locked by factory before ex-factory or not. When it is "0", it indicates non-factory lock; "1" indicates factory-lock.

Table 7. SECURITY REGISTER DEFINITION

bit7	bit6	bit5	bit4	bit3	bit2	bit1	bit0
x	x	x	x	x	x	x	Secured Area indicator bit
reserved	reserved	reserved	reserved	reserved	reserved	reserved	1 = factory lock (default)
volatile bit	volatile bit	volatile bit	volatile bit	volatile bit	volatile bit	Non-volatile bit	Non-volatile bit

(19) Write Security Register (WRSCUR)

The WRSCUR instruction is for changing the values of Security Register Bits. Unlike write status register, the WREN instruction is not required before sending WRSCUR instruction.

The sequence of issuing WRSCUR instruction is: CS# goes low → sending WRSCUR instruction → CS# goes high.

The CS# must go high exactly at the boundary; otherwise, the instruction will be rejected and not executed.

The sequence is shown as [Figure 28](#).

(20) Read SFDP Mode (RDSFDP)

The Serial Flash Discoverable Parameter (SFDP) standard provides a consistent method of describing the functional and feature capabilities of serial flash devices in a standard set of internal parameter tables. These parameter tables can be interrogated by host system software to enable adjustments needed to accommodate divergent features from multiple vendors. The concept is similar to the one found in the Introduction of JEDEC Standard, JESD68 on CFI.

The sequence of issuing RDSFDP instruction is CS# goes low→send RDSFDP instruction (5Ah)→send 3 address bytes on SI pin→send 1 dummy byte on SI pin→read SFDP code on SO→to end RDSFDP operation can use CS# to high at any time during data out.

SFDP is a standard of JEDEC. JESD216. v1.0.

Read Serial Flash Discoverable Parameter (RDSFDP) Sequence

Table a. Signature and Parameter Identification Data Values

Description	Comment	Add (h) (Byte)	DW Add (Bit)	Data (h/b) (<i>Note 1</i>)	Data (h)

POWER-ON STATE

The device is at the following states after power-up:

- Standby mode (please note it is not deep power-down mode)
- Write Enable Latch (WEL) bit is reset

The device must not be selected during power-up and power-down stage until the VCC reaches the following levels:

- VCC minimum at power-up stage and then after a delay of tVSL
- GND at power-down

Please note that a pull-up resistor on CS# may ensure a safe and proper power-up/down level.

An internal power-on reset (POR) circuit may protect the device from data corruption and inadvertent data change during power up state.

For further protection on the device, if the VCC does not reach the VCC minimum level, the correct operation is not guaranteed. The read, write, erase, and program command should be sent after the below time delay:

- tVSL after VCC reached VCC minimum level

The device can accept read command after VCC reached VCC minimum and a time delay of tVSL.

Please refer to "[Figure 29. Power-up Timing](#)".

Note:

- To stabilize the VCC level, the VCC rail decoupled by a suitable capacitor close to package pins is recommended.(generally around 0.1uF)

INITIAL DELIVERY STATE

The device is delivered with the memory array erased: all bits are set to 1 (each byte contains FFh). The Status Register contains 00h (all Status Register bits are 0).

ELECTRICAL SPECIFICATIONS

ABSOLUTE MAXIMUM RATINGS

RATING		VALUE
Ambient Operating Temperature	Industrial grade	-40°C to 85°C
Storage Temperature		-55°C to 125°C
Applied Input Voltage		-0.5V to 4.6V
Applied Output Voltage		-0.5V to 4.6V
VCC to Ground Potential		-0.5V to 4.6V

NOTICE:

1. Stresses greater than those listed under ABSOLUTE MAXIMUM RATINGS may cause permanent damage to the device. This is stress rating only and functional operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended period may affect reliability.
2. Specifications contained within the following tables are subject to change.
3. During voltage transitions, all pins may overshoot Vss to -2.0V and Vcc to +2.0V for periods up to 20ns, see "[Figure 3. Maximum Negative Overshoot Waveform](#)" and "[Figure 4. Maximum Positive Overshoot Waveform](#)".

tHHQX(2)	tLZ	HOLD to Output Low-Z			6	ns
tHLQZ(2)	tHZ	HOLD# to Output High-Z			6	ns
tWHSL(4)		Write Protect Setup Time	20			ns
tSHWL(4)		Write Protect Hold Time	100			ns
tDP(2)		CS# High to Deep Power-down Mode			10	us
tRES1(2)		CS# High to Standby Mode without Electronic Signature Read			8.8	us
tRES2(2)		CS# High to Standby Mode with Electronic Signature Read			8.8	us
tW		Write Status Register Cycle Time		5	40	ms
tBP		Byte-Program		9	50	us
tPP		Page Program Cycle Time		0.6	3	ms
tSE		Sector Erase Cycle Time		40	200	ms
tBE		Block Erase Cycle Time		0.4	2	s
tCE		Chip Erase Cycle Time		3.5	6	s

Notes:

1. tCH + tCL must be greater than or equal to 1/ fC. For Fast Read, tCL/tCH=5.5/5.5.
2. Value guaranteed by characterization, not 100% tested in production.
3. Expressed as a slew-rate.
4. Only applicable as a constraint for a WRSR instruction when SRWD is set at 1.
5. Test condition is shown as "Figure 5. INPUT TEST WAVEFORMS AND MEASUREMENT LEVEL" & "Figure 6. OUTPUT LOADING".
6. The CS# rising time needs to follow tCLCH spec and CS# falling time needs to follow tCHCL spec.

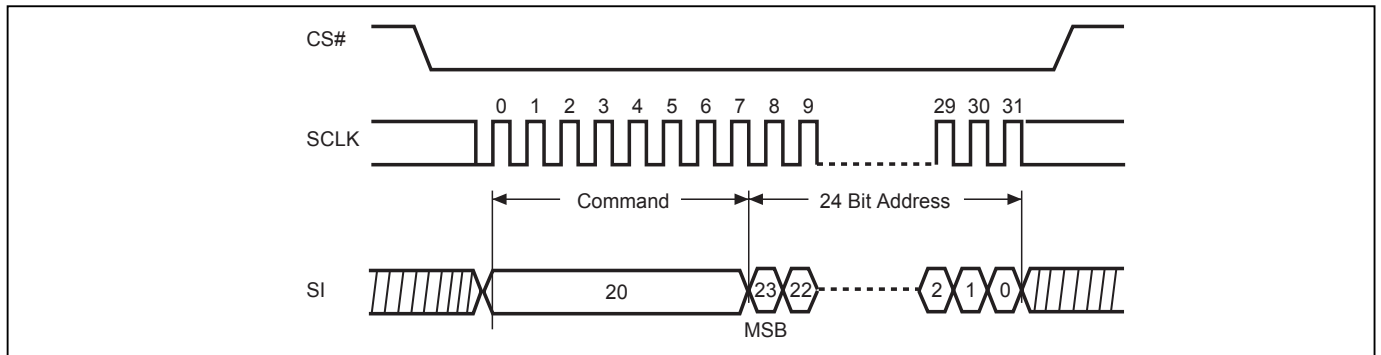

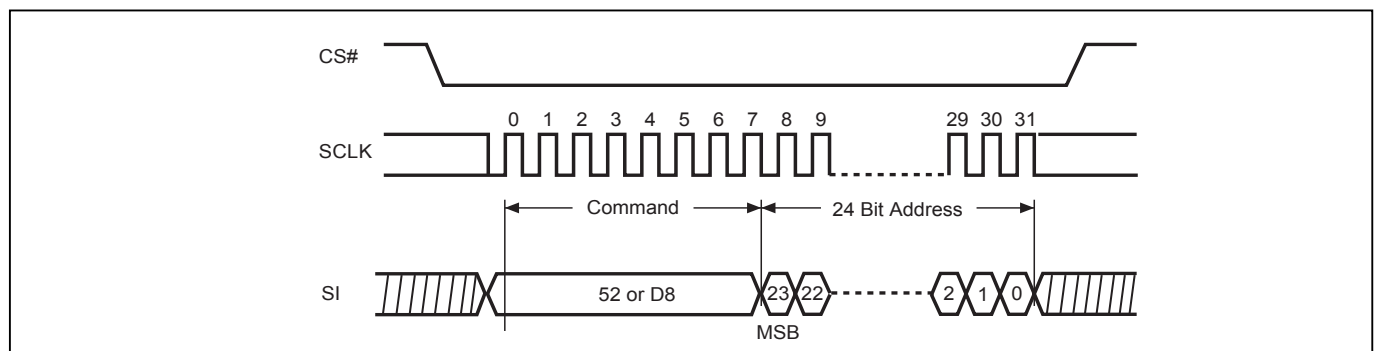

Figure 18. Sector Erase (SE) Sequence (Command 20)

Note: SE command is 20(hex).

Figure 19. Block Erase (BE) Sequence (Command 52 or D8)

Note: BE command is 52 or D8(hex).

Figure 20. Chip Erase (CE) Sequence (Command 60 or C7)

Note: CE command is 60(hex) or C7(hex).

Figure 21. Page Program (PP) Sequence (Command 02)

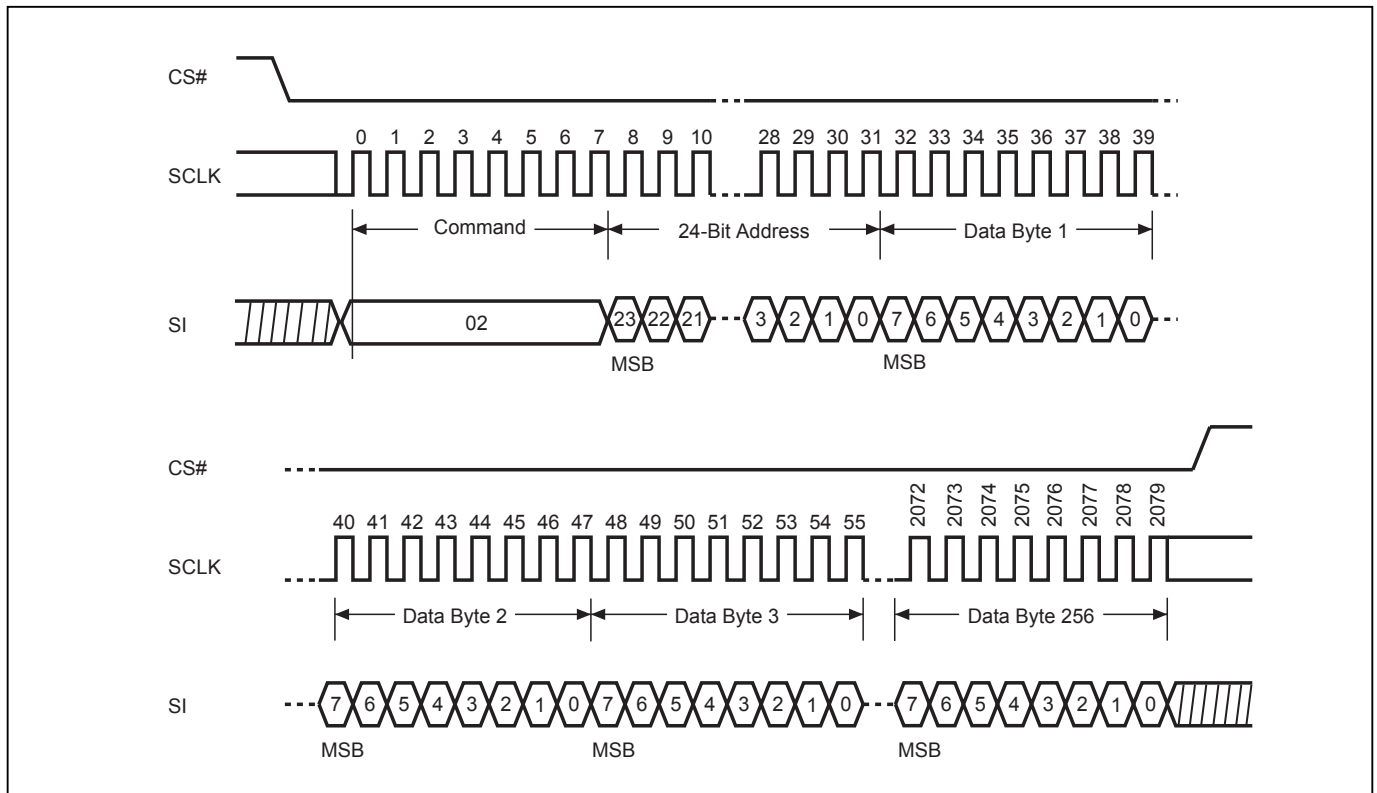

Figure 22. Deep Power-down (DP) Sequence (Command B9)

Figure 23. Release from Deep Power-down (RDP) Sequence (Command AB)

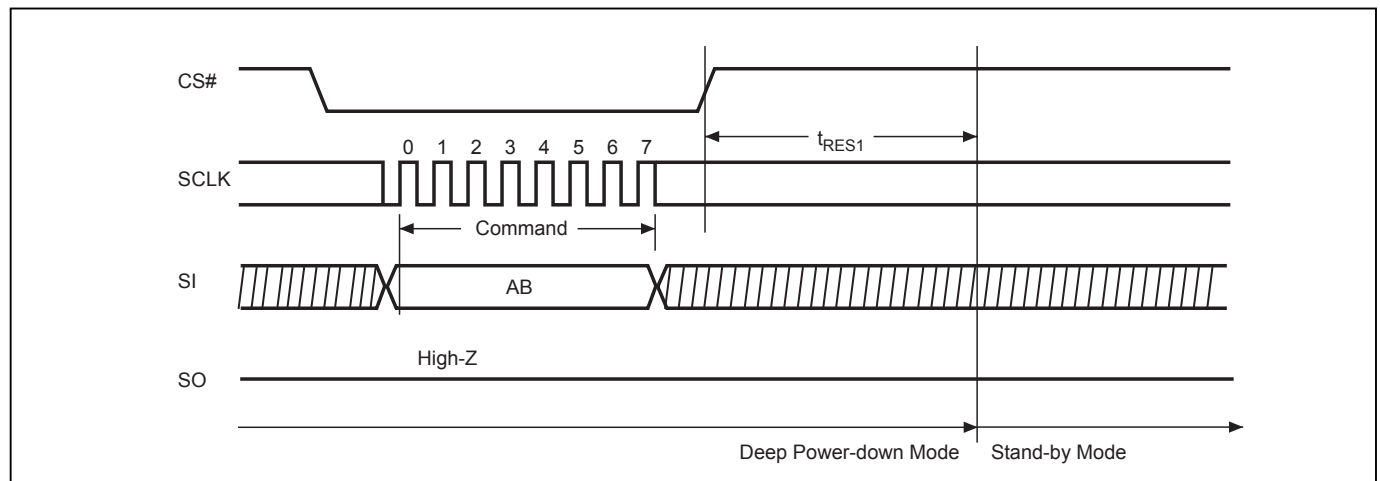

Figure 24. Read Electronic Signature (RES) Sequence (Command AB)

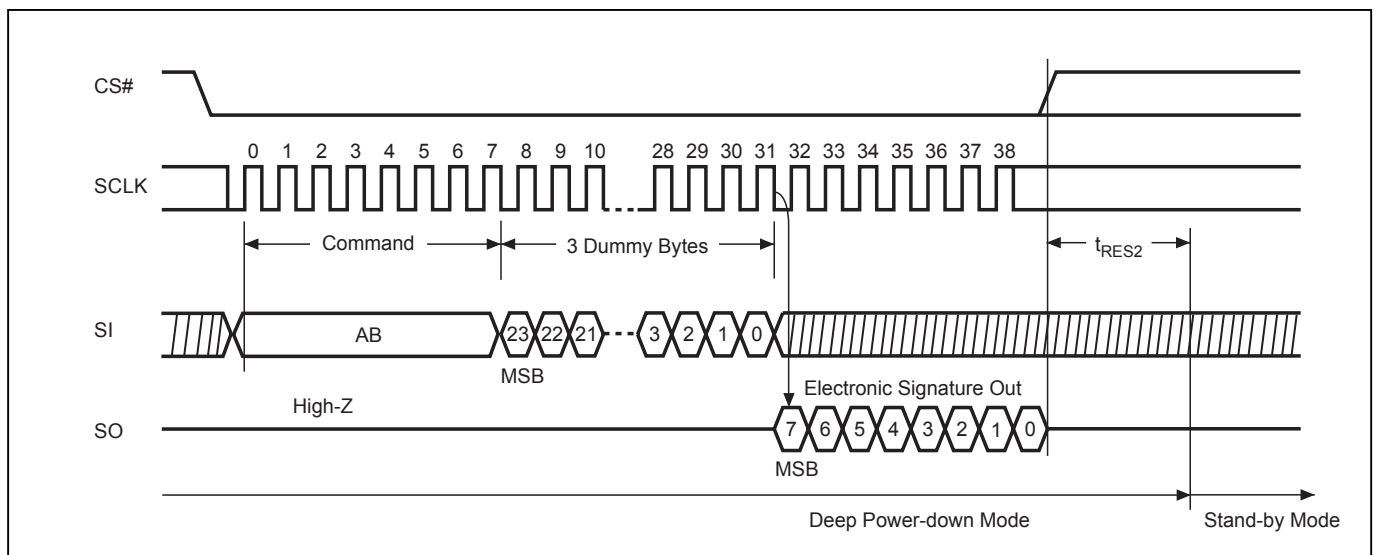

Figure 25. Read Identification (RDID) Sequence (Command 9F)

Figure 26. Read Electronic Manufacturer & Device ID (REMS) Sequence (Command 90)

Notes:

- (1) ADD=00H will output the manufacturer's ID first and ADD=01H will output device ID first
- (2) Instruction is either 90(hex).

Figure 27. Read Security Register (RDSCUR) Sequence (Command 2B)

Figure 28. Write Security Register (WRSCUR) Sequence (Command 2F)

Figure 29. Power-up Timing

Note: VCC (max.) is 3.6V and VCC (min.) is 2.7V.

Table 10. Power-Up Timing

Symbol	Parameter	Min.	Max.	Unit
tVSL(1)	VCC(min) to CS# low	200		us

Note: 1. The parameter is characterized only.

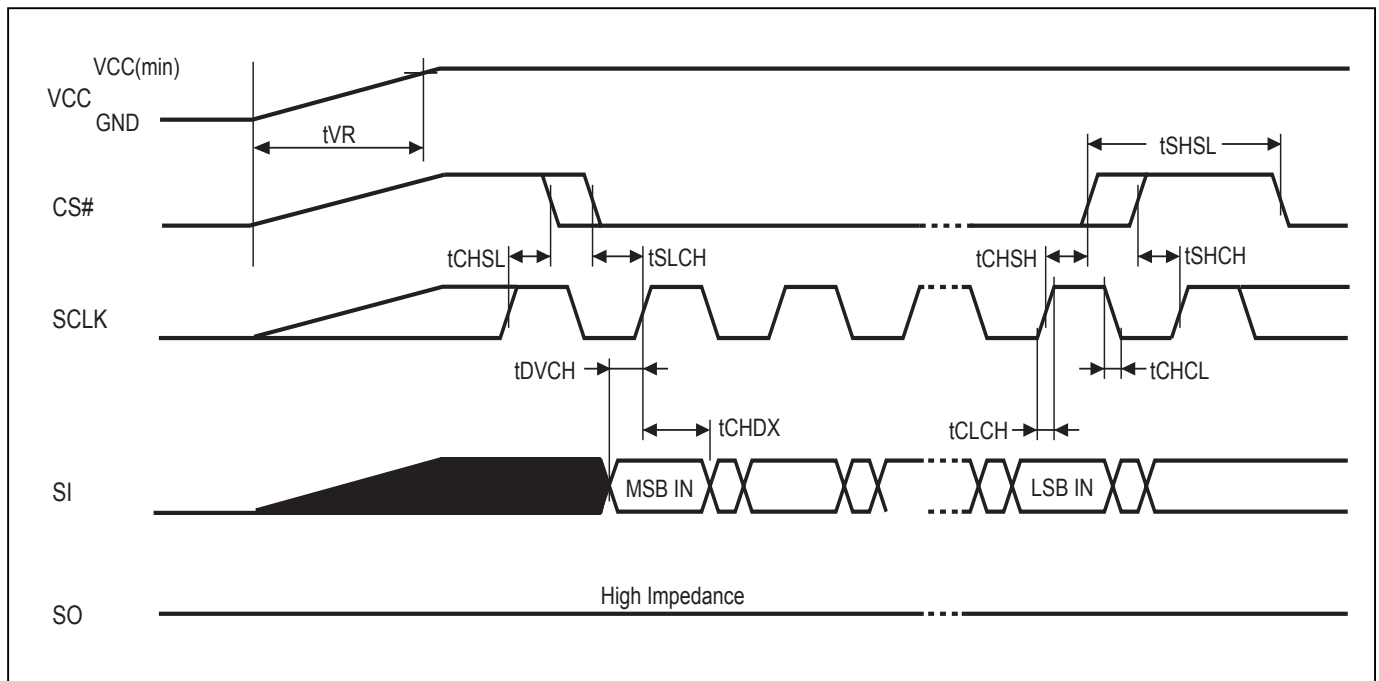

OPERATING CONDITIONS

At Device Power-Up and Power-Down

AC timing illustrated in "Figure 30. AC Timing at Device Power-Up" and "Figure 31. Power-Down Sequence" are the supply voltages and the control signals at device power-up and power-down. If the timing in the figures is ignored, the device will not operate correctly.

During power-up and power down, CS# need to follow the voltage applied on VCC to keep the device not be selected. The CS# can be driven low when VCC reach $V_{cc(min)}$ and wait a period of t_{VSL} .

Figure 30. AC Timing at Device Power-Up

Symbol	Parameter	Notes	Min.	Max.	Unit
t_{VR}	VCC Rise Time	1	20	500000	us/V

Notes :

1. Sampled, not 100% tested.
2. For AC spec t_{CHSL} , t_{SLCH} , t_{DVCH} , t_{CHDX} , t_{SHSL} , t_{CHSH} , t_{SHCH} , t_{CHCL} , t_{CLCH} in the figure, please refer to "Table 9. AC CHARACTERISTICS".

Figure 31. Power-Down Sequence

During power down, CS# need to follow the voltage drop on VCC to avoid mis-operation.

ERASE AND PROGRAMMING PERFORMANCE

Parameter	Min.	Typ. (1)	Max. (2)	Unit
Write Status Register Time		5	40	ms
Sector Erase Time		40	200	ms
Block Erase Time		0.4	2	s
Chip Erase Time		3.5	6	s
Byte Program Time (via page program command)		9	50	us
Page Program Time		0.6	3	ms
Erase/Program Cycle		100,000		cycles

Notes:

1. Typical program and erase time assumes the following conditions: 25°C, 3.3V, and checkerboard pattern.
2. Under worst conditions of 85°C and 2.7V.
3. System-level overhead is the time required to execute the first-bus-cycle sequence for the programming command.
4. Erase/Program cycles comply with JEDEC: JESD-47 & JESD22-A117 standard.

DATA RETENTION

Parameter	Condition	Min.	Max.	Unit
Data retention	55°C	20		years

LATCH-UP CHARACTERISTICS

	Min.	Max.
Input Voltage with respect to GND on all power pins, SI, CS#	-1.0V	2 VCCmax
Input Voltage with respect to GND on SO	-1.0V	VCC + 1.0V
Current	-100mA	+100mA

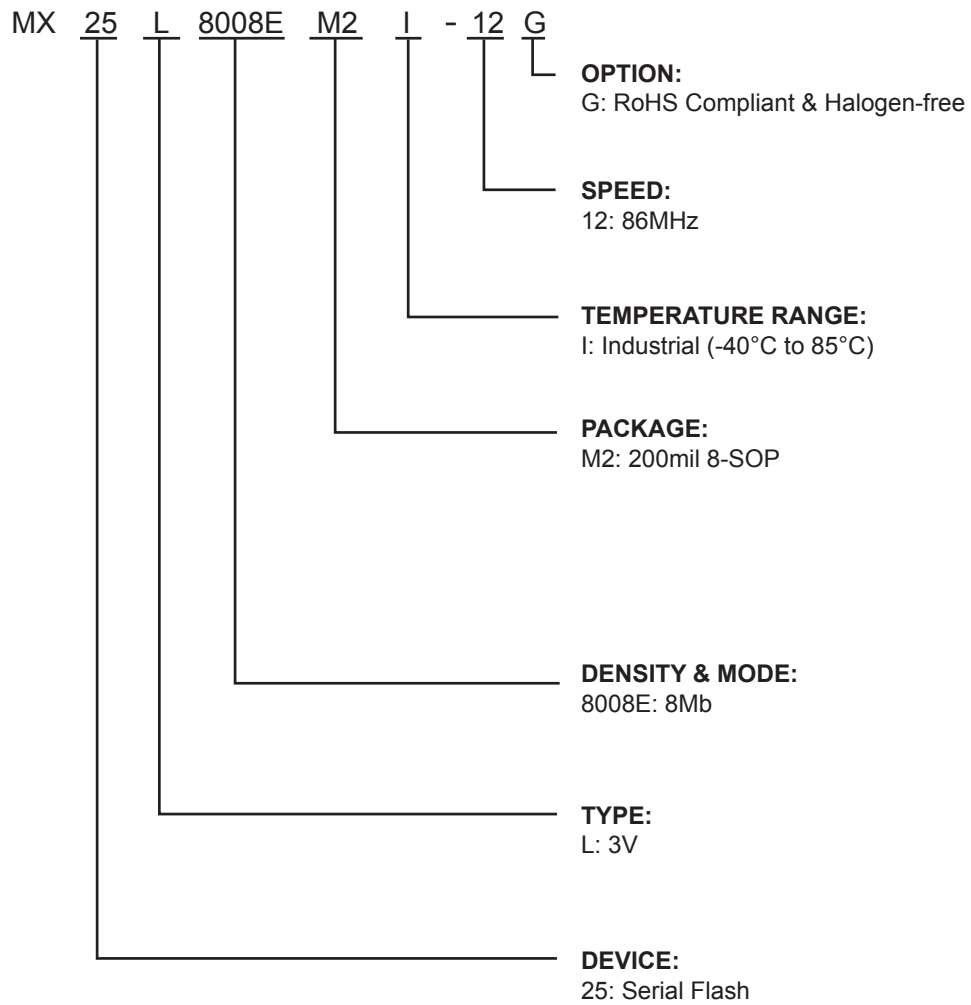

Includes all pins except VCC. Test conditions: VCC = 3.0V, one pin at a time.

ORDERING INFORMATION

PART NO.	CLOCK (MHz)	TEMPERATURE	PACKAGE	Remark
MX25L8008EM2I-12G	86	-40°C~85°C	8-SOP (200mil)	RoHS Compliant

PART NAME DESCRIPTION

PACKAGE INFORMATION

Doc. Title: Package Outline for SOP 8L 200MIL (official name - 209MIL)

REVISION HISTORY

Revision No.	Description	Page	Date
1.0	1. Upgraded the document version to 1.0.	All	MAR/26/2013
1.1	1. Updated parameters for DC/AC Characteristics 2. Updated Erase and Programming Performance	P32,33 P5,48	DEC/10/2013

Except for customized products which have been expressly identified in the applicable agreement, Macronix's products are designed, developed, and/or manufactured for ordinary business, industrial, personal, and/or household applications only, and not for use in any applications which may, directly or indirectly, cause death, personal injury, or severe property damages. In the event Macronix products are used in contradicted to their target usage above, the buyer shall take any and all actions to ensure said Macronix's product qualified for its actual use in accordance with the applicable laws and regulations; and Macronix as well as it's suppliers and/or distributors shall be released from any and all liability arisen therefrom.
